obtain a CD-ROM of the class collection of resources for teaching. By 1999, influenced by cognitive flexibility theory (Spiro, Feltovich, Jacobsen & Coulson 1991) that suggests you “criss-cross the landscape” to gain understanding of complex or ill-structured knowledge domains (in this case multimedia construction), activities were designed to “flip” students from one multimedia construction tool and task to another. They were then asked to: “Create a portfolio to demonstrate what you have learned in this subject, and illustrate your skills in information technology. You should link to your web site, describe your Hyper Studio project, list strategies for classroom use of the web site and Hyper Studio stack, and also present a collection of web sites you have identified as useful resource collections or sites for student use.” Many were shocked by how quickly they forgot the mechanics of web site construction, as they proudly finalized their Hyper Studio projects. Tools impacted on the way they processed information, but tools were evolving, so students had to move beyond reliance on a particular product to a deeper awareness of general principles of multimedia construction.

The purpose of this portfolio was to prompt students to reflect on what they had learned, demonstrate their skill development, relate their projects to classroom application and archive their work for the subject. Course structures evolve, and by 2000, these two electives were replaced by a flow of four more specialized electives that either emphasized one style of construction tool (such as web authoring or card-based multimedia presentation) or an aspect of production such as resource management or working with a “real” client. The portfolio task was retained as the final activity in each subject, and its purpose was re-oriented towards assessment, with a heavy emphasis on more specific and in-depth skill demonstration to do with a range of resource production tools. In 2001, within the final elective of the sequence, students were targeting future employers as the audience for their electronic portfolio. A number were accessed within job interviews with positive outcomes.

The infrastructure for these workshop mode classes has been rich, with plentiful access to hardware and software that has enabled students to engage in sustained media construction in a collaborative fashion. Careful group selection, peer tutoring and access to technical support can maximize the learning gains from group diversity and use of technology.

The key lessons learned from the evolution of electronic portfolios in these multimedia electives are their highly motivating nature when you allow some flexibility (such as choice of tool for construction), balanced by a need to clearly articulate the purpose, the target audience and the scope. The first element calls for early negotiation of assessment criteria; the second and third elements can be supported by access to past examples of a broad range of student work. Repetition of an activity within a flow of subjects diminishes student concern regarding the nature of the activity and allows them to focus more on the quality and depth of content.

Issues that inform future directions include the need to maintain these summative electronic “products” in an ongoing archive for subsequent deconstruction, adaptation or inclusion in the final marketing portfolio.

**Example B: Compulsory first year IT subject in a 3-4 year program**

The core compulsory ICT subject within the three-year primary degree has been designed to embed ICT functionally within the life of a teacher, based around four teacher roles – learner, manager, designer and researcher (Brown 2002). Since 2000, this framework has been made explicit as a required electronic folder structure that is to house a collection of tasks the students choose from a set of options. Fourteen options were offered in 2000, and the number was reduced to eight in 2001, based on the popular choices from the previous year.

The purpose of this portfolio is formative, even though it represents a collection of discrete “products”. Students are required to create a collection of folders as one potential structure for an ongoing archive of the electronic documents they generate from university and classroom activities. The aim is to equip students with the skills to organize and manage a collection of files. The hope is that they will maintain the habit throughout their course. Earlier activities in the subject ensure students develop some familiarity with database, web site and card-based multimedia construction tools. They get the opportunity to extend these skills through a range of the portfolio activities that are richer tasks. It is always delightful to see the ease with which students hop from one application to another after they have re-visited tools and processes a number of times in self-determined, peer or tutorial-driven sequences.

The infrastructure required for weekly one-hour tutorials is laboratory access with adequate hardware and core software tools. Presentation facilities are vital for student presentations, and tutorials
allow tutors and fourth year demonstrators to model a vast array of teaching strategies in a laboratory environment. A substantial team of lecturers, tutors and demonstrators are available for student support. Flexible attendance (ability to attend extra tutorials) caters for students who need additional help and reduces the stress associated with assignment submission that is constrained largely to tutorial time.

The key lessons learned from this experience are associated with portfolio assignment submission. Many students have little faith in electronic submission and wish to give you wads of paper “just in case”. The “teachable moment” lies at the point of submission, and if your attitude is supportive and you help students correct obvious problems or take the time to demonstrate that their files are functional, this can be the most productive moment for the student in the subject. One person needs to coordinate assignment collection and this means a very heavy week for that person. The paper trail that accompanies submission requires students to self-assess their work and allows them to comment on any extenuating circumstances related to equity. It remains vital evidence of receipt of electronic material.

Issues that inform future directions include the need to apprentice other staff to the key coordination role that is crucial as a model for students and faculty, faculty wide awareness of student capabilities so newly acquired skills can be re-visited and refined through options offered in other subjects, adequate technical infrastructure so students can maintain their momentum in a self-regulated way, and faculty level consideration of the value of a product oriented portfolio at the end of the course that builds on the process this subject initiates.

Example C: Lecture and tutorial series in an annual subject and degree

The Graduate Diploma of Education is a one-year course currently composed of both annual and semester-long subjects. ICT integration is formally addressed in a six-week slice of the annual subject “Pedagogy” early in the year, and informally continues throughout the year. This allows the portfolio activity to feature a seven-week school practicum mid-year. Although the four teacher roles described in Example B are discussed in the lecture series, they are adapted to suit the availability of schools, and re-organized to mirror the teaching cycle. Students first research their school ICT environment, design activities with their supervising teacher, manage those activities and evaluate what they have learned. A structured report stitches the experience together, accompanied by electronic folders containing resources, activities and student work. Submission protocol mirrors that for Example B.

The purpose of this portfolio is both formative and summative. The formative nature is anchored to the folder organization and the request for students to collect all available resources and target student work. Unless they have evidence of what the students achieved, they cannot make a meaningful self-assessment of their performance or the value of the ICT they used. The report is the summative component that is assessed as a product.

The infrastructure required for six weeks of one-hour tutorials is laboratory access with adequate hardware and core software tools. Presentation facilities are vital for tutor and demonstrator presentations, given the short time frame. Two lecturers and demonstrators manage the group. Flexible attendance (ability to attend extra tutorials) is offered to support those in need, and additional tutorials are programmed throughout the year to allow for staggered assignment submission and support.

The key lessons learned from this experience relate to the staggered nature of the “subject” and the ability to focus ICT use on a school practicum. Although students “switch off” to the tasks when the lecture series is complete, the break leads to a more realistic self-appraisal of what they initially learned. The school-driven agenda that emerges from the practicum ensures that students have many rich and unique experiences to share on their discussion forum for later review and analysis.

Issues that inform future directions include the impact of staggered student-driven access to facilities on timetabling and staffing, and the need for more meaningful links with the supervising teachers in schools.

Discussion

Electronic portfolio construction has emerged from an intensive workshop environment with localized infrastructure (Example A) and is occurring in a more student-driven environment without routine laboratory contact (Example C). There is no doubt students engaged in electronic portfolio construction in Example A have the opportunity to utilize the power of electronic composition environments. For students
in Examples B & C, faculty wide support is required to capitalize on the benefits of these subject-based experiences. Jonassen (1998) attributes the failure of many projects to poor implementation because the designers or technology innovators “failed to accommodate environmental and contextual factors affecting implementation. Frequently they tried to implement their innovation without considering important physical, organizational, and cultural aspects of the environment into which the innovation was implemented.” Good ideas can be foiled by lack of attention to the day to day practical details. To gain value from Examples B & C, the faculty needs to support the idea by addressing three key issues—infrastructure, staff professional development and curriculum leadership.

Infrastructure encompasses hardware and software (sufficient lab access for regular student use), technical support (relative to student needs, rather than simply hardware focused), storage space (for ongoing student storage of their work archive) and backup facilities (particularly for staff) to ensure some degree of student use equity. Staff professional development is needed for electronic assignment collection techniques if they are to understand how ICT can change classroom management. Alternately, there should be a system developed for collection of electronic material across the faculty, possibly staffed by fourth year students for whom the experience would be highly relevant to school protocol. Professional development should also embraces staff links with teachers who are supervising our students. Curriculum leadership is necessary to consider flexible timetables and team teaching where deadlines are staggered. It is also a program level curriculum decision to adopt electronic portfolios.

If the faculty were willing, then I would make a series of recommendations. Begin with a process approach that emphasizes file management associated with electronic archive production. Students need to develop their own mental model of how they wish to organize their work. Providing an initial top-level folder structure can support student management of electronic documents and help them keep track of their electronic work. Support staff professional development if the process approach is applied to an electronic collection of student work throughout the program. Individual lecturers can be involved as little or as much as they feel comfortable. Many lecturers don’t think outside the scope of their subject, but student access to archival material permits them to stitch ideas together, re-visit theoretical material and annotate it with class examples, and juxtapose different theoretical models to rationalize differences. Balance the process approach with product focused portfolios that help students refine reflection and presentation skills. Complete the program with a marketing portfolio geared to employers, that pushes students back through their course material to illustrate what they have learned.

The Intimacies of Electronic Portfolios:
Confronting Preservice Teachers' Personal Revelation Dilemma

Joanne M. Carney
Education Division
Mercyhurst College
United States
jcarney@mercyhurst.edu

Abstract: This paper presents findings from a qualitative study of six preservice teacher portfolios—three web-based and three traditional paper format. Using a sociocultural frame, the researcher considered how the tool chosen for authoring afforded and constrained the writer in representing and communicating teacher knowledge. These six cases of portfolios done by secondary certification candidates in a Masters in Teaching program reveal a tool-related personal revelation dilemma. Teacher education programs ought to be aware of this dilemma and take measures to ameliorate preservice teachers' concerns about exposing problems of practice to potentially critical portfolio readers.

Introduction

Portfolios have become common practice in teacher education programs around the country (Georgi & Crowe, 1998). Colleges of education have incorporated them for a variety of reasons: to prompt reflection, to provide a record of professional development, to demonstrate achievement of program goals, to encourage professional discourse, and to give students a portable artifact for job interviews. Underlying these uses is a common assumption: that a portfolio is a good device for representing teacher knowledge. Indeed, portfolios' numerous proponents are able to cite strong theoretical support for the use of portfolios to document, assess, and develop teacher knowledge (Wolf, Whinery, & Hagerty, 1995).

Though the vast majority of teacher portfolios are currently traditional print text, preservice and inservice teachers increasingly are being encouraged to use hypermedia and web technology. Colleges of education, under pressure to incorporate additional technology into teacher preparation programs, often see electronic portfolios as a way to develop preservice teachers' computer competencies (Levin, 1995; McKinney, 1998) and solve many of the logistical problems associated with portfolio storage, ownership, and access (Georgi & Crowe, 1998).

The rapid movement toward all forms of web-based communication makes it likely that, in the future, this particular electronic medium will play an important role in the communication of teacher knowledge. However, we know very little about the implications of using the web for teacher portfolios. In using new technologies for the portfolio, the assumption seems to be that we can substitute one medium for another—keeping the benefits of traditional print formats while adding a host of new conveniences. Our past experiences with innovative technologies would suggest one technology cannot be so easily swapped for another. The introduction of a new tool into human activity often changes that activity in ways unanticipated and sometimes profound (Wertsch, 1995). All tools have particular affordances and constraints—that is, they make certain actions easy to carry out, and others difficult (Gibson, 1979). In analyzing or planning for tool-mediated action, we need to consider how such a device shapes an activity by limiting some of our potential actions with it, while it facilitates others. How will the distinctive affordances and constraints of web technology transform teacher portfolios? Does hypermedia offer teachers new ways to conceptualize and represent their teaching practice? How can we best use electronic portfolios for teacher learning and professional development?

My study suggests some answers to these questions. I will report here on findings related to a personal-revelation dilemma faced, to some extent, by all teachers who author portfolios, but especially preservice teachers. My finding suggest that the use of web technology for portfolio authoring may impose some special constraints on these preservice teachers.

The Study
Case studies of six preservice teacher portfolios were developed in an effort to understand how electronic and traditional portfolios help preservice teachers conceptualize themselves as teachers, represent their knowledge, and communicate it to others. This study used a sociocultural frame to consider how the tool chosen for portfolio authoring interacts with other artifacts in the setting to influence conceptions of portfolio audience, purpose, form, and content. The cases included both a paper and an electronic portfolio from three different secondary subject areas: language arts, social studies, and science (physics). Study participants were in the final quarter of a Masters in Teaching program at a large research university. Data was collected by means of think-aloud commentaries, participant interview, examination of the Teacher Education Program (TEP) guidelines and rubrics for portfolio construction, as well as careful analysis of participants' completed portfolios.

Findings

One finding of my study is that the act of authoring portfolios is a highly personal process for preservice teachers; five of the six participants expressed strong concerns about revealing their deeply-felt motivations for teaching and their most intense student teaching experiences. "This whole process feels so intimate," confided Hannah, a novice social studies teacher and traditional portfolio author.

Doris, another traditional portfolio author, explained her worries and how they caused her to limit personal revelations in her portfolio: "I didn't reveal a lot about, you know, my failures, and I know that, that was part of the process, we were asked to make...but I did not go into any kind of emotional depth in my portfolio. And I could have, but I just, I didn't feel like I could trust it. I just couldn't trust it. (D-I, p. 11).

In contemplating personal revelations, participants who authored traditional portfolios seemed most concerned about prospective employers who might later be readers. The participants who posted their portfolios on the web, on the other hand, worried not only about an audience of school administrators, but also about other unknown, potentially critical readers who might be part of a vast audience on the Internet. Unlike traditional portfolio authors, who could at least decide who had access to their finished portfolio, those who posted their portfolios on the web gave up that control.

Two of the three electronic portfolio authors communicated strong concerns about revealing personal information or speaking candidly about the problems they might have faced during student teaching. Both indicated they had left important things out of their portfolios as a result of these concerns. Maggie, a language arts electronic portfolio author, spoke of her unwillingness to reveal mistakes in her portfolio because she felt this would be like "advertising" herself as a finished product to an imaginary person on the web:

It's not like I'm afraid to say, I made a mistake here, and this is what I would do differently; there are just like different levels of mistakes, you know there are some that are so fresh and awful...you don't just open those up to people who might not treat that wound kindly...I probably wouldn't do a portfolio in the future on the web, because it's just a spot where I am now, it's not, and I'll be changing from that spot, and I wouldn't want...I guess I'm just really hypersensitive to some imaginary person thinking that I think that where I am now is good enough, that I think that where this portfolio is right now is, shows the best teaching that I can ever do. That's something I really don't like about publishing it on the web, you know...like advertising this is who I am. And because, I guess I feel very fetus-like still (M-I, p. 5,7).

Mark, a preservice social studies teacher and electronic portfolio author, also grappled with this issue of personal revelation. It was a particularly troublesome dilemma for him because it involved the possible revelation of his sexual orientation. Mark would have liked to include artifacts in his portfolio that dealt with issues he faced as a teacher who is also a gay man, but felt he was unable to do so.

I really would have liked to have included more about issues that I have as a gay teacher. In particular, dealing with homophobia among my students and the different issues I had dealing with that. I would like to have had an artifact where I talked about how I dealt
with that and why it was different for me than if I were a straight man dealing with it. And how it kind of made it even more of a challenge for me, and how I felt, not only did I feel that I couldn’t be out, but the vice principal even told me I could not and that, I just would have really liked to have talked about some of these issues and about how I was in a school where supposedly diversity is treasured on the one hand, but on the other hand, when actually faced with having to deal with diversity, they don’t want to deal with it (Mk-I, p. 9).

Although Mark had been open about his identity as a gay man among colleagues in his Teacher Education Program (TEP), and he was “out” among the faculty where he student-taught, he was warned by the assistant principal at the school not to disclose his sexual orientation to students. Mark acquiesced because he was afraid that being fully out might make it difficult for him to get a job. For this reason, he avoided including artifacts in his portfolio that explicitly identified him as gay. He said he could only present these issues in indirect ways in the portfolio—for example, by including a drama script that showed students dealing with homophobia in their school, and in his classroom management plan, where he discussed how he would deal with gender issues and homophobia in the classroom. But these artifacts were not sufficient for Mark to feel that he had faithfully represented himself as a teacher. He said sadly, “So that whole aspect came out in those two ways in a very limited sense, but as far as being able to include that part of myself, I definitely feel like there’s a hollow kind of space where this portfolio doesn’t represent me fully” (Mk-I, p. 10).

I found it interesting that Mark produced a CD version of his portfolio that differed from the one he posted on the web in one significant way. The dedication page of his CD portfolio has one phrase the web portfolio does not: “[I thank] my partner, Brett (pseudonym) for his loving support.” In the web version Mark thanks his “family.”

The third electronic portfolio author in my study, a physics teacher whom I referred to as “Kyle,” did not speak of worries about personal revelation in his web portfolio. However, this does not mean that Kyle was not concerned about revealing problems he encountered during student teaching. It seems to be due, instead, to the narrow audience and purpose he defined for his portfolio. Unlike the other participants in my study, who attempted to achieve multiple purposes in their portfolios (i.e., seeking to demonstrate reflective thinking and the achievement of program goals for TEP readers at the same time they produced a product suitable for job interviews), Kyle designed his portfolio for the prospective employer and trusted that it would, in the process, also meet university requirements. As he explained it: “I tried to think of it in terms of the ‘gettinajobedness’ of it, and then I figured the ‘gettinajobedness’ of it would end up meeting the university requirements (K-I, p. 7).

As a result of this focus on a single reading audience—the K-12 administrator—Kyle experienced fewer tensions than the other authors, who attempted to achieve multiple purposes and meet the needs of diverse readers. However, Kyle’s definition of the prospective employer as primary audience, had an unfortunate effect: his portfolio contained only four incidents of what I termed critical self-exposure (remarks exposing inadequacies in one’s teaching practice). He speaks of just two problems he experienced during student teaching: managing a classroom so as to minimize behavior issues and preparing students adequately for somewhat unstructured lessons. Kyle’s discussion of these issues is unusual in that he ascribes all his weaknesses to a lack of on-the-job experience. His statements are very much in accord with the prevailing belief in schools that one only learns how to teach in the classroom. The kind of theoretical knowledge universities value is portrayed as inadequate. In taking this stance, Kyle is displaying a strong awareness of audience and has clearly adapted his message his audience’s beliefs and prejudices.

What is the significance of Kyle’s lack of critical self-exposure in his portfolio? I would consider a portfolio author’s willingness to engage in critical self-exposure to be a necessary condition for reflective thinking about one’s practice (Zeichner & Liston, 1995). The preservice teachers in my study avoided critical self-exposure. Table 1 below shows the incidence of such comments in the portfolios:

<td>3 suggested modifications in instructional method</td>
<td>3 suggested modifications in instructional method</td>
<td>10 suggested modifications in instructional method</td>
</tr>
</tbody>
</table>

Table 1: Incidence of Critical Exposure in Preservice Portfolios
Considering that these portfolios contained eight to ten artifacts, each with an attached entry slip in which the author was to engage in reflective thinking, these preservice teachers identified few troubling puzzles of practice. (Author’s note: Although Mark, an electronic portfolio author, has engaged in more critical self-exposure than the other participants, most of his comments are found in a paper he had written previously for a university class, and included as an artifact to demonstrate his capacity to use research sources. He indicated to me that he felt safe in including it because he didn’t think any prospective employers would plow through its dense academic prose.)

What does this paucity of critical exposure mean for teacher education programs that mandate portfolios for their preservice teachers? How does the use of electronic portfolio authoring tools and publication on the web influence the manner in which preservice teachers represent themselves and use portfolios as devices for reflecting on problems of practice? I will discuss these issues in the following section of this paper.

Conclusions

My study suggests preservice portfolio authors are very concerned about how the reader will perceive them—especially if that reader is a prospective employer or someone unknown. As a result, they will tend to avoid talking about aspects of self or student teaching that might be viewed negatively. Their personal revelation concerns caused them to avoid the kind of critical self-exposure necessary for truly engaging with problems of practice. If portfolios do not provide a place for such reflective thinking, it doesn’t seem likely that they will result in the kind of improvements in teaching practice or continuing teacher knowledge development that advocates hope for.

Electronic portfolio authors seemed particularly worried about potentially critical readers. Publishing on the web offers these portfolio authors the great affordance of being able to communicate with a wide audience, anywhere in the world. This affordance could actually be a constraint for preservice teachers, however. Insecure in their knowledge of a new profession, they are reticent about revealing to unknown readers out there on the web how they struggle with problems of practice—their “wounds,” as Maggie called them.

These findings suggest a personal revelation dilemma for teacher education programs that encourage their preservice teachers to post portfolios on the web. The technology that affords teachers the opportunity to share teaching knowledge widely may prove too revealing for novices to deal candidly with problems of practice. And in establishing a situation that inhibits preservice portfolio authors from dealing honestly with the difficulties they experience in student teaching, we may inadvertently contribute to the current culture of isolation in the profession. Imbued with idea that mistakes ought to be hidden, teachers are forced to construct their knowledge of practice privately rather than in a community of practitioners.

Yet web portfolios have great potential for developing teacher knowledge, and we ought not reject them out of hand. Knowledge is developed in a profession as practitioners talk about problems of practice with others in their professional community. Teachers have traditionally lacked the tools and venues for communicating their professional knowledge. Web technology may enable us to establish that discourse online. Wineburg (1997) saw portfolios as opportunities for social learning—web portfolios may extend that social learning beyond the confines of the local setting. To do so we may need to solve the personal-revelation dilemma.

I suggest one structural and two technological solutions to this personal-revelation dilemma. First, we ought to distinguish between showcase and growth portfolios. A showcase portfolio is one designed to show off the successes of one’s practice for potential employers and interested strangers. A teacher’s “growth” portfolio—with its personal revelations and deep reflection on problems of practice—is more appropriately shared only with those whom one knows would be supportive. If we post portfolios directly on the web, this study suggests they should be showcase versions.

One technological solution to the personal-revelation dilemma may be to create password-protected environments for small communities of teaching practice. Efforts like the University of North Carolina’s Lighthouse project (DeWert, Jones, & Carboni, 1999) give us some ideas about how we might...
establish a setting where novice teachers can talk about problems of practice with cohort peers and supportive university and school teacher mentors.

A second technological solution to the personal revelation dilemma would be to produce the complete portfolio on CD, uploading only a showcase version to a web server. Authoring one’s portfolio for CD presentation allows the teacher to better control who will read it. Perhaps several different CD portfolios could be produced, each designed for a different reading audience or to accomplish different purposes. The ease with which one could adapt a full growth portfolio for various audiences would provide a great advantage over portfolios done with traditional media, which don’t readily lend themselves to being reassembled multiple times in different ways.

As new technological tools are developed, we need to carefully consider how they might be used to further our goal of developing the professional knowledge of teachers. New web technologies offer us many new affordances that ought to capitalized upon. Conversely, the constraints of electronic portfolio tools ought to be recognized and, if possible, ameliorated through careful portfolio design. This paper suggests some possible solutions to the personal-revelation dilemma experienced most acutely by preservice teacher s who author portfolios on the web.

Abstract: The College of Education at the University of Nebraska at Omaha has been developing a digital portfolio for pre-service teaching candidates. This portfolio is database-driven and can be accessed by teacher candidates through a web browser. This portfolio has been developed to be systemic, covering all of the candidate's courses. The teacher candidate has the ability to include artifacts from any of their coursework. Pre-service teaching candidates can review and reflect on work from previous course work for inclusion in their summative portfolio. This process has also enhanced communication between candidate and faculty as well improved the learning process.

Introduction

The use of portfolios for pre-service teacher candidate assessment has been emerging as a trend to be considered when planning for candidate assessment. Portfolio assessment allows teacher candidates to collect, select and reflect on artifacts that allow them to demonstrate teaching competencies and standards. The use of technology in the portfolio development process greatly enhances this process. Rather than storing bulky notebooks or boxes of artifacts, teacher candidates can create and present their portfolios in an electronic format. Rather than flat files, electronic portfolios allow for interactive demonstrations of teacher candidate competence. Multimedia artifacts can be included in the portfolio. Candidates can add digital video, audio, still digital images as well as interactive application presentations created in software such as PowerPoint and Hyperstudio. Text-based reflections and observations of peers and other evaluators can be added to the portfolio as well. The sum of these parts presents a much richer picture of the teacher candidate's abilities than a traditional assessment.

The use of the Internet in the portfolio development process increases the candidate's ability to effectively create and use their teaching portfolio. This process also allows the them greater flexibility in the portfolio development and reflection process. The use of the web browsers to interface with the digital portfolio provides the opportunity to for candidates to work asynchronously from any place that they have access to a computer with a web browser. It also allows evaluators to view and provide feedback to candidates with the same flexibility. Combining the use of databases and interactive web pages also amplifies the effectiveness of digital portfolios. Traditional paper portfolios can be cumbersome to review and assess, especially in universities that have large numbers of teacher candidates. Digital portfolios that are web and database driven can increase the communication between candidate and faculty. These portfolios have the capability to generate email as a communication tool as well provide rapid feedback in the portfolio.
development process that at times is missing in traditional portfolios. In addition to providing an avenue for the candidate to reflect on their work, the digital portfolio can be electronically modified to accommodate a variety of audiences and purposes such as college administration, performance exhibitions, or potential employers. The web-based digital portfolio also allows for a more systemic assessment of candidate performance. This portfolio permits candidates to reflect on their growth over a long period of time and across courses while giving them a much clearer picture of how their coursework and field placement activities are inter-related.

The University of Nebraska at Omaha (UNO) has undertaken the development and implementation of a systemic, web-based, database-driven teaching portfolio for pre-service teaching candidates. UNO’s digital portfolio has been under construction since November of 2000 and has been used by over 400 pre-service teaching candidates. This portfolio process is currently a work in progress. The digital portfolio changes as more discoveries are made about the capabilities of this process. The digital portfolio was developed as a result of a Preparing Tomorrow's Teachers to Use Technology (PT3) grant, a need to more effectively assess pre-service teacher candidates and a need to meet NCATE standards for accreditation. UNO’s digital portfolio serves a variety of purposes. First, it provides candidates with the traditional portfolio advantages. It allows them to collect, select and reflect on artifacts in their portfolio. Since it is web-based candidates can present their portfolio to a variety of audiences. The portfolio has a mechanism to demonstrate both INTASC teaching standards and ISTE technology teacher standards as part of a summative portfolio. As the candidates progress through their undergraduate careers, the portfolio gives them an electronic area in which they can collect artifacts that they may want to use for their summative portfolio. The digital portfolio gives them the opportunity to select specific artifacts that will be used to demonstrate the teaching standards. Since the portfolio is database driven it also allows the artifacts that candidates have in their portfolio to be customized for different audiences.

The portfolio is both formative and summative. PT3 staff work with course instructors to develop a series of activities that become artifacts for the formative portfolio. In many cases these artifacts were originally artifacts that teacher candidates were required to include in paper portfolios. The formative portfolio is a work in progress. This area may include many different types and qualities of a teacher candidate’s work. These artifacts serve as the basis of the candidate’s formative portfolio. As candidates progress through their course work they can select specific artifacts from their formative portfolio for inclusion in the summative portfolio. Currently the summative portfolio is based on both ISTE and INTASC teaching standards. The artifacts selected to be included in the summative portfolio must go through a reflection stage. In this process the teacher candidate reviews the artifact and then refines it with the assistance of college faculty. Since college faculty have already reviewed the artifacts this process assists in the evaluation of the summative portfolio. Once these artifacts have been refined and polished they then become part of the candidate’s summative portfolio and are available to be view by appropriate audiences.

The use of a digital portfolio at UNO has lead to unexpected benefits for candidates and instructors. Since instructors work with PT3 staff to develop individual course portfolios, each one is customized. This has lead to another dimension of the teaching portfolio beyond collection, selection, reflection and presentation. This added dimension involves teaching and learning. The use of technology combined with collaborative efforts of the PT3 team and instructors permits the development of activities that fully integrate teaching and assessment. Some activities that become artifacts in the portfolio require candidates to collect data and then analyze it. Prior to using the digital portfolio candidates were able to use only the data they collected. As a result of allowing candidates to enter the data into the web-based database, they have the advantage of sifting through all of the other candidates’ data in order to gain a greater understanding of the teaching process. Journal entries and reflection on field placement activities that were originally placed in paper portfolios now take on a new dimension. Including them in the digital portfolio allows the college faculty to give candidates rapid feedback on their reflections and has helped to communicate potential problems and resolve them in a timely manner.

UNO’s digital portfolio is still a work in progress and as the process evolves it will be refined to make both the learning and assessment process one that will serve teacher candidates and faculty.
Using Digital Video Tools to Promote Reflective Practice

Abstract: This paper reports the findings of preliminary trials using digital video and digital video editing to encourage reflective practice in preservice teacher candidates. Initial digital video editing projects were piloted to guide future program-wide efforts to integrate digital video tools for capturing and reflecting on teaching practice in a meaningful and productive manner. Issues of technology skill development, access to hardware and software, in addition to the technical aspects of collecting, editing, and publishing large video files all affect program-wide integration. Strategies and technologies for addressing these issues and implications for future research are suggested.

Introduction

Capturing and assessing the performance of teacher candidates in the field is an integral part of traditional teacher education programs, and technology tools play an instrumental role in efforts to document performance. A study of the student teachers’ reflections on videotaped performance suggests that the use of videotape supports the development of reflective practice (Jensen, et al., 1994). Recent developments in digital video technologies permit teacher candidates to collect, review, and manipulate video to demonstrate their growth as a professional and as a reflective practitioner. Models from the Bank Street College of Education suggest that reflective practice should be nurtured within the context of teacher education programs (Freidus, 2000). Current technologies exist to simplify the integration of digital video and digital video editing into teacher preparation programs, allowing faculty to foster reflective practice, while candidates develop valuable technology skills throughout the professional phase of their programs. The Department of Education at Wake Forest University established long-range goals for the teacher education programs that include program-wide integration of digital video recording and editing for all teacher candidates. Pilot studies with teacher candidates using digital video camcorders and digital video editing equipment have generated information about the process as well as questions about the content of final performance products. Efforts to determine the best technologies for capturing and storing large, high quality video files in a way that meets the needs of the department and the candidates resulted in the purchase of DVD-R equipment which facilitates the creation of non-linear videodiscs without requiring authoring skills. This article focuses on the technologies used to support the process of recording, editing, storing and retrieving large video files, and considerations for program-wide integration.

Digital Video Tools
Several tools are necessary to collect, edit, and store large digital video files. Although VHS videotapes can be easily digitized for editing on a computer, the advantages of capturing video directly on miniDV make it the preferred method for data collection in the classroom. The smaller, more discreet camcorder makes taping in a student-centered classroom easier, and FireWire/IEEE connections allow fast transfer of data to a variety of storage options. Inexpensive video-editing software applications are easy to use and provide enough options for developing attractive and professional video products. Access to digital editing software on a laptop allows teacher candidates opportunities to review, reflect, and edit their videos with more flexibility than use of a desktop in a lab, even when the camcorder and laptop are shared among several teacher candidates. Short, simple videos consume a lot of space on the hard drive (a fifteen-minute movie take up to 3.5 GB). Storage space for lengthier movies, or collections of student work, presents a challenge. When candidates share a laptop for editing, it is not possible to store unfinished projects on the hard drive, so any unfinished editing projects are saved onto miniDV tape for later editing. Currently, completed video projects are stored on miniDV tape for output to VHS for the candidate to take and share with potential employers. The ease of use and multiple playback options led to DVD-R as the choice storage medium for departmental archiving of video projects generated by all teacher candidates. The camcorder can be connected directly to the DVD-R with FireWire for high speed transfer of video files. Recording directly to a DVD-R obviates the need for the user to possess multimedia-authoring skills and generates a versatile storage solution for the large, high quality video files. On screen buttons and barcodes can be created to facilitate non-linear access to student projects on DVD for analysis of teaching methods, documentation of performance-based assessment, or for presentations. The current assumption is that VHS tape is the most useful storage medium for teacher candidates because of price and the potential for playback to a variety of audiences. But the department is ready to provide teacher candidates with DVD-R copies of their videos as price of DVD-R drops and availability DVD playback equipment becomes more ubiquitous in the educational arena.

Program-wide Reflective Practice - Implications for Integration

Preliminary projects have produced several noteworthy results for integrating student-created digital video projects into teacher preparation programs. Perhaps the greatest influence on program-wide integration is the realization that the creation of a meaningful and reflective video takes a great deal of time; not because of technology, but because critical reflection is a skill that teacher candidates are just beginning to develop during their programs. Candidates participating in initial projects admit that the editing process encourages them to pay close attention to videos of their teaching and requires them to be critical about the clips they select to communicate their growth. Results indicate that candidates spend a great deal of time selecting video clips to communicate their growth, but less on reflection of the performance captured in the video segment. Candidates are quite capable of creating quality videos, but pilot studies suggest a need to improve the quality of their reflections. This revelation supports the program-wide reflective model in use at the Bank Street College of Education (Freidus, 2000).

It is clear that all faculty teaching in the professional preparation phase of teacher candidate development must participate in this learning process. Thus, faculty acceptance of this method for developing reflective teaching videos is necessary when the process spans the professional preparation phase of the program. Getting faculty to embrace this new process is the result of several factors. Presentation and discussion of pilot projects during faculty meetings help generate awareness of the potential of digital video editing and acceptance of this method for recording candidate performance and reflection. Further, selection of technology tools that are simple, effective, and do not detract from the content of the video also encourage faculty to participate in this change. Finally, pilot projects give all faculty an opportunity to contribute to the development of the video-reflection process and encourage input on the process, protocols, and expectations for candidate performance.

The Department of Education at Wake Forest University is currently in the second phase of pilot projects with digital video collection, editing, and reflection. Results of phase one pilot projects generated insights into the use of digital video technologies, and guided purchase of equipment necessary to support the process for all teacher candidates. The second phase of pilot projects will focus on methods for improving the quality of the video reflections while expanding faculty participation. An internal Culpeper grant has been
awarded to one faculty member to consolidate the results of the pilot projects and develop an integration outline with protocols for video capture and reflection that can be used by the department. The goal is program-wide integration for all teacher candidates beginning academic year 2002-2003.

Conclusions

Although technology is integral to this process, the decision to use digital-video tools to support the reflective practices of teacher candidates is a departmental commitment to changing performance-based assessment. In order to reach the long-range goals successfully, it is vital to engender the support of every faculty member involved in the process. Teacher candidates are capable of using digital-video editing tools, are eager to embrace this method for documenting performance, but need help with critical evaluation and reflection. Making the decision to integrate digital-video editing and recording tools is an expensive commitment, and there is no turnkey solution that works for teacher preparation programs. A great deal of effort is necessary to research, plan, and practice with technologies to determine which resources meet the needs of the program goals and the people involved in the process, now and in the future. The focus must stay on the final product, and technology should facilitate, not drive, the development of quality video-based performance assessment. Finally, the need to plan, practice, revise, and reflect on the process of program-wide integration takes the time and efforts of faculty working in concert. Although a slow and detailed process, the lessons learned from initial pilot projects provide important results that shape permanent changes in performance-based assessment and technology integration in the teacher education program. These lessons, so far, have proven valuable to moving the department closer to its long-range goals of requiring video-based teaching reflection projects of all teacher candidates and providing meaningful opportunities to promote reflective practice throughout teacher preparation program.

Promoting Standards, Assessment, and Technology Competencies Through Digital Portfolios

Harold L. Daniels
College of Education
East Tennessee State University
United States
DanielsH@etsu.edu

Abstract: This paper discusses the process of integrating web-based electronic portfolios into the training of pre-service and inservice teachers as part of a college-wide effort to integrate technology competencies and technology-based pedagogies into the training of teachers. In an attempt to establish a systematic method for addressing the numerous standards that they are expected to adhere to and document, a graduate level educational technology class was re-designed to include the documentation of both teacher candidate and p-12 learning within the digital portfolio framework. Both inservice and pre-service teachers sought to demonstrate technology competencies as well as learned society and college goals via the use of digital portfolios. Success of the revision will be measured by diagnostics of technology competencies, assessment of professional organizational standards addressed in sample work, and self-assessment by students. Preliminary data are presented as well as feedback from students and their content area professors concerning the portfolio organization, standards addressed, confidentiality, media delivery and storage issues, and assessment methodology.

Introduction

Institutions that prepare teachers currently find themselves in a sea of standards that they are expected to meet. Nearly all accrediting agencies (NCATE, SACS), professional teacher organizations (NCTM, NCSS, etc.) and organizations focused on educational technologies (ISTE, AECT, etc.) have developed standards that are used to gauge in service teacher's knowledge, skills, and expertise in leveraging technology in their teaching. In addition, teacher preparation institutions are now expected to document not only their teacher candidate's competencies and knowledge but also those of the P-K students who interact with the teacher candidates. The sheer volume of these standards and accompanying assessment needs can be intimidating and frustrating for those trying to adapt existing assessment methods or develop new ones that accommodate these standards. Add to this the institutional, unit, and program goals and objectives that address the use of technology and it becomes clear that assessment of both inservice and pre-service teachers' ability to use educational technology should be viewed holistically rather than individually.

Portfolios have emerged for both teachers (Barrett, 2000; Martin-Kniep & Giselle, 1999) and students (Chen & Martin, 2000; Goldsby & Fazal, 2000) as tools for reflective learning and self assessment, documenting growth, and providing evidence of mastery. In addition to providing evidence of content and pedagogical skills and knowledge, digital portfolios provide an authentic means to embed technology standards into the assessment process in the proper context: as a teaching and learning tool rather than a competency separated from the context of teaching. The use of technology with a process based portfolio approach provides an easily accessible and transferable product for the documentation of teacher education program effectiveness to local, state, and national agencies (Smith, Harris, Sammons, Waters, Jordan, Martin, Smith, & Cobb, 2000). This would also seem to be an efficient means to demonstrate mastery in an authentic performance of educational technology standards.
The Pilot Study

The college of education at East Tennessee State University has begun to revise core education courses for teacher candidates to include technology as an integral and appropriate tool for inquiry, communication, research, assessment and development. Rather than institute a static, "one size fits all" approach to the course revision process, we elected to develop a dynamic and flexible method. Pioneering the process is MEDA 5400: Integrating Technology into Teaching and Learning. This graduate level course is designed for both preservice and in-service teachers enrolled in one of four areas of the masters of teaching program. The course was redesigned in the fall of 2001 and will be implemented in the spring of 2002. Following the recommendations of a needs assessment preliminary guidelines were developed for the digital teaching portfolio which addressed organization, assessment, program area implementation, storage and distribution.

The revised course assignments (explicitly linked to the ISTE standards for teachers as well as other college and unit goals) require a planning document addressing content standards (professional society, state standard, etc.) as well as ISTE standards for students plus an authentic field based artifact(s) documenting evidence of learning. Each of assignment is placed into a "developing portfolio" of digital files. As the semester progresses each student will have the opportunity to reflect on and revise the assignments. The final product reveals growth as well as "best work". Thus an account of p-12 learning is documented as well as their own increased skills, knowledge, and dispositions. This dynamic system will provide pre-service and in-service teachers with the tools and opportunities to select multiple ways of viewing their evolving teaching practice, reflect on that practice, and use various representations to meet performance-based assessments as they build digital multimedia portfolios.

Evaluating the effectiveness of this approach includes documenting changes in curriculum, evidence of teacher candidate and p-12 learning (both content area and technology). Assessment will include pre and post course performance based assessment of the NETS for teachers, self-assessment of candidates on their use of technology, and portfolio assessment of technology integration. Teacher candidate's digital portfolios will all be evaluated as a part of their program area assessment, with new criteria for the use of technology to enhance classroom teaching. Finally, program area professors, field based teachers, and p-12 students will be asked to critique the teacher candidate's effectiveness in both their content and their use of technology.

As we adapt to the use of this process to document standards and performance indicators in preparation for utilization in Spring 2001, courses are being modified and a "phase in" plan is being developed that allows for adjustment and absorption by both faculty and students. Based upon the quantitative and qualitative data gathered we plan to revise and improve the portfolio process to document performance standards in multiple domains, producing a system that is both standards based yet flexible.

Abstract: Electronic Portfolios in Evolution describes a dynamic process of transformation. The story began with a single university class attempting to present limited artifacts of teaching skills electronically and is now moving to an entire school of education working together to create electronic portfolios based on INTASC and ISTE standards. Also included are the AIMS standards, which are the goals exclusive to the Department of Teacher Education.

This project is called Electronic Portfolios in Evolution because, just as horticulturists can take a wild fruit and through cross pollination, grafting, and selective reproduction produce a wonderfully delicious and beautiful fruit, so have the electronic portfolios at Brigham Young University come from a crude beginning and matured into something quite desirable. This maturation involved cross-disciplinary conversation within the David O. McKay [DOM] School of Education, which led to refinement of the portfolios through both augmentation and reduction.

Overview

This paper will show how electronic portfolios developed by elementary education majors at Brigham Young University evolved through:
- Collaboration with other faculty members,
- Ongoing conversations with small groups of students,
- Input from public school administrators,
- Technical support from the department in both equipment and personnel,
- Help from PT3 funding for training (both local and national), and
- The enthusiastic desire of students to create electronic portfolios.

This evolution was made possible through a PT3 grant i.e. training of faculty and public school people from the BYU Public School Partnership, training of lab assistants to provide help to the students doing electronic portfolios, utilizing the expertise of specialists (such as Helen Barrett), attending national conferences (SITE), and numerous other helps.

Another component that helped in the evolution of the electronic portfolio was bringing on board master teachers from the public schools to spend two years at the university assisting in the teacher education program. These teacher educators (called Clinical Faculty Associates) brought outstanding technical skills that have had a major impact on the development of electronic portfolios.
The following chronology will tell the story of the evolution of electronic portfolios over the past three years in the Teacher Education Department at Brigham Young University.

**Chronology of the Evolution**

**Spring 1999**

The idea of the electronic portfolio was born out of a request from the department chair that something be done by a cohort (a group of approximately thirty students who take all of the education courses together) to involve the students in using technology. As the cohort class was not a technology class, the first challenge was to find something required in the class that could be done better with the use of technology and not merely add another assignment to the extremely heavy workload of the students. After a careful analysis of the course assignments, the instructors decided to replace the students' least favorite assignment, the paper show portfolio, with an electronic portfolio. Students had complained that the traditional portfolio was of little or no value since employers were not interested in seeing them. Electronic portfolios seemed, by their very nature, to have greater potential appeal to the students as well as the ability to show to a broader degree the strengths of the pre-service teacher.

**Summer 1999**

One of the cohort's instructors took a class on "Creating Electronic Portfolios". The creation of what seemed to be a simple product became a nightmare when an attempt was made to include a small sound file. The rendering of the file was so slow that the thought of including sound and video files in the electronic portfolios seemed nearly impossible. Nevertheless, the idea of using video and sound in an electronic portfolio was presented to the department chair. Discouragement once again set in as he explained the vast amount of memory required for digital video and the lack of available hardware within the college to make its use feasible.

Although the path leading to the creation of electronic portfolios was daunting, a vision had been created in the mind of the course instructor. The advantages of an electronic show portfolio over the paper version as envisioned at that time were: to create a portfolio that would be of interest to employers; to show the students' personality, teaching strategies, and management through video; and to showcase students' technological skills. The first experience of having students create electronic portfolios would have been best characterized as a lonely, painful expedition; there was no one else in the department producing electronic portfolios with whom to collaborate.

**Fall 1999**

Naiveté on the part of the instructors allowed them to start the horrendous process of developing electronic portfolios with a cohort of students. The idea of changing to electronic portfolios was presented to students. Students were given the option of either continuing with the traditional paper portfolios or creating portfolios in electronic format. All thirty students chose to do electronic portfolios. The categories for organizing the electronic portfolio were the same as those used with the paper version, i.e. educational philosophy, effective teaching, classroom management, the learner, diversity, personal and professional development, curriculum, assessment, and parents and community. Those involved in this project had no suspicion of the challenges they would face breaking new ground at the university in capturing and editing video, creating multimedia presentations, accessing hardware to compress video, and utilizing hardware to burn CD's.

After attending a class offered by the university, the instructors decided to use PowerPoint as the software for organizing and presenting the portfolios. They soon discovered that many of the students were unfamiliar with PowerPoint, and none showed any skill in capturing and editing video. Since outside help to teach PowerPoint was not available, a team member condensed the PowerPoint manual into a simplified step-by-step tutorial that could be used in creating the electronic portfolio.
Winter 2000

The first real challenge in the project came after the thirty students had all been videotaped. How would they import the video into their portfolios? Not only were the students lacking the skills to perform the task themselves, but also the required hardware was not available to undergraduate students. Expertise from another faculty member was sought and the grueling work began for one of the instructors to capture and compress all the video clips and burn them onto CD's for the students to include in their portfolios. To determine whether or not they were pursuing the right course, the instructors searched the internet for examples of electronic portfolios with minimal success, leaving little possibility for comparison.

The first electronic portfolios generated did effectively demonstrate that video and still images greatly enhanced the visual appeal of the presentation of students' abilities. However, both the format and content of the portfolios were in the initial stages of the evolution.

Spring 2000

As an assistant to the dean and others in the department saw that electronic portfolios were becoming a reality, funding was given to purchase two additional digital video cameras and offers to give additional support were made.

Summer 2000

Through a PT3 grant, summer workshops were offered providing training in creating multimedia presentations in PowerPoint, digital imaging, adding sound to presentations, and scanning. These seminars gave those involved in the project greater confidence in their own technological skills as they assisted students with their electronic portfolios.

Fall 2000

Electronic portfolios were introduced to a second cohort. As with the first group of students, they were given the option of compiling either the traditional paper portfolio or an electronic one. Once again every student chose the electronic format.

Problems in creating the electronic portfolios experienced by the first students were still in place with the second cohort. One of the goals for this group was to give them more responsibility in capturing and editing the video before its compression. This was extremely difficult because of the availability of only one computer in a graduate student lab to accomplish the task. Students had to schedule their work around the graduate students' use of the computer, which added additional stress in the development of the electronic portfolios.

As an assistant to the dean learned of the difficulties students were having in gaining access to the hardware needed, he arranged for the new computer lab that was under construction at that time to be modified to help meet the needs of students doing electronic portfolios. Five video editing stations were added to the original plans, complete with software, CD burners etc.

A fellow professor and one member of the technology support staff in the department worked with the cohort instructors to train them in the use of iMovie and other software. They were also instrumental in seeing that lab assistants in the new lab would be trained to give support to the students.

Technology workshops continued to be offered by the department to give assistance. The employee in the department over external affairs attended conferences and brought back ideas of what others were attempting to do with electronic portfolios.

A turning point in the evolution of the electronic portfolios came as the professor assigned to evaluate the department goals and student growth viewed several samples of the portfolios. As one student showed his electronic portfolio and then proceeded to tell this professor what he had learned from creating the portfolio and the insights he had gained into his teaching strengths and weaknesses, the professor responded, "That's what should be in the portfolio." As the electronic portfolios were shown to other
professors and staff, similar comments were made. There was a glaring weakness in the electronic portfolios—the lack of reflections.

The focus up to this point had been in refining the technical aspects of portfolios, but after those conversations changes were made to incorporate more reflection on the artifacts in the portfolios.

**Winter 2001**

A great boost came as the department adjusted scheduling to allow a professor who created video teaching ethnographies with his students to also teach the cohort. Since his teaching ethnographies required students to create a CD with video clips of their teaching, they were learning skills and gathering artifacts that would be used in compiling their electronic portfolios. Collaboration took place as instructors from both courses worked together to provide experiences in the public schools for students to record and analyze their teaching philosophies and practices.

During this semester the new computer lab was finished, which gave students access to the hardware and software needed for their electronic portfolios. However, problems still existed as computer lab assistants lacked sufficient training in the software being utilized, and graduate students used all the hard drive space for their projects. As difficult as it was, students were still successful in creating their electronic portfolios, and the workload for the instructors was significantly reduced. Portfolios produced that semester were also more reflective than those from previous cohorts.

The INTASC standards were presented to the education faculty as the standards the state would be using for new teacher licensure. They were then introduced to the students as a possible framework for organizing their portfolios. This was the beginning of a shift from showing evidence of being able to meet local expectations to meeting teaching standards (INTASC) more widely recognized throughout the country.

Samples of electronic portfolios from the cohorts were shown to all thirty-eight elementary school principals in the Alpine School District to see if they would be interested in viewing electronic portfolios as part of the hiring process for new teachers. (Previously, principals had not shown interest in seeing paper portfolios.) All principals indicated in a questionnaire they would like to view the electronic portfolios when interviewing.

Two of the cohort instructors attended the SITE conference in Orlando along with other department faculty. At that conference, another milestone in the evolutionary process occurred. Helen Barrett opened their vision to the deeper, more encompassing purposes of electronic portfolios. To this point, portfolios produced by cohorts were collections of artifacts with some reflection added. It was evident that previous efforts at producing portfolios had focused on creating show portfolios for prospective employers. Working portfolios, with the tremendous opportunities they afford students to evaluate their practices and philosophies, had not been given adequate emphasis. It was determined while at the SITE conference to arrange for Helen Barrett to conduct a workshop at Brigham Young University for the faculty in the David O McKay School of Education.

The leadership in the David O McKay School of Education committed the necessary resources to make it possible for education majors to construct electronic portfolios. Because of this commitment the Alpine team presented samples of electronic portfolios to partnership liaisons and leaders responsible for the cohort program in other school districts. This group seemed impressed with the electronic portfolios; however, most felt they were not ready to attempt electronic portfolios because of inadequacy with technical skills. To address concerns and help in the creation of electronic portfolios a task force was formed. This task force began a dialogue with those who teach the technology courses and other faculty to build a support system for students to create portfolios electronically.

**Summer 2001**

Helen Barrett instructed the faculty for three days in the purposes of portfolios and how they could be enhanced electronically. Her instruction proved helpful in refining and emphasizing the goals of the working portfolio.

---

1 Helen Barrett, professor at the University of Alaska Anchorage, is a leading authority on electronic portfolios in teacher education. See her website at: http://transition.alaska.edu/www/portfolios.html
The purposes of the portfolio had now evolved into an opportunity for students to carefully study their teaching as they progressed through the teacher preparation program and to design a sampling of their philosophies and skills that would be of interest to prospective employers. They were built upon the INTASC standards with ideas from Helen Barrett added to refine what had previously been done. The fall cohort had already spent a semester working on their portfolios, so they were not required to change the structure of what they had started but were invited to make the change if they desired. Fifteen of the twenty-three students adopted the INTASC standards and incorporated many of Helen Barrett’s ideas.

A high point of the semester was the enthusiasm the students exhibited as they caught a vision of how the portfolio could show evidence that they were meeting generally accepted teaching standards, both during their pre-service experience, and as they met licensure requirements in the first years of teaching. Students who desired were invited to meet with the instructors beyond class time to collaborate on developing electronic portfolios. Students were anxious to meet to share ideas, ask questions and get feedback. The synergism of the group was tremendous as they realized ownership of their portfolios. Much of the energy seemed to come as students recognized that their ideas were valued as much as those of the instructors. They moved from merely collecting artifacts for an assignment to gathering evidence of their own teaching skills.

Some BYU faculty and teams of technology leaders from the partnership districts traveled together to the Classroom Connect Conference in Las Vegas for the purpose of building cohesion in the technology skills taught at the university and those needed by classroom teachers. Many benefits came from the conference, but one in particular was the district’s support of electronic portfolios. Since the majority of the new teachers in Alpine District come from BYU, they were excited to learn of the skills that the graduates would bring to the district. They expressed their support for continuing electronic portfolios with those new teachers as they collect evidence to meet licensure requirements during their first two years of teaching.

Several other administrators from the Alpine District met with students and viewed their electronic portfolios. Involving the administrators had a two-fold purpose. The main objective was to provide feedback to the students from a public school viewpoint. Another objective was to evaluate the portfolios in general to see if they actually showed (from an administrators’ point of view) evidence that students met the INTASC standards. The response was very favorable from the administrators, but showed that the working portfolios would need to be modified to accomplish show portfolio goals.

Several students who produced portfolios in previous semesters provided some interesting insights into the worth of the project. One stated she was very grateful she had produced her portfolio because of the technological skills she had developed. Another stated that even though the technical aspects of creating her portfolio electronically had proven beneficial as she began her teaching career, she valued the insights she gained into her teaching much more highly. She felt that viewing herself as she taught from an outside perspective was invaluable.

The Future

Electronic portfolios seem destined to play a prominent role in pre-service education at Brigham Young University. Greater acceptance of the INTASC standards within the [DOM] School of Education and more varied technological skills of the faculty are creating an openness to change. The value of media not traditionally connected with paper portfolios in reflection is beginning to open the vision of a relatively new resource to analytical minds.

As the evolution continues, possible changes being considered are: (1) Utilizing HTML format to allow easier accessibility in the show portfolio and to enable artifacts consisting of full pages of text to be displayed in the working portfolio. (2) Beginning the working portfolio in the semester before entering the upper level course work and continuing gathering evidence throughout the two cohort semesters. (3) Creating the show portfolio after the student teaching experience.

Just as cross pollination in the plant world can be used to produce a more desirable fruit, flower or vegetable, so can collaboration improve practices in education. Collaboration has been and will be essential in the evolution of the electronic portfolio.
A Comparison of Two Electronic Portfolio Models

Sebastian Foti, University of Porto, Portugal, US

Introduction
In this session we will share the beginning year of two electronic portfolio projects. One at the University of Porto, Portugal, the other at the University of Florida, Gainesville, Florida, United States (http://www.coe.ufl.edu/school/portfolio/index.htm). These projects were developed and implemented independently of one another yet have many similarities. Our experiences have shown that electronic portfolios have the potential to contribute to a richer learning environment for students, and encourage students to reflect more on their learning and education. In addition, portfolios are changing the way professors and colleges of education approach assessment.

The Projects' Goals
Pedagogically, the assemblage of an electronic portfolio is a classic example of a constructivist activity. Dewey (1915) believed that true, new knowledge and intellectual growth are constrained by the systematic teaching method of assignment, study and recitation, and instead argued for a more learner-centered classroom where exploration and engagement were encouraged. Both colleges believe that the construction of an electronic teaching portfolio enables students to continuously construct and revisit their knowledge, beliefs, and biases about the profession.

The purposes of the electronic portfolio at both schools are to:
- present student selected illustrations of competency
- effectively use and integrate technology in their educational experience
- develop and present a professional vita over time
- provide a forum for connecting a student's university experience to personal and professional insights.
- assist the student in coming to a better understanding of their profession

The portfolios are organized around the following pedagogical and technological goals:
- encouraging student reflection
- promoting student self-assessment
- Using technology for communication, development, and publication

Lessons Learned
We will share the similarities and differences of the two programs, the conceptual frameworks that undergird each program, and the support mechanisms that facilitate their implementation. In addition, actual student portfolios will be shared. Future goals and project objectives will also be presented.

Conclusion
Portfolios may be used effectively to model 21st century uses of technology to preservice teachers. As students began to reflect on their work and their learning experiences, they began to discuss ideas with their peers.

Both colleges continue to have questions about portfolio development. We believe that by managing the vast amount of information in their portfolios, deciding how to build a public representation of their accomplishments and of who they are, and trying to integrate the various components of their public and personal histories, our students will develop skills and perspectives that will serve them well in the future. The construction of an electronic teaching portfolio forces students to continuously construct and revisit their knowledge, beliefs, and biases about the profession.

The RIMS/BTSA Electronic Portfolio for Teacher Professional Development

Zeno Franco, Graduate School of Education, U.C., Riverside, US
Linda Scott-Hendrick, Graduate School of Education, U.C., Riverside, US
Scott Lowder, Graduate School of Education, U.C., Riverside, US

Introduction

This presentation focuses on the development of an electronic portfolio project designed by the Riverside, Inyo, Mono, San Bernardino Beginning Teacher Support and Assessment (RIMS/BTSA) program, a large scale beginning teacher induction program in the State of California. Providing mentoring and support services to over 1,400 new teachers and 700 support providers per year, across 56 school districts in 4 counties, RIMS/BTSA is the largest and most geographically dispersed beginning teacher induction program in California. In order to meet new State requirements mandating that the program be responsible for performance-based assessment as one of the components of licensure for the beginning teachers, the program elected to develop an electronic portfolio to manage this new and logistically challenging task.

Prior Art: A Literature Review of Portfolios in Teacher Professional Development

A review of extant literature on portfolio usage and design will be offered as an introduction to the presentation of the RIMS/BTSA Electronic Portfolio for Teacher Professional Development® (EPTPD). This review will examine the topic from three different perspectives: (1) the usage and effect of portfolios with individual teachers (micro-level), (2) the dyadic and social interactions that portfolios engender between teachers, their mentors, and their community of learners (mezzo-level), and (3) the interface between the first two levels and the need of institutions which train and monitor teachers to be able to conduct performance-based evaluations as a part of teacher licensure (macro-level) (Fisher, 1994; LaBoskey, 2000; Poironi, 2000; Milman, 1999; INTASC, 1998). The inherent tensions and emergent benefits resulting from the attempt to maintain the essence of the teacher portfolio while incorporating them into a larger framework of accountability and assessment will be addressed. Additionally, the conceptualization, design, and usage of previous electronic portfolios and how those projects have informed the RIMS/BTSA EPTPD® will be discussed (Penta, 1998; Barrett, 2000).

Description of the RIMS/BTSA EPTPD®

In January of 2001, the RIMS-BTSA collaborative partners designed an electronic portfolio pilot program to be implemented in the 2001-2002 school year. Over the following six months, RIMS/BTSA technical and research staff at the University of California, Riverside outlined the purposes of the electronic portfolio. These include:

1. Increasing the mentored, reflective practice for new and experienced teachers
2. Promoting dialogue among experienced and new teachers, even when geographical distance is prohibitive
3. Allowing new teachers to demonstrate competencies across the California Standards for the Teaching Profession (CSTP)
4. Providing a “real-world” compliment to the California Technology Standards for Teachers and encouraging technology usage and competency for new teachers
5. Providing RIMS/BTSA administrative staff with an organized, high-speed system for performing authentic assessment of new teachers which would be tied to the pre-existing RIMS/BTSA Information Management System

Based on the experiences of other projects which have used electronic portfolios, the UCR RIMS/BTSA staff also established several minimum technical requirements for the EPTPD®. The EPTPD® should be:

1. A World Wide Web based application – in order to ensure high availability and easy access
2. Cross platform / browser compatibility – the system must be accessible by PC and Macintosh computers, running either Internet Explorer or Netscape browsers
3. File type flexibility – the system must be able to accept and display a wide variety of media types. This includes video, audio, Adobe Acrobat PDFs, HTML documents, PowerPoint presentations, photos, and simple word processing documents, etc.

The EPTPD® was constructed as a web application on a Windows 2000 web server running IIS 5.0, Active Server Pages, and SoftArtisan’s FileUp component. Database features are maintained through Microsoft Access 2000. The portfolio has a “working area” – a completely private zone for the new teacher, an “assessment area” – accessible to the new teacher’s support provider and the RIMS/BTSA program, and “presentation area” – a publication option which posts selected portions...
of the portfolio to a common area accessible to the entire community of learners. Finally, a copy of the portfolio is provided to each participant upon exit from the RIMS/BTSA program on a CD-ROM disk.

The Case Study: Data, Interactive Demonstration, and Discussion

By capturing the conceptualization, construction, and implementation of the RIMS/BTSA EPTPD as a case study, this presentation examines each major step in its development within a complex organizational and institutional consortium. Some of these steps include:

- The processes of capturing the essence of a teacher development portfolio in a fully digital environment
- Examining the strengths and weaknesses of previous electronic portfolio projects
- The decision to build a custom, in-house solution from the ground up
- Hardware, software, and staffing requirements
- Programming languages
- Coordinating training and mentoring of the EPTPD in member districts
- Training new teachers and support providers to use the EPTPD
- Assessment methods for new teacher portfolios in the EPTPD
- Testing and trouble-shooting
- Lessons learned from successes and false starts

As part of the presentation, client computers will be available for seminar participants to use all aspects of the system, including the participating teacher interface and the support provider interface.

Research Components / Assessment of the System

A mid-project report based on participating teacher and support provider self-reports will be presented. This information will be collected through surveys, focus groups, and individual interviews. Data collected from project participants will include perceptions of the EPTPD's efficacy as a staff development and assessment tool, its ease of use, and its ability to provide applied instruction in technology. Qualitative information gathered by EPTPD trainers during training sessions will be included to provide insight into these issues. Interviews with districts officials involved in the project will also be conducted to incorporate the view of the EPTPD from an administrative perspective.

1 Support for this project is provided by the UCR Graduate School of Education and the Riverside County Office of Education. Data are provided by the Riverside, Inyo, Mono, and San Bernardino (RIMS) Beginning Teacher Support and Assessment (BTSA) program of California.

Electronic Portfolio Assessment in Teacher Education

Constance Geier, Ed.D.
Associate Professor of Education
Northern State University
Aberdeen SD 57401

geierc@northern.edu

The School of Education at Northern State University is using the electronic portfolio as an assessment tool and as a means of integrating technology throughout teacher education. The electronic portfolio offers a unique opportunity to build preservice teachers' proficiency with technology as well as showcase their expertise in teaching.

This institutional session will focus on the process used to develop electronic portfolios and the method used to implement electronic portfolio assessment in teacher education. In addition, participants will have the opportunity to view student-created electronic portfolios guaranteed to knock their socks off!

Why electronic portfolios? Electronic portfolios emphasize process as well as product and are multi-sensory in nature. They provide the perfect format for facilitating the integration of technology throughout the teacher education program. Let's investigate three reasons why portfolios have become so popular in the field of education.

First, today's educators have embraced constructivism -- the belief that teaching is an active and learner-centered process. This philosophy recognizes that students build their own understanding of the world by using what they already know to interpret new ideas and experiences. Constructivists emphasize not only what students know, but what they do.

Secondly, the growing interest among colleges of education in performance assessment makes a transcript of grades and a score on the National Teachers' Exam (NTE) seem inadequate indicators of competence. A wise person once said: AThere is a lot of difference between naming the tools and building the house.@

And thirdly, there is stiff competition for teaching jobs in most areas of the country. It is imperative that prospective teachers be able to demonstrate their teaching competence in concrete ways -- to university faculty, to prospective employers, to policy makers at the state and national levels, to parents, the media, and the general public.

After piloting the use of electronic portfolios with 12 teacher education students during the 1998-1999 academic year, the School of Education at Northern State University began implementing electronic portfolio components into teacher education methods courses. The elementary education program was targeted during Year 1, the secondary education programs were targeted during Year 2, and this year the focus is on K-12 programs in art education, health and physical education, music education, and special education. The model used for electronic portfolio integration solicits proposals from faculty members planning to add electronic portfolio components to their methods classes. To date, twenty-one methods instructors have received summer stipends to plan and integrate electronic portfolio components into their courses.

Teacher education faculty members are currently creating a rubric that will be piloted during the electronic portfolio showcase in December. Two education faculty members will review each student's electronic portfolio using the newly created rubric to guide the assessment process. Students' portfolios must demonstrate mastery of the ISTE National Technology Standards (NETS) and performance indicators for teachers. In addition, students must address each of the five components of the knowledge base for teacher education at Northern State University: Knowledge of Self as an Individual, Knowledge of Content, Knowledge of the Learner, Knowledge of Pedagogy, and Knowledge of Self as a Teacher and Member of a Learning Community.

The implementation of electronic portfolios in teacher education programs at Northern State University has not been without challenges; however, teacher education faculty believe, as did Dewey (1904), that Athe purpose of education is to allow each individual to come into full possession of his [or her] personal power.@ In this regard, electronic portfolios rule!
IMPLEMENTATION OF THE E-PORTFOLIO

Grant Abstract

Preparing Technologically Skilled Novice Teachers
A University-Wide P-12 Collaborative

Eastern Kentucky University plays a critical role in reducing the digital divide that exists in its Appalachian service region. The importance of this role is magnified by the fact that EKU is the largest preparer of teachers in the Commonwealth and because our graduates serve one of the most educationally and economically depressed regions in the nation. Through PT3, EKU can substantially improve the preparation of teachers: enabling them to be more adept at applying technology to learning strategies which will, in turn, enhance student performance. Our project has three major goals: (1) creating "clusters" of both Education and Arts and Sciences faculty, as well as pre- and in-service teachers, to work together to integrate content, pedagogy and technology through the redesign of technology-rich general education and educational foundations courses for future teachers; (2) establishing "service units" to coordinate and disseminate outcomes; and (3) creating an electronic/multimedia portfolio assessment system through which future teachers will document their proficiencies and amass strategies to enhance their future teaching.

Electronic Portfolio Rationale

The Eastern Kentucky University PT3 2000 implementation grant is a very unique, collaborative effort among the College of Education, College of Arts and Sciences, and P-12 partners with a focus on transforming the education of future teachers through the infusion of technology throughout the core curriculum.

As the largest preparer of teachers and educational professionals in the Commonwealth, our emphasis on teacher education is a campus-wide priority through which content areas, pedagogy, and instructional technologies are fully integrated.

Our cluster teams are working very hard to develop a core curriculum that continues to challenge our students through academic rigor while exposing them to cutting-edge technology. We are very excited about the positive impact the results of this grant will have on the preparation of our future teachers. As an example of this collaboration, two College of Education faculty members who were instrumental in the development of Eastern Kentucky University’s original education portfolio, one College of Arts and Science biology professor, one P-12 teacher, the coordinator of educational technology and his graduate assistant formed the portfolio cluster. The charge of the “cluster” was to focus on reconfiguring the portfolio to an electronic format. The cluster worked for one year to develop a template for the electronic-portfolio (e-portfolio).

The e-portfolio is required of all Eastern Kentucky University teacher education majors and is based on the Kentucky New Teacher Standards. The e-portfolio provides an opportunity for students to showcase their course work and demonstrate their competence in implementing technology.

It is the intent of the presentation to share the framework for developing the e-portfolio and the implementation of its use in the Educational Foundations Class (EDF 203). Review of the objectives for the portfolio and the rationale for developing a template will be discussed.
Successes and pitfalls of implementing the e-portfolio in eight EDF 203 classes taught by seven different instructors will be discussed.

Objectives for the presentation are to: (a) provide overview of the PT3 grant’s objectives, (b) review objectives for the e-portfolio, (c) provide a framework for implementing the e-portfolio with approximately two-hundred and fifty students enrolled in an educational foundations class, (d) share observations of successfully implemented strategies and some failures, and (e) share reflections of the process of integrating the technology.
Electronic Portfolios: Where Should the Portfolios Be Stored?

Abstract: Student portfolios contain artifacts from performance-based learning activities that attempt to substantiate learning toward one or more measurable outcomes. Typically the parameters for portfolios follow traditional academic presentations on paper and videotape that are compiled, organized in a binder and presented at specific times for evaluation and comment. Electronic portfolios presented digitally and mirror web environments can include electronic pages hyperlinked together, multimedia, video and audio streams, and other presentation formats that enhance the work. A necessary topic in any electronic portfolio discussion is how and where to store the portfolio.

A student portfolio submitted on paper was never a serious consideration among the faculty in the elementary program. Their collective vision for innovation through a multi-year curriculum development process that aligned INTASC standards to NCATE guidelines and then state performance outcomes as well as maintaining institutional character always sought to have an electronic portfolio. How this electronic portfolio was to be developed and presented were the next decisions. Discussants were highly influenced by the pervasive growth and ease of use the World Wide Web offered. It captivated discussions about the way students could handily develop web pages that faculty could navigate through to read artifacts and reflections. It was the desire to use the web that plotted the course of action.

The faculty quickly learned that the onset of a course of action that includes innovations not common in day-to-day university operations necessitates convincing others that policy changes were needed and network functionality expanded to allow students access to a specific university server to develop, store, and present a portfolio. Initiated in 1995, the faculty had a series of early stage roadblocks that are more easily solved on most campuses today.

This paper reviews a three phase, six-year electronic portfolio history that began with a locally controlled Internet-based environment, a second phase allowing for intranet viewing only along with software support for video streams, and a third phase that outsources to a business which supports web based teaching resources, lesson planning, and allows for electronic portfolio development. When viewed across the developmental continuum, the third phase appears to be the most promising yet. The first phase, Internet-based portfolios, was brief as confidentiality concerns associated with pictures of schoolchildren posted on the Internet were too significant to overlook, and the second phase, intranet-based portfolios, is ongoing.

Electronic portfolio development in a performance based learning environment provides portability, scalable and robustness that simply surpasses what a paper portfolio accomplishes. The portability is evident as students are able to work on the portfolio from any networked campus computer, or with the use of file transfer protocol, ftp, portfolio access is even greater. FTP allows a student to retrieve the electronic portfolio, work on it, and then post it to the server for later use. From the faculty perspective, electronic portfolios can be accessed for review at designated times or upon request. No longer are paper notebook binders carried from place to place nor stored. All artifacts and reflections are presented digitally. Scalability, the second topic, is managed with web-editing programs such as Netscape’s Composer, FrontPage, HomePage, etc. which make it possible for a browser to open files and navigate the portfolio with relative ease regardless of the development platform used.
Electronic portfolios are robust. The flexibility of the web, video streams, animations, Flash, Splash, and other programs provide the portfolio developer with multiple tools to present her/his artifacts and reflections. When electronic portfolios are developed with an organizing template and pre-service teachers are guided through specific requirements and reflective writings, electronic portfolios simply supplant paper portfolios. Once the web page software is learned, portfolio development follows.

Storage issues are significant. How big will the portfolios be when graphics, animations, artifacts, presentations and video streams are included? Should individual student limits be set or can students have nearly unlimited amounts of server space to complete the portfolio? Initially, the unlimited size for each student electronic portfolio was confounded by earlier decisions. Mainly, a three bay server was purchased with an eight-gigabyte drive in each bay. Two drives where set up to mirror each other with duplicate student folders on each drive. Students could opt to develop on either drive. One was on the Internet and the other was intranet only. The first year of development this system worked well. Late in the second year disk capacity was maximized. This coincided with looming deadlines and high student demands on the server, an unfortunate time to realize the system’s limits. Through the responsiveness of the university’s network services technicians, the server was reconfigured to allow students continued use by breaking the mirroring which freed disk space. While this server continues to function, a larger server with 70 gigabytes of hard drive space was purchased. To date, only the storage demands for video streams have caused limits to be set.

Stability remains a critical issue. Placing the server on a network makes it available through student login procedures, and tremendous value-added elements are realized because the university’s network includes redundancy, high priority server status for 24/7 maintenance, technicians, and regular software upgrades. The relationship with network services support personnel is important. Servers require regular maintenance, access codes, and eventual replacement. Further, backing up student files is an extremely important safeguard in the event of a physical server crash. Who does the data backup, how often, and where is it stored? The electronic portfolio server has data backed up every 24 hours, and a complete server back up each week. In the event of a physical crash, the server can be re-built with only the information from the previous 24 hours lost. Thus, establishing server priorities with network services, making back up data tapes, setting up utilities to add student portfolio folders, and servicing the server are important processes requiring time and expertise. Faculty often do not have time to take care of such routine matters, so university network services meet the electronic portfolio infrastructure needs.

At this writing, the third phase of portfolio storage is coming into view. There are a number of factors contributing to this change. Currently the two servers largely dedicated to electronic portfolios are aging. The department underwrites their replacement costs and must decide to use technology funds for servers or other technology for teacher preparation and academic needs. Given state budget shortfalls coupled with increasing technology demands in preparing teachers for P-12 schools, shifting to a third party service provider is likely. In addition, pre-service teachers can receive more services from a service provider than the university can provide. Costs are nominal especially for pre-service teachers. A one-time charge of approximately $60.00 allows the pre-service teacher multiple years of access and file storage in a web based work environment. Technology costs, replacements, software upgrades, technical support, and other user services are all included in the service charge. Shifting these ongoing costs and services away from the university to a business is fiscally sound. Educationally, the service provider organizes resources to assist learning and professional development. Through templates students can create new works, include state standards, add curriculum frameworks, access other lesson plans, locate web resources, specify lesson formats, link to websites, create webquests and more. Existing resources on the web site such as lesson plans are readily available for students to access, include, organize, and modify. The electronic resources can be organized into a portfolio and presented to specific faculty and students on the web for feedback and editing, or specific resources can be posted on the Internet for review and use. This purchased service is a significant electronic resource including state and professional society standards, lesson ideas, websites, etc. and simply surpasses what is currently available on the university’s electronic portfolio support system.

The three electronic portfolio phases span a six-year venture into electronic portfolios. Each phase represents faculty innovations, their reflections, and responses to modify processes that allow pre-service teachers to take advantage of computer technology and present their learning and reflections in as useful a manner as possible.
Where's the Science? The State of Science Content on U.S. Secondary and Middle School Web Sites.

Thomas M. Keating and Christopher Doucette
Boston College Lynch School of Education

The World Wide Web has diffused from a handful of K-12 schools in the United States in 1993 to near ubiquity in 2001. At present, middle and high schools use the WWW as a vehicle for advertising the school and its mission, extracurricular activities (e.g. sports, clubs, and band programs), academic programs, calendars of events, alumni information, teacher and course web pages, and web pages constructed for and about students to highlight their academic work and projects. It is our contention that the latter category, web pages constructed by students that expand the audience for student academic work and projects, begins to capture the full potential of the World Wide Web in school settings.

In this study we investigated the degree to which student generated artifacts of science learning are represented in U.S. middle and secondary school web sites. A content analysis was performed on 20 randomly sampled high school web sites from each of the 50 states and the District of Columbia (total n=1020) to determine the presence and source or absence of science content. The sample was culled from secondary and middle schools listed by state in the Education Category of Yahoo (http://www.yahoo.com). Each web site was explored in depth to identify science content. A coding scheme was developed to represent the origin and purpose of science content:

0= No reference to science or science content present
1=Science content of an administrative nature (course and faculty listings)
2=Teacher generated science content (science faculty pages and course pages)
3=Student generated science artifacts (papers, projects, and web sites)
4=Exemplary student generated content

Preliminary results indicate that 40 percent of middle and high school web sites make no reference to science, a core academic subject. Approximately 30 percent of schools feature science information of an administrative or informational nature. Twenty percent of schools contained science teacher web pages or pages in support of their courses. Student generated materials were found in only ten percent of the web sites sampled. Of the ten percent, half featured student work that we determined to be exemplary and point in directions that communicate robust science learning in middle and secondary schools. Examples of exemplary web sites will be featured in this presentation.

We conclude that as the World Wide Web approaches the second decade of its presence in K-12 schools, on the whole it remains a one-way conduit into science classrooms. The full potential of the World Wide Web for science education will not be realized until the diffusion of information includes the artifacts generated by teachers and students, and central to teaching and learning, in their classrooms.
A Large-Scale Web-Based Electronic Portfolio System: Developing the Purdue Electronic Portfolio (PEP) System

Abstract: Electronic portfolios offer a powerful tool for students to demonstrate mastery of performance-based standards for teacher education. As one part of P3T3: Purdue Program for Preparing Tomorrow's Teachers to use Technology, Purdue University's School of Education is developing a large-scale, web-based, electronic portfolio system called the Purdue Electronic Portfolio (PEP) system. This customized portfolio system relies on a web-based interface to a database in Microsoft's SQL Server hosted on a large server with nearly two terabytes of storage space. The system allows students to store files and create artifacts, which are coherent collections of files coupled to reflective narratives that address specific standards. The system provides templates, which give users flexibility while providing ease-of-use and some flexibility. Completed artifacts are "published" as web pages. Pilot testing with several hundred users in the fall of 2001 suggests it is an effective tool.

Introduction

The national movement toward performance-based standards for teacher education has prompted much interest in the use of portfolios by pre-service teachers to document their knowledge and teaching performance (Barrett, 1999; Read & Cafolla, 1999). Portfolios are purposeful collections of student work that demonstrate effort, progress, and/or achievement (Barrett, 1999; Russell & Butcher, 1999). They are relevant to the student, individualistic, and can show growth and development over time, providing a richer picture of that understanding than can be achieved through more traditional, objective measures. They provide an opportunity for the pre-service teacher to demonstrate and organize his/her understanding of teaching and learning. Of course, they also provide one means by which pre-service teachers can be assessed.

Much of the interest in portfolio development is now focused on the use of electronic portfolios (Barrett, 1999, 2001; Read & Cafolla, 1999). Electronic portfolios offer several advantages compared to their paper-based analogs, including: reduced storage demands, ease of back-up, portability, ability to create links, and development of students' own technology skills (Barrett, 2001). In the context of developing pre-service teachers' own technology skills, electronic portfolios have the potential to help address the shortcomings of teacher preparation with regard to the use of technology that have been noted in a number of national reports (e.g., Moursand & Bielefeldt, 1999).
Purdue Electronic Portfolio System

Purdue University's School of Education is now implementing restructured elementary and secondary teacher education programs. These new programs feature a cohesive set of courses anchored by four strands – technology, diversity, field experience, and portfolio assessment. Purdue's PT3 implementation grant, entitled P3T3: Purdue Program for Preparing Tomorrow's Teachers to use Technology, is helping to support the implementation of these new programs. One P3T3 initiative is the development of a dynamic assessment system that provides pre-service teachers the tools and opportunities to select multiple ways of viewing their evolving teaching practice, reflect on that practice, and use digital representations to meet performance-based assessments. This large-scale customized electronic portfolio system is designed to accommodate the approximately 2300 students in teacher education, and provide for reasonable consistency in how students and faculty deal with portfolios. The Purdue Electronic Portfolio (PEP) system consists of a database developed using Microsoft's SQL Server, a popular web-based database engine. Access to the database is provided through web pages that use Microsoft's Active Server Pages (ASP) technology. This allows for dynamic interaction with the database through a simple-to-use web front end that is familiar to users. The entire system is hosted on an in-house server with nearly two terabytes of storage space, enough to give each user the equivalent of a CD-ROM's worth of personal storage.

Students can use the system to upload files and create artifacts. In our parlance, an artifact is a collection of files that the student assembles in the eportfolio system to address teaching proficiency. Students may classify artifacts according to three broad locally-developed themes as well as the ten INTASC principles that undergird many teacher preparation standards. To display the artifact, the PEP system features a template system that allows students to integrate a reflective narrative with links to various files that relate to a specific artifact (e.g., a written lesson plan, course assignment guidelines, a digital photo or even video of the lesson being taught). The templates provide flexibility in determining how the artifact will look, while providing consistency and ease-of-use. Once completed, the artifact is "published" as a web page with links to the integrated files. Initial pilot testing of the PEP system began in the fall of 2001 with about 400 students in Block I of the teacher preparation program. Results indicate the system provides the necessary functionality for student portfolio creation. The system may provide a model for other teacher education institutions interested in electronic portfolios. For more information, visit our website at: http://p3t3.soe.purdue.edu.

Abstract: This paper describes a process used to guide written reflections used for entries in technology portfolios that are required for teacher licensure in North Carolina. While supporting artifacts are important evidence of meeting ISTE’s technology standards for teachers (NETS-T), we believe the focus of our electronic technology portfolios should be on our preservice teachers’ ability to reflect about their personal and professional uses of technology for teaching and learning. This paper includes an example of an entry from our model electronic portfolio that clearly delineates all the steps of The Reflection Cycle: selection, description, analysis, appraisal, and transformation.

Introduction
Reflection is a highly valued attribute of effective teachers (Henderson, 1996; LaBoskey, 1994; Lyons, 1998; Ross, Johnson & Smith, 1992; Zeichner & Liston, 1987). Without the disposition to reflect on their performance, teachers are less likely to improve their practice or to be able to see the links between theory and practice. While some research states that only 20% of teachers are naturally reflective (LaBoskey, 1994), we believe that this habit of mind is so important that we must try to teach all prospective teachers how to reflect on their practice. One way we do this is to use a specific model of reflection with our preservice teachers while they are developing their teaching and technology portfolios.

In our teacher education programs at The University of North Carolina at Greensboro (UNCG), we provide many opportunities for reflective writing including response journals, electronic discussions, self-assessments, and peer coaching. We also explicitly teach a process for reflective writing in our elementary education program and emphasize this practice while our teacher candidates are gathering evidence for their technology portfolios. Reflective thinking and reflective writing are required in our curriculum, but we focus on developing these skills during the preparation of technology portfolios that are required for initial licensure of every teacher in North Carolina. In our post-baccalaureate elementary teacher education program, we also focus heavily on reflective writing, as these students must prepare an integrated teaching and technology portfolio as a requirement for the Masters degree. Another incentive for teaching our students a specific process of reflective thinking is that the state of North Carolina requires initially-licensed teachers to prepare a performance-based (PBL) product, which is essentially a teaching portfolio, in order to obtain a professional teaching license. In an effort to help our prospective teachers be successful in developing their PBL product, we begin teaching them a specific process for reflective writing using The Reflection Cycle (see Figure I) during their preservice teacher education program. We hope that this process has heuristic value for our students as they move into their chosen profession, so that they will think reflectively about their students’ learning, the curriculum, and their teaching practices.
Figure 1. The Reflection Cycle

Integrated teaching and technology e-portfolios

While some teacher education programs at UNCG require separate technology portfolios, most require teaching portfolios with technology integrated throughout them. Technology and teaching portfolios emphasize reflection that requires descriptive, analytical, and transformative writing about the evidence presented in these portfolios. Although our portfolios are organized around standards, including the ISTE NETS-T and the INTASC standards (or our state's Advanced Competencies for Master Teachers for M.Ed candidates), our prospective teachers are asked to use The Reflection Cycle to justify how their artifacts meet each standard. The overall goal of this focus on reflection is to foster understanding of how technology will impact teaching and student learning. We find that pushing our preservice teachers to go beyond describing the evidence in their portfolios to analyzing and appraising it, and then to thinking about how it transforms their practice, requires a concerted effort on their part and ours.

Recently we have begun the process of moving from print to electronic portfolios that integrate teaching and technology standards, following models developed by Helen Barrett of the University of Alaska. However, our version of e-portfolios continues to emphasize reflection and use of The Reflection Cycle. In fact, we spend as much time helping students learn to reflect on how they can use technology to promote student learning as we spend on refining their own technology competencies as professional educators. As our preservice teachers begin collecting evidence to demonstrate mastery of the NETS-T and INTASC standards, they simultaneously learn and practice their reflective thinking and writing skills. Evaluation of their e-portfolios is based mainly on their success in using The Reflection Cycle to (a) describe each entry, (b) analyze why and how their evidence meets a particular standard, (c) appraise their evidence against their effectiveness for teaching and learning, as well as against the goals, values, and philosophy of the standards, and (d) write transformative statements about how the evidence applies to their teaching practice and how they will do things differently in the future.

Scaffolding reflective writing

Among the supports we provide our preservice teachers as they learn to use The Reflection Cycle are examples of reflective writing based on this model. We provide both good and poor models of reflective essays so that our preservice teachers can identify elements of The Reflection Cycle in examples that are well-written and those that need revisions, or may even have essential elements missing from the examples. We follow this with written feedback on drafts of reflective essays submitted with supporting evidence, which will eventually go into their teaching/technology portfolios. We also provide opportunities for peer coaching and peer feedback when at least half of the preservice teachers have become adept at using The Reflection Cycle.

The following example, which is taken from the model Teaching/Technology E-Portfolio that we have online at http://www.uncg.edu/soe/affiliates/teachers_academy/e_portfolio/main.html, actually has the parts of The Reflection Cycle labeled, so that readers can easily see the selection, description, analysis, appraisal, and transformative sections of the reflective essay. This example meets NETS-T #6 (Teachers understand the social, ethical, legal, and human issues surrounding the use of technology in PK-12 schools and apply those principles in practice.), as well as INTASC principles # 9 (The teacher is a reflective practitioner who continually evaluates the effects of his/her choices and actions on others (students, parents, and other professionals in the learning community) and who actively seeks out opportunities to grow professionally.) and #10 (The teacher fosters relationships with school colleagues, parents, and agencies in the larger community to support students' learning and well-being.). In fact, in the e-portfolio, standards that are indicated in parentheses are hyperlinked to copies of these standards. There are also hyperlinks to specific artifacts that provide supporting evidence for the reflection, such as the PowerPoint slideshow discussed in this example.

Example of Reflective Portfolio Entry about Social, Legal, Ethical, and Human Issues (ISTE-NETS-T #6)
Select: I developed and facilitated a PowerPoint presentation for parents and teachers at a PTA meeting at Verifine Elementary School (INTASC #9, #10). The presentation was about social, ethical, legal, and human issues with respect to technology use (NETS-T#6).

Describe: During my presentation (see Artifact #1-PowerPoint slideshow) we discussed how to protect one's privacy while using the Internet. We identified problems and dangers that students might encounter when using the Internet and I demonstrated the filtering software that we use at Verifine School (see Artifact #2 – link to information about filtering software). Then we brainstormed rules that students would follow when they are online to avoid these problems (INTASC #10). Next, I explained the Acceptable Use Policy (AUP) at Verifine School (see Artifact #3 – copy of AUP). Each parent received a copy of the policy to discuss with their child before signing and returning it. (NETS-T #6, INTASC #10). Next we examined equity issues around technology. I shared statistics demonstrating gender inequity with regard to computer technology (NETS #6). We brainstormed strategies that students can use to recognize bias in materials. We also discussed some of the things that students need to consider when collaborating on projects, especially computer-based projects. We discussed what students and parents need to know when evaluating the authenticity of material found on the Internet. Finally, we talked a lot about copyright issues, especially how it relates to electronic material and how the "fair use" policy is used by educators (Artifact #4-link to copyright information).

Analyze: I think parents and teachers learned a lot from the presentation. I am also confident that they will share this information with their children and model responsible ethical and legal decision-making concerning technology (INTASC #9, #10, NETS-T #6). I found that my presentation was aided greatly by my use of technology (INTASC #9). Using PowerPoint helped me organize my presentation into a series of slides that contained talking points. As I facilitated the presentation and ensuing discussions, the slides kept me focused without having to look at my notes.

Appraise: I realized that parents are receptive to learning new things about educational uses of technology. They were glad to hear more about our AUP and to know that we are teaching how to use the Internet responsibly (INTASC #10). I believe that PowerPoint was an effective use of technology because it created a bright and appealing visual aid that kept the audience focused.

Transform: If I were to do this presentation again I would definitely use PowerPoint, but I would change two things. The first thing is that I would invite parents and students to come to the meeting together. The presentation is appropriate for children and they would have also learned a great deal. I think this would be a great opportunity for parents and children to learn something together (INTASC #10). The next thing I would change would be to include specific scenarios that deal with social, legal, ethical, and human issues around technology (Artifact #5-example of scenario about piracy). I think such examples would make the presentation more interesting and the content more understandable for the learner (INTASC #9, NETS-T #6). In the future, I also plan to make use of PowerPoint in the classroom because the visual nature of the slides will help some students stay on task and the organizational schema will help students understand and remember material – especially my visual learners.

Progress toward reflective thinking in e-portfolios

We believe the quality of our teaching/technology portfolios has improved over the five years we have required them. Such improvement seems to be commensurate with the focus we have placed on integrating the reflective cycle into our professional courses. By the time our prospective teachers graduate, reflecting seems to be a natural process and, hopefully, is one habit of mind they will take not only into their induction period, but throughout their teaching career. As we evaluate this year’s teaching/technology portfolios we will continue to refine our efforts to support prospective teachers as they learn to reflect about their practice and about their students’ learning. We feel that they have made progress during the past five years, but we will continue to strive to help our students develop into reflective practitioners.

A WEB Based Electronic Portfolio System for Tracking, Assessing and Displaying Candidate Performance

Leroy Metze and Mark Pitcock

Western Kentucky University’s College of Education and Behavioral Sciences has received an Innovation Challenge Grant from the United States Department of Education. The project, called e-train express, will implement programs and strategies that increase the number and quality of new teachers who are highly effective in using technology to facilitate, assess and communicate learning for all students.

Since only 20% of current teachers feel comfortable using technology in their classrooms and over two million new technology proficient teachers will be needed in the next decade, Western Kentucky University (WKU), along with partner schools [schools in the 28 districts of the Green River Regional Educational Cooperative (GRREC)], the Compass Learning Corporation and NetTango are implementing programs and practices designed:

- To ensure that all teachers who graduate from our teacher education program can use technology to increase student achievement;
- To ensure that all graduates can use technology to assess student learning;
- To ensure that all university faculty from both teacher education and the arts and sciences departments can model effective technology-assisted instruction for prospective teachers;
- To ensure that electronic portfolios are used as the primary means of gathering data used in the evaluation of teacher performance;
- To use technology to show K-12 students that teaching is a good career option; and
- To set up an electronic clearinghouse that will give teachers and teacher educators throughout the country access to exemplary technology-assisted lesson plans and assessments.

Western Kentucky University believes that technology has the potential to make teaching and learning far more efficient than in the past. Technology not only gives people access to new information, it gives them more opportunities to work together. The e-train express will enable WKU to integrate technology in teacher preparation courses and use technology to spread the best practices that develop from them.

During the first year of the e-train project the focus has been on two areas: Ensuring that all university faculty from both teacher education and the arts and sciences departments can model effective technology-assisted instruction for prospective teachers and establishing and using an electronic portfolio system for tracking, assessing and displaying candidate performance and assessing our program. This paper focuses on the development and use of our electronic portfolio system.
This paper describes:

- The process of developing critical performances for every course taken by teacher candidates in teacher preparation courses and courses in the arts and sciences;
- The process of developing scoring rubrics for these performances;
- The development of a web-based electronic portfolio system for tracking candidate behaviors related to each critical performance;
- The development of an assessment system for evaluating candidate work using the electronic portfolio system;
- The development of a process for making selected student work available for perspective employers and others to view;
- The development of a procedure for assessing our program using data from the electronic portfolio system; and
- The process that has been developed for other colleges and universities to share our system.

For more information about e-train express, please see [www.etrainexpress.com](http://www.etrainexpress.com).
Development of Digital Portfolios in a Outcomes Based Curriculum

Jacques Morin, Zayed University, AE

Zayed University is located in the Gulf Region in the United Arab Emirates. It is a 3 year old all female institution providing undergraduate education in an outcome based curriculum.

This year, the university will graduate its first ever class. All students are required to create a digital portfolio related to the published outcomes for each of the colleges.

Two departments are involved in assisting Faculty in the development of these portfolios for students. Media Services and Information Technology.

This paper describes the start up issues of Media Services and IT and the training required for Faculty to allow them to be technologically competent to assist student in the development of digital portfolios.

As the institution moves towards digital portfolios for students, several key factors have been identified as requirements including the level of technology competence for Faculty and the availability of production facilities.
Electronic Portfolios in Teacher Education: From Design to Implementation

Abstract: In this session, we share results of our second year of electronic portfolio design and implementation. We highlight the pedagogical and programmatic considerations that have emerged from the portfolio models. Suggestions for other institutions who are considering electronic portfolios centered on reflection and performance based artifacts will be shared. Our presentation includes specific portfolios representing various licensure areas.

Background

Due to concomitant national and international teacher education initiatives, namely performance based assessment and educational technologies for teaching and learning, the implementation of electronic or digital portfolios as a major means of assessment is growing. By June 2002, our university is mandated to have a performance-based Unit Assessment Plan (UAP) in place. Our institution has identified student electronic portfolios as one performance assessment instrument for demonstration of multiple competencies. Engaging in the electronic portfolio process will also help students to develop technology-related knowledge and skills.

Our portfolio model includes a focus on student reflection and performance-based artifacts. Given the longitudinal nature of the student portfolio, reflection will become more rich and complex as students continue in the program. Students use course assignments along with outside experiences as potential artifacts to demonstrate competency in the INTASC and state standards. Building with their first education course through student teaching and induction years, candidates will offer an evolving portrait of their growth as prospective teachers supported by hyperlinked artifacts that demonstrate and exemplify this reflective development and competency.

Preliminary Findings

We highlight only two issues from our on-going analysis for promoting reflection and demonstrating competency in electronic portfolio environments.
Reflection

The anticipated level of reflection was not apparent in the students’ electronic portfolios. Even though the students were told that their portfolio was a place to process, the students did not want or feel comfortable reflecting on highly personal or ambiguous issues in a web-based format. One student shared that the gloss of a web page forced her to write in a way that appeared as “finished” and “clean”. In addition, the reflections are mainly text-based as students made limited use of hypertextual language structures and almost no use of other digital media. Students reported a lack of experience across their curriculum with writing in electronic hypertextual environments. The quality and depth of reflection in the oral portfolio presentation however, was far greater than the students’ written text. The ability to reflect orally in presentation format and in interactions with instructors and peers holds great promise for capturing rich reflection.

Artifact Choice and Justification

The artifact choice in a portfolio may well be one of its most important components. In our portfolio model, the artifact is matched to a standard and is meant to document current competency. Equally important is the artifact rationale in which students articulate their justification for inclusion in relation to a particular standard. The rationale is meant to make implicit and explicit connections for the student as well as for the reader. Students were to 1) explain why the artifact was filed under a particular standard, 2) describe how the artifact fits into a student’s growing competency, and 3) explain their strengths and weaknesses in relation to a particular standard.

Many students struggled with a coherent fit between the standard, the artifact, and the rationale. This was more prevalent with freshmen that were just becoming familiar with the various standards while trying to learn the technology and make decisions about appropriate artifacts. Upperclassmen who already had working knowledge of the various standards were better able to choose and create appropriate rationales for artifacts. This discrepancy may also be influenced by the wealth of potential artifacts that the older students had available to select from, as well as their confidence in their knowledge and ability to justify their progress in their degree program. For many however, the rationale and artifact were treated as isolated items with little relation to each other. It will take time in the program to teach students how to “think” about their work in portfolio terms.

Significance

Increasing numbers of universities moving to electronic portfolios will require university educators to provide assistance in the process of deep reflection and performance-based competency in this new medium of representation. While our data are not generalizable to other contexts, the issues raised here may alert others to similar areas of concern. One potential danger lies in the treatment of knowledge as superficial and “thin” at a time when the concept of knowledge as constructed and dynamic in nature persists. In an attempt to infuse technologies into the teaching and learning process for preservice students, we may inadvertently misdirect our students in terms of representing knowledge growth. Our initial work demonstrates the importance of the purpose of alternative assessment method as capable of capturing long term process and alternative representations of knowledge.
Data from this study suggest that researchers in this area may need to explore new methods of collecting reflection as it appears in new hypertextual and hypermedia forms. These data also suggest that instructors must teach students how to explicitly make the connections between artifacts and meaning-making rationale. The way in which we ask preservice students to verbalize abstract, complex, possibly ethereal, and certainly fragile understandings of the learning to teach process affects what and how they tell us. If language creates a particular view of reality and of the self, we need to investigate how language and meaning are mediated by digital environments. Van Manen (1990) raises the issue of the epistemology of language and text when he states:

> We must not forget that human actions and experiences are precisely that: actions and experiences. To reduce the whole word to text and to treat all experience textually is to be forgetful of the metaphoric origin of one’s methodology (p. 39).

The Model of a Teacher's Electronic Portfolio: Enhancing Instructional Planning

Ju Park
School of Teaching and Learning
University of Florida
United States
juwonp89@hotmail.com

Abstract: The purpose of the short study is to suggest how a teacher's class web site, as an electronic portfolio, can be efficiently designed for instructional planning. The findings guide a teacher to avoid haphazard web site designing. Specifically, the suggested model of a class web site covers the sections of a teacher's biography and course information.

Introduction

Teachers have used various types of technical skills and products such as web sites, multi-media presentations, educational videos, and so forth to facilitate learners' achievements (Shuell & Farber, 2001). Upon finishing a particular lesson, a teacher usually starts to evaluate students' results or productive outcomes in several ways. Students who actively participate tend to have a stronger learning experience through integrated instructional technology (Fischer, 1996).

An electronic portfolio has become a new method for faculty's assessment of student's lesson outcomes and even for pre-service teacher education (Read & Cafolla, 1999). Furthermore, teachers have used their own electronic portfolios as a supporting instructional resource. However, there are some aspects to be critically considered for designing efficient faculty's class web sites. With respect to sections on a class web site, one can differentiate, customize, and develop his and her class web site that stores text, photos, and graphics; even pictures on a class web site produce diverse meanings upon viewing (Zammit, 2000).

According to the study of Lankes (1995), there are several types of electronic portfolios: Teacher planning, proficiency, showcase, employment skills, and college admission. The electronic portfolio as a class web site is based on the perspective of a teacher-planning portfolio.

Using the suggested model of faculty's web site (Ruffini, 2000) is to serve for a teacher's electronic portfolio. Ruffini's model has three main sections: Biography, course information, and publications. Those are critical for portfolio development, which demands several developing stages such as collecting, inspecting, purpose and audience, and so forth (Barrett, 2000).

Advantages of an electronic portfolio as a class web site

Electronic communications in schools have created opportunities for teachers to interact with their students quickly without limitation of time and location. In order to have this advantage, teachers and students need to have computers, printers, fax machines, and other equipment for various communication ways. Among these, a teacher's electronic portfolio serves as a class web site that gives students more convenient access to updated information and better understanding about the class. The teacher's class web site becomes the storage of students' completed projects, allowing other students see what classmates have produced for each project. In comparing others' works on a teacher's electronic portfolio as a class web site, students can do the following:

- Improve her/his productivity, Adjust new information to one's learning strategy, Have answers to questions via updated information, Create and innovate new idea, Raise critical comments in group activities, Improve access-quality beyond the limitation of time and location

A class web site at schools becomes not only a collection of a student's work, which demonstrates her/his skills and achievements in projects or activities, but also a class electronic bulletin board, which posts class schedules, current students' activities, students' personal directory, an upcoming assignment information, and so on. Among models suggested by Lankes (1995), the teacher planning electronic portfolio is used as a class web site and a collection of students' accomplishment. A teacher may use an electronic portfolio to receive information about incoming students in order to effectively plan both a class curriculum and instructional design and strategy. As a result, the teacher may have an idea of the level of knowledge and employ the electronic portfolios as a pre-assessment for classes before a class starts.

A teacher may store a sample of an assignment while students start to create an assignment. For example, if assigning the creation of the timeline of American Civil War in Florida in a social studies class, a teacher may post several sample works in order to give students in and out of a class better understanding of format and components. In viewing these samples, students are able to consider what they need for a project and to provide sufficient information for specific events in American Civil War in Florida. Furthermore, students in a group activity can communicate with group members and discuss their projects via an electronic bulletin board in a class web site.

Suggested factors in a class web site
In designing a class web site, a researcher found that employing systematic approaches will help prevent a haphazard web site because an ill-planned web site may cause students to be confused and distracted when they attempt to retrieve information (Ruffini, 2000).

To design an effective class web site, a teacher may include the following factors:

- Target Audiences, Objectives, Contents, Page Design and Structure

In terms of appropriate level of instruction, a teacher should consider prerequisite skills and knowledge, learners' current levels of knowledge, and predicted objective outcomes. In considering these factors, the teacher can design a class web site that is user-friendly accessible and appropriate for the incoming students. When a teacher designs a class web site, the teacher should ensure that the information included for students is consistent with instructional objectives. Several reasons to have the class web site consistent are; it reduces vagueness of instructional objectives, emphasizes the purposes of the class, and clarifies the information required for assignments, projects, and class preparations. With respect to contents, accurate information is critical to make a class web site a relevant information resource. Inaccuracies in the content of the class web site may misguide students.

Zammit's research on graphic icons (2000) shows that "pictures and graphics are more likely to be seen by different users in different ways than would chunks of text" (p.217). Due to that, a teacher should, upon planning and designing, consider user readability. It would be difficult to satisfy all students' comprehension of information provided in a class web site. However, as long as the class web site is not e-commerce web sites, which are typically long and complex, a teacher may be able to create and maintain an unequivocal class web site. When applying these ideas, a class web site serves as a teacher's electronic portfolio and may include several sections: Instructor's background, information for the class, and a collection of students' products; each section may also have several sub-sections.

Conclusion and Discussion

"E-mail is used to facilitate communication among students or between the instructor and students; and electronic discussion boards and liaison are used to expand classroom discussion" (Shuell & Farber, 2001, p.119). Other than e-mailing, some of the valuable ways in which electronic portfolios can be used are: Posting outcomes of students’ learning, management of teachers’ instructional strategies, and storing and supporting academic information by school library media specialists. The electronic portfolios can be designed systematically in order to facilitate maximum functions with respect to delivering and storing information. If a teacher cannot store or manage many students' electronic portfolios due to capacity of file volumes and computer system, media specialists should manage such huge portfolios for most teachers and students in a school media center (McDonald, 1997). There are issues concerning the collaboration between a teacher and a media specialist in meeting instructional needs of students' electronic outcomes.

Year Two of the Electronic Portfolio Project at the University of Florida

Gail Ring, University of Florida, US

Abstract: In this session I will report the results of the first year of implementation of the electronic portfolio project in the College of Education at the University of Florida. I will address the successes of the project as well as project weaknesses.

Background

The college of education at the University of Florida has completed its first full year of implementation of the Electronic Portfolio Project in which all preservice teachers are required to develop, publish, and maintain electronic teaching portfolios. During this first year we have learned what contributes to the success of such a program as well as what impedes its success.

The Purpose

All students majoring in Early Elementary Education, Elementary Education, and Secondary Education at the University of Florida are required to develop and maintain an electronic teaching portfolio. The purposes of the portfolio are to:

- present illustrations of competency in the 12 Florida Accomplished Practices;
- promote the use and integration of technology in the educational experience at UF;
- promote the development of a professional vita;
- provide a forum for connecting a student's university experience to personal and professional insights;
- provide a better understanding of professional requirements for certification beyond the University of Florida, i.e., National Board Certification.

In addition, our students have come up with different ways to use their portfolios. For example, some students use(d) their portfolio as a teaching tool, others as a way to push themselves to learn more about innovative uses of technology.

Strengths of the program

The Electronic Portfolio Program has enabled the college to involve students in their education. Students have commented that throughout their program they were often just taking classes, not really thinking about what it was they were learning. More than one student noted that the development of the portfolio enabled them to step back from their assignments and reflect on what they were learning and its relevance to their teaching. Student comments such as: "After I began to work on my portfolio and put all the elements together, I began to see that I really had learned a lot!" reiterate that reflection is a necessary element of the portfolio development process.

Weaknesses of the Program

The first year taught us a great deal about the implementation of a college-wide innovation. We learned that the success of the project is directly correlated to the level of classroom integration. In other words if the faculty don't actively support the project the students are often going to feel that it is an add on and will go away, or that no one will look at the portfolios so they can be put together quickly at the end of the semester.

Student Benefits
The e-portfolio was designed as way to encourage students to make connections between the theories they are learning in their courses, their assignments, and the authentic experiences they have in their field work. In addition, developing a web-based portfolio of their work enables students to learn how to use and integrate technology throughout their graduate program. This provides our students with technological fluency. In addition, through their reflective (rationale) statements students provide tangible evidence that they have a clear understanding of the Florida Accomplished Practices.

Programmatic Benefits

The portfolio project is part of an intensive change effort at the college, and as such has the potential to impact the curriculum, level of technology integration, and evaluation. Change, however, is rarely easy and not embraced quickly and evenly. Although many professors had little involvement with the portfolio project in the first year, by the second year, many are beginning to discuss portfolios with their students and seeking ways to integrate the electronic portfolio project in their courses. In addition, many professors who have not previously used technology in their teaching are taking advantage of the faculty development opportunities available to them in the college.

Future Directions

As we proceed with the project we continue to have many questions about portfolio development such as: What factors in the development process contribute to richer student learning? How will developing a portfolio contribute to students' ability to reflect about their own work and their own progress? How does developing a portfolio contribute to the students' perceptions of themselves and their own abilities? As we continue to work with our students and their portfolio development, we hope to address these issues.
The Good, The Bad, & The Ugly: lessons learned from electronic portfolio implementation

Ann Rose, West Liberty State College, US

At the SITE 2001 Conference, we were inspired by the work being done with electronic portfolios. Returning to campus, we knew that this was something we wanted to do. It fit so nicely with what we had heard about the new NCATE guidelines. So, during the past year, West Liberty State College, a small 4-year state institution in northern West Virginia, undertook the challenge to move to performance-based assessment and electronic portfolios within the Professional Education Department. As a result, over 900 of the institutions 2500 students are now creating electronic portfolios for student and program assessments.

This decision was not made quickly or lightly and reflects our commitment to remain aligned with the new NCATE guidelines and the NETStandards. Through the development and implementation of our plans, we learned many lessons that should be valuable to any other institution considering a similar program. Our faculty required education on portfolios and performance-based assessment before we could begin discussing portfolios, electronic portfolios, or artifacts and structures. This lead to an enlightenment that perhaps some very tried, if not true, teaching methods might need to change. We conducted workshops and in-services in addition to one-to-one mentoring sessions. In addition to motivation for the common good of our students, we are approaching an NCATE review next year.

Once a commitment to portfolios was formalized, albeit some reluctance, a committee was formed to make a proposal. The format was determined to be electronic with a meshing of our NCATE Conceptual Framework and the INTASC Standards. Students would be required to select two artifacts to support each standard and provide a written reflection offering (1) a description of the artifact, (2) a statement relating how the artifact demonstrates work related to that standard, and (3) a personal reflection of future growth goals in this area. Additionally, each portfolio would include a personal statement/resume, a philosophy of education, and any additional information the student wished to include. Finally, it was decided that the portfolio would be conceptually introduced in the first education course, Introduction to Education and the technological mechanics would be addressed in the first technology course.

The second hurdle was the decision of how to “use” the portfolios. The department agreed that this should be an assessment portfolio demonstrating breadth, depth, and growth on the part of student. A comprehensive rubric was developed and a decision made to assess the student reflections rather than the specific content of each artifact. As a result, we back peddled and decided that each and every EDUC, READ or SPED course would include multiple assignments that would be designated as “potential” portfolio items. Each assignment should be performance-based and assessed within the course where it was assigned. The instructor of each course would be required to assess the assignment and give a course grade. From this collection of “potential” portfolio assignments, the student then selected the items for reflection and inclusion within the portfolio. The initial evaluation of the portfolio would be at the time of formal application to the Education Program. This usually occurs after approximately 60 credit hours. A committee of two faculty members would review each portfolio in conjunction with other admittance criteria.

The second assessment would occur midway through the professional/student teaching semester. At this time, the portfolio would be assessed to determine how the student demonstrated mastery of each of the standards. Again, a rubric was developed to guide a committee of three faculty members. Scores for each standard were noted and used to determine weaknesses in our program and courses. Students received an unacceptable, developing, acceptable, or exemplary rating. Feedback from this assessment is used for program modifications and department decisions.
One of the most challenging decisions was to use an electronic format. Several faculty were not comfortable with this idea. Unfortunately, these people are not comfortable with much of the technology available today and reflect many of the skills still found in our local schools. For this purpose, it became necessary to select a platform that was advanced enough to provide a comprehensive picture of the candidate's knowledge, skill and attitude yet still be consistent with what might be useful for future purposes (i.e. interviewing). We chose to build web-based portfolios with electronic documents, scanned documents and images, digital photos, video clips, and audio clips. Students were encouraged to link PowerPoint presentations, Web Quests and other projects as artifacts.

We have worked on this for one year and now know what we did right and what we did wrong. Our first set of portfolios has helped us to see what we should have considered. The largest problems we are facing are reluctant students and overworked faculty members. The students don’t see the value/need for these. They are very comfortable with the tried and true lecture to me and then give me two tests model. Many are kicking and screaming about a shift to performance-based assessment. Yes, it is more work for them; and for us, the faculty, too. The faculty found more work than expected in designing, developing and grading these portfolio assignments. Faculty had the additional burden of assessing the portfolios. Let’s see... 90 student teachers with 3 evaluators each means 270 assessments divided among 12 faculty members who don’t all do share. Sound familiar? This was the ugly part!

The actual portfolio results have been both good and bad. Some are disappointing. Others made it all worthwhile. The elementary students have more motivation but sometimes lacked the depth of reflection or technical skills. Some of the secondary students really showed their expertise and have portfolios on CDs that will certainly open many job doors. Some others, often by major, are less satisfactory. For us, we will continue and hope that we can grow from our lessons learned. Perhaps, our lessons learned will help you too.
Promoting Paperless Portfolios as Assessment in Graduate Level TESOL Programs

Annis N. Shaver  
Department of Teaching and Learning  
University of Miami  
United States  
ashaver@miami.edu

Mary A. Avalos  
Department of Teaching and Learning  
University of Miami  
United States  
mavalos@miami.edu

Abstract: This article describes curriculum and course design innovations for electronic portfolios used as a final evaluation in a graduate level TESOL program. Components of this portfolio are authentic documentation of the abilities mastered by the inservice teacher during the course of graduate study. The highlighted components, among others, are compiled into an electronic portfolio, making use of a multi-media format (i.e., digitized video clips, tape recordings, photographs) in a PowerPoint presentation.

The use of portfolios as a means of authentic assessment and evaluation has become increasingly popular in undergraduate as well as graduate programs (Tellez, 1996). Graduate programs often make use of portfolios in place of traditional comprehensive exams as final student evaluation. As technology becomes the norm in all areas of education, such evaluation portfolios are becoming paperless. Recent research indicates that paperless portfolios in graduate programs have distinct advantages over other conventional forms of assessment, such as the traditional portfolio or comprehensive exam (Jackson, 2000; Swain & Ring, 2000). Benefits of electronic portfolio assessment are demonstrated both in terms of authentic student evaluation and in students’ ongoing use of technology in their practical and professional endeavors. This presentation describes an electronic portfolio evaluation being developed for teachers in a graduate level TESOL program. While the concept of the paperless portfolio is well founded in the literature, the design is innovative.

The context for this qualitative study is a Teaching English to Speakers of Other Languages (TESOL) Master’s degree program at a large university in the United States, whose participants include beginning and veteran teachers. This presentation includes a description of components of the electronic portfolio based on core course work, the ESL Standards for Pre-K—12 Students (TESOL, 1997), Preprofessional Competencies for Teachers of the Twenty-First Century (Florida Education Standards Commission, 2000), and National Board Certification Standards (National Board for Professional Teaching Standards, 2001). The portfolio contents are assembled by the program participants during the year-long program of study for the Master’s Degree. The skills acquired by participants will be beneficial in promoting technological expertise.

An innovative twist to this portfolio design is the integration of the components across the program curriculum. As we researched previously designed electronic portfolios and planned implementation of such a portfolio into our program, we noticed that components of many such portfolios were based on one specific set of standards, i.e., best teaching practices, with the student required to document competency in each area. Because teaching is such a complex and integrated field, we decided it would be a more authentic form of assessment to design components enabling teachers to demonstrate multiple competencies over time and across graduate courses. Our faculty collaborated to design portfolio components that integrate the objectives of several classes, and to re-design class projects in order to support these components. They worked to ensure that each exercise would be a truly authentic assessment of TESOL pedagogical practices. One component, for example, is a case study that integrates language assessment with knowledge of linguistic subsystems, knowledge of second language acquisition, and knowledge of TESOL theories and practices. Other features of
this innovative electronic assessment include video clips of the students teaching, and student-designed internet-integrated curricula for K-12 students learning English as a second language.

The Linguistic Assessment Case Study component was the result of a brainstorming session of the TESOL faculty. It integrates material learned in four courses: Applied Linguistics, Language Assessment, First and Second Language Acquisition, and Theories and Practices in TESOL. It also integrates the TESOL Standards dealing with language and assessment, seven of the twelve “best” teaching practices and five of the twelve National Board Standards. When preparing this component of the portfolio, the student will implement an on-going authentic assessment of a learner with limited English proficiency (LEP) for one academic year. The learner’s progress will be assessed through a collection of interlanguage samples. Progress will be scored using analytical rubrics and the assessor’s knowledge of linguistic structures as they relate to these subsystems. The learner will be assessed in the areas of speaking, reading, writing and content areas. Second language acquisition will be assessed compared to the theoretical sequence of second language acquisition. TESOL theories and practices will aid the assessor in prescribing curricula for the learner based on the assessed needs.

The Integrated Webquest Unit integrates two TESOL standards, nine accomplished practices, and eleven National Board Standards. Using the combined knowledge of TESOL theories and practices, concepts in multi-cultural education, and curriculum design for LEP students, the student will design an integrated multi-media/web-based unit for second language learners.

Another opportunity to demonstrate knowledge and skills acquired throughout the program of study is the Practicum Portfolio. While working with an experienced ESOL teacher, the student will have the opportunity to observe and reflect on teaching practices, and to prepare and present lessons in the classroom. The Practicum Portfolio will be a collection of the lessons taught, reflections on teaching practices and issues in the LEP classroom, observations on lesson modification, and a collection of classroom students’ work.

The implementation of each of these components, and other portfolio elements, requires the student to learn many technology skills. Students become proficient with PowerPoint software, video equipment, and scanning techniques, while creating the portfolio. While many teachers and students already have technical proficiency and use it in the classroom, there are many more who do not. By preparing this electronic portfolio, students are required to hone these skills in order to prepare a quality product.

While our electronic portfolio is still in the implementation phase, preliminary work by current graduate students has produced positive comments. The master’s degree program is intense, lasting slightly over one calendar year, but students feel the benefits of the electronic portfolio far outweigh the extra work required to prepare it. They already predict the implementation of the portfolio will lead to better knowledge and understanding of the concepts for teaching ESOL students. The opportunity to put these concepts into practice works to strengthen the student’s academic self-efficacy. These teachers expect to make use of the technology skills learned in this process in their own classrooms. Many have commented that they foresee the electronic portfolio as a useful tool in securing a teaching position in the TESOL field.

To summarize, this presentation showcases the innovative, integrated components of this TESOL Master’s Degree electronic portfolio. In addition, we exhibit the usefulness of the paperless portfolio as an authentic, visual future reference for prospective employers. Finally, this presentation displays how the electronic portfolio assessment augments students’ technological expertise, preparing them for the challenges of teaching diverse students in an increasingly high-tech classroom.

Meeting Technology Competencies: The Digital Portfolio Approach

Liz Stephens, Southwest Texas State University, US
David Byrum, Southwest Texas State University, US

Prospective employers and accreditation agencies expect preservice teachers to provide documentation of their work in education. Universities are moving from traditional scrapbook portfolios to digital portfolios (Aschermann, 1999). The traditional teacher portfolio is a collection of artifacts from course work and field experience in a three-ring binder (Louisiana Tech University, 1997). In contrast to the traditional portfolio, the digital portfolio is simple to update and makes distribution of multiple copies reasonable. The digital portfolio eliminates storage issues while providing preservice teachers with a powerful means of circulating their work (Polonoli, 2000). Preservice teachers who create digital portfolios enhance their technology skills and make themselves more marketable (Milman, 1999).

Recently, we received a PT3 grant to extend our “Viewing and Doing Technology” program into the elementary school blocks and our field-based faculty. Training sessions for the elementary faculty are held throughout the Fall and Spring semester conducted by faculty who have expertise in certain areas of technology. These new technology skills are in turn used by faculty to model and assign technology components in their classes. For a more complete description of the “Viewing and Doing Technology Project” please see our website http://www.ci.swt.edu/vdt/vdt.html. As part of the grant, the committee charged with setting the standards for the VDT program decided to begin a digital portfolio process for the preservice teachers in the elementary program. The digital portfolios will contain artifacts demonstrating the technology skills acquired during their course of study.

The following are several of the many questions we addressed in considering a digital portfolio showcasing the preservice teacher’s technology competencies.

1. Which technology standards should be used? (ISTE, TEKS, INTASC, others)
2. Which should have prominence in the portfolio, the standards or the content (artifacts, reproductions, productions, and attestations)?
3. What format should the digital portfolio take? (web based, hyperstudio, pdf, PowerPoint)
4. Which web authoring program should be used? (FrontPage, Dreamweaver, Netscape Composer)
5. Should the portfolio be template driven or should students be allowed to create a portfolio from scratch?
6. How much time will it take for students to assemble the portfolio?
7. Should step-by-step instructions be developed to guide the student through the process?
8. What type of artifacts should be included?
9. Should the artifacts be in their native format (for example, a Publisher or PowerPoint document) or should they all be converted to pdf files?
10. How should artifacts be stored prior to being put in a digital portfolio? (floppies, zip disk, CD-RW)
11. How should the portfolio be distributed? (Web based or CD-R)
12. At what point in their professional program should students begin assembling their digital portfolio? (first semester, second, or third)
13. Organization: how should the standards be displayed or presented and linked to the teachers work?

This paper/presentation will discuss many of the questions posed above. The presentation—rather than repeating the printed material—will share the digital portfolio products created by students.

Collect, Select and Reflect: Using the Electronic Portfolio in Teacher Preparation

Paul Walsh, Johns Hopkins University Center for Technology in Education, US
Gigi Devanney, Johns Hopkins University Center for Technology in Education

Traditionally artists used portfolios to demonstrate their work. More recently many artists have created websites to highlight their accomplishments, expand their client base, and increase opportunities for feedback from the art community. The education profession can reap great benefits from shifting from the three-ring binder scrapbook approach for portfolios to a web-based, standards-driven collaborative tool for both pre-service teacher preparation and professional development. The Electronic Portfolio developed by Center for Technology in Education at Johns Hopkins University offers a comprehensive view of a teacher’s performance and potential. This web-based tool hosts selective collected works, interpretations of standards, professional development goals, educational philosophy, journal entries, resume, and the ability to gather feedback from throughout the education community.

Electronic Portfolios have the capability to increase professional growth, improve teacher quality, and ultimately raise student performance. Accessible anywhere users can get to the web the Electronic Portfolio becomes the teacher’s online filing cabinet as they gather potential artifacts. Refinement of these resources involves reflection on the part of the teacher and collaboration with peers and advisors. Reflection is an integral part of the Electronic Portfolio as users seek to interpret program standards and integrate a solid foundation of subject matter expertise with the most current knowledge base on teaching and learning. Being electronic, users have the ability to request feedback from others on any element of their portfolio, without giving access to the entire portfolio. This allows users to craft their interpretations, rationales, reflections, and evidence without surrendering control of their portfolio.

Working with the nationally recognized traditional portfolio structure required in the Masters of Arts in Teaching Program at Hopkins as a foundation, the Center for Technology in Education has created this Electronic Portfolio application that allows teachers to analyze their own practices with the ease of an intuitive, web-based tool. The Masters of Arts in Teaching Program has embraced this solution and now requires all MAT students to use the Electronic Portfolio to collect their evidence and present a finished portfolio to a review team. The review team also benefits from the move to an electronic portfolio conducting preliminary evaluation and scoring prior to a face-to-face presentation.

This presentation will highlight the functionality of this application developed by the Center for Technology in Education (CTE) and the reflective process conducted by the Masters of Arts in Teaching Program (JHU) to implement a program wide electronic solution. Participants will gain an understanding of the promise of Electronic Portfolios and their implementation across an entire program. The presentation (lecture-interactive) will start with an identification and honest appraisal of traditional portfolio programs followed by the goals set out for development of an Electronic Portfolio system. Hurdles such as faculty and student training and implementation will also be discussed.

In that any set of standards or principles can be entered into this application (ATE, INTASC, etc) presenters will use ISTE NETS to showcase the functionality of this tool. Presenters include those who developed-coded the application, those who have implemented it across the MAT program, and MAT faculty to ensure a complete program team capable of engaging a wide audience on a number of levels. Presenters will demonstrate actual teacher portfolios, not just samples. A website explaining the Electronic Portfolio and offering a brief tour will be complete prior to the conference (www.cte.jhu.edu/epweb).

Participants need no prior knowledge of Electronic Portfolios.

Abstract: A PT3 team discusses their trials, tribulations, and triumphs of implementing electronic portfolios at a larger teacher certification university with programs across several departments and colleges. The presentation will share the templates designed, training provided for implementation, and technology advancements and purchases dictated by the implementation.

With the move of NCATE toward a documentation developmental portfolio, many teacher education institutions are taking the process to a digital format. This makes a lot of sense considering the wider range of artifacts that can be included in a very compact archiving format. The ease of cross-referencing artifacts to multiple standards is another benefit. Over the last few years, we have attended many conference presentations on digital portfolios. We have gained much insight into format, style, and artifacts. However, we were often left wondering how to translate the information to our particular situation. Many of the presentations dealt with relatively small student populations and a few faculty members in the portfolio development process; but our institution is considerably larger with over 100 faculty and approximately 3000 teacher certification students. Our college has decided that electronic portfolios will be required as part of all teacher education programs. Students are required to have an electronic portfolio begun as part of their admission process to the teacher education program. Fall 2001 was the first year of this new admission requirement, so in three years ALL education majors will have developmental electronic portfolios. This paper will share the lessons learned though our last two years as we have begun the development and implementation of electronic portfolios. We will share information on the questions we asked and answered, the problems that occurred, and the team building that was necessary for a project this size.

Building Ownership

While the PT3 grant team had been charged with assisting with the implementation of the electronic portfolios, we knew that we could not infuse the portfolios across the entire teacher certification program by ourselves. Because the programs are distributed across multiple colleges on campus, we decided to use a built-in mechanism to assist with the implementation. The College of Education Associate Dean provides the central link for all the undergraduate teacher certification students across campus. His office is responsible for filling the applications with the State Department of Education. This Associate Dean established a Teacher Education Coordinating Council (TECC) that works on the unifying processes that are necessary to have conformity of
requirements. In the past this council has dealt with such issues as student teaching evaluation forms, student teaching handbooks, and pre-student teaching meetings. This group seemed the logical place to begin.

The members of our PT3 team attended several meetings of TECC, explaining the expectations of NCATE and the potential of electronic formats. A committee was then formed from TECC and PT3 to work with the Assistant Dean to establish some standards for the electronic portfolios at IUP.

The Templates

The portfolio committee met several times debating questions such as: content that should be required of all students, what should be optional, confidentiality of information, what the expectations should be, rubrics, and formats. The student teachers had been required to make portfolios for several years; however, these were hiring portfolios created in their senior year. The requirements for these portfolios gave us a place to start with some of the content requirements. It was decided that all portfolios would include a resume, philosophy statement, health screenings, clearances, and transcripts. The final discussion was the inclusion of standards — Which ones? We had seen portfolios built on NCATE standards, ISTE standards, and INTASC standards. After some discussion, it was decided to use NCATE standards in our electronic portfolios. Members of the committee put together three different forms of the portfolio as examples to share with TECC: PowerPoint, HTML, and Word.

Templates were created that the students would be able to personalize, but the basic content would remain consistent. The templates began with a home page. This page included the name, contact information, major plus links to the resume, philosophy statement, health screenings, clearances, and transcript pages. A menu line is included on all the major pages of the templates allowing for easy navigation. Instructions on the pages tell the students to cut and paste information into the page or insert images of scanned documents.

The standards page becomes a little more involved. The NCATE standards can be rather lengthy to include all of them on one page, so the committee decided to abbreviate the standard statements on the initial page. When you click on an individual standard you are taken to another page that provides the entire standard statement. Students are then to include artifacts that illustrate their progress toward meeting the standard. We have established practices of reflective statements in our education programs, so this was continued into our electronic portfolios. The students are asked to reflect on the artifact attached to a statement, explaining why it is being used and what it says about their working toward the standard. Students are encouraged to use artifacts to illustrate multiple standards, which was difficult in a traditional portfolio.

Spreading the Word

One week long workshop on creating portfolios was offered during the summer. Faculty at this workshop were taught how to use Netscape Communicator and how to modify the templates. The foreign language faculty attending the workshop wanted to include their professional standards into the templates. The PT3 team assisted with this modification. During Fall 2001, the PT3 team offered a series of workshops focusing on implementing the portfolios. Workshop topics were: Using Netscape Communicator to Create Electronic Portfolios, Using MS FrontPage to Create Electronic Portfolios, Inserting Graphics into Electronic Portfolios, Adding Video to Electronic Portfolios, Adding Audio to Electronic Portfolios, Using a Digital Camera for Electronic Portfolio Artifacts, Incorporating Artifacts into Electronic Portfolios, and Burning CD’s. Interest in portfolios began to increase as people began to see ways to utilize the portfolios in their individual courses. Handouts were created on each of these topics to enable faculty to review on their own and to reduce the amount of preparation time they would need to introduce portfolios in their own courses.

The PT3 team attended a meeting for the education faculty across campus looking at the upcoming NCATE review. The electronic portfolios were shared at this meeting. We offered to assist departments with the implementation. Subsequently, we attended a departmental meeting to share the portfolios and answer questions. The PT3 team worked with several departments, making nearly 20 visits to individual classes,
modeling for faculty how the portfolios could be developed with students. The templates have been made available to students in classes, from internal servers, and our PT3 site (http://www.coe.iup.edu/PTTUT).

One faculty member, who had been a part of the TECC Portfolio Committee, began the semester utilizing portfolios with the students in her program. She has provided the PT3 team with much needed feedback on how the templates work and how we might improve the process. Similarly, by co-teaching classes with faculty, we gained feedback that was used to improve our templates and handouts.

During the semester break two separate workshops were offered. One day long workshop assisted faculty members in making example portfolios for their individual programs and courses. The second workshop encouraged departments to begin looking at the larger picture of where artifacts could be created and how their department would systematically integrate electronic portfolios.

Support for Student Portfolios

The College of Education and Educational Technology at Indiana University of Pennsylvania actively supports and assists the students as they develop their portfolios. Not only do we provide portfolio templates for our students and train our faculty how to teach the students the necessary computer skills to create their portfolios, but we also provide a special Portfolio File Server for students to use as a repository for their portfolio files. Each student is currently provided 40 megabytes of storage on the Portfolio File Server, and students can request more space if needed. Each student has a folder, identified with their user name, on our Portfolio File Server, and the access rights are set such that only the student has access to the folder and any files within the folder. The Portfolio File Server does not provide web access to student portfolios because of our concerns about confidentiality.

In addition to the Portfolio File Server provided by the College of Education and Educational Technology, the university provides additional special server storage space for students to share portions of their portfolio with their faculty on a Project Directory Server. The graphic below shows the folder structure of the Project Directory Server. Each semester, a folder for each course taught at the university is created on the Project Directory Server. Within each course folder, there is a folder for each section of the course. Within the section folder, there are several folders including a hand-in folder for students to submit assignments, an information folder where faculty can place files they wish to share with students, and a student folder for use by the students enrolled in the particular section of the course. Within the student folder, there is a separate folder for each student, and only the student and the faculty member teaching that section of the course have read and write access to the individual student folder. The student folder provides space for sharing files, including portions of their portfolio, with the faculty member teaching the course. Since only the students have access to their own personal folders on the Portfolio File Server, students can copy portfolio artifacts from the Portfolio File Server to their folders within a course section on the Project Directory Server where their faculty member can view the files.
Figure 1: Project Directory Server File Structure

Since the Portfolio File server does not provide web access, if students wish to place part or all of their portfolio on a web server, we recommend that they use one of the many free web hosting sites or contact their Internet provider for web space.

Students can burn a copy of their portfolio to a CD when they need to share their portfolio with other people. We have provided multiple CD burners for this purpose in each lab within the College of Education and Educational Technology at the university. All of the computer labs within the college have scanners, CD burners, and web page development software.

The College of Education and Educational Technology has also created a Portfolio Studio where students can get additional instruction on using CD burners, scanners, digital cameras, video editing equipment, web page development software, and other helpful tools for portfolio development. A graduate assistant and practicum students are available in the Portfolio Studio to assist students and faculty.

Conclusion

While the integration of electronic portfolios is far from finished at our institution, we feel we have made great headway. There are still questions to be answered and hurdles to be overcome, but the departments are beginning to wrestle with them. For example, questions still remain on mechanisms for advisor review of portfolios at different stages of student progress through their programs, as well as on organizing the college portfolio server. Moreover, the PT3 team could not design each program's portfolio - that needs to be done internally. Nonetheless, the challenging task of creating the training, instructional materials, and infrastructure for nearly 3000 teacher preparation majors to create electronic portfolios is well under way at our university.
Providing continual and detailed faculty development for all teachers is now absolutely vital as every teacher's role has shifted to meet the demands of a rapidly changing society. A growing commitment in some PK-12 school districts and institutions of higher learning is creating a stronger need for effective faculty development.

American education must be transformed to meet the needs of an emerging information society as new communications technologies impact higher education. Attaining this goal requires that teachers meet professional standards. Today's society needs a workforce that can apply knowledge, reason analytically, and solve problems. Faculties must be trained to determine the most appropriate tools for design, support and delivery of courses. The challenge for continuing professional development and renewal to adapt to this changing environment has become critical. Faculty must use recently acquired knowledge and new skills to adapt existing courses to implement new technologies. The standards for teachers supporting these new skills have been developed by the professional organizations governing accreditation in each academic field (NCATE, 2001).

Both the International Society for Technology in Education (ISTE) and the National Council for the Accreditation of Teacher Education (NCATE) have specified the technology skills that teachers are expected to have when they enter the teaching field. These organizational standards provide the foundation for the professional development programs designed for higher education faculty. ISTE suggests that teachers be able to meet these standards: apply tools for enhancing their own professional use and productivity, use technology in communicating, collaborating, conducting research and solving problems, promote legal and ethical use of technology, use technology to support their instruction, and plan the delivery of instructional activities that integrate technology (ISTE, 1998).

The papers included in this section address various approaches available to meet the professional development challenge of these new standards. The papers represent the four areas of long papers, short papers, interactive sessions, and institutional sessions. The 26 long papers cover general informational clusters as diverse as pre-service and preK-12 initiatives in professional development, online and other distance education initiatives in staff development, campus models for faculty development, program implementation strategies and technologies, and case studies and research in faculty development. Specific topics range from "Technology Integration in Teacher Education: Changing the Way Learners Think About and Do Their Work" and "Integration for ESL Success: TESOL Standards, Multiple Intelligences and Technology" to "Tracking a Faculty Online Course Impact" and "Project Merlot: Bringing Peer Review to Web-based Educational Resources". Additional detailed papers cover a center-based approach to assessing the integration of technology within a context of change, perspectives of coaches and players in faculty technology development, and the use of a problem-based learning methodology for faculty development.

The 23 short papers cover topics on the changing roles of college faculty, using a questionnaire to induce reflection on educational practice, making technology meaningful to faculty, a peer mentoring program that empowers higher education faculty to use technology to enhance teaching and learning. Papers concerning Web-based instruction in undergraduate nursing education, a joint instructional technology and library needs assessment program, the transition period between technology and careers, and faculty adoption of technology are also presented.

Three interactive session papers are included. Michael Utendorfer of New York Institute of Technology describes "Adding "FLASH" to your Faculty Development Program." David Deorgi of California State University at Bakersfield discusses "Operationalizing a Technology Standard with Proficiency Skill Sets" and faculty from the University of Alabama at Birmingham contribute "Technology Committee Function: Holly Jolly Technology Folly."
The two institutional session papers are entitled “Re-creating Curriculum Integrity through Professional Development in the Information Age” from the East Windsor Regional School District and “Evidence for Campus Transformation Through Instructional Technology Faculty Development” at Southeast Missouri State University.

This diverse collection of Faculty Development papers describes effective initiatives and innovative models that have been designed and conducted to improve the use and integration of technology at institutions of higher education and PreK-12 educational settings worldwide. Taken as a group, the methods and models provided will aid in the effective training of faculty and will address the critical need for continuing professional development and renewal to adapt to the rapidly changing technological environment.

Faculty Development with Technology Integration: A qualitative analysis of faculty mentoring.

Ronald Abate, US
Judy Stahlman, Cleveland State University, US
Abu Nasara, Cleveland State University, US

Abstract

The Modeling Instruction With Modern Information and Communications Technologies (MIMIC) Project was funded through a U.S. Department of Education Preparing Tomorrow’s Teachers to Use Technology (PT3) Implementation Grant. The MIMIC Project focused on faculty development in the integration of technology in pre-service teacher education. A classroom teacher as mentor / faculty member as mentee approach served as the model for faculty development. Data was collected from both technology mentors and faculty participants. This data included qualitative components including; implementation plans, monthly log data, and journals. Project evaluation activities were conducted to address both formative and summative evaluation questions that examined the validity and impact of the project. The evaluation was designed to provide performance feedback throughout the grant period, allowing the project staff to monitor progress towards the desired outcomes.

A comprehensive sequence of qualitative evaluation activities were implemented to insure that the goals proposed by the Mimic Project were addressed satisfactorily. A monthly review form tracked project activities and verified if planned activities occurred as scheduled. Progress notes were recorded and used to modify planned activities. Mentors together with each faculty member prepared an implementation plan and maintained notes on support provided. This qualitative data was used to modify mentoring plans. Logs of technology activities implemented by participating faculty and supervising teacher provided qualitative data documenting technology use by the participants.

This paper examines the results of qualitative analysis of participant journals, implementation plans and monthly logs. Content analysis and data management analysis was implemented using NUDIST. Patterns indicated in the data analysis pointed to critical factors for increasing the level of faculty modeling of technology in pre-service teacher education.
Integration for ESL Success: TESOL Standards, Multiple Intelligences and Technology

Abstract: English language learners need an education that builds upon their strengths and acknowledges their differences while developing their English language proficiency. They also need opportunities to develop information technology skills that will prepare them for the increasingly technological job market. The TESOL standards for Pre-K-12 ESL students make it possible for ELLs to achieve the standards for academic subjects while developing English language skills. Teachers incorporating MI theory for ELL instruction support the rich diversity of cultures and languages in the classroom, provide a framework that enhances teaching and help students develop all of their intelligences. The integration of technology, TESOL’s standards, and Multiple Intelligences supports learning differences, promotes technological competency and develops English language skills across the curriculum. Preparing preservice teachers who can integrate technology, TESOL standards and the theory of Multiple Intelligences provides their future students with an equitable education.

Introduction

English language learners (ELLs) generally differ in native language, cultural heritage, social experiences, and prior learning from native English speakers. They need an education that builds upon their strengths and acknowledges their differences while developing their English language proficiency. In addition, they need opportunities to develop the information technology skills that will prepare them for the increasingly technological job market. By 2006, half of all jobs will be in information technology or will require information technology skills (Carvin, 2000). In order to provide English language learners with the opportunity for a viable economic future, we must prepare them to become technologically competent.

To cultivate teachers who can meet the needs of a variety of students, teacher educators must rethink and reassess preservice teacher education. Teacher education graduates should go into their classrooms with a repertoire of professional skills and instructional methods, an understanding of second language acquisition and cultural diversity, expertise in second language teaching methods, and competency in the effective integration of technology. Our graduates should be able to teach students who differ in cognitive strengths, cultural background and language proficiency. Preparing preservice teachers to integrate technology, TESOL standards and the theory of Multiple Intelligences (MI) provides their students with an equitable education that supports learning differences, promotes technological competency and develops English language skills across the curriculum.

Diversity in Schools

Within the United there are 176 languages spoken at home (Grimes, 2000). In addition, there are some 154 indigenous American languages (Estes, 1999). Between 1979 and 1995, the number of school age children who spoke a language other than English and who had difficulty speaking English rose from 1.3 million to 2.4

Each cultural group has its own set of learning expectations and its own emphasis on what should be learned (Hopkins, 1998). Gardner asserts that learning characteristics are the consequences of cultural, motivational, and experiential factors that can be enhanced when teachers teach to students' strengths in the Multiple Intelligences (MI) (as cited in Ghosn, 1997).

Federal and state mandates require accommodation for the needs of English language learners (ELLs). Yet only 76.8 percent of limited English children in public and non-public schools were in programs designed to meet their educational needs (NCBE, 1998). The remaining 23.2 percent percent received little or no support for their English learning needs. Teachers who are not trained in second language teaching methodologies often find themselves with ELLs in their classrooms. But only 20 percent of classroom teachers report feeling well prepared to meet the needs of limited English proficient students or those from diverse cultural backgrounds (National Center for Education Statistics, 1999).

Information Technology

By 2006, half of all jobs will be in information technology or will require information technology skills (Carvin, 2000). Education, as preparation for constructive citizenship, requires the preparation of technologically competent individuals who can locate, manipulate, and organize information to solve problems, create new knowledge and produce useful outcomes.

Children vary in their access to technology. For example, there is a 50 percent gap in computer ownership between households earning $14,000 or less and those earning from $50,000 or more (Nickell, 2001). Many ELLs are from homes where the income level is at or below the poverty line. Eighteen percent of Hispanic children use a computer at home as compared to 52 percent of White children (ERIC Clearinghouse on Urban Education, 2001). Similarly, the proportion of rural Native American households with access to computers is 26.8 percent, almost half that of the national average (Luening, 2000). Only 2 percent of children living in poor, rural households have Internet access (Children's Partnership, 2000). Children from the poorest households and living with adults with the least schooling are the least likely to have Internet access at home. Moreover, because eighty-seven percent of documents on the Web are in English (The Children's Partnership, 2000), the web is largely inaccessible to an estimated 32 million Americans who are non-English speakers (Children's Partnership, 2000).

For ELLs, schools are a primary location for accessing information technologies and for developing computer skills. However, schools with the largest concentration of children in poverty had a 9:1 ratio of students to computers as compared to the national school ratio of 5:1 (Cattagni & Westat, 2001). In high-income areas, 74 percent of classrooms have Internet access, in low income areas 39 percent of classrooms do (Carvin, 2000). Teachers in poor inner-city and rural schools have less technology training than those in wealthier schools (Kleiman, 2000). Thus, children in the poorest regions of our nation have the least access to computers and the Internet at school. Many of these children are ELLs.

Though there are few studies on ELL children using information technologies, the research suggests that the integration of technology can improve academic achievement, promote English and native language proficiency, augment positive self-concepts, enhance motivation, stimulate positive attitudes towards learning, and foster higher level thinking (Diaz, 1984; Knox & Anderson-Inman, 2001; Meskill, Mossop & Bates, 1998).

Information Technologies, Multiple Intelligences and TESOL Standards

Information technologies provide varied entry points to learning that match the learners cognitive strengths and intelligences, as well as language proficiency level. Technology combined with cooperative learning not only increases instructional effectiveness and efficiency, but also promotes positive social interactions (Johnson, Johnson, & Stanne, 1986; Schlechter, 1990). Cooperative learning at the computer enhances ELLs' communication skills (Steinberg, 1992), meets the needs of those with strong verbal/linguistic and interpersonal intelligences, and develops social and collaborative skills. Partner and small group work offers an authentic purpose for oral communication, as well as peer support for academic content and development of technological competencies. Multimedia, computers and the World Wide Web can address the
multiple intelligences through varied forms of input and output. For example, they relay text, music, video, photographs, and visual art. Voice recognition and digital sound recording allow for oral/aural input and output, while graphics provide ELLs with comprehensible input.

Teaching that incorporates MI theory helps support the rich diversity of cultures and languages in the classroom while providing a framework that enhances teaching and helps students develop all of their intelligences. Information technologies combined with MI theory enrich students’ learning experiences and induce students to want to learn because the learning activities appeal to their personal intellectual strengths.

The Teachers of English to Speakers of Other Languages (TESOL) standards for Pre-K-12 ELLs "articulate the developmental English language needs of English language learners and highlight special instructional and assessment considerations that must be given" so that these children may “benefit from and achieve the high standards proposed for other subjects” (TESOL, 1997, p.2). The TESOL standards are guidelines that help teachers address the challenges accompanying the increasing numbers of English language learners.

Content and language instruction that incorporates technology and TESOL standards has multiple benefits for ELLs. The integration of TESOL standards with MI theory and information technologies provides a structured, intentional approach to the development of second language proficiency across the curriculum while enriching the learning experience. This integration ensures an equitable education by providing access to technology for authentic purposes to those students least likely to have that access outside their school. MI theory and technology afford numerous entry points into the academic content while the TESOL standards allow teachers to plan for students’ English language growth in a variety of contexts and for a variety of purposes.

Figure 1: Sample activities integrating information technologies, MI theory and TESOL Standards

Figure 1 illustrates how learning activities can integrate technology, MI theory and the TESOL Standards across disciplines. These sample activities address content area knowledge, higher level thinking, and...
problem solving, while building on students' intelligences and developing English language skills. Integrated activities such as these make learning meaningful, transferable and engaging because they complement students' preferred ways of learning, develop weaker intelligences, and engage students in genuine communication. Technology in this approach becomes a viable means to attain information, reconstruct knowledge, and demonstrate learning. Technology thus serves as a means to an end, rather than as the end itself.

Teacher Education

Given the rich diversity in America's classrooms and the continuing inequitable access to technology, teacher education programs must prepare future teachers to meet the needs of their diverse students. Preservice teachers not only need to spend time in multicultural classroom settings, but they must demonstrate professional skills, instructional flexibility and the ability to apply a variety of methodological approaches. Because future teachers will likely have ELLs in their classrooms, all preservice teachers should know and be able to use a number of second language teaching methods. Preservice teachers must not only be familiar with the TESOL standards, but be able to apply them in classroom instructional activities.

Graduates of our teacher education programs should translate theory into practice, including MI theory and language acquisition theory. This ability can be fostered by explicitly drawing attention to their own learning and to their instructor's modeling of effective instructional practices. Preservice teachers do not readily perceive how their instructors apply theory to teaching while they are immersed in the process of learning. To see the link between theory and practice being modeled by education faculty, preservice teachers must be observers, not just participants. Education faculty should help preservice teachers reflect on what they observe and see how teachers' instructional behaviors are linked to theory. For example, the instructor may ask the class which theories underlie the learning activity they have just participated in and which multiple intelligences were addressed during the class period. In short, the teacher educator must make explicit what is implicit in their own teaching and serve as models of good teaching.

Preservice teachers also need to know more than how to use a computer and run software applications. Such knowledge can be gained outside the College of Education. Computer knowledge and competency does not readily translate into effective integration of technology in the classroom. In order for preservice teachers to understand how technology becomes a part of effective instruction, they must see inservice teachers and education faculty using technology. They must discuss what they observe school teachers and university faculty doing with technology in the classroom, understand what are essential and what are nonessential uses of technology, and evaluate the educational value and appropriateness of software applications and Internet sites. They must learn how to use technology to meet educational objectives. And they must have opportunities to practice planning and using technology for instruction.

Similarly future teachers need to learn how to effectively connect technology with the diversity and multiplicity of intelligences. Teacher educators should model the integration of technology, TESOL standards and MI theory in their own teaching. In learning how to create lesson plans, preservice teachers can assess the quality of online teacher-created lessons in terms of appropriateness of technology integration, support for multiple intelligences, incorporation of TESOL and state standards, and provision for linguistically and culturally diverse learners. This assessment develops awareness of how lessons can be adapted or improved to meet the needs of diverse learners. Once preservice teachers understand how technology, TESOL standards and multiple intelligences can be integrated, they can begin to plan and implement such lessons.

Attaining the goal of graduating teachers who can teach to a diversity of learners, help ELLs expand their second language proficiency, and use technology in pedagogically sound and effective ways is not easy. It requires faculty and administrative commitment, faculty development, technological resources and conscientious planning. But ultimately, the integration of technology, TESOL standards and multiple intelligences is a win-win educational experience for preservice students and, in turn, for their future students.

Vocation or Profession?
The Changing Roles of College Faculty

Bob Bermant and John Knight
Department of Psychology and Department of Philosophy
University of Wisconsin Waukesha
rbermant@uwc.edu and jknight@uwc.edu

The emergence of online course software such as BlackBoard, Prometheus, and Web-CT has made it relatively easy for faculty to add a web-based component to their traditional classroom courses and it has fostered the evolution of new pedagogical strategies and formats including web-enhanced, hybrid, and completely asynchronous instruction. As a result it is likely that faculty are investing significant time to develop materials and modify pedagogy so that it is appropriate for and compatible with these new instructional modalities. Therefore in important ways the demands on contemporary college faculty are changing and along with these changes have come new roles with very different expectations. This paper investigates the impact of these changes and explores faculty perceptions of how the work of the professoriate is evolving in an age of rapid technological change.

A colleague recently asked the following question, “Do you use BlackBoard or a blackboard”? A few years ago the question would have seemed absurd. No longer. Today instructional technologies such as BlackBoard, are fostering new and for some confusing opportunities to re-engineer their courses. For faculty in our own institution, the University of Wisconsin Colleges, the pace of technological innovation is breathtaking.

At the beginning of each year we are confronted with new options, new opportunities, and new reasons to feel overwhelmed. This year for instance our IT staff held short courses on everything from Outlook to Acrobat and from BlackBoard to Win2K. Pity the poor faculty member who is struggling just to stay on top of work in his own discipline. Now he must juggle .doc files, Ethernet cables, and the virtual “F” drive on the server. No wonder, among our peers, prescriptions for Prozac are skyrocketing.

Simply put, the job we took some twenty-five years ago and the job we have now display some superficial similarities, but in important ways they are very different. Yes, we still teach or try to teach that bunch of teens that seems to miss many of our jokes and fails to appreciate our sartorial brilliance. But today we compete with MTV, AOL Instant Messenger and cell phones that ring during our classes. It is tempting to ask, “is it for me”? Of course change is inevitable, but that doesn’t make it desirable.

So what has happened in those twenty-five years? Well, the PDP-11 down the hall with those large 8” floppies has been replaced by the iBook on a desktop with Wi-Fi. The floppy is or should be nearly extinct, and the web, merely a twinkle in the eyes of Tim Berners-Lee back in the frontier days of the late ’80s, has emerged and become pervasive, indeed inescapable.

Today, who or what does not have a www address? BB is thinking about getting one for his foxtt-errier, www.zeke.org. Cable modems, and DSL have replaced those 56k guys which in turn have replaced modems that not that long ago operated at an incredible bandwidth of 28.8 k! Now our TI’s sometimes bog down and seem slow! The alphabet soup of technology pervades the college quad; mp3s, XP, 10.1, urls, jpeg, gifs and we suppose, a few gafts. Don’t get it? Well, “you’ve got trouble, my friend, trouble right here in River City” as the Music Man once said. Trouble indeed. Just try to remember the Chinese symbol for misfortune can also mean opportunity.

Sometimes we feel like novice carpenters who have just picked up a shiny, new Craftsman toolkit at the local Sears store. Look at all those wrenches, ratchets, pliers and planes. Nice to have, for sure, but what the heck do we do with all this stuff?

The sociologist down the hall has a beautiful array of PowerPoint slides; the graphic artist in Southview loves Photoshop, and the PE fellow across the way does kinematic analysis on his laptop. And the math folks upstairs, they do mysterious things with MathCAD, Maple, and Macs. The English tutors pride themselves on their virtual writing lab. The philosopher among us has a club on-line and the psychologist will confess to using BlackBoard for
just a few things. What is the point? Simply this: information/instructional technology (IT) is seeping into our lives, changing what we do, and more importantly, how we do it. Are you college professors? Yes, but sometimes we wonder.

Steve Jobs, CEO of Apple Computer, once characterized the computer as a “bicycle for the mind.” Like a physical bicycle, a computer can transport you anywhere you choose to go. Problem is, you have to have a destination before you can get there. So, where are we going and how will we know when we have arrived? The multiplicity and diversity of applications makes instructional technology tough to define. It is difficult to distill its essence, assess its influence, and quantify its impact.

We recently surveyed our faculty to learn about their experiences with and perceptions of information technology. One hundred fifteen surveys were completed representing twenty percent of the sample. We discovered that about seventy-five percent of our faculty use some form of IT and that their response to it has generally been favorable. Although faculty indicate that IT enhances their teaching, they also note that it takes additional time, that technical support has been lacking, and that it can be difficult to navigate. On the other hand, our faculty appear to value their increased accessibility, e-forums for discussion, and the ability to put materials on the web where students can get at them 24/7. And yet at the same time, they complain about the lack of institutional recognition combined with not so subtle pressure to use IT, persistent network glitches, the absence of adequate evaluation, and the emphasis on “WHAT we can do; instead of WHY we are doing it.”

Computers and more importantly, the WAN and LAN infrastructure gives us easy access to distributed resources, wherever those resources may physically reside. Text, graphics, images, audio, and video files are just a mouse-click away. It is no longer an exaggeration to say that, “the world is at our fingertips.” But another equally appropriate aphorism comes to mind, “the world is what we make it.” Given immediate access to an exponentially expanding electronic universe, sometimes it is tough to discriminate a meaningful signal from what often appears little more than a sea of random noise. Sometimes it is tough to separate the wheat from the chaff.

Perhaps that is why we seem to struggle with technological stress. We wrestle with computer-driven constructivism, worry about courses as commodities, fear the art of teaching will be lost among the ruins of technology, and mourn the loss of physical presence. And yet, however dissatisfied, disaffected, disillusioned, and disheartened, we still come to class on Monday. We still cherish the possibilities of the classroom.

Just as some of our courses have assumed a hybrid character, combining face-to-face meetings with Internet-mediated time-out-of-class; arguably, our roles as teachers have also become an amalgam, requiring not only disciplinary expertise, but a not inconsequential level of technical skill as well. BlackBoard or blackboard; vocation or profession? Perhaps the answer is somewhat less important than the question. Teaching and learning remain quintessentially human endeavors. Yes, XP is cool, Wi-Fi (802.11b to the cognoscenti) really rocks, and the web can be a wonderland. Some things have changed but the most important things have not.

Whether we are thinking about adopting a textbook or constructing a web site; choosing a compelling software application or finding a new anthology, the task remains much the same. As teachers our job to identify the best resources whatever form they may take, discover the most effective ways to use them, and then continuously evaluate their impact. In this as in so many other endeavors, sound analytical skills and good old common sense make an unbeatable combination.

It is easy to be seduced by technology, and to be infatuated with the thrill of “connectivity.” There is a certain undeniable sex appeal in a shiny new laptop, a colorful array of PowerPoint slides, a well-constructed web site emerging from the ether, and evidently, a cell phone that rings during class!

In the hands of an artisan the most primitive of tools can yield a masterpiece; after all, Shakespeare wrote with a quill. But even with a 1.2 GHz Pentium and a broadband connection, a monkey probably couldn’t do very much of note. Just as tools don’t make a carpenter, technology doesn’t make a teacher. Carpenter or teacher, the tools can make a tough job a bit easier, but in the final analysis it isn’t the tools that make a difference; it is what we do with them that counts.
Inducing Reflection on Educational Practice with a Questionnaire Tool

Jo Breda, Kim Waeytens, Mieke Clement
University Educational Support Office
University of Leuven
Belgium
Jo.breda@duo.kuleuven.ac.be
Kim.waeytens@duo.kuleuven.ac.be
Mieke.clement@duo.kuleuven.ac.be

Abstract: In order to encourage the acceptance of student course ratings by faculty and to provoke reflection, a questionnaire tool was developed that allows faculty to select questions that closely fit their personal subjective theories on education and their specific educational practice. As a first stimulus for reflection, frameworks are introduced that need to be used in the tool to describe educational practice and subjective theories. As a second stimulus for reflection, feedback on subjective theories and educational practice is given. The hypothesis was that the questionnaire tool heightens the commitment of faculty to the evaluations results and enlarges the impact of student course ratings on faculty’s thinking.

Introduction

Student course ratings are often used to enhance professional development. One of the common problems in the use of student course ratings is a failure to tune the questionnaire to the educational practice and subjective theories of faculty. The proposed questionnaire tool is designed to be flexible and adaptive to the specific needs of the users.

Faculty accept results of evaluation better when they feel committed to the evaluation and when they have a perception of high usability of the evaluation instrument (Waeytens, Elen & Lowyck, 1999). To heighten the commitment to the evaluation, contribution of faculty to the evaluation process is maximised. In the questionnaire tool, faculty decide themselves whether they want an evaluation, which aspects will be questioned and what exact questions will be posed. To heighten the perception of usability, the content of the questionnaire needs to be in accordance with the way the user perceives reality (Smyth, 1990). In the questionnaire tool, faculty are invited to express their subjective theory. This theory will influence the questionnaire that will be the result of using the questionnaire tool. The challenge is not only to help faculty accept student course ratings as important feedback on their specific educational practice. The challenge is also to help faculty reflect on their educational practice, so that a student course rating can be a starting point to improve teacher thinking. Indeed, reflection upon professional educational action can be an important learning activity and a motor for improvement of teacher thinking (Clarke, 2000). As a first stimulus for reflection, the tool introduces frameworks that need to be used by the faculty to describe their educational practice and subjective theories. As a second stimulus for reflection, feedback on their subjective theories and educational practice is given.

Description of the questionnaire tool

The questionnaire tool consists of three modules. These modules are organised linearly, but strolling back and forth is encouraged through hyperlinks. At the end of the tool, which is the end of the third module, feedback can be given that refers the user to the first module, which makes the tool circular. The first module consists of a measurement of subjective theory. This measurement is based on Samuelowicz and Bain’s (1992) dimensional model about conceptions of teaching. This model proposes five constituent dimensions that underlie a global dimension reaching from student centred to teacher centred. For the tool these dimensions were extended to eleven dimensions, based on an overview of literature. These dimensions were transposed to eleven forced choice items. After filling out the forced choice items, users receive integrated feedback on different levels. The feedback consists of textual feedback on three clusters of items (items about
knowledge, the teaching process and educational goals). At the most basic level a textual elaboration is given for every forced choice item. After this feedback, faculty can loop back to the forced choice items to change their answers.

The second module consists of an analytic scheme with the form of a hierarchical network to describe educational practice. The parent nodes are organised in a global scheme of interconnected elements within a learning environment: student characteristics, educational goals, information, teaching methods, evaluation and student activity. Faculty is invited to indicate all the relevant aspects in the hierarchical network underlying this global scheme.

The third module combines both information sources (subjective theory and description of educational practice) in order to propose relevant questions for the faculty to compose a questionnaire. For every selected element of the analytic scheme, the list of questions is shown that is congruent with the subjective theories of the faculty. If faculty do not find their choice in the list, they can choose to select a question that is not congruent with their subjective theory. At that point they are suggested to check and change their answers in the first module of subjective theory. In this way, the system is circular since the faculty is redirected to the first module when their selection of questions deviates from the measurement of subjective theory. Users can also decide to go back to the second module and change their description of educational practice in order to receive different lists of questions to choose from.

The selected questions are printed on paper questionnaires and administered to the students. Faculty receive paper reports with their results compared to the results of the same questions of the whole university, and (if appropriate) with former evaluations. The possibility for electronic administration of the questionnaires will be offered after the initial test time.

Results and perspectives

The questionnaire tool is designed to be used on individual basis as well as integrated within a faculty development training. The questionnaire tool is currently in use in a training for beginning faculty. The tool will be filled out on an individual basis before the first collegial consulting session where the resulting questionnaires will be discussed. The second collegial consulting session shall be treating the results, the interpretation and planning for amelioration.

The individual use of the questionnaire tool seems to provoke reflective thinking and could as such be considered to be a powerful instrument to induce learning experiences. Preliminary findings of ongoing research suggest that users accept the framework of the subjective theory module. At the same time the feedback on subjective theory seems to induce reflection in that it opens perspectives to different views on education. The framework of the second module, the hierarchical network of concepts, seems to be difficult to understand and to work with. Maybe this framework does not relate strong enough to faculty’s personal interpretation of their educational practice. Further research on the way faculty can describe their educational practice is needed. An exploration of the frameworks non-users utilise to describe their practice, in comparison to the one used in the tool is launched in order to resolve this shortcoming.

Abstract: DePaul’s School of Education was the first implementation of a Needs Assessment designed jointly by the university’s Instructional Technology Development (ITD) area and the University Libraries. The goals for the Needs Assessment were to identify areas in which an expanded, unified and comprehensive faculty development training and support package would both address faculty’s perceived needs while also improving adoption of existing instructional technologies and/or services. The Library’s education bibliographer and the ITD consultant for education interviewed faculty representing a cross section of departments and programs as well as technological expertise. The results were analyzed; issues were sorted according to faculty priority and by length of time and resources needed to address them.

Introduction

In the months following a reorganization, two units in the newly combined Office for Teaching and Learning Resources – the General Library and Instructional Technology Development (ITD) – examined ways in which to deliver course management software training for faculty. In the first year, the two support areas established a successful working relationship by collaborating on faculty training for Blackboard, the course management system adopted for use at DePaul. The introductory Blackboard training session – led by instructional librarians – combined both an introduction to Blackboard as well as an overview of web-accessible library resources such as online journals, databases, and electronic reserves. From these initial collaborative efforts the need to identify and deliver an expanded, unified and comprehensive support package to specific academic units became apparent. The School of Education was the first implementation of the resulting Needs Assessment process.

Goals and Process

In planning for the Needs Assessment, four goals were identified: first, to ascertain opportunities, unique to the School of Education, to enhance faculty skills in instructional technologies and in online library resources; secondly, to design a training plan for the School of Education, based on results of the needs assessment; and thirdly, to provide an opportunity for Education faculty to become aware of the
services and tools available to them through these two offices. Lastly, the process developed would become a model for training needs assessment that could be applied to other DePaul academic units in the future.

Twelve open-ended questions were designed to stimulate critical reflection on the possibilities of electronic resources and instructional applications. Some questions referred to specific features of existing applications (i.e., “Education faculty could use the assessment features—online surveys, tests, and gradebook—in Blackboard to ______”). Other questions were more general in nature (i.e., “What have you seen others do that you’d like to do?”). Eight SOE faculty were selected to be interviewed; they represented a cross section of departments and programs as well as technological expertise. The Library’s education bibliographer and the ITD consultant for education met with each faculty member in individual sessions lasting approximately one hour. The results were analyzed; issues were sorted according to faculty priority and also—on the part of the Libraries and ITD—by length of time and resources available to address them.

Process Issues and Suggestions

Suggestions for future Needs Assessments fall into four categories: when to perform a needs assessment, what questions are to be asked, who is to be interviewed, and who will perform the interviews. In terms of when, the DePaul Needs Assessment was performed soon after an accreditation report that suggested improving technology integration throughout the school. It was found that by timing such a venture to coordinate with the school’s program review or accreditation cycle, faculty members were ready—and in some instances, eager—to comment on technology adoption issues. Questions referring to specific functions or applications may need to be altered for faculty who are not acquainted with that function. So a question such as: “If all Education courses had a Blackboard web site then ______” might be altered to: “If all Education courses had an easy-to-access web site where students could access resource materials, assignments, and hold discussions then ______.” Adding a question that could elicit suggestions on how to operate most effectively within the School’s unique culture might assist academic support areas in formulating successful training and support activities.

Faculty members in DePaul’s School of Education vary widely in their adoption of technology. It was, therefore, important to include among the interviewees as wide a range of users as possible, also making certain to include representatives of the various departments within the school. This meant that several faculty who were interviewed were previously unknown to the Library and ITD interviewers. The combination of using, for interviewers, the Library bibliographer for the academic area and the ITD consultant for the school or college seems best suited for DePaul’s unique academic support situation.

Conclusions

The process of meeting with key faculty members and hearing their input while introducing them to the work and services of these two support areas immediately strengthened the working relationships between the Libraries, ITD and the School of Education. The professional staff participating in the interviews became better acquainted with key faculty members. These faculty members, in turn, are more fully aware of the central services available to them from these two academic support units.

Short-term goals, which can significantly affect the current level of faculty understanding and application of currently available services—such as Carl UnCover—include simple-to-implement paper and e-mail communications specifically tailored for School of Education faculty. Workshops and Brown Bags on specific topics also provide immediate impact with minimal additional resources. It will be important to work closely with the School of Education in developing and advertising these sessions. In addition, success rates may increase if these sessions can be held either in or near School of Education offices.

In the long term, ITD and the Libraries can benefit from a continuing alliance with Education faculty on several issues and resources, including design of online versions of induction and continuing education courses, the curriculum materials center, redesign of computer classrooms, research and advocacy toward streaming video and audio, as well as applications to support streamlined administrative processes (e.g., Syllabi on line) and improved learning (e.g., database of case studies with video examples).
Making Technology Meaningful to Faculty:  
Two Approaches over One Semester

Lavinia McGhie  
Action Communities for Teaching Excellence  
University of Houston  
United States  
laviniamcghie@yahoo.com

Abstract: This paper provides two different examples of work during a single semester with two different faculty and two different PT3 team members. Example one shows how much technology learning can be accomplished over one semester with an open-minded and excited professor. Example two shows a different approach with a more technologically reticent professor. Each illustrates how different strategies must be enlisted for varying instructor needs and interests.

Introduction

Faculty contact is a chief component of the PT3 program because the knowledge the faculty members acquire through these services can then be delivered to the pre-service teachers. In this area, team members are assigned at least one professor to work with on integrating technology into their curriculum. In this paper, two different examples of work throughout one semester are discussed with the purpose of showing specific goals that can be accomplished in this amount of time.

Example 1

The first meeting with a new faculty is one of the most important meetings. In this, not only the importance of integration of technology into their curriculum is established, but the faculty is allowed to express their ideas and needs for the following semester. The technology fellow serves as both an assistant and a guide in the completion of the faculty's requests because he has access to hardware, training, and discipline-specific media that is easy to use (Groves & Zemel, 2000). In order for the approach to be successful, these three components are vital.

One of the strengths of this approach is that presenting technology in a way that is relevant to their individual needs can stimulate the instructor's engagement. In this example, the professor was a relative novice with little exposure to technology beyond basic word processing and email. She was intrigued by the possibilities of using technology in her curriculum, and her hesitancy was diminished by the one-on-one support of the technology fellow.

During the first meeting the discussion focused on what the professor wished to accomplish during the semester. In this instance, the faculty member's specialty was art education, and the display of graphics and images were central to her curriculum interests. PowerPoint was the most logical application to begin with, and it offered a convenient lead-in for the introduction of graphic file formats. Soon the instructor was requesting to learn about digital cameras and CD burners, as well as asking for server space. This instructor's enthusiasm continued, carrying her to learn Netscape Composer to begin to create web pages for her classes. As always, the technology fellow walked through the web process with the professor so that her comfort level was high and her understanding was guaranteed.
The whole process of working with faculty was extremely successful because it facilitated the transformation of an educator who gained important technology tools for teaching.

Example 2

The relationship between faculty member and Tech fellow is an integral part of the faculty experience within the fulfillment of the PT3 Grant. In this case, the faculty member was quite comfortable with his level of technology, but not particularly interested in new skills. Since the professor delivered a high number of presentations each year, PowerPoint was suggested as an alternative to his customary transparencies.

The initial meeting with the faculty member provides an opportunity for the assessment of needs. The professor’s method and style of presentation and the technologies that are utilized are all concerns that should be addressed. As found by Vannatta and Beyerbach (2000), the relevancy of technology issues and applications are key points in engaging the faculty in using new technology. The faculty member was particularly fond of his outline process for using transparencies, and needed to be assured that the transition from using the overhead to PowerPoint was a logical one. To demonstrate this, the technology fellow created two different versions of one of the instructor’s presentations. Upon seeing the prototypes, the faculty member was swayed by the flexibility and potential of digital presentations. He was quickly interested in learning to compose his own PowerPoint based on another set of transparencies for the next meeting. The tech fellow instructed the basics of the program informally by helping the professor convert another of his earlier presentations from transparencies to PowerPoint.

After the professor’s initial success with PowerPoint basics, he became more interested in the special effects aspects of PowerPoint and wanted to learn more advanced features within the application. He was particularly interested in inserting JPEGs and links to related websites that might be of importance to his class. Soon, the professor had created a slide show that he felt was ready for presentation. He showed confidence with the program and expressed interest in acquiring a CPU and projector for his class. By this time, he was also becoming interested in other programs such as Win Zip, and made plans for further technology interests.

Time is often a major factor for many of the faculty contacts and this professor was attracted by the conservation of time that the program offered. What seemed to impress him even more was the versatility of a program that could be utilized every semester. The overall experience for the faculty member seemed to be an invigorating one in that he took great pride in his creations and his expanding knowledge base and the contribution that by this grant was a motivational concern to all Technology Fellows. The coming year will hopefully encourage progress within the integration of more technology into his classroom and with time saved there may be an opportunity to include the usage of further applications.

Conclusion

The process of working with faculty through this grant was successful because the approach was individualized for each professor, and the resources such as training, hardware, and media were all available. The time and effort invested into this branch of the program has already paid for itself: professors are using technology in their education courses, and our pre-service teachers are understanding how the integration of technology can facilitate a lesson.

Project Merlot: Bringing Peer Review to Web-based Educational Resources

Ralph Cafolla, Ed. D.
Associate Professor, Educational Technology and Research
Florida Atlantic University, USA
cafolla@fau.edu

Abstract: The unprecedented growth of the Web has resulted in a profusion of educational resources. However, the challenge for faculty is finding these resources and integrating them into their instruction. Even after the resource is found, the instructor must assess the effectiveness of the resource. As the number of educational web sites mount into the millions, this task is becoming increasingly difficult.

To address the problems of finding instructional sites, evaluating their educational value, determining their accuracy and assisting professors to integrate the resource in a learning environment, the Multimedia Educational Repository for Learning and On-line Teaching (MERLOT) was established. The MERLOT virtual repository (www.merlot.org) of instructional materials is hosted by the California State University Center for Distributed Learning. The project also provides a peer review process to ensure the quality of the educational resource.

The exponential growth of the World Wide Web has resulted in a profusion of educational resources that are potentially useful in higher education. The challenge for faculty interested in using web-based resources as an important aspect of their instruction is finding these resources and integrating them into their instruction. Even after the resource is found, the instructor must assess the effectiveness of the resource. As the number of educational web sites mount into the millions, this task is becoming increasingly difficult.

The unparalleled growth of the Web is partly due to the fact is that just about anyone can develop a Web site. With the aid of inexpensive or free Web editors, creating a Web site is almost as easy as using a word processor. There are also a myriad of companies that will host your site for very little or no money. Since it is so cheap and easy to establish a web presence, the number of web sites, both good and bad, have proliferated. While using the traditional search engines can be useful in finding educational sites related to a specific topic, experienced Web users know how difficult it can be to find relevant information. Search engine may find a few million sites it deems relevant, but it does not separate the good from the bad.

Educators have a particular responsibility to ensure that Web resources that they use in their courses are authoritative.

The concept of authoritative gets at the question, “Who says this material is accurate?” By knowing the background of the authoritative source of a work, one can judge how much one trusts it. For example, if you access the Microsoft® knowledge base (Technet, 2001) to look up information on installing a new NT driver, you would tend to trust what you read. Also, if you access a particular professor’s course web site, you would know that the professor is the authority behind the information on the site. The professor’s students would know that they need to believe what they read, at least for the rest of the semester. Since these pages are probably posted on a university’s server, the reputation of the institution also gives it additional authority. However, until recently, there has not been any “objective” review of higher education Web resources available.

Even after finding the educational resource and determining its accuracy, the potential user must determine if the resource is effective in teaching or demonstrating the concept. A Web page could be both relevant to your topic and accurate, but may not be useful by the target audience you want to use it with. If it is pure text with no interactivity, has inappropriate vocabulary, or is simply ineffective instruction, you would probably not want to use it. To address the problems of finding instructional site, determining their accuracy, and determining how to integrate the resource in a learning environment, the Multimedia
Educational Repository for Learning and On-line Teaching (MERLOT) was established. The MERLOT virtual repository (www.merlot.org) of instructional materials is hosted by the California State University Center for Distribute Learning. As the project evolved, a peer review process initiated to "improve the effectiveness of teaching and learning by expanding the quantity and quality of peer-reviewed online learning materials" (University of Michigan, 2000). The balance of this paper discusses both MERLOT as a virtual repository of web based educational resources and as a source of peer reviewed resources.

MERLOT as a Virtual Repository of Education Resources

The MERLOT community has established and maintained a virtual collection of educational resources. Membership in the MERLOT community is open to any interested educator and there is no cost for membership. Once you have registered as a member on the MERLOT web site (www.merlot.org), you can contribute to the MERLOT community by posting links to web-based materials or by providing user comments to sites already posted. MERLOT members also receive periodic updates about MERLOT activities and projects.

Experienced Web users know that there are several ways to find information on the Web. When one is interested in searching for broad topics, a Web index like is useful. These indexes are useful for browsing, using hyperlinks to make it easy to navigate through a Web site. However, when you are looking for something more specific, a powerful search engine may be more useful. These search engines allow for complex searches using Boolean logic and sometimes even use artificial intelligence to find information. To accommodate both of these approaches, the educational resources, called learning objects in MERLOT terminology, can be accessed by either browsing through the materials by broad subject areas or using a powerful search engine.

Browsing the MERLOT Site

As shown on the MERLOT home page (see Figure 1: The MERLOT Home Page), the learning objects are categorized by both subject area (Arts, Business, Education, etc.) and academic discipline communities (Biology, Business, Chemistry, etc.).

Selecting a subject under the Browse Materials menu takes you to a screen showing the sub categories of the subject. For example, Figure 2: Science and Technology shows the categories produced by click on the main Science and Technology subject.

Figure 1: The MERLOT Home Page

Selecting a subject under the Browse Materials menu takes you to a screen showing the sub categories of the subject. For example, Figure 2: Science and Technology shows the categories produced by click on the main Science and Technology subject.
The discipline community index works in a similar manner. For example, selecting the Information Technology discipline from the Discipline Community drop-down menu displays the sub-categories of the discipline (see Figure 3: Information Technology Discipline Community).

While having two indexes to the site may be a little redundant, they provide two easy ways to browsing the MERLOT site. They are both excellent ways to become familiar with the variety of learning resources available. However, as noted above, sometimes a powerful search engine is better suited for the task.

**Searching the MERLOT Site**

The MERLOT search engine provides for both simple string searches and advanced searches that allow you to specify the fields you want searched. The advanced search facility also allows the use of Boolean (AND/OR) operators to refine the search. As Web users know, sometimes your initial search is too broad and returns too many hits. To address this problem, the site recently added an advanced sub-search capability. This allows you to narrow the results of a search by adding additional conditions.
These searching and browsing capacities alone make MERLOT a valuable source for finding educational learning objects. However, as the project developed, it became obvious that MERLOT could perform an additional valuable service by providing some means of indicating the educational quality of the websites. In 1999, a rigorous peer review process was initiated (MERLOT History Page, 2001). While only a small percent of the websites on MERLOT have currently been peer reviewed, the number is constantly being increased. This will make MERLOT an even more valuable resource in locating and using quality, authoritative learning objects.

**Peer Review**

Traditionally the quality of published educational materials has been ensured by the publisher. Publishers use processes including peer review, editorial assistance, and other procedures to ensure that published materials are authoritative and up to scholarly editorial standards. Because publishing on the Web has little or no expense, all of the expertise involved in the publishing process above the author is often eliminated. This means that the author, who sometimes isn’t even identified, becomes the sole authority for the site. The MERLOT community decided to implement a peer review process for leaning objects to ensure that the sites are well designed and contain accurate information.

In order to develop a scholarly method for peer review, three models of peer review were considered: the peer review process used by journals, the process used in reviewing published materials, and the methods used for pre-publication reviews. All three of these methods select materials and review a bit differently.

Scholarly journals require the author to submit previously unpublished materials for review. In general, authors are expected to have knowledge of journal’s standards and must submit the material in a specific format. It is incumbent upon the author to follow the journals style and subject area. The paper is generally sent out to several scholars in the field for review. The more scholarly journals perform a blind review to ensure fairness in their acceptance policy. The journal will then read the reviews and make a decision on the fate of the work. The editor may accept, reject, accept with revisions, or reject with recommendations.

Book companies use a pre-publication review to both determine if a manuscript is worthy of being published and how it can be improved. As such, it is more formative in nature. The reviewers are generally professionals in a field who are given a small honorarium for the review. The reviews are usually given to the author along with “suggestions” from the publisher.

After a work has been published, the editor of a professional journal may wish to have it reviewed. The editor selects both the reviewers and the book to be reviewed. Obviously, this type of review is for a different purpose. It is to evaluate the quality of an already published work rather than determining if something should be published.

Despite these differences, all of these models of scholarly peer review processes follow similar general processes to assure quality. For example, all of these publications establish evaluation standards and communicate these standards to their academic community. Reviewers then apply the evaluation standards to determine the worth of the material and write some sort of recommendation regarding the material. The model developed by MERLOT is a synthesis of these models.

**The MERLOT Peer Review Process**

In order to help higher education faculty to decide if online learning resources are appropriate for their courses, MERLOT provides a structured peer review process. To ensure the validity of the review, they are all performed by experts in the academic field of the topic being reviewed, not by instructional technology experts. (Unless, of course, if the academic topic is information technology.) All reviewers are professors that actually use Web based resources in teaching their academic discipline.
The reviews are all conducted by at least two higher education faculty members who use Web based resources in their courses. A composite review form based upon the individual reviews is posed to the MERLOT website. There are now twelve discipline-based communities conducting reviews.

The peer reviews evaluates learning resources along three dimensions: 1) quality of the content, 2) usefulness as a teaching tool, and 3) ease of use. Each review evaluates each dimension using a 5 point rating system. The ratings rate from 1 star (poor) to 5 stars (excellent). Only sites averaging 3 stars or higher are posted on the site (MERLOT Peer Review Page, 2001).

The MERLOT review process focuses on specific leaning modules (or learning objects) rather than entire Web sites. This allows professors to incorporate these modules into their own Web sites. Materials that have higher ratings come up first on MERLOT’s search engine.

It should be noted that Merlot is not the only guide to academic Web sites. For example, see the World Lecture Hall at the University of Texas’ World Lecture Hall (World Lecture Hall, 2001). Many scholarly associations and other groups have developed guides to course materials for their specific subjects, but these sites generally don’t assign ratings to resources (Young, 2000).

Conclusion

Historically, college professors are rewarded for their scholarly activities. A professor that publishes a book with a respected publisher is able to use that scholarly accomplishment for promotion and tenure. Unfortunately, if one chooses to publish electronically, it may be difficult to get the proper “credit.” The reason for this is partly due to the fact that the traditional scholarly processes used to validate a work have not been in place for the electronic media. MERLOT offers a solution to this problem. "If you spend a lot of time working on a module, then you should get some credit for it," says Cathy Owens Swift, a professor of marketing at Georgia Southern University who is one of Merlot's reviewers. "People spend a lot of time developing modules, but nobody else ever sees them except their students." Merlot's also plans to recognize professors who have developed excellent sites by mailing notices to their department heads (Young, 2000).

Helping to Prepare Tomorrow's Teachers Using Technology: Faculty Development

Gloria J. MacCorkindale, Campus K12, CA

Prosperity in the global information society of the 21st Century is dependent upon the success of schools across the United States to increase students’ knowledge and skills in all subject areas. As the demand for highly skilled workers increases in the workplace, the school system must network students and teachers to resources to help prepare them for jobs when they enter the workforce. Computing technologies are vital to support the educational needs of students and teachers to address these issues.

The rapid changes and pace of technology around the world, generates a requirement for the United States to have the necessary pedagogues to support the development of a knowledge-based economy and learning society, and to transfer the resulting knowledge into organizations, institutions of learning and companies for worldwide utilization. As a result, partnerships with businesses and the education community are necessary to address these important challenges of the 21st century.

The potential for increased access and reaching out to previously unmet education and training needs through learning technologies is a highly visible growth area. Funding for education is being reduced at a time when educational institutions need to maintain and increase a focus on the learning process. One way to address this challenge is to provide teachers with access to a central repository of state-of-the-art curricula using information technologies.

Current instructional system design and development techniques, evaluation methods, tools for lesson plan development and pedagogical issues in the design of effective instructional materials are being addressed by technology. The need for a unified curricula to enable collaboration via standardized curricula databases has surfaced. A technology-based learning approach could serve to tie together subject-specific educational learning needs with information technology learning technologies for personal growth and staff development to help teachers face the challenges that lie ahead.

With the introduction of these educational technologies, a radical disruption to the pedagogical foundations of the work of teachers has resulted. Computer technology and increasing access to educational resources through the Internet require teachers to rethink how they teach and how they assist students to prepare them for the digital workplace. The rapid change and pace of technology requires school districts, local schools, and school administration to consider facilitating teacher staff development through the use of computer-based educational technologies and tools.

The question is: how do we best prepare tomorrow's teachers to support their personal growth and development to help them maintain and stay ahead of technological advances?

A Solution?
A technology-based knowledge and skills development system to provide the opportunity to prepare tomorrow's teachers to use technology effectively, efficiency and in a cost-effective manner to address their learning needs and support the student learning process is the solution. A knowledge and skills development system, consisting of three main components: 1) a Standards Proficiency tool; 2) a Learning Plan Delivery tool; and 3) an Authoring- and Publishing-to-the-Web tool is the answer.

1. Standards Proficiency Tool
The Standards Proficiency management tool will allow administrators, teachers or students to check compliance to Federal, State or Local Standards; for example, this could include the ISTE National Educational Technology Standards for Teachers and/or Students, or the ISTE Technology Standards for Administrators (TSSA).

This standards proficiency-based tool will analyze a school district's core knowledge, skills and attitudes (KSAs) required for teachers to perform an established set of professional responsibilities. Using a
systematic assessment of staff development needs for the incorporation into teacher staff development curriculum will involve defining optimal performance, assessing actual practice, and identifying the gap between the two. Further, the standards proficiency tool can be used as an advanced organizer to maintain an up-to-date knowledge and skills base for standards' proficiency at all levels.

2. Learning Plan Delivery Tool
The *Learning Plan Delivery* tool will allow on-line chat sessions, on-line self-study sessions, synchronous "real time" instructor-led lectures and courses, web-delivered learning activities, instructor assignments; for example, reading a chapter in a book, writing an essay, as well as threaded discussions to increase teachers' knowledge and skill. This tool will provide the opportunity for teachers to select staff development activities to address their individual learning style in a just-in-time manner.

3. Author and Publish to the Web Tool
The *Author- and Publish-to-the-Web* tool will automate the content publishing process to allow teachers and staff development instructors to create on-line courses. The uniqueness of this tool is the authoring system is based upon sound instructional design principles. Further, the theoretical underpinnings are based on Bloom's Taxonomy of Learning Objectives and Gagne's Nine Events of Learning.

Instructional design is the iterative process of planning instruction. It is based on research findings on how learning takes place, and considers the conditions of learning of both external events of instruction, and previously learned capabilities which are stored in memory. The design phase is a detailed plan that defines, describes and prescribes methods and procedures for the development, implementation, and management of an instructional episode. Three points must be in agreement for the design. They are: the performance objectives, the instructional materials, and the evaluation instruments.

This authoring- and publishing-to-the-Web system will be aligned to relevant learning activities as prescribed learning interventions in the *Learning Plan Delivery* tool. This tool will help achieve the intended learning outcomes based on sound instructional design practices and principles. Further, this tool will allow for the automation of the instructional design process overall, and will facilitate automated collaboration between staff development content designers and subject matters experts (SMEs) to create on-line courses for teachers, administrators and students.

Summary
New staff development methodologies and technologies are being developed in response to the rapid technological changes within schools and the school community. To keep pace and ahead of these changes, staff development is required to support a flexible learning environment in order for teaching staff to respond and adapt quickly to these changes. Due to educational computing technology innovations, staff development no longer needs to be isolated from the school or the school community. Developments, like the *Standards Proficiency* tool, the *Learning Plan Delivery* tool, and the *Author- and Publish-to-the-Web* tool, now allow for distributed staff development to occur anytime, anyplace.
Faculty Development in Educational Technology

Cathy Cavanaugh, Ph.D. Curriculum & Instruction, University of North Florida, USA. ccavanau@unf.edu

Abstract: Many education faculty members do not feel qualified to integrate and model the use of technology in their own teaching. A faculty development program is one college's approach to expanding the confidence and abilities of education professors to use technology as a teaching tool. The college's Technology Committee conducted a needs assessment consisting of focus group discussions and a survey to discover and prioritize the technology interests and abilities of faculty. In response to the needs, the committee prioritized technology purchasing, developed an online technology FAQ, sponsored a technology open house, and held small Tech Friday focused learning sessions.

While faculty members in colleges of education generally agree that children in the information age need technology fluency, and therefore teachers need expertise in teaching with technology, the majority of faculty members do not feel qualified to integrate and model the use of technology in their own teaching. The faculty development program described in this paper is one college's approach to expanding the confidence and abilities of education professors to use technology as a teaching tool.

The National Council for the Accreditation of Teacher Education (NCATE) regularly evaluates the practices of teacher education programs, and technology has become an important part of the evaluation process. NCATE unit standards give technology an important role in teacher preparation: importance is placed on "the unit's commitment to the integration of technology to enhance candidate and student learning." In fact, the conceptual framework of a teacher education program is required to address its commitment to technology. The unit's conceptual framework(s) reflects the unit's commitment to preparing candidates who are able to use educational technology to help all students learn; it also provides a conceptual understanding of how knowledge, skills, and dispositions related to educational and information technology are integrated throughout the curriculum, instruction, field experiences, clinical practice, assessments, and evaluations. (NCATE, 2000)

The target of teacher education programs is developing candidates who "present the content to students in challenging, clear, and compelling ways and integrate technology appropriately." In order to meet these standards, teacher education professors must have the skills and interests to integrate technology into their teaching. NCATE states, "Teaching by the professional education faculty reflects the unit's conceptual framework(s), incorporates appropriate performance assessments, and integrates diversity and technology throughout coursework, field experiences, and clinical practices." In short, the success of a teacher education program depends in part on its ability to produce novice teachers who can effectively teach with technology. In addition to NCATE requirements, the state mandates that teacher education graduates document that they can teach using technology. None of this is likely to happen unless faculty model and integrate technology into teaching.

Over the last academic year, our college of education at a regional state university embarked on a mission to improve the technology integration among faculty. The college's technology committee led the mission. The process began with a needs assessment intended to discover and prioritize the technology interests and abilities of faculty. The technology committee began by hosting two hour-long technology focus group discussions, during which professors were invited to describe their views on technology in the college and to elaborate on their needs. The focus group sessions brought to light the main concerns of professors related to teaching with technology and helped to build consensus about the most urgent needs of the college.

Based on the issues presented during focus group sessions, the technology committee conducted a formal survey of faculty technology needs. In order to direct the college's technology resources in ways that best met their needs, faculty were requested to answer five questions. The questions concerned their current use of technology to support teaching, scholarship and service, and the forms of support that would best enable faculty to better use technology in their work. In an attempt to make the survey as user-friendly as possible, it was distributed on paper, and each question included a list of possible choices along with the option to write in a response. The majority of professors completed the survey.

The surveys showed that the faculty fall along a wide continuum of technology use and skill. A few professors used no technology at all, a few were expert users of advanced technology, and most had experience with
one or two technology applications that they use regularly. A small minority felt comfortable teaching with technology. Among the faculty at large, technology was used in several ways to support their activities. In their teaching, professors used technology for presentations to students, presentations by students, preparing print or electronic teaching materials, locating or providing online materials for students, and email. In research, technology was used in writing, data collection, data analysis, electronic searches, and reading the work of others. To support their service responsibilities, professors used technology for committee reports/agendas, gathering information for committee work, work with schools, and work with professional organizations.

When asked to indicate the technology topics about which they most needed training or seminars, faculty listed the following, listed in order of preference: Digital video, Web design, Electronic portfolios, Presentation design, Online course management (Blackboard, Lotus, Learning Space), Digital cameras, Palm/PDA, Databases, Online audio/video conferencing, Scanners. The vast majority of professors stated that they preferred small group sessions for learning technology integration, and several stated a preference for on-to-one personalized instruction. Very few preferred large group or online learning experiences. There was a strong desire among faculty to bring their own work to the technology sessions, so time would be used productively. Faculty also requested informal sessions that fostered two-way dialog with a facilitator who understands the education setting. One professor said, “Anything us better than what we have now.” Faculty suggested Friday afternoons for workshop sessions, because that is a time with no competing demands on time such as teaching or meetings.

Based on the survey of the technology needs of college faculty, the college technology committee launched a plan to progress toward meeting faculty needs. The department chairs agreed to fund small grants for faculty who request assistance in integrating technology into their teaching. The technology committee prioritized their purchasing plan based on the needs expressed in the survey. A technology fair open house was scheduled to acquaint faculty with the technology resources and support available in the college educational technology center. A web-based technology FAQ was developed. A series of Tech Friday faculty development sessions was offered to teach the most-requested skills. The sessions featured small groups in a relaxed and interactive atmosphere led in project-oriented learning by a colleague. While groups on campus previously offered similar workshops, education faculty did not participate, saying that they preferred to learn new skills among colleagues in an education context. Learning from an “in-house” educator also made long-term follow-up with faculty more effective.

The Tech Friday sessions were seven half-day hands-on seminars led by a variety of faculty members who have had success using the technology and who wanted to share their experiences. A schedule of sessions was posted and emailed to faculty, who were invited to sign up for sessions. Faculty were requested to bring materials or ideas related to their goals or projects to enable the session leader to provide more practical guidance. Workshop materials including printed guides and handouts were supplied. Tech Friday topics were digital camera basics, digital camera intermediate skills, scanners, web browsing and searching, presentation design basics, presentation design intermediate skills, creating CD-ROMs, digital video basics, digital video applications, electronic portfolios, Blackboard online course system overview, Blackboard applications, web design basics, and web design intermediate skills.

The anticipated results of these activities included faculty who recognize their technology integration support network, faculty who model effective uses of technology in their teaching, and students who are successful in integrating technology into their work and teaching. Professors have responded very positively to the new opportunities to learn technology skills. They have been enthusiastic participants in all activities. Immediately, professors began requesting technology equipment and using it in their courses. Several professors stated that prior to hearing about and participating in the Tech Friday sessions, they simply didn’t know they had access to such technology for their teaching. Now the technology spends more time out of the closet than inside it. As our department chair says, “If the technology becomes obsolete before we wear it out, we’re not using it enough!”

How to Effectively Integrate Technology
Into the Curriculum—Through Faculty Development

Donna L. Cellante, Ed.D.
Robert Morris University
Department of Computer & Information Systems
United States
cellante@robert-morris.edu

Abstract: Many school and higher education faculty are being faced with a paradigm shift in the way they convey information to their students and communicate information to their peers. Many are fearful of technology; many more do not understand technology's function, and still others are not aware of technology's capabilities in their particular fields. My role as director of instructional technology at Robert Morris University is to help faculty to effectively integrate technology into their curricula. I will show the process I have used thus far to get the faculty involved in integrating technology.

Introduction

The following is a discussion of technology in education, how society can be encouraged to integrate technology and the ways in which I aid Robert Morris University faculty to integrate technology. Technological changes in the 20th century have enabled us to access information quickly and make effective decisions that used to take considerable time. The American society has embraced computer technology and allowed it to reinvent the ways in which we create, find, exchange, and even think about information. The workplace and the operation of businesses have encountered rapid changes. So has the education arena. As we enter the 21st century, educators must find answers and solutions to the concerns and issues surrounding the use of technology as an information tool.

Education is one of the areas where technology has had a direct impact on the way information/knowledge is delivered. Technology in education is no longer a novelty in instruction. It is a basic component of education like reading, writing, and arithmetic. When implemented effectively, technology can help support achievement by enabling learners to be independent, competent and creative thinkers, as well as effective communicators and problem-solvers (Edwards, May 21, 2000).

Technology in Education

Technology in education is a tool; a means to an end with endless specific implementation possibilities. Some of the numerous potential uses of technology in educational settings include support for individual learning activities through CD-ROM or Internet-accessed resource bases, support for group learning activities with E-mail supporting group communication or presentational software to allow groups to collaborate on presentation, support for instructional management through management of student portfolios, and support for development of individual student instructional plans, communications, and administrative functions through support for attendance and accountability.

The CEO Forum (June 2001) report argues that the 21st century demands a new set of skills necessary to prepare students for life and work in the digital age. These skills include: digital literacy, inventive thinking, effective communication, teamwork, and the ability to create high quality products.

According to the CEO Forum, technology can help to develop 21st century skills through improved basic skills, improved digital age literacy skills, improved inventive thinking skills, improved effective communication and interpersonal skills, and improved productivity (p. 6). The North Central Region Education Laboratory (NCREL) has developed the following list to help visualize 21st century skills.

21st Century Skills
Digital Age Literacy

1. Basic, Scientific, and Technological Literacy
2. Visual and Information Literacy
3. Cultural Literacy and Global Awareness
   Inventive Thinking
4. Adaptability/Managing Complexity
5. Curiosity, Creativity, and Risk Taking
6. Higher Order Thinking and Sound Reasoning

Effective Communication
7. Teaming, Collaboration, and Interpersonal Skills
8. Personal and Social Responsibility
9. Interactive Communication

High Productivity
10. Prioritizing, Planning, and Managing for Results
11. Effective Use of Real-World Tools
12. Relevant, High Quality Products

Ehrmann (September/October 1999) discussed the Third Revolution in higher education for using technology to improve access and quality. The key technologies include silicon chips, a globe-spanning network of optical fibers and satellites, telephones, fax machines, video cameras, and the communications and data-storage agreements that undergrid the World Wide Web (p. 3).

Getting Faculty To Embrace Technology

With these in mind, the question becomes “How then do we get teachers to embrace technology?” That is a question I struggle with in my new role as director of instructional technology at Robert Morris University. RMU has invested thousands of dollars in state-of-the-art presentation classrooms. These rooms include an overhead projector, a computer, a document camera, cabling for a laptop, and a VCR. At RMU the problem is not equipment, but rather how to help faculty overcome their fears, prejudices, and uncertainties. My first step was to help faculty decide in what ways could technology be integrated into the curriculum to allow faculty to significantly enhance learning. Pierson (Summer 2001) states that unless a teacher views technology use as an integral part of the learning process, it will remain a peripheral ancillary to his or her teaching. True integration can only be understood as the intersection of multiple types of teacher knowledge and, therefore, is likely as rare as expertise.” One of my goals as director of instructional technology, taken from CEO Forum (2001) is “to use technology to transform the learning environment so that it is student-centered, problem and project centered, collaborative, communicative, customized and productive (p. 5).”

In September, we began offering training sessions for the faculty that addressed issues such as operating the various types of presentation classrooms (deluxe, Smart cart, console), Group Wise (our E-mail system), grade submission, adult pedagogy, on-line education, and application software, such as PowerPoint and FrontPage. These sessions were designed to aid the faculty in their teaching and learning.

Some of the benefits our faculty can realize through education technology include:
1. Improved ability to meet student education outcomes
2. Improved professionalism
3. Improved instructional practices
4. Increased communication and collaboration
5. Improved efficiency and more constructive time spent on administrative tasks.

Kagima and Hausafus (2001) report that recent studies indicate that faculty are not supported with in-depth staff development or follow-up activities, which results in minor integration of new instructional technologies in their teaching.

According to Kagima and Hausafus (2001), educators are not easily disposed toward replacing familiar strategies, techniques, and methods of instruction learned over several years that have worked successfully (Hope, 1998). For educators to integrate technology into their teaching and learning environments, they need to believe that using technology is more efficient and effective than their familiar methodologies (Hope, 1998; Simonson & Thompson, 1997). Dagga and Huba (1997) notes that although implementation of technologies is growing, acceptance of new technologies does not occur readily. Several barriers have been identified that hinder educators’ capacity to adopt computer-related technologies in their educational practices. Herring (1997) and Kelsey (1997) identified career concerns, lack of institutional support, fear of being replaced by the technology, and the lack of technological competence as
Several educators identified time as one of the most critical barriers to integration of technology (Albright, 2000; Beaubodin, 1990; Dillon & Wright, 1993; Leggett & Persichitte, 1998). In relation to time needs, Leggett and Persichitte (1998, p. 33) notes that faculty require:

1. Time to plan, collaborate, prepare, and use technology in the classroom.
2. Uninterrupted time during the day to go online.
3. Time during and outside of the school day for technology training.
4. Time to personally explore, digest, and experiment with technology as well as maintain skills.

Teachers need to design/redesign the staff development process so it meets their needs—includes time to practice using the equipment, to watch teachers model lessons that infuse technology into the curriculum, and to mentor other teachers. Educators must have the time to work together, to explore, and to play with technological tools (Schrum, 2001).

Aiding Faculty to Integrate Technology

My role as director of instructional technology is to share with the faculty some literature and suggestions for incorporating technology into the classroom. Many of the faculty are very accustomed to using the technology, but they wanted some suggestions (with supporting documentation) of ways to effectively use technology in the everyday classroom.

The suggestions I shared with them are as follows:

1. Have clearly defined learning objectives. According to Eib (May/June 2001), “to know the best ways to use technology in teaching and learning, educators must know the learning objectives (p. 2).” For example, if the objective is to provide a map as one piece of information about a country or region, then any map will do. However, if the objective is to see where cities, national forests, and waterways are located and relate to a certain population, then another tool may have been more effective (Eib, May/June 2001).

2. Have some general ideas about the technology available to use. Lim and Clark (1998) offer a whole list of technology curriculum integration ideas for faculty to use. For example, there is multimedia software such as PowerPoint, Hyperstudio, or Web pages. Using this software to create lecture supplements, to present or assess information to create calendars of events or faculty/staff pages, or to conduct guided searches of the Internet aids learning.

3. View technology as a tool. According to Schrum (2001), if it’s clear that technological tools will help them achieve their goal of having student’s learn, educators will use those tools. In a technology-rich environment, students are active learners—producing knowledge and presenting that knowledge in a variety of formats. A tool is intended to aid in the learning process. For example, various software packages have specific intents.

4. Establish roundtables with other members of the school and department. Share ideas about what works and what doesn’t over lunch, through a department meeting, or by visiting others’ classrooms. Show demonstrations/ samples of projects. Coordinate strategies to move to a student-centered environment. Some faculty are comfortable with inviting their peers to sit in their classroom and observe the strategies and techniques used.

5. Observe others in the discipline to “see” technology use in action. Determine frameworks that will work for the classroom. Talk with others through “chat lines” to discuss ideas for
projects, etc. Either visit in person or on-line to see the actual technology being used. Find ways to make yourself comfortable with using technology.

These are some of the ideas I have shared with the faculty at Robert Morris. We have made some advances to get faculty to incorporate technology into the classroom, but the process is slow.

The technological changes in the 20th century have caused educators to change their viewpoints about the use of technology as an information tool. In this paper I have discussed the use of technology in education, how society is encouraged to integrate technology, and ways in which I aid the RMU faculty to integrate technology.

Empowering Higher Education Faculty to Use Technology to Enhance Teaching and Learning: A Peer Mentoring Program

Regina Chatel, Saint Joseph College, US

ABSTRACT: This paper describes a peer mentor program to help college faculty integrate technology into their teaching and to use technology for personal learning and professional development. In order to help faculty become more comfortable with and use technology, a faculty mentoring program was created which centered on a faculty memberserving in the capacity of a faculty mentor. This paper reports from the mentor's perspective the technology-centered concerns that the faculty reported in an initial survey, the nature of the mentoring program and the current effort to make the mentoring program into an institutionally supported position.

Faculty Technology Survey
Faculty technology mentor conducted a survey to explore the nature of faculty concerns with respect to technology issues on campus. Survey results indicated several major areas of concern, including:

Faculty Concerns with Respect to Technology and Student Learning
- How to make this activity (electronic discussion) supportive of course objectives is an important question...if it just seen and experienced by the students as a gimmick, it will not be helpful. What is unique about the use of discussions that makes it worthwhile for student learning? I think I know but students don't always seem to be as motivated to get on the lists and participate.

Faculty Concerns with Respect to Technology and Time & Management
- Haven't had time or success with working with IT on these more instructional type issues.
- Workshops are slow and general: I want an intense session specific to my needs. I can't give 3 hours to many workshops, but 1/2 hr one-on-one is extremely helpful.

Faculty Concerns with Respect to Technology and Information They Needed About Available Hardware & Software in Classrooms & Various Sites
- ... am interested in transposing my overheads to Power Point (or some other more technology-based media). I have run into several barriers: Equipment (I can't be assured of having a way to project the images in my classroom at Beach Park); Information about resources - such as, do we have a way of scanning images?

Faculty Concerns with Respect to Technology and Technical Support from the IT Department
- I will need the ability to run Java applets on the machines in the networked classrooms in fall 2001...The issue was not resolved at that time but I will need it (the capacity to run the applets from actual files developed by students) for a course in the fall.
- I increased by enrollment one semester in .... because I was promised support. However, the assistants were not able to help in ways anticipated, and they were not trained or interested. They seemed annoyed to even be asked.

Faculty Concerns with Respect to Integrating Technology into Their Own Teaching
- Need to know how to use technology in my teaching methods courses, other than word processing. Need the appropriate equipment: hardware & software; need to know what others in similar teaching areas are doing in this area

Faculty Concerns with Respect to Technology and Support in Handling Student Concerns
- ...need to know how to address student concerns, particularly their skills and available facilities/equipment at the college and home

Faculty Concerns with Respect to Technology and Institutional Support
- I don't feel we have the support at SJC (maybe until now!) to help make things work right for faculty and students...

Faculty Reported Some Integration of Technology into Teaching
- I don't like our email system (Electronically mediated discussion such as threaded discussion using our email system) for threaded discussions, and I have started to use Blackboard instead, which student appreciate!

Professional Development Activities
Faculty technology mentor provided professional development activities based on the needs expressed by faculty as indicated in the table below:

<table>
<thead>
<tr>
<th>I am interested in Professional Development Options: (February, 2001)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Personal</td>
</tr>
</tbody>
</table>

688
Page 627
In order to make my work meaningful to the faculty, I conducted a needs assessment survey. Survey results indicated six general areas of need as expressed by the faculty. During the course of the spring semester, I spent 57 hours in direct contact with faculty either individually or in small groups focusing on the six areas of need. As indicated below, many projects have been completed. However, many have been started and work will continue in fall.

1. Personal Web Pages
   - Developed and posted 6 faculty personal web pages; 3 of these will require further development in the fall.
   - Started work with 6 other faculty members and will continue this fall in the development of their personal web pages.

2. Department Web Page Development
   - Continuing work with Religious Studies Department to develop web page.

3. Electronically Mediated Discussion
   - Shared research in support of the use of electronically mediated discussion.
   - Held one orientation meeting for faculty; 11 faculty members attended.
   - Mentored 3 faculty members in setting up and using public folders in conjunction with traditional instruction.
   - Anticipate working with these faculty members in the fall in terms of providing technical support the first time they try this with their classes.

4. Online Course Development
   - Shared research in the development and teaching of online courses.
   - Held one orientation meeting for faculty; 16 faculty members attended.
   - Mentored 4 faculty members in the development of CTDLC grants. Psychology Dept., Chemistry Dept., Biology Dept., and Counseling Dept. have developed and submitted CTDLC proposals for funding to online course development.
   - Continuing to work with English Dept., Nursing Dept., Nutrition Dept., Psychology Dept., and Counseling in the development of CTDLC proposals for the next round of grants.

Accessing email & Public Folders off campus
Developing a technology vision for SJC
Shared with interested faculty the process for conducting electronic research.

6. **Accessing email & public folders from home**
   - Shared with interested faculty the process for accessing email & public folders off-site.

**Institutional Support for Faculty Technology Mentor**

The technology mentor position has been incorporated into the 5 year technology plan. Furthermore, it is specified that the person who will be a mentor is a member of the Faculty. The position taken is that such a program would be best staffed by a faculty member because of the specialized knowledge and closely related to the academic mission. There was much support for having a faculty member who understood how technology could be applied within the context of a pedagogic framework. This position has the full support of the Faculty and the college administration.
Faculty Development for Moving From Class Rooms to Learning Spaces.

Abstract: The recent popularity of distance learning has brought increased pressure for change in institutions and for those who teach in them. Cheaper computers, greater capabilities, applications programs, inexpensive telecommunications, and more savvy groups of learners have built pressure for faculty and administrators to change for survival. One university has embraced a number of formal and informal methods to prepare, develop, support, and encourage faculty to adapt and change. These methods include faculty-driven efforts, administration sponsored peer-learning, monetary rewards, and availability of grant funds to encourage better use of technology in distance learning, and in taking that knowledge back into the traditional classroom.

Introduction

The process of facilitating learning, or providing “education” has remained basically unchanged for several millennia. Much of what happens in classrooms today—at primary, secondary, and post-secondary levels—is modeled after the Aristotelian approach of gathering students about the feet of the master. The teacher gathers students in a classroom, decides what is to be taught and proceeds to dispense information. Incremental changes in that model have been facilitated by technology beyond chalkboards and chalk, (opaque projectors, film-strips, films, overhead projectors, videos and television), though the model has remained largely teacher-centered, linear, and prescriptive in that the teacher sets the agenda, timing, and method of delivery.

Technology and Change

During the last decade, the application of relatively cheap, easy-to-use and fast-evolving technology has permitted and even required different ways of approaching learners and learning. Inexpensive and high-powered computers, affordable mass storage, generic and application-specific software, and telecommunications have come together to drive a revolution in education whether in the classrooms or on to the anytime-anywhere concepts, with many hybrids in between.

The application of technology to the teaching and learning process is not a panacea. Its potential is both broad and deep, it does not appear to answer every student or every learning need. There are some students for whom technology will be especially helpful, and some who might not find the benefits so great. There are some topics for which technology can provide a tremendous advantage, and others where application is more difficult to envision and apply.

Pressure for Change

This technology revolution has had a significant impact on colleges and universities. Traditional post-secondary educational organizations now face demands from customers (students, those who employ them, faculty, administrators, and other stakeholders) for greater flexibility and quality of course offerings. The need for flexibility is demonstrated by increased demand for learning from non-traditional learner groups, working adults, and for learning opportunities in technical and other fields that are not readily
available to large groups of people. The need for “anytime-anywhere” learning is becoming
obvious. (Boettcher 2000)

For-profit organizations of various types are adding to the pressure for change by moving to the
forefront of higher education and providing alternatives to those offerings long considered to be the
exclusive province of traditional higher education institutions: not-for-profit universities, colleges and
community colleges. In response, universities have begun to adapt and to adopt new practices, tools and
technologies. The implementation of that change also requires retooling and developing faculty to
effectively use the new opportunities.

Both academics and the marketplace have shown that distance learning in various forms can
provide acceptable levels of learning. (Chernish and McNeil 2000; Industry Report 2001; Grayson 1999;
Bond and Finney 2000). The one challenge is to develop faculty and institutional capabilities to deliver
learning which is more effective and more efficient than the current model permits. (Olcutt 1999)

University of Houston

The University of Houston has offered continuing and some limited forms of “alternative
education,” “continuing education,” for much of its history. As an urban institution serving a broad range
of student needs in its four campuses, faculty members have been developing different and experimental
learning delivery initiatives as a matter of course. Many of these efforts have been independent and only
loosely coordinated or communicated among peers. Some might be described as “skunk works” efforts to
push the envelope without the sanction or even the knowledge of central administrators.

The University has formally delivered coursework by distance for more than a decade, first using
instructional television (ITV), and also using online tools. This outreach has brought about recognition that
many of the traditional models, rubrics, and methods from the classroom require rethinking. Use of
technology also surfaced the need for new and different skills for dealing with graphics, programming,
application of telecommunications and related skills; skills which most faculty members do not have, and
do not care to develop mastery.

The university has evolved a collaborative model for distance learning which brings together
faculty members (subject matter experts, or SME’s), instructional designers, technical support personnel,
and administrators in a team. This team develops materials, content, and approaches to move learning from
the classroom to cyberspace; and it also provided opportunities for improvement of traditional classroom
activity as a valuable byproduct of distance learning efforts.

Faculty Development

Over the past decade, a number of informal and more formal approaches to preparing faculty for
changes in educational and learning practices have evolved at the University. Among them are the
following:

Moles. In 1994, several faculty began meeting informally to discuss technology issues in education. They
chose the name “Moles” not because it represented any acronym, but rather that moles were furry creatures
that burrowed underground without the benefit of sight. The Moles group grew to conduct monthly
meetings and informal electronic communications to provide peer support and to share developments and
challenges. Issues of technology (in distance settings, and in the classroom), sharing innovative efforts, and
quiet encouragement had been, and continue to be Mole roles. Much of the leadership and innovation in
the Moles came from the late John Butler, associate dean in the College of Natural Sciences and
Mathematics who also maintained a Moles web page (http://www.uh.edu/~jbutler/professor/uhmoles.html).

COWS. The University Distance Learning office began more formalized development and support for
system faculty several years ago when Sandra Frieden offered an off-site seminars that become known as
COWS, Campus Online Workshops. These three-day gatherings for a broad range of system faculty from
all University of Houston campuses combined peer-interaction, as well as staff and technical expertise.
Peers are able to share experiences, successes, and impediments in a manner that has veracity and
applicability to other faculty present. Staff is able to contribute information regarding current capabilities
as well as anticipated changes and upgrades in technological capabilities. The workshops also provide an
opportunity for introduction of instructional design principles to teachers whose previous knowledge of
teaching and learning has come from their own experience in classrooms as students or professors. Finally,
the COWS process provides an ongoing opportunity for faculty collaboration, interaction, networking and
research.

**Technology Grants.** The office of the university provost has offered tangible support to faculty involved
in distance learning through an annual competition for Faculty Development Improvement Grants (FDIP).
This program permits faculty to propose small projects for application of technology to distance learning
and to receive funds to implement the projects. FDIP grant funds can be used for hardware, software,
technical assistance, multimedia development, and even teaching assistant support to further technological
applications. The current round of grants will award up to $6000 to successful proposals.

**College staff Support.** The information technology side of the University has also contributed to the
development of faculty and technical skills for distance learning by creating a system of distributed support
personnel in the various colleges. This technical support augments central staff technical expertise by
placing knowledgeable and trained support personnel at the college level where they are able to develop
working relationships with those involved in distance learning and application of other learning
technologies.

**WebCT.** The University is currently using WebCT™ as the standard learning support system, for both
distance and on-campus use. Many users have found the program to be very useful in a broad variety of
areas, although the learning curve has been described as fairly steep. To aid new faculty users, and to
upgrade those who have been using some of its functionality, the University has provided workshops,
online materials, and technical assistance to users. As might also be expected informal peer support
system has evolved within and among colleges to use the program.

**Compensation.** Faculty who develop and deliver distance learning through the recognized University
channels are eligible for, and receive, additional compensation. Current practice provided a fee for
developing a course (paid only once, without respect to later revisions, whatever their nature), and a
separate fee for delivering the course by distance. This compensation may provide the incentive for
inexperienced faculty to address distance learning, and may encourage experienced faculty to develop new
offerings, and to continue to participate in ongoing delivery of coursework.

**Recognition.** Additional incentive for faculty to attempt and to excel in distance learning initiative may lie
in campus-wide recognition through naming of one faculty member as having made outstanding
contributions to distance learning at the University. The award is of those few announced at annual
commencement exercises and carries a handsome financial reward.

**Other Issues.**

On a less formal basis, many of those interested in distance delivery have worked outside of the
formal University organization to team-teach innovative courses, participate in doctoral classes, serve as
live case studies for graduate students, and to assist in the development of masters and doctoral research
projects.

A number of these collaborative efforts have been used to begin to assemble a set of “best
practices” for learning evolution in this new century. The experiences have produced results which range
from different course structures, adjustments to the traditional “hours of class” requirements, portability of
learning, greater convenience to students, and improved faculty skills.

Development of the collaborative approach has involved the use of several faculty and staff
development tools at the University System, campus, college and departmental level. The efforts have
involved three-day workshops, shorter and more focused seminars, an informal listserv discussion, and
training in specific skills for teachers and technicians. All of these have provided significant development
challenges for each of the team components: instructional staff, instructional designers, technical staff, and
administrators.
Challenges. Challenges in the application of technology and implementation of distance learning abound. Issues such as economic feasibility, and quality of learning offered remain largely unaddressed. Distance learning is being offered by traditional educational institutions, by proprietary educational organization, and in many other forms and formats within and among industry. International opportunities exist and will present unique problems and challenges. Faculty, and institutions, is struggling with questions of intellectual property, ownership of materials, and residual rights to delivery of instruction that has been recorded for distance delivery.

Circularity. Development of faculty for participation in distance learning cannot be viewed as a stand-alone challenge. Distance learning is changing the very fabric of the higher educational process as it seeks to deliver more anytime-anyplace learning opportunities. At the same time, the lessons, techniques, and technology of distance learning must necessarily flow back into the traditional classroom. (Dollar 1999) More and more, classroom teachers are using technology in the actual classroom, or to support other related learning exercises. Classrooms are becoming paperless, learning resources are available from nontraditional sources (Armstrong 2000), the World Wide Web has become a primary source of information, and learners are becoming more able to utilize the multimedia learning resources and tools available online and otherwise. Those who design and facilitate the learning processes must do no less. Perhaps the model evolving at the University can serve as a basis for development activities in other settings as well.

Abstract: Supported by teacher accreditation organizations promoting technology standards for teachers, and supported by teacher recruiters who are striving to hire new teachers with technology skills, education departments and faculty members are investigating professional development regarding technology. This paper describes an innovative study that collected data through personal interviews from one hundred members of a faculty of education to ascertain views of professional development and professional development needs. Faculty responses provided the field of professional development for educators a more coherent and comprehensive view and linkage with present theory and a foundation for a new model of professional development for faculty involved with educating pre-service and active teachers.

Introduction

Faculty members in departments of education are interested in the impact of technology on education. Faculty members interested in their own professional development regarding technologies to support preservice and in-service teachers are supported by organizations such as the International Society for Technology in Education (ISTE), the American National Council for Accreditation of Teacher Education (NCATE), Canadian provincial governments responsible for education such as Alberta Learning, and by teacher recruiters. ISTE is recommending and NCATE is adopting the inclusion of educational computing and technology standards in the American accreditation for teachers. The Department of Learning in Alberta is including the integration of technology in the provincial curriculum objectives (Alberta Learning), and one superintendent in Alberta is stating a preference to hire only teachers with a strong technology background (University of Alberta, 2001). With interest from faculty, and promotion of technology from accreditation and government bodies and teacher recruiters, this research study was established to better understand professional development for faculty with regard to technology to ultimately support pre-service and in-service teaching/learning.

Wilson and Berne (1998) completed research in the field of professional development for educators, and their work reinforces the need for this study. Wilson and Berne conclude that professional development for educators is only successful if educators drive the content and opportunities themselves. In order to create or enable professional development opportunities for faculty in departments of education in universities, this research study was initiated to investigate the professional development needs.
The Study

The research study used a convenience sample—all one-hundred and twenty faculty and administrative members within one Faculty of Education were invited to participate in the study by meeting personally with one of three experienced graduate student interviewers. Of the 120 invited for interviews, 100 participated. Confidentiality and security measures were implemented and communicated to participants. The interviews were taped and transcribed. The data was then carefully read and sorted and entered into an electronic database where data could be resorted, queried, and classified. Findings were condensed and presented back to the faculty at an open invitation meeting extended to all 120 invitees.

Findings

Responses from faculty member participants (faculty members) in the study provide practical information on what professional development means in their world of work, what they want to learn in the future and how they want to participate. Responses from faculty members also provide the field of professional development for educators a more coherent and comprehensive view and linkage with present theory and a foundation for a new model of professional development for faculty involved with educating pre-service and active teachers.

Perceived Technology Needs of Pre-service and Service Teachers

Faculty members in the study identify technology areas they perceive to be most important to pre-service and in-service teachers. Teachers need to be comfortable learning technology continuously from a variety of sources including their students because technologies are so rapidly changing and evolving. Teachers need to learn to use technology responsibly, to effectively integrate technology with the curriculum, seek creative ways to use the technology to enhance learning, and to use technology to their advantage in their administration. Teachers need to learn to think critically of technologies, to critique materials and equipment, ask what the technology can be used for, question sources of information, consider gaps in accessibility, and consider issues, impact of technology and ethics. To support these perceived technology needs of pre-service and in-service teachers, faculty members seek professional development opportunities. When asked about professional development involving technology, faculty members identified what they are interested in and how they would like to participate.

Faculty Member Participants Choose What to Learn

Participants in the study identify the major barrier to professional development as “lack of time,” therefore, when determining what to learn, participants indicate a real need to be selective because there is so much available it is impossible to get to it all. “There is no way in hell you can read it all” (faculty member participant #42). “Need to look real hard for professional development opportunities that will nourish” (85). One participant was appreciative when the technology group selected and recommended training. “Moved to different email and professional development was setup to go with it—that was good” (65). Faculty members state that they are very busy within their own area of interest and want people involved in the technologies to keep them informed; they want people involved in the technologies to be their watchdogs for new and emerging technologies. Participants are also looking to people with experience using any of the technologies to share best practices. In addition to faculty searching for information about technologies, technology specialists and colleagues using technology can help faculty members overcome their lack of knowledge about what is available. “We don’t even know what we don’t know” (67). Faculty members want a smorgasbord of choices and they want to be sold on the technology. “Someone has to show me good examples and illustrations how technology might be used. A supermarket presented in a way accessible to me. I’d say, I could use that. I’d then need people to help me learn and develop the expertise. I have to see it to see how it would fit what I am doing” (67). Faculty members want to learn about everything from “leading edge whatever” (40) to “pretty basic stuff” (28) and they want to...
use technology “more effectively, more broadly” (27). For example, faculty members want to investigate how to better search and store, communicate, use bibliographic tools and research analysis programs, integrate technology with curriculum, and use technologies in their planning, teaching, research and management.

What Professional Development Means to Faculty Member Participants

Faculty members indicate their professional development is every day, it is self-directed and it is eclectic. Participants practice skills, investigate what is new and what the technology is capable of, what special requirements would be required, and the purpose. Faculty members self-learn and learn from sharing experiences and best practices. “Talk with people, watch what they are doing, figure out if we can do it that way” (22). Faculty members learn by belonging to professional organizations and by going to and giving presentations. Presentations are “invigorating and informative” (36). Participants also identified reading, reflecting and research as part of their professional development. “Teaching is professional development, writing and research is professional development” (19). Faculty members also learn from local events, documentation, help systems, and tools and services.

Faculty members indicate they want to learn and refine their skills using technology to communicate with student applicants, students, cooperating teachers, teachers, administrators, and colleagues worldwide. Faculty members also want to investigate how technology affects teaching/learning, the integration of technology with the curriculum, the relationship between technology and their area of interest, the impact of technology, gaps in access, ethics and issues regarding technology to support pre-service and in-service teachers.

Practical Professional Development Opportunities

From a practical view, participants identify logistics and characteristics of ideal training initiatives. Demonstrations to preview new software. Bring your own projects workshops, “bring your own data and have a website built in a day” (13), for example. Relevant content with immediate application if it is to be learned and retained. Interaction within courses or workshops with an instructor or students rather than a technology. Faculty members want delivery to be hands-on and interactive. Any demonstrations or courses need to be offered fast, one-half day courses for instance, and they need to be offered multi times so faculty members can choose times to fit their schedules. One-on-one is ideal, but small class sizes and homogenous groups. Objectives need to be included in the course description. The instructor should not assume students’ skills, experience or levels of expertise. Instructor needs to break away from computer jargon and speak in plain language. An overhead needs to be used to display computer screens and the instructor needs to physically navigate throughout the room to help everyone keep up. Faculty members want instructors to have better facilitation skills to keep themselves and the class on track and to handle questions that typically hold up the class or divert the class from the objectives.

Faculty members are also suggesting that workshops and courses, no matter how good, need follow-up. “The follow-up must be very specific” (98). “Tutors available after the workshop” (76). Follow up by documentation, help, tools and services, or a community of learners to draw help from. “How do I know about the guy in biological sciences working with similar graphics when I want to do something in graphics” (16). Participants also recommend people in the department become champions of processes to turn around and teach or help others in the department. Participants also suggest the need to find training and support from software companies. Help can be from formal sessions, from informal sessions or online. It was suggested that it is not productive to learn without help. ”Learning without help is not an effective use of my time” (86).

All colleagues use hallway help by asking their neighbors for quick verbal help at the time they need help, by having a colleague drop by for a few minutes to provide direction, by informal chats to pick up on tricks and tips, and by faculty working and learning together. Participants described extensive use of and appreciation of hallway help, but draw our attention to their feelings of taking up too much of colleagues valued time, thus they are recommending a formal registry of faculty who can help, a help desk, and house call help. Participants want help available when they need help on whatever topic or program they might be stuck on. Help is requested for horizontal or generic programs such as word processing,
spreadsheets, databases, presentation packages and website development, and help is requested for vertical or specialized training programs such as the research analysis tools. Help desk help can be a formalized help phone line or email, but it can also include a registry of people with expertise who are willing to share or teach others at a specific time or place. An immediate response is preferred but faculty members recognize replies might be delayed depending on the complexity of the question. In addition to wanting a help desk, participants also request house calls. Participants can see the value of house calls to increase their productivity—for a person to come in and help with a specific application or project, to come in and watch to improve efficiency, or to come in and make technical adjustments. One participant makes us aware that some people do not want to read to learn, they want a personal visit. “No, I don’t want a list of steps, I want face-to-face, hand-to-hand, I want to have my private tutor” (22). Others, however, are redefining a personal house help call to include an electronic connection. “Want someone to come into my office by linking by speaker phone to walk me through it - like yesterday C&S [Computing and Network Services] walked me through a complete change, it took about 40 minutes” (23).

Faculty members identify tools and services that could be provided to help them with their use of technology. Tools such as grade management programs, centralized databases, telephone answering equipment, virus protect programs. Templates or forms that are user friendly, and advertised and made accessible to faculty members. Services for one-time or once-a-year projects such as a poster or for one-time long-time tasks such as scanning. Faculty members identify the need to have equipment/software and training available and accessible, and constant technical and application support.

**Professional Development Model Emerges**

Based on input from faculty members, a model for professional development involving technologies emerges. Participants need a system or infrastructure in place to support training and development and an ongoing follow-up system, professional development activities rooted in constructivism, and delivery in line with andragogical principles.

Just as Moore & Kearsley (1997) raise awareness of the need for systems theory when working with technologies, faculty members identify the need for an infrastructure to be in place. The infrastructure is needed to support access to technologies, technical support, professional development training activities, ongoing follow-up support, and a community of users and specialists to draw on. Drawing a comparison, the faculty members’ infrastructure equates with Moore & Kearsley’s need for systems theory or an interrelated and interdependent system in place to support the use of technology.

When professional development activities are designed, faculty members are demanding principles of constructivism to learn technology in context with their work and with their prior knowledge (Crawford, 1998). Supporting constructivism and the faculty members’ recommendations, Wilson and Berne (1998) conclude that professional development for educators is only successful if driven by the educators themselves.

Faculty member participants demand a learner-centered approach in the design and delivery of professional development activities, an approach Boettcher (1999) claims is relevant to both constructivism and andragogy. The learner centered approach to include relative objectives and concepts, interaction with instructor and students rather than the technology, design and delivery tailored to specific learning styles, in plain language, delivered individually or to small numbers of participants, in homogenous groups, by a facilitator trained to keep the class on task, in short courses offered at multi times. The learner centered professional development activities need to be project based, fixed achievement, variable time (10). Boettcher’s (1999) conclusions promote relevance of content, participation of learners in the design and implementation stages of the course, self-directedness, facilitated learning and linking of resources to learners, reflection on experience and knowledge, and collaboration or interaction between instructors and learners and among peers to support problem solving and critical thinking. One participant summarizes with the need for adult education. “Need the basic principles of adult education, they need to know how adults learn and apply that to their education designs” (10).
Contribution to Tomorrow’s Teachers and the Profession

Although this study is limited to faculty members, other faculties of education may be able to identify with what faculty members in this study want to learn and how they want to participate in professional development. The underlying goal being to discover and disseminate knowledge about the impact of technology, and the integration of technology with teaching and learning to tomorrow’s teachers and to fellow colleagues.

Faculty members in departments of education are recognizing the need for both pre-service and active teachers to learn to continuously incorporate technology and become comfortable and innovative in their approach to technology throughout their teaching career. Pre-service teachers need to learn to use the technology to meet accreditation standards. As researchers, faculty members are also interested in what the effects and affects are of technology on learning, and they are interested in issues regarding the present and future use of technology. In their own professional development, faculty members are interested in how technology is or can be implicated within their area of expertise, their teaching, and in their research. Faculty members recognize the need to participate in professional development opportunities to extend their learning and to model attitudes and approaches to technology to tomorrow’s pre-service and in-service teachers.

Engaging Teachers in Building Curriculum Webs
A Promising Strategy for Re-Energizing Professionals

By Craig A. Cunningham, Ph.D.
Research Associate
Center for School Improvement, University of Chicago

For the past five years, my colleagues and I have been training teachers to build curriculum webs in the Web Institute for Teachers, an intensive summer professional development experience at the University of Chicago. We have also conducted a professional curriculum development project called Chicago WebDocent that utilizes teachers as curriculum writers in the creation of web-based curriculum materials based on the resources of Chicago-area cultural institutions. Out of these experiences, I have come to believe that the outcomes of teacher growth and engagement are at least as important as web development skills or subject matter knowledge in these efforts.

A curriculum web is a web page or pages designed to support a curriculum. Building an effective curriculum web is excellent preparation for teaching an effective curriculum unit. Teacher involvement in curriculum development and web design fosters improvements in teaching and in teachers. This is the only way teachers can improve, but it is one way, and it is one that is timely and increasingly available to teachers in schools and in colleges of education.

Curriculum webs are easy to make, given a basic understanding of curriculum development and mastery of the basics of web page creation. Once a teacher or other curriculum developer has produced a few simple curriculum webs, he or she will be ready to incorporate increasingly sophisticated technical and pedagogical techniques. Curriculum webs provide a natural pathway for teacher growth and development, while helping the teacher to keep up with technological and curricular changes.

The availability of information on the Internet and World Wide Web leads to a new role for teachers. In the classroom, teachers who develop their own curriculum webs can become facilitators of learning experiences specifically designed for their students, based on a careful assessment of the students' needs. By engaging in the process of curriculum planning, teachers grow as teachers and as learners, modeling the process for the students as they grow.

Building a web site for learning is itself a process of learning in which meaning is created. Meaning consists of associative relations among concepts or experiences. As people learn, these relations, or meanings, intertwine in complex webs that are built in the medium of ongoing experience. Designing a web site is like creating a mental web of meaning in a set of experiences. In order to design the site, the teacher who creates a meaningful curriculum web becomes at the same time a more knowledgeable and effective teacher, with a more sophisticated mental map of the subject.

The International Society for Technology in Education's National Educational Technology Standards for Teachers (NETS-T) set forth what teachers should be able to do at three levels: before starting their student teaching; after their student teaching and internship, when they are ready to take over their own classroom; and at the end of the first year of teaching. Among the important things that teachers must learn is to:

- "engage in planning of lesson sequences that effectively integrate technology resources and are consistent with current best practices," and
- "plan and implement technology learning activities that promote student engagement in analysis, synthesis, interpretation, and creation of original products."

These skills are precisely the ones that can be furthered by having teachers in training develop their own curriculum webs. Additional skills fostered by this process include: critical thinking; data collection; ethical behavior; assessing and selecting resources; planning effective learning activities aligned to standards; creating assessment activities to generate information that can help to improve instructional planning, management, and implementation of learning strategies; and using technology tools to collect, analyze, interpret, represent and communicate data for the purposes of instructional planning and school improvement.

My paper will explore some of the theoretical and practical justifications for promoting the role of teachers as curriculum makers, and will describe some of the practical issues discovered in our work in
the Web Institute for Teachers and in Chicago WebDocent. This is suitable for either a paper session or a roundtable.

---

Database for Classroom Plans

Jesse Drew, ISU, US
Marcia Rosenbusch, Iowa State University, US

The purpose of this poster/demonstration is to clarify the issues that must be addressed in developing a database for teacher-developed activity plans, lesson plans, and unit plans.

Today, classroom teachers are exposed to an abundance of information about instruction much of which is not relevant to their needs. The Internet is an effective means of providing instructional resources to classroom teachers, but the quality of these resources depends on the professional knowledge and skill of the Web site designer. In a collaborative effort among nationally recognized foreign language educators and technology innovators we have designed a Database for Classroom Plans designed to be an effective teacher resource for pre-service and in-service teachers. We will focus on the design process for this database in this poster/demonstration.

We designed this database to help classroom teachers with the planning process. This database is designed to be very flexible. It will allow classroom teachers to view activities, lessons, and units designed specifically for the content area they teach, and, in addition, this database will allow teachers to connect to a variety of content areas, thus, enhancing interdisciplinary planning. The majority of the examples currently on the database are designed for the content areas of foreign languages and technology. Leaders in foreign language education are encouraging classroom teachers to integrate technology into the foreign language curriculum as suggested by the national student standards for foreign language education. More importantly, foreign language educators need resources that will enable them to increase the integration of technology into their curriculum.

After much thought and discussion about what categories of information are essential in planning and communicating the essence of the plan to others, the following were agreed upon and are included as categories in the database:

- Content area (foreign language, mathematics, science, etc.)
- Subject area (Spanish, multiplication, etc.)
- Title
- Grade level (Pre-K – 16+)
- Performance level (beginning, intermediate, advanced)
- Objectives
- Procedures
- Assessment
- Reflection (author[s]' reflections on the activity in use)
- Author(s)' name(s)
- Author(s)' school, city, state, email and type of author (whether the primary or secondary author)
- References
- Resources
- National standards (currently available only for Foreign Languages and Technology)

The demonstration and discussion of this Database for Classroom Plans will enable the creators to clarify key issues that relate to on-line resources and to receive feedback on this database and to inform educators about a database that can be effectively used for classroom planning by any content area.
Case Studies of Professional Development

John Fischer, Trinka Messenheimer, Sarah Bombich, Kelly Madger

This presentation is a self-reflective case study of the authors’ involvement in a faculty professional development program. This case study of our professional development teases out what might be learned from an innovative program that teams a faculty member involved in teacher education one on one with a “knowledgeable” graduate student. Our experiences over the first year have led us to believe that this form of professional development provides contextual learning in a job embedded manner, such that faculty members leave the experience better prepared to infuse the use of technology into their work with preservice teacher candidates.

For years, the university has struggled to infuse technology in its teacher education programs due to lack of resources and equipment, lack of faculty expertise in technology integration, and lack of programmatic alignment with the ISTE Recommended Foundations in Technology for All Teachers. Recently, the barrier of inadequate equipment and resources has been addressed at the university as well as area K-12 schools. However, program restructuring, curriculum revision, and faculty training are imperative for effective technology infusion in teacher education. The overall goal of the project is to enable preservice teachers to fully utilize modern technology for improved learning and achievement in their future classrooms.

To describe and support the notions of professional development for technology these cases are framed around the topics of: partnering, structuring the work, characteristics of learners, evolving roles, and impact. The case studies are based on the experiences of two professors and their graduate student mentors for technology training. These case studies represent different learning styles in the professional development process. The similarities and differences will be addressed. Clear indications present us with the need for individually driven / motivated effective professional development.

Standards are only somewhat threatening in the abstract. However, in real practice, especially practice that is reflective, our own work, skills, knowledge can cause us to back away from the enormity of what NET-T means for faculty involved in teacher education. We are not experts. One of us describes herself as having played with a lot of hardware and software at a surface level, but is overwhelmed by the potential for classroom use. The other claims that he plays with the various technology tools, even though they don’t work all the time. Sometimes he feels like they don’t work at all. And yet as professionals we have been acting to push ourselves and our institution to look at, investigate and struggle with meeting the ISTE standards in one of the largest teacher education programs in the United States. We are seeking to do this by involving ourselves in a PT3 funded program.
Faculty Development Using a Problem-Based Learning Methodology

Penny Ann Garcia, Ph.D.
Department of Human Services and Educational Leadership
College of Education and Human Services
University of Wisconsin Oshkosh
Oshkosh, Wisconsin USA
garcia@uwosh.edu

Abstract: This paper is based on the premise that university faculty will utilize technology when it solves problems they routinely encounter in their profession. It theorizes that the construction of hypermedia case studies by faculty can encourage the extension of basic skills in technology proficiency into high-end production tools. Faculty view both the product and process as beneficial not only to their students' needs but to their own professional requirements as well. A problem-based learning approach is used that both stimulates dialogue across teams representing universities and k-12 schools and allows for individual team enterprise, direction and creativity.

Introduction

Teacher educators voice many concerns regarding technology integration in their courses. These concerns focus on 1) time and resources for learning the technology and considering how it may be integrated into courses; 2) ongoing support while in process on a technology enhanced project; 3) an overwhelming frustration at the speed of technology innovation; and 4) valuation of this work in conjunction with promotion and tenure needs. For teacher educators to value, support and model the integration of curriculum and technology with preservice educators, these concerns must be addressed within a framework that allows faculty to consider how technology might address issues routinely faced by teacher educators. Norton (2000) suggests six areas in which technology can assist in solving teacher educators' problems. These include 1) helping students prepare for class, 2) supporting students' grasp of concepts through collaborative meaning-making, 3) publishing and sharing insight, 4) promoting resource-based problem-solving, 5) modeling how theory translates into practice, and 6) communicating with students to meet diversified learning needs. This author suggests the addition of a seventh: facilitating faculty tenure, promotion and merit needs.

Consideration of these seven areas by faculty informs the basis for the University of Wisconsin Oshkosh, College of Education and Human Services (COEHS) Faculty Developed Hypermedia Case Studies project. This professional development opportunity is rooted in problem-based learning, traditional case study methodology, and hypermedia learning theory. While the ultimate outcome of the project will be hypermedia case study products to assist preservice students in the observation of, and reflection on, the complexity of the teaching and learning interactions, the process by which those materials are developed is really the focus of the project.

The project fits into a five-year plan for technology integration in the College of Education and Human Services at UW Oshkosh. Over the past two years faculty have availed themselves of numerous opportunities for development of technology skills and the integration and demonstration of those skills with curriculum in their courses. The third year affords teams of university faculty, k-12 faculty and undergraduate students the opportunity to engage in a collaborative inquiry into pedagogy, case study methodology, and hypermedia technologies.

Rationale

As COEHS faculty consider themselves to be students of how technology can be integrated with curriculum, a problem-based approach was an ideal vehicle for delivering this project. Problem-based learning
proposes that situated learning (Brown, Collin, & Duguid, 1991) in an authentic context (Stepien & Gallagher, 1993) will simultaneously engage students' curiosity, stimulate cognitive mapping, and promote problem-solving and content learning. In the context of the Faculty Developed Hypermedia Case Studies project, this approach followed these steps: 1) use of an ill-defined problem that provided the opportunity for dialogue, investigation, collaboration and problem solving; 2) faculty meta-analysis of the big problem leading to identification of specific problem for investigation; 3) infusion of resources - text, mentor, and equipment - to illuminate the processes and theories of case study methodology and hypermedia development; 4) time to collaboratively investigate and collect artifacts; and 5) technical assistance leading to hypermedia case study materials for teacher educators' use with their students.

A problem-based approach was also selected to allow faculty members to again experience the difference between the conventional approach to education and that used both by what Lave (1988) refers to just plain folks (JPFs) and experts in fields. Brown (1991) explored the common reasoning processes of these two groups by examining the practices of JPFs and then comparing these observations to those made of highly competent physicists by Roschelle and Green in 1987. Brown found surprising similarities in the reasoning process of the two groups. Both experts and JPFs have a belief system that treats learning as a sense-making pursuit that grapples with ill-defined problems. Both are heavily situated. Both try to produce reasonable, causal stories about their world. Both negotiate with the situations. Both take as much advantage as possible of their embedded position to help them make inventive and insightful assumptions and approximations.

This is very different from the sort of cognitive activity that Resnick (1987) has shown as being championed in our current educational system. It also differs greatly from past models of problem solving which evolved from the imposition of the discourse method of scientific methodology. While there appears to be a continuum between the JPF and the expert, there is clear discontinuity between the student and the expert (Figure 1).

Figure 1: Learning activity: JPF's, Students, and Experts

Traditional courses for teacher education students often deal with theories that act upon abstract concepts dealing with problems that fall neatly within the parameters of the theory under discussion. In the real field of the classroom, problems teachers encounter can rarely be linked to individual theory much less solved by strict application of any theoretical constructs. Therein lies the conundrum faced by first year teachers. Having been nurtured by years by an educational system that champions learning as an individual process in which opaque and disconnected symbols are manipulated with little connection to the real world, it is little wonder that teachers often express aloud that they learned little in their undergraduate coursework that was of use when they actually started teaching and that the best learning occurred on the job.

Case-based instruction may serve as a means for addressing this problem. Merseth (1999) sets forth four categories in which case study instruction is of benefit to teacher education students. She states that cases and case-based instruction help students to develop skills of critical analysis and problem-solving, encourage the development of higher order cognitive thinking and the generation of multiple pedagogical techniques, foster reflection, and help present a realistic picture of the complexities of teaching.

A hypermedia approach to case study was selected because of the potential for learning afforded faculty members and for its benefit to students as well. Hypermedia is a common methodology today for constructivist learning environments. Its features can support learning as well as learning strategies. It can support learning through enhanced motivation, encoding and retention of the knowledge, and the use of the knowledge. This support is facilitated through the use of good organization and sequence of the hypermedia program. Hoffman (1997) recommends the application of elaboration theory in hypermedia design thus beginning with the big picture and then sequentially adding the depth of details and artifacts. While hypermedia
programs may not incorporate actual interactions within their scope, it is important to provide features that support learning strategies. These strategies do not occur solely on-line; rather, they acknowledge the need for a facilitator outside the program to guide students in interactions, reflections and activities that extend the information presented within the hypermedia program.

Project Design

In spring of 2001, the Hypermedia Case Study project was announced at the annual Collegiate Classrooms for the New Millennium symposium. Over the next two weeks, nine faculty members indicated interest in the project. Those university faculty members were asked to team up with a k-12 faculty member of their choice. During the summer of 2001, teams could request funding to begin to consider what direction their individual case studies might take. It was suggested to each team that it was appropriate to think beyond the usual case study subjects and extend their investigations into those areas that are notoriously difficult for teacher education students to grasp, critical to their first year of teaching, and typically not covered in the usual course work.

In September 2001, the teams - both university and k-12 faculty - came together at a one-day retreat. Dr. Selma Wassermann, professor emeritus of Simon Frasier University, was scheduled to be the guest facilitator. Unfortunately, the events of September 11 prevented her from flying to Wisconsin. We were able to continue the retreat through the use of on-line video conferencing and phone conferencing with Dr. Wassermann. Each team presented their area of focus. These ranged from student discipline issues in a middle school social studies class, the formation of a charter school within a school at two local elementary schools, ESL techniques with elementary school children, serving special needs students in the regular classroom, technology infusion in curriculum, to a holistic view of an elementary classroom from multiple perspectives of analysis.

Dr. Wassermann led teams through an analysis of a case study that then led to consideration of the critical elements for any case study. Next, teams were introduced to the concept of storyboarding and were asked to consider how the case study they worked on with Dr. Wassermann might have been storyboarded and how it might have been enriched with supporting artifacts. Next, examples of hypermedia case studies were presented and discussion of those examples centered on the format selected and the artifacts needed to bring the case study to life. Teams were given a selection of books for background information. These included Multimedia for Learning (Alessi and Trollip, 2001), Who Learns What from Cases and How (Lundeberg, et al, 1999, Getting Down to Cases: Learning to Teach with Case Studies (Wassermann) and Introduction to Case Method Teaching: A Guide to the Galaxy (Wassermann, 1994).

Each team received both a digital video camera and a digital still camera. Brief instructions were given in the use of the equipment with each team signing up for a subsequent longer session with a staff member of the UW Oshkosh Instructional Development and Authoring (IDEA) lab. Faculty were asked to begin to collect artifacts - still photos, videotapes, student work, lesson plans, etc. - for inclusion in a team database of materials available for hypermedia formatting at a later date.

Individual teams also made appointments to meet via phone with Dr. Wassermann to discuss their project's goals and objectives. As was expected, Dr. Wassermann indicated that each group was in a different place on the continuum of the project scope. Some were just beginning to focus on an area, others were on their way with well-defined plans of action and two teams were still seeking k-12 faculty partners. During the following two weeks, the two teams requiring k-12 faculty partners made their connections and conferenced with Dr. Wassermann. She remains available for feedback and support to each group; to date, one group has met with her extensively via phone conferencing.

In January, teams will meet with our instructional designers to discuss alternative software packages available for publication of their hypermedia case studies. The available alternatives have been selected to cover a range of difficulty and include PowerPoint, SuperCard, Flash, Director and Authorware. Teams will be encouraged to push their limits; settling for PowerPoint because it is familiar and safe was not what the grant intended. After the presentations, teams will meet to consider their needs and learning styles. Based on the software selected, they will be matched to an individual IDEA lab staff member for mentoring in both learning the software and preparation of the materials.

During the spring 2002 semester, additional workshops will be held on the use of digital video editing software, photograph manipulation software, and the hypermedia software selected. An additional workshop with Dr. Wassermann is planned in late April of 2002. Undergraduate students will join the teams in the spring
as well. They will preview the materials and make suggestions from a user’s viewpoint. Some teams may opt to have the undergraduate students ask questions of the k-12 faculty for inclusion in the hypermedia case study. In the summer of 2002, university and k-12 faculty will work with IDEA lab partner to complete their video case studies. Pending availability of funding, additional case study projects will be funded in the 2002-2003 academic year.

**Conclusion**

The Hypermedia Case Study project has been well received by the faculty in the College of Education and Human Services at the University of Wisconsin Oshkosh because it fulfills Norton’s criteria as well as that proposed by the author. The final product – the hypermedia case study – will assist teacher education students to be better prepared for their student teaching experience, will support students’ grasp of concepts through collaborative meaning-making and shared insight, promote resource-based problem-solving, and modeling how theory translates into practice. Case study methodology presented in a hypermedia format does meet diversified learning needs. Finally, faculty are pleased to be able to use technology to produce a product that will facilitate their tenure, promotion and merit needs.

Again, the finished product was not the goal of the grant that funded this initiative. Rather, this project was about the process of developing that product. The collegiality and study with fellow faculty members at both the university level and the k-12 level and with those at a distance were fundamental to the process. The experience of participation in a problem-based learning situation, the willingness to grapple with the discomfort of self-selected project scope and sequence, and the assumption of risk in learning new technologies – digital cameras, video editing software, photo manipulation software and hypermedia production software – have proven to faculty that they can be at the cutting edge of technology innovation and utilize those skills in their teaching and scholarship.

Operationalizing a Technology Standard with Proficiency Skill Sets

David Georgi and Javier Ruiz
Teacher Education Department
California State University, Bakersfield
USA
dgeorgi@csub.edu

Abstract: This paper begins with an overview of the existing program which operationalizes the California technology standard for K-12 teachers with the California Technology Assistance Program (CTAP) Region 8 technology proficiencies. It is supplemented by a link to a PowerPoint presentation and demonstrations of the following web sites: 1) the CTAP Region 8 site (http://www.ctap.org/ctc/) includes a rubric for three levels of certification and digitized video examples of exhibits at Levels 1 and 2; 2) the California technology standard (http://www.csub.edu/~dgeorgi/contents/techstand.htm); 3) the PT3 grant that helped coordinate these efforts (www.projecttnt.com). Next, a description of the process involved in coordinating this certification process with K-12 districts and teacher credential programs. To date, over 500 teachers have been certified including growing a cadre of Level 3 leader/mentors. An interactive discussion on implications for those present will conclude the session.

Introduction

In 1997, the California legislature passed a law mandating the development of a technology standard for K-12 teachers that would be used in the credentialing of new teachers and in the review of teacher credential programs. The Technology Education Advisory Committee (TEAC) was selected from among diverse constituencies to research the topic and develop recommendations for the Commission on Teacher Credentialing (CTC). The TEAC met many times over the next year and engaged the services of the State Librarian to research the efficacy of technology on the teaching and learning process (Umbach Report). A preliminary set of recommendations was sent to all pertinent institutions and individuals for field review. Taking the feedback from the field, the TEAC proceeded to develop language for a technology standard with a number of “factors to consider” that would be used to accredit teacher preparation programs (http://www.csub.edu/~dgeorgi/contents/techstand.htm). The recommendations were presented to the CTC in December, 1998 and were accepted. At first, the new standard was to be made effective in January, 2000, but a number of institutions requested more time and currently the standard will be effective in January 2002. All teacher preparation programs in California have been requested to submit plans for implementation of the standard and a number of methods have been proposed and were accepted. In September, 2001 California adopted a whole new set of teacher credential standards. The Technology Standard was slightly reworded and included as Standard 9. The technology plans written to Standard 20.5 are still in effect under the new standards.

Meanwhile, the California Technology Assistance Program (CTAP), a consortium of regional offices coordinated by the California Office of Education, was working on developing its own technology standards for teachers. Region 8, consisting of four central California counties, decided to build on the work of the CEAP by taking the technology standard’s factors to consider and using them as skill sets for technology proficiencies. The CTAP Region 8 Advisory Committee met several times and developed a rubric for assessing technology skills (http://www.ctap.org/ctc/). The rubric has been used by K-12 districts to organize professional development activities and by teacher preparation programs at CSU Bakersfield. A federal PT3 project included a task force on Technology Proficiencies and helped coordinate the effort (www.projecttnt.com).

The CTC technology standard divided its levels of proficiency to articulate with the system for obtaining a teacher credential in California, which is a two level system. Meeting level 1 is a requirement for a candidate must be recommended for a preliminary credential. Meeting level 2 is required for recommendation for a professional clear credential. Level 1 is primarily personal computer skills with some application to teaching responsibilities; level 2 involves the integration of computer skills into teaching responsibilities.
CTAP Region 8 proficiencies have been organized into a rubric based on the two tiers described above and added a level 3 for advanced certification. All certification is done on the basis of portfolios assembled by the teachers. Teachers can be certified at level 3 as either mentors, whose main responsibility is training other teachers, and leaders, who serve as tech coordinators or administrators. Level 3 teachers can certify level 1 and 2 teachers.

Results

As a result of implementing a coherent approach to certifying teachers at various proficiency levels, a number of positive results have occurred.

First, technology skill training is directed toward meeting the levels of certification. This ensures that teachers attending training sessions are at an appropriate skill level and for specified skill development; avoiding some teachers being lost and others bored. This also allows all training at K-12 schools and university teacher credential programs to be articulated on the factors underlying the technology standard.

Second, teachers are encouraged to attain certification at all levels. Some schools offer a bonus for attaining level 2. Level 3 teachers often receive stipends for the training and administrative tasks they perform.

Third, by having level 3 teachers certify levels 1 and 2, the presence of expertise has been greatly expanded. Most local schools have at least one level 3 teacher and many schools are including the attainment of specified percentages of faculty attaining each level by specified deadlines. A strong cadre of level 3 teachers is being developed and will soon be adequate to provide technical support for local schools.

Fourth, by having a common certification system, unprecedented collaboration is occurring among schools and university teacher credential programs. Level 3 teachers are participating in the writing and implementation of a variety of grants and projects involving technology. One example is the Preparing Tomorrow’s Teachers to Use Technology Implementation federal grant, which includes a Technology Proficiencies Task Force. CTAP Region 8, local teachers and university professors have collaborated in developing a web site that includes the technology proficiencies rubric, application for certification, and examples exhibits that meet most proficiencies. In addition, a list of certified teachers is maintained at the CTAP Region 8 office and is posted on its web site. This is a further incentive for teachers to attain certification as it indicates that all teachers are expected to have demonstrated technology skills.

In addition to the positive results of this system, a number of problems have emerged.

First, articulation between CTAP Region 8 and instructors in the university teacher credential programs has had difficulties. University professors have been slow to get certified to level 3. CTAP Region 8 has offered to provide such professors with level 3 teachers so students in university classes can have their portfolios certified officially.

Second, it is difficult to ensure that all candidates will have access to certification. The university credential programs have submitted a plan to the CTC stating that by June, 2001, all credential candidates will be required to attain levels 1 and 2 in order to be recommended for the preliminary and then the professional clear credential. Because of the large number of credential candidates, an independent study course in Technology Portfolio Certification is being developed to meet the needs of out of state teachers and others who fall through the cracks. In addition, the state of California has contracted with National Evaluation Systems to develop a test for the above procedure for level 1, primarily for out of state teachers.

Third, some universities in the region refuse to participate in the system, citing turf issues. They will be required by the state to meet the technology standard in their own ways.

Fourth, other regions and the state level CTAP are developing their own systems, which may have a future impact on the Region 8 system. Similarly, the ISTE standards are seen by some as a model on which to base training. In response, a correlation chart has been developed, which indicates where specific skills are located in each system.
Conclusion

The implementation of a technology proficiency skill sets certification system based on a state technology standard has had dramatic positive effects on the development of technology skills in local schools. The certification of hundreds of teachers at levels 1 and 2 has encouraged many teachers, including those with life credentials, to develop technology skills that enhance the teaching-learning process. The increasing presence of level 3 teachers is providing that most commonly missing element in technology professional development: adequate and accessible technical support. As an added benefit, the awareness of the importance of technology in schools among level 3 teachers has produced that second most commonly missing element: equipment and training as a result of grant writing activities. As the new technology standard goes into effect, the system described in this paper can be expected to continue to promote the development of technology fluent teachers in local schools.

Teaching with New Technologies, a federal PT3 project www.projecttnt.com
Technology Leadership Community - Students as Teachers

Scotty Govaars, Department of Defense Dependents Schools - Europe, US
Pat Ridge, Department of Defense Dependents Schools - Europe, US

This poster session will focus on case studies of students and teachers from several of the Department of Defense Dependents Schools throughout Europe who are currently offering a new course, entitled "Technology Leadership Community" or "TLC".

TLC Course Description

The course is about teaching, learning, and learning to teach. The domain of information is technology and technology skills.

Technology Leadership Community (TLC)

Grade Level: 7-12

Length Of Course: 18-36 Weeks

Recommendations:

Experience with PCs, strong working knowledge of applications used in school and capacity to learn newest technologies, interest in education and teaching. Students must be self-motivated and have a high level of personal responsibility.

Major Concepts/Content:

The TLC class merges learning the newest computer technologies with learning how to effectively teach others those technologies. Students collaboratively study and learn new software packages and computer skills while learning how to become effective trainers and educators. In addition to raising the technological knowledge of the school community, TLC students examine their own roles as teachers and learners, increasing their learning abilities in all other classes.

Major Instructional Activities:

This course is designed to train students to become effective teachers and learners by complementing the technology support in their school community.

Technology study includes Internet navigation and searching, web page creation, server management, desktop publishing and graphics applications, GIS, CAD, and other specialized software. Pedagogical study includes methodology of teaching, materials preparation, presentation strategies, evaluation techniques, and formalized self-reflection activities such as log-keeping and using videotape to observe, analyze, and improve their own teaching efforts.

Teaching activities include weekly one-on-one mentoring sessions with faculty, staff, students or community members; teaching in larger group situations (such as another classroom learning a single application); and preparing manuals and other instructional materials for their "clients." Other activities include regularly assessing the school’s technology learning needs and developing strategies to effectively meet those needs.

Major Evaluative Techniques:

Students will create their own assessment rubrics and goals. Doing so enables them to set learning objectives and have a clear understanding of what is expected of them. They do this individually with the teacher. The students will also be graded on completion of tasks and participation and there will be several take-home essays that reflect what the student has learned at different points in the semester.

Assessment Will Be Based On:
How well they learned to identify, analyze, and improve their teaching abilities through their video and writing work. This will be based on survey and writing assignments, comparison of pre/post surveys, and essay writing.

How well their mentees learned the technology material. Teachers and other mentees are asked in survey form to assess their experiences with the TLC students. The TLC student assesses himself and a combination of this data describes how the student performed.

The degree in which a student's technological knowledge improved. The TLC teacher, along with the student, will examine the pre/post surveys and determine how much of the technological knowledge the student learned. Students are expected to attain a high level of competence in one or two applications, rather than learning only a little about as many applications as possible.

Essential Objectives:

Upon completion of the course, students should be able to

Demonstrate how teaching others enhance one's own learning abilities and styles, in any subject.

Demonstrate technological competency on at least one application. Competency is defined as thorough knowledge of the program, fluency with operation, and ability to explore with the tool.

Design a teaching unit or activity, including an assessment piece about a specific software or technological application.

Demonstrate growth in communicative, developmental and social areas. For example, students learn how to become articulate, develop confidence to communicate clearly with adults and youngsters, become methodical in their learning styles, attain a very high degree of responsibility.

Help the school use the complex technologies already in place, working with and complementing the training tasks of the Education Technologist, and also develop new training programs to meet changing demands.

Demonstrate that work of this nature is directly tied to real-world workplace skills.

This is a course that engages the student in the learning process. The content and activities serve to get students to think of themselves as learners, identify their own learning patterns and styles, and improve as learners. They do this by studying how to teach, by teaching others, and by reflecting upon themselves as teachers and learners.

The topic they teach is technology. This is not a technology learning class per se; it is not a computer education, application, or programming course. Those topics may be included, but it is primarily about learning how to teach technological information to others.

This is also not a "students-as-techies" course or program. While students in the TLC may learn how to service an LCD projector or a printer, their job is not to visit a classroom and change a printer cartridge, but rather demonstrate to the faculty in one-session maintenance procedures on a range of common technological equipment. TLC students are the leaders of the school, and presumably the leaders of tomorrow; therefore it wouldn't make sense to exploit their knowledge by having them tasked to fix problems everywhere.

The TLC course contains rigorous academic activities as well as demanding technological experiences.
Expanding Teachers’ Literacy in Science and Mathematics: Basing Technology Professional Development on Histories of Classroom Practice and Beliefs

Abstract: One hundred four middle school mathematics and science teachers committed to participating in a professional development summer institute with approximately 90 hours of instruction in the use of educational CD-ROMs, calculator-based laboratory, and microcomputer-based laboratory. Prior to the institute we were able to make classroom observations of teachers and collect various types of data in order to construct a rich description of the teachers. This paper will describe the types and frequencies of activities in the classroom.

Introduction

As pressure is exerted upon educational systems to implement instructional technologies, teachers’ abilities to accept change and adopt innovations become key factors for success. Finding successful methods for educating teachers to use new technologies and working with them to adopt new pedagogical approaches is a widespread concern.

Evaluation of summer professional development institutes often takes the form of collecting data at the beginning of the institute, in the form of tests or surveys, and collecting data again at the end of the institute (Fenstermacher & Berliner, 1985; Lock & Dunkerton, 1989). Recently, more studies have been designed to follow the teachers during the school year after the institute (Barrow & Sawanakunanont, 1994; MacArthur et al., 1995; Shroyer & Borchers, 1996). The impact on teachers participating in summer professional development institutes has often been reported without definitive knowledge of the teachers’ performance prior to the institute. Using a constructivist framework, evaluators would recognize that teachers do not begin the institutes as “blank slates,” rather they begin with a history of classroom practice and beliefs that become part of the institute.

This study is based on work with a group of rural middle school teachers assigned to teach mathematics and science in eastern North Carolina. The intensive, 3-year, high support program began with a summer workshop with 90 hours of instruction in the use of CD-ROMs, CBL, MBL, and inquiry techniques. These technologies were not previously widely available in our state’s middle school classrooms, particularly in rural areas. The teachers entered the EMPOWER program in math-science teams from 41 schools. Teaming teachers was important for potential interdisciplinary cooperation, social environment necessary for diffusion of innovation, and support structure for adopting math and science reforms (George, Stevenson, Thomason, & Beane, 1992; Rogers, 1995; Sparks, 1997).

Design of the Study

The study’s focus was the generation of a rich description of the entering characteristics of rural middle school mathematics and science teachers prior to entering a long-term inservice program. Data collection procedures involved observation of participants, document analysis, an open-ended essay questionnaire, a personality type instrument, and a questionnaire investigating the type and frequency of activities in teachers’ classrooms during the spring before the initiation of the inservice program. This paper will highlight the type and frequency of classroom activities.

Sample

EMPOWER was an inservice program for middle school mathematics and science teachers sponsored in part by the National Science Foundation (NSF). One hundred and four practicing teachers participated in the workshop instruction. The participants represented a wide range of backgrounds, years of teaching experience, and teaching assignments. The teachers were primarily from rural middle schools in eastern North Carolina. Some participants had used computers and calculators in the classroom before, but many had never used MBL, CBL, or graphing calculators.
Types of classroom activities

A self-report questionnaire was used to measure the activities of instruction for an 8 week period of the spring semester. The instructional activities listed in the questionnaire were based on the Local Systemic Change through Teacher Enhancement: 1997 Teacher Questionnaire, K-8 Science (Horizon Research, 1996) and the 1997 Local Systemic Change Classroom Observation Protocol (Horizon Research, 1997). The teachers were instructed to use their lesson plan books or planning calendars to categorize activities and count frequencies with a 1(daily) to 6(never) scale. The teachers were asked to do the counts on the first math or science class taught each day. A wide range of possible classroom activities were included along with open-ended items.

Data analysis and results

Although participants had used computers and calculators in the classroom before, many had never used graphing calculators and none had used MBL or CBL to collect data. The 10.87% of the teachers who had never used calculators in teaching were all assigned to teach science. Graphing calculators were used by over half of the teachers for computation. Computers were used by the largest percentage of teachers for word processing, drill and practice and spreadsheets.

Conclusion

Middle school mathematics and science teachers may need more experience with the many uses of graphing calculators and computers. In particular, using them as tools for data collection should be addressed. Providing experience and practice in many facets of calculator and computer use should be considered in designing professional development programs. Teachers need time to develop a comfort level with the technology and time to consider and develop teaching strategies to accompany the technology. The many possible uses of graphing calculators and computers for data collection and problem solving should be introduced to teachers, particularly when large numbers are teaching out of field. Their methods courses as preservice teachers would not necessarily touch upon these subjects. The instruction in these technologies could be used as an anchor for introducing subject matter content.

Effective schools, Effective learning, Effective tools

Merrell Hansen, Brigham Young University, US
Robert Gentry, Provo School District, US

The interest in technology has been altered substantially. It is now seen as a critical application of effective teaching and learning strategies. It is a facilitative experience in using and acquiring knowledge and information. This represents a study and examination of a school committed to renewal and improvement. It has carefully initiated teacher leadership activities and practices. It has sought ways of incorporating meaningful change within the classroom context of teaching and learning. Technology and its wise and appropriate use are critical to this enterprise. This session will consider the application, analysis, interpretation, and summary of technological strategies to promote student learning, increasing the effectiveness of the teacher and the teaching process. Specifically it will consider the use of the IPAQ computer in a middle school talented and gifted program. Data and information will be shared that exemplify best practices for teachers, students, prospective teachers, and administrators. As a part of the report, the impact that technology and this specific program will be examined as these relate to preservice and inservice dimensions of professional growth.
Using Video Ethnographies for Professional Development of Educators

Carl Harris, Brigham Young University, US
Peter Chan, Brigham Young University, US
Ping Zeng, Brigham Young University, US
Carol Greene, Virginia Tech, US
Susan Magliaro, Virginia Tech, US

Purpose
This panel will provide an extensive examination of an emerging approach to professional development—video ethnography from four different perspectives: pedagogical foundations, demonstration, national and international applications, and current research studies.

1) "Pedagogical Foundations of Video Ethnography" by Carl Harris
The pedagogy for video ethnography is based in specific principles of constructivist learning. According to learning scholars there are at least four critical elements of learning that must exist if learners are to be fully engaged in the learning process and develop deep, reflective thinking patterns that will transfer to other contexts. First, learners must be confronted with problems and frame questions that genuinely mirror the world beyond the classroom. Second, the problems and questions must come to have personal meaning to the learners. Third, the process of teaching learners how to frame questions and inquire after solutions must model active inquiry pedagogy (i.e., practice in inquiring about and finding their own answers). Fourth, the display of learning must be to real audiences, for example, those who can benefit from and who have a vital interest in the problems and questions, in addition to teachers and peers. In developing the pedagogy for the use of video ethnography and in the development of video ethnographies, Harris has attended carefully to the inclusion of opportunities for students to engage in learning tasks that address these four critical elements of learning. While scholars might log on to the video ethnography web site and use the case to illustrate points in their lectures, the deep learning that can accompany this work emerges only as one embraces not only use of video ethnographic cases but the pedagogy of video ethnography as well.

2) "Demonstrations of Video Ethnography" by Peter Chan
This part of the presentation will focus on demonstrating the actual CD-ROM interface. The Video Ethnography CD-ROM consists of three main parts: (1) Exploration, (2) Creation, and (3) Supporting Functions.

Part 1: Exploration
This part of the CD-ROM includes several study buttons. Each button launches six to nine “probe” buttons, which represent the study of the case teacher from a general educational principle. Each “probe” button brings a video clip showing classroom activities that illustrate a particular aspect of the principle. A video slider is located at the bottom of the video screen so that users can slide to any part of the video when they choose to repeat part of it. At the bottom of the display are the perspectives (commentaries) on what happened in the video clip. The perspectives may come from the case teacher, another teacher, a student, a teacher educator, a school administrator, and professional literature depending on the nature of the case. Each of the perspectives is in both audio and text formats.

Part 2: Creation
The second part of the CD-ROM allows users to create their own video ethnographies by manipulating the provided video clips into any desired order and commenting on what they perceive to happen in these clips. This part of the CD-ROM may be used for recording personal reflections, comments, elaborations, and new insights related to what they have studied in the Exploration part. It may also be used as an instructional, researching, and demonstrating tool.

Part 3: Support Functions
The CD-ROM has supporting functions such as text transcriptions, Internet connection, tutorial, and general help.

3) “National and International Applications of Video Ethnography” by Carl Harris, Peter Chan, & Ping Zeng

This part of the presentation will show various applications of video ethnographies from elementary to higher education and from Utah to Beijing and Xian, China. It will be broken down further into three shorter sections.

(a) “Julene Kendall Case Study: A Video Ethnography of Teaching in an Elementary English as a Second Language (ESL) Classroom” by Carl Harris

The Julene Kendall Case Study allows teachers to explore strategies and principles of teaching ESL students. Furthermore, the case study engages learners in building and documenting their own interpretation of the Kendall case from various perspectives. Students share and seek feedback from peers as well as the course instructor. The cases, while interesting in and of themselves, are most interesting because they allow students to see the theory in practice and the practice of theory. This duality is made visible for and accessible to students through the pedagogy of video ethnography.

In the Julene Kendall Case Study the strands of focus articulated by the case author are 1) Building Community in the Classroom; 2) Visual Cues; 3) Hands-on Activities; 4) Guarded Vocabulary; and 5) Classroom Management. Each of these strands is represented by a study button that links to seven probes: 1) Use of Names; 2) Chance to Share; 3) Comfort Zone; 4) Social Skills; 5) Use of Space; 6) Friendly Environment; and 7) Cooperative Learning.

(b) “Experiences from using video ethnographies with teachers from Beijing and other parts of China” by Peter Chan

Besides the applications in the United States, video ethnography CD-ROMs were also developed in Chinese for professional development of Chinese teachers. The first two Chinese CDs focused on developing thinking skills of elementary and secondary students. Ten teachers in Beijing were asked to extensively evaluate these CDs over a four-day period. Multiple methods were used in the evaluation. The CDs were also used as the parts of the key instructional materials in two consecutive Chinese conferences on teacher education and received positive responses from the participants. An American video ethnography on persuasive writing was translated into Chinese earlier this year for intercultural studies, which will also be demonstrated at the conference.

(c) “Content Design of A Video Ethnography of the Pre-service Student teaching in A Foreign Setting” by Ping Zeng

Normally, pre-service students have little idea about the countries where they would have their teaching experience. What they would prepare as the possible teaching plans, instructional and assessment tools may not fit the target cultural settings. Similarly, the host schools in the countries other than America need to know about how, on the one hand, to utilize the resources of the student teachers and their teaching methods to benefit the local students, and, on the other hand, to make the environment more favorable for the career development of the pre-service students. Without some background training, these students will have to face some possible cultural barriers and difficulties in their teaching and their social life in the unfamiliar cultures.

This paper aims at introducing a combination of a new technological tool, a video ethnography and some constructive principles of content design to serve the purpose of solving the problems listed above. The template, developed by Dr. Carl Harris and David Baker, is chosen to be the instructional tool and its content format is designed to contain the substantial data about the real teaching experiences of the BYU students in Xi’an, China. The final product can be used to acquaint the future pre-service students in advance in the aspects of educational system, prevailing pedagogies, problem-solving skills, cultural traditions, and customs. It should be able to help not only these students adapt to new cultures quicker and easier, but also benefit the host school administrators, providing them with information of the educational performances in North
America, and of how much and in what aspects such performances are constructive to the local curriculum development. Consequently, the co-teaching and the cooperation between the student teachers and the local teachers can be more successfully executed. Moreover, teacher educators may also use it for academic studies, particularly in the areas of comparisons of educational systems and the teacher education in foreign settings.

4) "A Technology-Enhanced Field Experience" by Susan G. Magliaro and H. Carol Greene

This part of the presentation will show a research study using video ethnography.

This project added an experimental field experience component to an existing educational psychology foundations course for pre-service teachers that is offered at Virginia Tech. This was done through the use of video-based case studies. The focus was on the solving of authentic video-based cases that highlighted the psychological, emotional, cultural, and social dimensions of teaching and learning.

The specific objectives of this discussion are to focus on:

1. the learning outcomes related to principles of educational psychology,
2. the learning outcomes related to teaching practices, and
3. the enhancement of participants’ learning about and appreciation for diverse educational settings

While a full report of the findings will be shared at the presentation, a sample of the results is highlighted here. Preservice teachers noted several advantages of having the electronic field experiences. Among those mentioned were: opportunities to see classrooms and teachers from diverse communities; opportunities to see outstanding teachers from their respective fields; and opportunities for them to critically analyze a lesson. One student even mentioned the “bird’s eye view” the camera offered, allowing them to see the classroom and students from various angles and perspectives, rather than simply the view from the back of the room. Comments about the case studies increasing their understanding of educational psychology concepts occurred frequently. The students cited the videos as helping them to make concrete the concepts that seemed very abstract when read from the textbook alone. They also stated that seeing teachers perform the methods and strategies talked about in class served as a good modeling agent. This was enhanced by the fact that the “field experience,” because it was electronically offered, was both immediate and coordinated with the classroom discourse. The case studies immediately followed a topic or concept that was under discussion in the course.

Introduction
The problem of inappropriate integration of technology into the classroom is not the fault of the teacher, rather it is the current model of teacher training. Regardless of fault, the problem must be addressed. While education resorts to improving teacher use of technology through training, it is necessary that the current model of teacher training with technology be abandoned. A series of one-day seminars, or periodic after-school instructional sessions will not keep teachers at the pace of current school reforms (RAND, 1995). While the scope and scheduling of training must change, the content and approach to teacher training with technology must also be addressed. This paper will discuss the current model of teacher training with technology, technology and meaningful learning, and guidelines for teacher training with technology.

Current Model of Teacher Training with Technology.
Current teacher training involves the development of skills associated with various software. For example, at one rural school, each teacher was given a laptop computer. Prior to receiving the computer, each teacher had to attend a workshop on “How to Use PowerPoint”. While presentation software can be helpful in creating meaningful learning experiences, it was obvious that the focus of the workshop was to improve teacher presentations. There was no mention of methods to apply the computer to assist in student learning. Also, some software that would have more potential in creating meaningful learning environments are database programs, spreadsheet programs, concept mapping software, hypermedia construction software, and microworld environments software (Jonassen, 1996). While many of these could obviously not have been discussed in two or three after-school sessions (the length of the PowerPoint workshop), possibilities for their use in the classroom and the relevance of technology in education could have been introduced, discussed, and modeled. It is the modeling and implementing of relevant learning environments, in order to promote meaningful learning, using technology that must move to the forefront of training teachers with technology.

Technology and Meaningful Learning
“Students do not learn from teachers, they learn from thinking.” (Jonassen, et al, 2000). Activities that facilitate “thinking” can provide meaningful learning experiences for the learner. These activities should be active, constructive, intentional, authentic, and cooperative. (Jonassen, 1996) Active learning involves tasks in which the learners manipulate objects in the learning environment and observe the consequences of their actions. Constructive learning involves learners reflecting upon their learning experience, and articulating those reflections. Learners construct their own “mental models” to explain their experiences. Intentional learning occurs when learners are attempting to achieve a learning goal of their own. Authentic learning activities occur when learning tasks are modeled after real-world problems or situations. Cooperative learning occurs when individuals work with others in formulating “mental models” and communicate their findings to others (Jonassen, 1999). Each of these must be addressed as teachers are developing meaningful learning activities and environments for students.

There are a number of learning environments that promote the partnership between students and technology (Jonassen, 1999). One of these learning environments involves Internet Learning Activities. These include students creating home pages (student, class, or school), role playing on the web, cybermentoring (communicating through the Internet), and supporting scientific experimentation through the Internet. Video Learning Activities can also promote meaningful learning. These include activities such as video press conferencing, producing student talk shows, creating video documentaries, and developing video theater. Multimedia Environments, including multimedia environment software (Exploring the Nardoo) and constructing hypermedia, can also be used to foster meaningful learning with technology. Other examples include constructing databases, semantic networks, and expert systems. The purposes of all of these activities is to promote active, constructive, intentional, authentic, and cooperative learning environments.
Guidelines for Teacher Training with Technology

In order to change teacher training with technology, a number of guidelines should be implemented. The following is a list of guidelines for teacher training with technology. Teacher training should focus on:

1. the development of meaningful learning for the student.
2. the changing role of the teacher in a technological age.
3. methods of promoting student production.
4. implementing technology as a partner in the learning process.
5. methods in which teachers put students in the appropriate learning roles.
6. the implementation of technology.
7. fostering teacher-teacher and teacher-student collaboration, not just the student-student collaboration.

Conclusion

In this paper, numerous deficiencies in teacher training, with regards to the integration of technology into the classroom, have been addressed. Guidelines for general changes in the model of teacher training have been discussed. These guidelines cover the following topics:

- The types of activities currently occurring in Teacher Training with Technology.
- The new roles of the teacher and student when technology is integrated into the learning environment.
- The implementation of technology into the classroom.
- Collaboration between teachers and students, with respect to implementing technology.

In order for these guidelines to be implemented, the current model of teacher training must be abandoned. Activities that promote meaningful learning must be modeled for teachers. These activities must be modeled in a way that the teacher assumes the role of the student. This not only aids in modeling the types of activities that promote meaningful learning and provide teachers with a relevance for the implementation of technology in the classroom, but also models the actual implementation of the technology into the classroom. Collaborative activities are essential for meaningful learning. In order to promote and model collaborative activities, teacher training sessions need to promote collaborative environments. Collaboration between the instructor (trainer) and the students (of the training session) must be modeled and discussed. For teacher training to be successful, the scope and duration of workshops must be addressed.

While there are many issues related to the training of teachers with the use of technology, this paper addressed some issues that need to be addressed. By discussing the shortcomings of the current models of teacher training, it is hopeful that teacher training and technology become a much more potent partner in creating collaborative, meaningful learning environments, in the future.

Weekly IT Teacher Training: A Model for Success

Lorrie Jackson
Lausanne Collegiate School
U.S.A.
ljackson@lausanneschool.com

Abstract: Lausanne Collegiate School in Memphis, Tennessee (USA) has created and implemented a weekly, after school IT training program for faculty and staff called Tech Tuesdays. Since the fall of 1999, this program has met the needs and schedules of teachers at a school where hardware and software availability and usage was rapidly evolving. This paper documents the rationale behind the Tech Tuesday model, its origins, topic selection, process, and successes as evaluated by increased teacher skills and administrator feedback. Of particular note is the impact the school’s recent move towards laptops in grades 7-12 has had on the training needs and interest levels of teachers and staff. Tech Tuesdays is an easy-to-replicate faculty development program with a proven track record and the flexibility to adapt to the changing training and platform needs of K-12 teachers and staff.

K-12 schools are constantly faced with the need to train and retool their faculty and staff, as technology changes and the need for technology integration in the classroom grows. While administration and technology personnel recognize this need, time and resource constraints often impede effective training from taking place. A short, on-site, after school training model called Tech Tuesdays has proven a successful solution to the challenge of ongoing staff development for one school struggling with this issue. In this paper, the history of Tech Tuesday, presentation format, topic selection, and successes will be discussed, as will the impact of the new laptop program on Tech Tuesday. Finally, challenges and opportunities for future growth will be offered.

Lausanne Collegiate School (LCS) is a diverse, co-educational, private college-preparatory school for students in grades preschool through 12. Like many schools, LCS wanted to increase the technology skills of its staff so that the teachers and staff would in turn integrate technology, but found that existing technology training models were too long and not tailored to individual needs. Therefore, in the fall of 1999, Tech Tuesday was created as a way to provide very short and specific serving the faculty’s varying ability levels and interests.

Each week, an e-mail is sent to all faculty and staff announcing this Tuesday’s topic. Five minutes before each Tech Tuesday begins, an announcement is made over the public address system. Teachers and staff meet in the Lower School computer lab immediately following carpool and school dismissal. The Lower School technology integration specialist then begins a fifteen-slide PowerPoint presentation on the week’s topic. The PowerPoint explains why a topic is important and outlines very basic steps to achieving the skill or task. Each participant practices the skill on a lab computer or on a school-owned laptop while observing the presentation on the Smart Board. The presenter takes attendance and e-mails that attendance to each of the division heads (the administrators in charge of Lower, Middle, and Upper Schools). The PowerPoint presentation is then attached to an e-mail sent to all attendees and other staff who could not attend but who asked for materials. Finally, the presentation is uploaded to the school’s web site for later reference.

Topics vary widely. The topics for fall 2001 included: viruses, computer maintenance, web quests, finding lost files, hardware and software basics, adding pictures and hyperlinks on teacher web pages, and creating address books in the school’s e-mail program, among others. Administrators, teachers, and technology staff request topics to be covered. Because the specialist who teaches Tech Tuesday is also responsible for one-on-one training of teachers on a daily basis, she has a good understanding of staff skills and interests.

How successful have Tech Tuesdays been? Given that the sessions are “off-the-clock” and completely voluntary, attendance has been high, with over a third of all faculty and staff (includes librarians, development, and administrators) coming to at least one Tech Tuesday. Of these attendees, one-quarter has attended over half the fall 2001 sessions. Average attendance at Tech Tuesdays was ten, with weekly numbers varying from six to nineteen attendees.
Yet these numbers only tell half of the story. In a recent survey of faculty, staff, and administration, administrators report increased competency and confidence from their staff. Teachers cited “computer confidence” and e-mail proficiency as the two greatest improvements made by attending Tech Tuesdays. Increasing their knowledge and topics that were relevant were the two primary reasons for attending the sessions. The faculty responded that having the training on-site, keeping training short, having a dynamic and helpful instructor, and focusing on only one topic at a time made Tech Tuesdays convenient for them.

Beginning in the fall of 2001, all seventh and eighth graders purchased IBM Thinkpads to be used in classes. A campus-wide wireless network figuratively broke down the walls of the traditional classroom, while middle school teachers revamped their curricular and activities to take full advantage of the flexibility and freedom the laptop provides. With this new opportunity, however, came a need for retraining. Non-math teachers needed Excel training to use spreadsheets creatively. Teachers with limited computer skills faced a classroom of eager and competent students with the world at their fingertips.

LCS refocused its Tech Tuesday topics to help faculty meet the needs created by the laptop program. For example, Upper School faculty are preparing to teach next year’s entering freshmen who will have had a year of laptops in the classroom already. Yet, many of these teachers have limited computer skills themselves. The four technology department employees gave each one of the upper school faculty a hands-on practical assessment in six areas of technology: operating system (PC), First Class (LCS’ e-mail program), Internet Explorer, Microsoft Word, Microsoft Excel, and Microsoft PowerPoint. Teachers attempted to complete tasks in each portion of the assessment, and staff evaluated their ability or inability to do so.

Administration required faculty whose skills in a given area were average or below to attend a Tech Tuesday held on that given software or hardware topic. Once again, the presentation was limited to a 15-minute format with a PowerPoint presentation and handouts that gave concrete examples on how to use Excel, Word, etc. in a variety of content areas. Technology staff re-evaluated the faculty within weeks of a given session to see if skills had improved.

Replication of the Tech Tuesday model at other schools would be simple. Given the brevity of the training, sessions can be taught before or after school or during lunch or other free time as needed. Technology staff need not teach sessions if none are available. Keeping sessions short and targeted to the teachers’ needs, with step-by-step presentations and electronic texts (or paper handouts) for later use are the most important components.

At LCS, the ongoing challenge will be to keep pace with the advancing skills and needs of our laptop faculty while still offering basic instruction for new teachers or those with only basic skills. Recently, the school began requiring three technology professional development (TPD) hours this year, and five TPD hours in the following years. This new expectation will undoubtedly increase the numbers of teachers attending the sessions, but will they be motivated to learn or simply be present to fulfill a requirement? LCS tech staff must therefore double their efforts to ascertain and address the needs of the new “reluctant” attendee. Plans are also being made to open up sessions to other independent schools in the area. Finally, as teachers become experts, they too can begin leading Tech Tuesdays, providing technology success stories and inspiration for their peers.

Tech Tuesdays have met one school’s needs for short, on-site, relevant IT training for K-12 faculty and staff. With only a minimum of time and effort, this success can be duplicated elsewhere to provide effective staff development in a variety of educational settings.
Motivational Processes in the Integration of Technology into Teacher Education

Deborah L. Kalkman, Northern Illinois University, US
Corenna C. Cummings, Northern Illinois University, US
Lisa Mehlig, Northern Illinois University, US

For the past three years, the College of Education at Northern Illinois University has required all new faculty members to take a course - Integrating Technology in the Curriculum. This course is designed to assist faculty to more fully develop skills with respect to the meaningful integration of technology in the curriculum so as to serve as models for the use of technology in classrooms for teacher education students. This study examines the influence of the mandatory nature of this course on the motivation of the faculty to integrate technology into their teacher education courses. Self-determination theory provides the basis for understanding the process of internalization from externally regulated reasons for faculty taking the course to increasing degrees of internally regulated motives for these same faculty using technology in meaningful and effective ways in their courses.

Theoretical Perspectives: Self-determination theory suggests that intrinsically motivated behavior occurs when one acts autonomously - under their own volition (Deci & Ryan, 1985). Therefore, we would not expect someone who is required to take a technology course as a condition of their employment to be intrinsically motivated to do so. Likewise, we would not expect a technologically incompetent faculty member to be motivated to integrate technology into their coursework. Thus, the goal becomes one of creating a learning environment that promotes perceptions of competence and autonomy.

A person feels most autonomous when his behavior is internally regulated; that is, when the behavior is intrinsically motivated, or engaged in for the pure enjoyment of the task (Ryan & Connell, 1989), however, experience and logic tell us that it is not practical to assume all activities will be intrinsically motivating. Therefore, we need to consider the process of internalization as progressing on a continuum from external to internal regulation (Deci, Vallerand, Pelletier, & Ryan, 1991). Internalization "refers to the process by which an individual initially acquires beliefs, attitudes, or behavioral regulations from external sources and progressively transforms these external regulations into personal attributes, values, or regulatory styles" (Ryan, Connell, & Grolnick, 1992, p.171). The greater the internalization, the more it is perceived as being "caused" or endorsed by the self (Ryan et al., 1992).

Deci, Ryan, and others (see Deci & Ryan, 1985; Deci et al., 1991) have identified four types of extrinsic motivation: external regulation, introjected regulation, identification, and integration. The least autonomous behavior would be controlled via external regulations, such as following a rule merely to avoid punishment or to achieve a reward - "I will take this course and use technology so that I can get and keep my job." The primary "cause" of the behavior is external to the individual. Behavior that involves acting to avoid disapproval from self and others is referred to as introjected regulation - "I like my department chair, so I'll take this course and do what I can to integrate technology into my courses so I can please him." There is no inherent value to, or interest in, the activity or behavior itself, but neither is it controlled by external contingencies. More autonomously regulated, and therefore more autonomously engaged in behavior would be labeled as either identified or integrated regulation. An identified regulatory style involves acting because the goal itself is valued or personally important - "I might learn something valuable from this course, so I think I'll get the most out of it." The most advanced form of extrinsic motivation is integrated regulation - "As a teacher, it is important for me to use technology in meaningful ways to be more effective; therefore I believe taking this course is a valuable opportunity." "When regulatory processes are integrated, behavior is an expression of who the individual is -of what is valued by and important to the individual" (Deci et al., 1991). Each type of regulation involves a greater degree of internalization. The more internalized the reasons for acting, the more autonomously regulated, or self-determined the behavior.

Purpose: The goal of this study becomes one of understanding the relative influence of a mandated technology course for all new faculty in the College of Education on the integration of technology into teacher education courses. It begins with the question: To what extent and for what reasons have new faculty become engaged, behaviorally, affectively, and cognitively in the integration of technology into their courses? It ends with understanding the characteristics of this course that promote the internalization of reasons for technology integration in teacher education courses.
Participants: Nine of the course participants, three from each of the past three years, will be selected at random from the pool of new faculty in the College of Education (N = 41) who took the course each year. Only faculty currently teaching teacher education students at NIU will be eligible to participate in the study.

Data Collection: Structured interviews will assess each faculty participants’ use of technology in their courses, their attitudes and feelings about technology, and the degree and depth of their reflection on their integration of technology. The interviews will take a developmental focus beginning with the thoughts, feelings, and actions of the participants prior to taking the course, during the delivery of the course, and since completing the course. The participants will be asked to reflect on how the course may have influenced their behavior, attitudes, and thoughts. The initial cohort will have taken the course two years ago, so some longitudinal data will be available.

Observations of class sessions and review of course syllabi will provide information regarding each participant’s integration of technology in their courses.

Value of Study: In an ever increasing technological society, it becomes imperative that current prospective P-12 teachers acquire the knowledge and skills to effectively and meaningfully integrate technology into their instruction. To better prepare teachers for this task, teacher educators need to model and value the meaningful integration of technology in their courses, yet college faculty are often unprepared for this task themselves. This study seeks to explain how one mandated course on the integration of technology in the curriculum provides a catalyst for motivating new college faculty to use technology in their teacher education courses.

REFERENCES

Introduction

Organizations and institutions are increasingly offering online professional development opportunities to educators (Mather, 2000). This is especially true for teachers must keep up with new teaching strategies, the latest professional standards, and constantly changing technologies. Coincidentally, new technologies promise to facilitate access to learning at times and places chosen by the learner (Albion and Gibson, 1998). These web-based environments have the potential to transform teacher professional development through the use of new models of teaching and learning. They also have the potential to facilitate a sustained culture of sharing, collaboration, mentoring, and support for K-12 teachers.

In the design of these web-based environments, there are not only technical challenges, but perhaps, more importantly, there are social and cultural challenges and norms which must be addressed in order for these new models to succeed. While initial attraction and interest may be high, establishing long term, high quality learning opportunities is a much more difficult goal to reach. This is the story of one such environment.

The Learning to Teach with Technology Studio (LTTS) is a web based professional development system to integrate technology into their classroom. The goal is to provide short focused mini courses or modules that teach teachers to develop a technology-based classroom project for use in their own classrooms. The LTTS is a five-year project funded through the Department of Education/FIPSE. It is currently in year three of development at Indiana University and with partner organizations (University of Georgia, PBS Adult Learning Services, and IMS).

Challenges

As with many online systems, there are challenges with designing and scaling the LTTS system. These include:

- Technical issues with designing an online learning anytime, anywhere environment
- Instructional design issues with developing high quality problem based learning modules that are designed not only for teachers but by teachers
- Supporting teacher developers of modules who have content expertise but little or no skills in instructional design or experience with adult learners
- Scaling and sustaining such a system past the grant funding.

Technical Issues

First, the technical issues of designing an online learning anytime, anywhere environment are numerous.

We need to understand the strengths and limitations of the online environment and learn how to operate within these.

Instructional Design Challenges

In designing LTTS, the developers chose to use inquiry based learning framework as it best matches the goals of the type of instruction we wish to model. Since there are few models of online inquiry based learning, LTTS designers face the challenge of first developing a new instructional model for Web-based PBL. The goal was to take the best of PBL learning and develop a new instructional model that would work within a Web-based learning anytime, anywhere environment. Designing an interface and instructional model that not only used inquiry but modeled it was key. This choice impacted not only the instruction but the technical challenges the strengths and constraints of web-based instruction, learner characteristics, and the purpose of the LTTS, which is professional development.

We also have to understand what aspects of PBL will work in these environments. Since most commercial course delivery systems did not support inquiry, LTTS developed and implemented its own inquiry based interface and learning environment that models the type of teaching that was being promoted. This included making an interface that modeled the inquiry process with a problem posed, a collection of
resources, activities to scaffold the learning, and assessment guidelines that are provided as part of the module package. Designing all of this to work in a learning anytime anywhere environment has proved to be challenging because there is no instructor present. This is one of the trade offs of designing professional development in the context of learning anytime anywhere.

Supporting Non Instructional Designers

Perhaps the most difficult challenge of LTTS is to support teacher developers of modules. These teachers often have excellent content expertise but little or no skills in instructional design or experience with adult learners. LTTS has designed a support system with guidance, mentors, and resources to support teachers through the process of module development. However, there are still many challenges faced with helping teachers understand how to translate their content knowledge into high quality modules for other teachers. Since teachers are most often designing for preK-12 students and material for a specific content, LTTS has to provide scaffolding that will help teachers become designers of online instruction for other teachers focusing on teaching strategies and not necessarily content.

Through research completed with LTTS teacher developers, we have found they have particular challenges with learning to design modules for LTTS. These include: translating the projects or units they complete in their classroom into an instructional package that will help teachers go through a design process of developing such a project for their own classroom; finding high quality resources online that will support their module; and obtaining appropriate mentoring from instructional designers who often have little classroom teaching experience.

Scaling and Sustaining the System

Scaling and sustaining such a system past the grant funding is critical if these projects are to survive. LTTS is designed with an e-commerce model. In the future, royalties and usage agreements with schools will help keep the LTTS sustained and in use by preK-12 schools and preservice teachers. LTTS also plans to design an added component to support school- or district-wide professional development efforts in technology integration. Challenges include knowing the market for such a system with few examples to learn from and designing one system that can meet the needs of both preservice and inservice teachers.

Conclusion

In the design of these web-based environments, the technical, social and cultural challenges as well as the challenges of providing high quality learning opportunities is not easily done. Designers of such systems must have a critical understanding of the online learning environment and how to design inquiry based learning environments. Perhaps the most critical understanding is that of one’s audience and how to involve them in this ongoing design and development process. As professional development increasingly goes online, designers of such online learning environments will be challenged to build environments that are enticing, high quality, and ongoing.

Faculty Development by Design

David Knowlton, Southern Illinois University Edwardsville, US
Wayne Nelson, Southern Illinois University Edwardsville, US

Across the academy, preparing faculty members to teach is a pressing need. A doctoral degree in a discipline does not necessarily prepare a faculty member to effectively teach that discipline (Soder, 1996). While we agree that faculty members are sometimes unprepared for teaching, we also note that they often have even less experience with areas related to teaching, such as the design of curriculum or the development of instructional materials. But recently, new problems have arisen with the introduction and integration of technology in the teaching and learning process. Faculty members now have a new set of skills to acquire, but no more incentive or time to do so.

The axiom that “people tend to teach the way they were taught” may not always be the case, but the U. S. Department of Education has recognized the need for changing the ways that new teachers are trained to integrate technology into the classrooms around the country. And one of the areas identified as critical by the Preparing Tomorrow’s Teachers to Use Technology Program (PT3) has been the development of skills and modeling capabilities of the faculty who teach these prospective teachers. But if traditional faculty development approaches are used, it is likely that the same problems will persist. With the luxury of extensive resources and personnel provided through a PT3 grant, we have been able to establish a model for faculty development that is organized around the metaphor of design studios, employing principles of “learning by design” as a means of helping faculty integrate technology into their teaching, and effectively modeling technology integration strategies for their students.

Learning by Design and the Design Studio

Design is a human activity that has been described by some as the solution of unstructured, or “wicked” problems (Rittel, 1984) through the specification of artifacts or systems meant to achieve emergent goals that are continually generated and refined throughout the design process (Lawson, 1990; Mahotra et al., 1980; Mayer, 1989; Newell & Simon, 1972). Others view design as an experiential learning process where an individual constructively shapes the problem and solution through cycles of situated action and reflection (Schon, 1991; Suchman, 1987). But when viewed as a social process, design involves both shared and distributed cognition (Lanzara, 1983), with the design team developing through conversation and representations a shared understanding of the problem, and through individual and collaborative efforts, a solution to the problem (Hutchins, 1991; Walz, Elam, & Curtis, 1993).

Design is increasingly seen as an activity that can be used to facilitate learning in a variety of content areas and contexts. Perkins (1986) has proposed a description of learning based on the notion that design is a fundamental characteristic of human thinking that arise naturally from human social and cognitive activities. From students learning through the design and production of multimedia (Kahn & Taber Ullah, 1998), to students learning science by constructing and testing solutions to problems (e.g. Harel & Papert, 1991), project-based and problem-based learning that incorporate design tasks have become effective models for teaching and learning. Proponents agree that the effectiveness of learning by design comes from a variety of necessary elements, including context, collaboration, reflection, and inquiry.

To organize and manage learning by design activities, educators have adopted the model of design studios common in the practices of the visual arts, architecture, and other fields that emphasize design. Studios provide an open learning environment where the students use design tools and processes to complete various projects (often self-selected, or at least open to selection within some set of parameters), and the teacher offers assistance and critique when asked, or at various pre-determined points in the process. This collaborative atmosphere lends itself well to the self-organized and self-paced learning that occurs in studio design activities. While design studios are common in other fields, the application of the model to education is just beginning to emerge (Orey, Rieber, King, & Matzko, 2000; Rieber, 2000). Since this model supports many of the principles of adult learning recognized by various theorists (e.g., Knowles, 1989), as well as the theories of learning and instruction discussed earlier, we felt that it could be easily adapted to our faculty professional development efforts.

The Faculty Technology Design Studio

To assure that our faculty members develop the skills necessary to effectively model technology integration strategies to their students, the design studio model is being employed within the School of Education at Southern Illinois University Edwardsville as part of our PT3 program efforts. The design studio fits particularly well with the unique teacher education partnerships that have been developed recently. University faculty members work in a two-year, field-based program with the teacher education students and K-12 students, supervising teacher education students
and providing effective models of best practice, as well as delivering weekly content seminars where students are given opportunities to discuss various theories and methods. "Courses" are non-existent. Instead, various content areas are completely integrated across the two-year program. Students prepare portfolios to demonstrate their growth and competence in standards set by state and national certification and accreditation agencies.

There are several other reasons that we felt the design studio model was particularly appropriate for our faculty development goals. First, the faculty participants possess varying levels of skill development with respect to technology utilization and integration. Second, the faculty participants are already organized as teams to deliver the teacher education program at partnership schools, and therefore have developed a high degree of camaraderie and are used to collaborating. Third, a small core of faculty members who are highly skilled and experienced with various learning technologies were available to act as facilitators, or "lead designers" for each team. Finally, resources from the grant have allowed us to expand an already well-developed technology infrastructure and support system for development of various types of applications and resources. In other words, if the faculty technology design teams can dream it, we will be able to make it happen for our teacher education students.

The Faculty Technology Design Studio process began early in the fall of 2001. Faculty from the School of Education and the College of Arts and Sciences were invited to attend a kickoff meeting where the studio concept and plans were shared, along with information related to the new Illinois teacher certification standards for technology integration and utilization. Eight design facilitators and three project staff members facilitated the design studio activities as "lead designers", challenging the thirty seven faculty participants to identify opportunities for technology integration in their teaching activities, especially activities that might model appropriate practices or help teacher education students meet some of the new state certification standards. After much collaboration and discussion, more than 15 design projects were identified and described in written "design briefs".

Following the kickoff meeting, design facilitators continued meeting with the faculty participants to refine and elaborate the designs, and to identify available technologies or elaborate on specifications for technologies to be developed. Support personnel hired with grant resources are currently working to develop and assemble the custom-designed technologies to meet the design goals specified by the faculty participants. Faculty participants will then implement the technology applications and strategies with their students during the rest of the academic year, culminating in a "showcase" event where K-12 students, teacher education students, mentor teachers, and university faculty will come together to demonstrate and share with their communities the results of the year's activities.

Two examples taken from the 15 design projects being completed as part of the grant activities may help the reader to better understand the design studio effort and the expected results. It should be noted that by the time of the conference, several of these design projects will have been implemented, and the preliminary results will be shared with colleagues attending the conference session. For example, one group of faculty members is working with teacher education students to design and publish a research journal focused on teaching activities at the partnership school. Each student will be required to submit at least three manuscripts for the journal, with mentor teachers and university faculty will serve as editors for the journal, along with some of the students. An online article submission system is being developed, along with facilities for editors to communicate with students regarding revisions to the manuscripts. In addition, an artist will be working with the editorial staff to create graphics for the journal, which will be published as a traditional paper product, as well as in an electronic version.

A second group of faculty is developing a video-case library of teaching examples that illustrate various issues related to educational psychology and educational foundations. Students will be able to access the video cases through the web, participating in asynchronous discussions about the cases, as well as submitting their own analyses of the cases. Faculty members are preparing content that elaborates on the principles being illustrated by the video cases. In addition, teachers shown in the video as well as university faculty will be participants in the discussions, allowing students to ask questions about the video cases, and presumably, identifying issues for further learning and discussion. These are two examples of the many design projects currently being completed. Faculty are participating not merely as designers, but as developers wherever possible, thereby increasing their technology skills while working on something of utility for their teaching and their students learning. Again, an assessment of the growth of faculty knowledge and skills related to the various technologies and tools being employed in the Design Studios is currently being undertaken, and will be available and discussed as part of the presentation at the conference. Informal observations and comments to date indicate that the Design Studios are successful in promoting the kinds of faculty development we had envisioned.

"Views of an Online Course From the Participants at Morehead State University"

Dr. Lesia Lennex, Leadership and Secondary Education, Morehead State University, USA, l.lennex@morehead-st.edu

Abstract:

Online courses are becoming common for university offering. Some argue that the online courses are not well suited for the average student. Those same faculty would tend to agree that one needs to be at a perceived proficient level before undertaking an online venture. In this case, 60% of respondents believed that EDUC 599 is best suited to someone with a perceived apprentice level of technology. Critics might again argue that grading standards are not rigorous enough in online courses. Respondents in this study stated differently. The graph below shows the college identification compared to the perceived difficulty level of the course. Grading in the course was conducted by the individual instructors. The instructor responded to e-mail reflections and gave students scores of 0-7 points. The final project web page was valued at 15 points. 100% of the respondents stated that they felt feedback from the instructor was individualized.

Introduction and Background

Morehead State University (MSU) is known for ground-breaking in the field of technology facilitated classes. The institution was one of the first subscribers to industry leader Blackboard, and Internet Classroom Assistant, and has again shattered the limits with technology assistance in offering from Teacher Education Institute (TEI) an Internet-based course, "Teachers Discovering Computers."

The Internet-based course (hereafter referred to as EDUC 599 or "the course") is the result of a partnership with TEI in the Preparing Tomorrow’s Teachers to Use Technology (PT3) grant awarded to MSU in July 2000. As with many institutions, several faculty were pioneering the use of technology while others waited for the trend to end. The purpose of the course within our grant was to deliver more opportunities for undergraduates to use technology in the teaching environment. MSU’s PT3 grant focuses on undergraduate, preservice teachers. To offer this course to others, individuals must be directly involved with training preservice teachers. EDUC 599 is offered to MSU faculty, MSU teacher education students, K-12 cooperating teachers with student teachers, and K-12 administrators and technology coordinators in a five-county partnering region. The course is given with a tuition-waiver and students in the course receive a free textbook. Students eligible for graduate credit may elect to receive graduate credit, waiver-free. Faculty were given an additional incentive of $500 for completion of the course. Later, awards of $1,500 per person were made available for MSU faculty to apply their newfound knowledge. This award could provide release time to restructure courses, purchase equipment, support travel to conferences, etc. Students were given the option of applying the course toward program requirements for undergraduate or graduate degrees.

The class was initially offered in Fall 2000; a special section was started for K-12 administrators and technology coordinators in November, 2000. Students were given information for enrollment through classroom solicitation and word-of-mouth. Registration occurred only through the PT3 secretary. Pre-registration for Spring semester was conducted both through the PT3 secretary and MSU’s registrar. During Fall semester, EDUC 599 sought to prepare students to actively incorporate Internet and its resources, common educational software, and basic skills in web editing. Undergraduate students and K-12 personnel were asked to construct lesson plans complete with scoring guides. Students were allowed to visit Web sites in many different discipline areas to explore the potential for their classrooms.
Statistical Information from surveys

Despite many obstacles to enrollment for Fall semester, MSU Registrar records indicate 148 students were enrolled. Of these 113 completed the course with either an incomplete or final grade recorded. 107 persons from the completion group were sent an online survey in March 2000 (see http://people.morehead-st.edu/fs/j_lewis/educ599_survey.html). The 107 persons are broken into the following categories: 30 undergraduates, 13 student teachers, 11 K-12 cooperating teachers, 11 K-12 administrators or district technology coordinators, and 42 MSU faculty, staff, and administrators. A 20% return was seen on the survey with 21 people responding; 20 surveys were usable. At least one person from each category responded to the survey. It is important to note some reasons that the return was so low. Foremost, the email requesting participation was sent at an inopportune time. Although the request was sent from an America Online account, the MSU mail server was malfunctioning for many of its mailboxes. Mail was undeliverable, mail was eliminated, and mail was sometimes not returned properly from an MSU origination. The MSU server email accounted for a large portion of our potential responses. Students who were student teachers during Fall semester likely graduated and would not have had access to their MSU accounts. Finally, the specially created class from November, 2000 had not had grades posted to the Registrar at the time of this survey. It is possible that anyone receiving an incomplete or not having completed the course chose not to answer the survey. Only students having withdrawn were omitted from the survey.

This survey was designed to test the null hypothesis, “students will not demonstrate perceived increases in technology use or improvement in performance as a result of having taken EDUC 599.” This paper focuses on key components related to the null. For a lengthier discussion of the survey results, please see http://people.morehead-st.edu/fs/l_lennex/summary.htm

Before displaying some relevant results, it is important to note the following. The survey consisted of 5 males and 25 females. 100% liked to use computers; 95% reported access to a home computer; 95% were satisfied with the course and had their expectations met with the course; 90% had more than one e-mail account; and 41% accessed the Internet five or more times per day. The table represents a distribution of respondents by academic area.

This survey used definitions for skill level from the Kentucky Department of Education. The levels were novice, apprentice, proficient, and distinguished. The definitions are as follows: novice—demonstrates minimal and/or incorrect knowledge, apprentice—demonstrates basic knowledge, proficient—demonstrates broad knowledge, and distinguished—demonstrates extensive knowledge of the content area. The tables below show the results of a one-way t-test comparing the perception of skill level before and after taking the course. The perceived skill level increased from a mean of 2.2 to 3.0, or from apprentice to proficient level, after taking the class.

USD's Web Group:
Its Contribution to Faculty/Staff Development

Luby Liao and Jane Friedman
Department of Mathematics/Computer Science
University of San Diego
San Diego, CA 92110
liao@sandiego.edu, janef@sandiego.edu

Abstract. This paper is a companion to the paper we presented at AACE M/SET 2000 entitled USD's Web Group: A Service Learning Experience in Computer Science. It focuses on the web group's contribution to faculty/staff development. The web group is a friendly and accessible computing resource for faculty and staff across campus which complements the services provided by the Academic Computing whose main concern is the infrastructure of the campus computing. The web group does not limit itself to web-related problems. It promotes computer literacy by advising users, solving problems for them and wherever possible, training them to solve problems for themselves. The USD web group could be easily duplicated on other campuses and therefore this paper should be of interest to many.

This paper is a companion to the paper we presented at AACE M/SET 2000 entitled USD's Web Group: A Service Learning Experience in Computer Science. Interested readers can find out how the web group contributes to the USD community in many ways from the afore-mentioned paper. This paper focuses only on its contribution to faculty/staff development.

The web group was founded in the spring of 1999 to help the USD community with their computer-related problems. It consists of Computer Sciences students working under our supervision. We meet regularly for seminars on technical issues. Three years after its inception, the USD web group has become a respected institution on campus. The members of the web group are helping a variety of people and groups on campus and in the process educating themselves. The first author was honored with the USD Innovation in Experiential Education award in 2000 and Davies award for teaching excellence in 2001, both related to his web group activities. The USD web group could be easily duplicated on other campuses and therefore this paper should be of interest to many.

The web group is a friendly and accessible computing resource for faculty and staff across campus which complements the services provided by the Academic Computing whose main concern is the infrastructure of the campus computing. The web group helps users solve problems ranging from the most basic such as how to construct a web site, or how to convert a data set, e.g., an address book, from one format to another, to very challenging problems such as how to build an enterprise class web site.

To help faculty/staff develop their own web sites, we give 40-minute web site construction classes with web group students on hand to help the participating faculty and staff. We use a utility program to create a rudimentary web site for the participants instantaneously. We then use the Netscape editor to beautify their sites and make sure that they know how to publish on their own.

For more involved web projects, web group students are assigned to faculty and staff to design and construct the sites and train the users. This is particularly successful when we use systems that are amenable to collaboration such as Zope Web application server1. As an example, we are creating a web site for the Dean's office of the School of Arts and Sciences. This site will have many sub-sites that will be managed by different people who need not have any web sophistication other than some brief training. These managers can in turn train sub-managers to work under their supervision. To fix the idea, you are invited to visit a Taiwanese Forum/News

site\textsuperscript{2} that we put together for a SDSU Psychology professor Dr. Raymond Lee. Even though Dr. Lee did not have any prior web construction experience, he is able to manage the site after a 30-minute training. We are only needed occasionally to provide technical assistance. He trains other people to manage sub-sites.

The web group does not limit itself to web-related problems. It promotes computer literacy by advising users, solving problems for them and wherever possible, training them to solve problems for themselves. In the following, rather than giving a laundry list of all the things that the web group has involved in, we give some example cases to show that it will help wherever help is needed:

- Helping re-organize user data stored in spreadsheet files or even word processing files into a database using free and open source DBMSs such as MySQL\textsuperscript{3} and PostgreSQL\textsuperscript{4}. We have found that users are so strongly influenced by their spreadsheet programs and word processing software that they will use such tools even when they are not the right tools to use. Even after they migrate from spreadsheets to databases, they continue to think in terms of spreadsheets. This can cause them to use one huge universal table or to have difficulty designing their databases efficiently. With our help, they are able to come up with better designs and understand the importance of normalization.

- Advising users on
  - the merits of different operating systems such as Linux, MacOS and Windows
  - different Linux distributions and their licensing
  - hardware upgrading and the merits and demerits of double boots
  - different languages such as Java, Perl, Python and Tcl/Tk. Different technologies such as applets and servlets, ASP, PHP, JSP and application servers.
  - different web site construction software such as Dreamweaver and FrontPage
  - content and presentation as two different concerns in web site construction

- Writing programs to help users with tasks such as data formatting, conversion or look-up. Even if the users cannot fully participate in the programming projects, they can be educated. As an example, a user tried to construct a 500 plus member mailing list in the Pine mailer by typing one address after another. However, the data file already existed, although in a not readily usable form. We wrote an Expect\textsuperscript{5} program that automated the creation of the mailing list. The program took minutes to write and seconds to execute.

- Customizing and gluing existing software to meet the users' needs for online calendars, threaded discussion forums, mailing lists and Wiki\textsuperscript{6}-style collaboration.

This spirit of \textit{help wherever help is needed} has led the web group to expand beyond USD campus. Some of the beneficiaries now include elementary and secondary school classes and faculty members from SDSU.

Abstract: Technology continues to grow in today’s society and its influence on individuals is staggering. Research appears to have focused primarily on the use of technology to enhance education and productivity. Little research has focused on how technology is changing other aspects of the environment for individuals. As the educational and work environment change that pre-requisite skills and knowledge required for vocations changes. This article reviews current career theories, the changing nature of work and what can be done in the educational environment to deal with these changes.
development and decision-making of students?

John Holland (1997) developed a theory of vocational behavior based on the idea that people express their interests through their work choices and experiences. Holland assumed that people's impressions and generalizations about work, which he referred to as stereotypes, are generally accurate. However, with the recent advances in technology many of the stereotypes and knowledge that individuals have about the work environment may not be accurate. Without accurate stereotypes of the world of work, individuals may have difficulty expressing their interests in a choice of an occupation. Through utilization of these stereotypes, people and work environments are assigned to six different typologies. Within each of these typologies researchers have described sets of behaviors and knowledge that individuals typically possess. Additionally, researchers have examined the work environments and described the skills and knowledge required to be competitive in that environment. To make an adequate career choice an individual can examine the fit of his or her individual interests, skills, and knowledge with that required by various environments. Research on this approach to career counseling has shown that indeed a close fit between an individual and their work environment leads to many positive outcomes. However, with the changing world of work and the technological changes in education, are individuals getting an accurate picture of their unique skills and at the same time getting the information from educators about the changing skills and job requirements? Without accurate knowledge about themselves and the work world career decisions become more difficult and lead to more mismatches between individuals and their occupation.

Surprisingly few writers have tackled the daunting issue of the changing nature of the vast majority of careers that have for many years been thought of as consistent and immutable. Additionally, few if any researchers have examined how the changing educational environment with its incorporation of technology into almost all aspects is affecting the individual and how this change in educational practices may be influencing the career decisions of individuals. Clearly, research needs to focus on all areas of the changing educational and work environment and how these are affecting the career decision of individuals.

Despite the current lack of knowledge, based on theory there are many things that can be done in the educational realm to help individuals with career decisions. First, educators need to not only use technology to help students learn and master material, but they must demonstrate the link between learning technology itself with requirements of occupations. For example, an educator may be using a computer program to enhance math skills. While using the computer the instructor can remind children that they are not only learning math skills, but are also learning computer skills that may be important for future career endeavors. At the same time the instructor may point out a few occupations that use or require computer skills. This process would not only allow students to learn the math material, but also to start to make links between technology skills and the world of work. Along these lines, educators can develop plans to help students learn technological knowledge and skills specifically. It appears that in the educational realm, technology is being used to help students learn and master other material and not being directly taught to students. With the reliance on technology in the world of work, it behooves educators to not only use technology, but to teach students how to use technology. If students can learn technology skills and develop knowledge in this area, it may open many career doors for them.

On the other side of this issue is for researchers to begin to explore the changing world of work and provide information about how the requirements and skills that are associated with occupations have changed due to technology. Without this information educators will have no idea what technology skills are related to what particular occupational field. As researcher conduct these job analyses and delineate the skills and requirements for the various occupations this information can be relayed to educators who can in turn relay the information to students.

These are just a few of the many strategies that educators can employ to help students with the career development and decision process that they will face as they complete their education and enter the workforce. Technology is not only changing the educational and work worlds, but is having an impact on how the two interact. Without a clear understanding of the interaction and how the two complement each other we may be doing an injustice to our students and future workers as they struggle with careers and occupations.

Evolving with Technology in the Preparation of Teachers
(Lost in Cyberspace: A Trek in Technology)

Norene Vail Lowery, Department of Curriculum & Instruction,
University of Houston, United States (nlowery@uh.edu)

Abstract: Most teacher educators advocate and value the use of technology. Too often teacher preparation programs are negligent in modeling the implementation of technological applications. This paper highlights the implementation of technology into graduate level education courses and a field-based undergraduate course. The teacher educator (once lost in cyberspace) and students report gains in confidence and competence. Discussion follows the struggles and successes of implementing the use of hypergroups in these courses.

Researchers agree that understanding teacher knowledge and teacher thinking is critical to understanding teaching and learning how to teach (Fenstermacher, 1994; Grossman, 1995; Leinhardt, Putnam, Stein & Baxter, 1991). White (1996) advocates the use of technology to facilitate understanding and problem solving and critical thinking skills for preservice teachers. Advances in constructing teacher knowledge are needed. The importance of technology is emphasized in all areas of education. Most teacher educators advocate its value and use in the classroom for all content areas. Keeping pace with the technological advances can be overwhelming. Too often teacher preparation programs and graduate programs are negligent in modeling the implementation of technological applications. This paper highlights the implementation of technology in preservice teachers' methods courses in a field-based context, and in graduate courses in education. "Falling through the cracks" refers to those that have not had the opportunities to experience and/or master basic concepts in education. Discussion follows the evolution of the technological trek from traditional instructional strategies to approaches that successfully incorporate more technology. For those that are confident and competent in their technological explorations, there is merit in this story. Merit in the fact that not all have successfully made the passage and would benefit from patience and shared expertise.

The Context and Inquiry

One objective of this teacher preparation program is to provide professional development for faculty to implement components of technology into courses. Initial learning experiences and a support system in technology were provided. However, it is imperative that relevant, real-world application be experienced to facilitate learning (Brooks & Brooks, 1993). Merely attending in-service training does not provide the needed "real-world" context, as did this inquiry. The hypergroup was chosen to support the weekly learning environment for both the preservice field-based course and the graduate level courses. This allowed an ongoing dialogue and communication regarding course information while sharing experiences and creating a support system. Participants were 27 graduate students and 18 undergraduate students. Technology tasks included emails, posting reading reflections, and Internet website research (creating an annotated bibliography of websites). The abilities and experiences with technology, and in particular the use of a hypergroup ranged from expert to novice. The teacher educator had never used the hypergroup. Expertise was shared and much was learned by trial and error through the semester.

Data collection spanned a semester. A case study was chosen for this context-specific inquiry (Lincoln & Guba, 1985). The use of multiple data sources and methods triangulated information. Context-rich materials provided background meaning to support data analysis and interpretations. Norms of qualitative methodology were observed and facilitated the discovery and extent of knowledge construction in the use of the hypergroup. The teacher educator kept a reflexive journal. Small interactive discussion and information sessions were informally conducted throughout the semester during class time along with anecdotal records. Those that were more savvy with the hypergroup shared information as a means of promoting knowledge construction. Time in the computer lab was available during all class periods. For evaluation, all students responded to the following: Describe your "technology trek" through the semester. Address these points: Things I already knew; Things I learned; Things I would like to know; Advantages and Disadvantages; Improvement; and, Overall comments on using the hypergroup. (The undergraduate class also responded to this: Overall comments on creating the professional resource file in electronic format.)

These excerpts are indicative of the many positive responses that were reported in the data.
I do plan to make use of this type of curriculum planning in some form or fashion. ... Other technology in use within my future classroom will hopefully be a class web site, email for use with administration, other faculty, and parents, and a spreadsheet for grading purposes.

... I found this project useful both in incorporating technology into the classroom and planning effective lesson plans or curriculum. Thanks for coming up with such a forward-thinking plan about which all pre-service teachers need to learn.

I was very comfortable with the technology used in this class. I work in a very technology-rich environment where almost everything is e-enabled. I am on the Internet and use email on a daily basis. My team even has its own website. However, this was my first exposure to a hypergroup and I liked it. The biggest advantage was the ability to read the writings of the other students. This helped me to learn more about them as people and to learn about the real challenges facing teachers today. ...One side benefit was that the hypergroup became an easily accessible archive of all the work I had done during the course.

Wow, what a trek this course has been, and still is for that matter! ... I am not very comfortable with using the Internet and the only emailing I had used before this class was inter-district email at school. ... At the first of the semester I was not sure why we had to post our reflections to the hypergroup, why not just turn them in like last semester. It would be so much easier for me. ...I guess I should not be ashamed for falling behind in the game of technology, and not be afraid of asking questions. But the time it takes to become familiar with all that technology can offer is very consuming. ...I enjoyed reading the reflections and even discussed various points with other classmates. So in the very end it was worth the effort. So now that I am reflecting on my journey through technology land, I can say that I have leaned so much. I am feeling more comfortable with using both the web and email. ...it has been a great learning opportunity and being able to read the thoughts and views of my classmates has made the class that much richer. Thank you for pushing me to grow in an area in which I was not willing to go.

Summary

Reports indicate that the hypergroup learning experience was valuable. As the teacher educator, I believe the advantages of the hypergroup out weigh the struggle at the onset. The hypergroup is now a permanent component of all my courses. I am more comfortable with its use and its frustrations. The confidence achieved opens venues for implementing more technology. Being technological literate should be a goal for all education programs. The importance of this reflective inquiry helps in structuring appropriate experiences and encourages those that have fallen through the technological cracks. To those feeling Lost in Cyberspace and struggling along the technology trek, it can be accomplished, keep on trekking. It is possible to attain a level of competency and successfully implement technology components into teacher preparation programs. To those leading the way, be patient and diligent in your efforts to share knowledge and forge the way for those of us on your coattails. It is worth all of our efforts.

Abstract: This paper is intended to furnish advice for beginning professors who work in "publish or perish" environments. Publishing can be highly rewarding and enjoyable, but is an odious task for many beginners. The paper provides ten tips for establishing a productive scholarly agenda. The paper begins with advice about the importance of maintaining a positive attitude about publishing, and covers topics such as how to choose a topic, how to prepare a manuscript, and how to cope with and respond to rejection.

Introduction

Academic publishing is a condition of employment in most U.S. colleges and universities, and decisions related to promotion, tenure, and merit pay are heavily influenced by the quality and quantity of published articles. Many beginning professors fear that they may not be successful in the typical "publish or perish" environment, and regard publishing as a necessary evil and a major hurdle on the way to professional success. Such attitudes are unfortunate, since some of us find writing and publishing to be one of the great joys of academe, and look forward to the entire process of writing, submitting, revising, and eventually publishing our ideas and our research results.

There are probably various reasons why so many neophytes fear and dread the need to publish. One important reason, however, is that their doctoral programs and doctoral advisors did not provide the guidance and the practice needed to clarify what may appear to be a difficult and mysterious process. Therefore, this article will present a number of guidelines aimed at providing some of the basic information and advice beginners need. It is hoped that this advice will be of use to beginning professors, both in helping them to become successful writers, and, just as importantly, to enjoy the entire process.

Maintain a Positive Attitude Toward Publishing

One of the most important pieces of advice for beginning professors is to strive to maintain a positive attitude toward scholarship and publishing. Every department in every college in every university in the land has a number of cynical, perennial complainers who consume incredible amounts of time, energy, and enthusiasm telling (and retelling) whoever will listen about the unfairness of the requirement that they publish. A favorite refrain of these chronic complainers is that "the rules have changed" since they were hired, when, they maintain, publishing was not important.

There are many reasons for not paying attention to these pessimists. In the first place, their arguments, even if they were true, are completely beside the point. The fact is that most of us are required to publish, and no amount of whining or protesting will change that fact. Therefore, continuing to assert the unfairness of this requirement is simply an outrageous waste of time. In fact, if most of these individuals devoted even half the time, energy, and enthusiasm to their research and writing agendas that they currently spend complaining about the need to publish, many could become successful writers with nothing about which to complain.

Another reason to avoid the trap of becoming a chronic complainer about publishing is that it is self-defeating. Not only does it take time that could be far better spent on publishing-related tasks, but it becomes discouraging and debilitating, since it is difficult to become accomplished at anything about which one is negative and pessimistic. Thus, the complainers find themselves participants in a vicious circle in which their
hostile attitude mitigates against scholarly productivity, which makes them more negative and hostile and less likely to even attempt to succeed.

Then too, the argument that "the rules have changed" is not itself reasonable. In the first place, the publishing requirement has been in place in American universities for many years. Even if the rules did change, however, is this grounds for a complaint? Where is it written that those in any job have the right to expect that job requirements will never change?

Be Alert to Publishing Opportunities

I am frequently asked for advice on how to select the subject of scholarly writing efforts. There is no one best answer to this question, but there are some strategies that many successful writers find to be useful. I always carry a small, pocket-size notebook in which I jot down ideas for future articles, which often come to me in odd moments. In my office, I keep a file folder where I compile such ideas. As this article is being written, the file contains about a dozen different ideas. I periodically review this list, prioritize the topics, and add any details I have thought of that might help further define the article.

Where do these ideas come from? They come from many diverse sources. One piece of advice to help find research ideas is to make it a practice to spend several hours a week reading the research reports of others in the field. As I read such reports, I often think of ways a study could be improved, or get an idea for a new, but related research strand. My classes provide another source of ideas for articles. Anything my students find especially controversial, difficult, or interesting may make a publishable "how to" article or a good position paper. Position papers of professional organizations also sometimes provide a topic for an article. As I read such papers, I am alert for statements or ideas about which I agree or disagree strongly. Observations made in public school classrooms are another source of potential ideas. Sometimes I write about something I have seen and admired, while other times I am inspired to write about something I have seen about which I disagree strongly.

I have never found it difficult to find a topic to write about. On the contrary, I usually have more topics than time, and find that I can only write about a fraction of the things that interest me.

Consider Writing A Literature Review

Beginning authors should consider writing articles that are literature reviews. Good literature reviews are extremely valuable, but are rarely submitted. Every editor I know says they are constantly on the lookout for good literature reviews, seldom receive one, and would move a good one to the top of the list of articles waiting for publication. A good literature review summarizes the literature in a given area, identifies what is known or suspected, criticizes what has been done with an eye to common errors, and concludes with a description of needed future research.

Write for A Specific Journal

Once I decide on a topic, the next step is to decide where I will submit the article. The best way to do this is to inspect a few recent back issues of the journal under consideration. As research editor for Computers in the Schools (CIS), I find that many assistant professors make the mistake of sending articles to me that are clearly not appropriate for CIS, a fact they would have easily surmised if they had spent a few minutes looking through a few previous issues of the journal. Sometimes these articles are much too lengthy, or do not contain enough statistical detail. I even receive a few articles each year that have no relation to the use of computers in schools. Very often articles are not written in the proper style (American Psychological Association).

There are a number of commercially available books written for aspiring authors. These books summarize the requirements of many different academic journals. Such volumes can be helpful, but they are not good substitutes for examining recent back issues as they quickly become outdated and many are full of errors.

If there is any doubt about the appropriateness of a manuscript for a given journal, authors should feel free to telephone or email the journal editor. Most editors enjoy talking with potential authors, and can often provide valuable information not found in the formal journal author guidelines printed in back issues.
importantly, such a call may prevent an author from wasting several months by submitting an article to an editor who will eventually reject the article as inconsistent with the mission of the journal. If the editor indicates that such is the case, authors should feel free to ask for a recommendation of some other journal that might find the article to be appropriate.

Use Writing Strategies That Work For You

Only trial and error can determine which writing strategies will work for a given individual. Some writers like to formally outline the article before beginning, some make a few notes in narrative style, and others jump in "cold," begin writing, and let the article go where it will.

I find that for me, it is best not to begin writing immediately after I decide on a topic and select a journal. Instead, I do better if I defer doing any actual writing for a couple of days and let the article idea "percolate" in the back of my mind. I don't know why this works, but I think perhaps my subconscious mind works on the idea, because I find that after a few days, I often have a good idea about the structure of the article, and a fairly clear notion of what the beginning, middle, and end of the article will look like. I have no idea if this will work for anyone else, but I have been told by others that they also find this a useful strategy.

Prepare the Manuscript

Manuscript preparation is extremely important. Authors should find, and rigorously adhere to the specific target journal's guidelines for authors. These guidelines can be found in recent back issues or, increasingly, on the World Wide Web.

There are two separate, but equally important aspects of manuscript preparation that require very careful author attention. The first is the publication style specified by the journal. CIS, for example, requires that manuscripts be prepared according to APA (American Psychological Association) guidelines. However, very rarely do we receive manuscripts that even come close to rigorous conformity to these guidelines. Sometimes, manuscripts employ a totally different style, or, more often, a curious mix of several different styles combined with completely idiosyncratic elements of style. Failure to accurately employ the proper style is a grave error, because it conveys the covert message that the author is careless and lacks concern for precision and accuracy.

The other critical aspect is that of correct grammar, spelling, and other mechanical elements. I am constantly amazed at how many manuscripts I receive in which the first sentence makes no sense because a word or phrase has been omitted. Very careful proofreading and subsequent revision is essential. Improper spelling, bad grammar, or inadequate proofreading prejudices editors against a manuscript before its content has been evaluated.

A related problem involves the reference list and textual citations. APA style calls for textual citations that include only the authors' last names and date of publication. The reference list at the end of the article contains full details about the article. A very common problem occurs when the reference list does not include all articles cited in text, or vice versa. Such problems routinely delay publication of articles and are a major source of frustration for editors. A word processor provides an easy way to ensure that the reference list agrees with the articles cited. As soon as the author completes the manuscript, a copy of the reference list should be printed. Then, the author performs a global search, first for "19," then for "20." These searches will find all the citations in text, and each can be marked off the reference list as they are found. Any omissions will then be apparent and can be corrected.

Submit the Manuscript

The manuscript should then be submitted according to journal guidelines. Some journals will require multiple hard (paper) copies, some require files submitted on diskette, and some require both. Any diskettes submitted should be carefully labeled with the authors' names, the article name, and the format (such as Word for Windows). Some journals require a stamped, self-addressed envelope if the author wants the manuscripts
returned in the event of rejection. An increasing number of journals are charging a publication fee. Authors unwilling to pay such a fee should not send manuscripts to these journals. Most journals require that submissions be exclusive, and simultaneous submission to multiple journals is regarded as unethical.

Checking the Status of a Manuscript

Authors wishing to check on the status of a manuscript should use email or the U.S. mail, but should not telephone the editor. Editors often enjoy discussing a potential article with an author, but few, if any, welcome telephone calls to check on an article. Editors are busy people, and most are volunteers who receive no remuneration for their efforts. Checking the status of an article is a time-consuming, routine, record-keeping function, often requiring laborious file searches, and authors should refrain from interrupting editors with such inquiries. By using the mail or email, editors can assign the task to an assistant or perform it at their leisure.

Coping With Rejection

Every author experiences rejections. It is vital that authors strive to avoid the error of taking rejection personally. Most manuscript rejections occur because the submission was not appropriate for the chosen journal, not because the article was faulty or uninteresting. I have published somewhere in the neighborhood of 200 articles and 15 books, and I have been rejected on numerous occasions.

Unfortunately, higher education is full of professors who have been so devastated by a rejection or two that they have never recovered from the humiliation. Many of these individuals subsequently abandoned or greatly restricted their publishing attempts, and their careers have suffered greatly from this reaction.

The best attitude to have about rejection is that it is completely natural and unavoidable, and the best practice is never to give up on a rejected article. Be willing to edit, revise, or completely rewrite, but resolve that every article will eventually be published.

It is also important to be aware that there is more than one type of rejection. By far the most common rejection contains a statement that if listed deficiencies are addressed and corrected, the article should be resubmitted. Upon receiving such a rejection, authors are best advised to carefully read through the criticisms and set the letter aside for a day or two. It is unwise to use the heat of the moment to decide what to do about a rejection. After a few days, the rejection should be read again. If resubmission seems the best course, then authors should decide which of the criticisms are legitimate, and which, if any, are the result of poor reviewing or misinterpretation by reviewers.

The article should then be revised in response to each of the criticisms provided. Once the revision is complete, the article can be resubmitted along with a detailed letter to the editor. Authors should maintain a polite tone in this letter, and list each criticism and how that criticism has been responded to in the rewrite. Each point should refer to a specific page number and paragraph in the rewrite. If the author feels any of the criticisms are not legitimate, the letter should unemotionally state this fact and provide a complete justification for retaining the original, criticized sections. Finally, a photocopy of the original manuscript, plainly marked "original" should be provided, as well as a photocopy of the original rejection letter. These photocopies will make it easy for the editor to see what changes have been made in the rewrite.

A word needs to be said about the unlikely possibility that the original rejection letter is abusive, rude, or otherwise unprofessional. Authors should bear in mind that reviewers are volunteers who are almost never paid for their refereeing services, and that tenure, promotion, and merit committees typically give little, if any, credit for refereeing. Therefore, good reviewers are difficult to recruit and retain, and arrogant or abusive reviews sometime slip past an editor and find their way into the hands of a potential author. This is unprofessional and unfortunate, but probably unavoidable. If this occurs, authors should resist the impulse to shoot off a reply in kind. Some editors have long memories, and it never pays to alienate a colleague. The best course of action is simply to shrug off such a rejection as undeserving of comment, write off that journal for the present, and send the article someplace else.
Be Generous with Co-Authorships

It pays to collaborate. Not only does it bring added expertise to an article, but also often paves the way for future publishing opportunities. Beginners should choose experienced authors with whom to collaborate, and should carefully provide second or third authorships to anyone who had anything whatsoever to do with the article. I am always surprised at how many publishing and consulting opportunities have come my way because I was careful to include as an author someone who helped a little with an earlier article. While everyone needs a few articles with sole authorship, especially at the beginning of an academic career, most committees and potential employers regard multiple authorships as an indication of willingness to collaborate and an sign that a professor lacks a selfish, or overly competitive approach to scholarship.

Conclusions

Writing can be one of the great joys of academic life. Writing confers a little chunk of immortality that most of us find immensely rewarding. There is something comforting in the knowledge that many years after we are gone, some scholar, in some library, may stumble across something we have written that will prove to be exactly what was needed to inspire a new idea or begin an entirely new line of inquiry. Those of us who are privileged to work in universities need to remind ourselves that we stand on the shoulders of our predecessors, and that we owe a debt of scholarship to our successors. It is hoped that the advice in this article may prove useful to some new professors who are availing themselves of this unique privilege and striving to fulfill this important debt.
Lessons Learned from Project ImPACT: Graduate Student Perspectives on Implementing a Student-Faculty Mentoring Initiative

Michael D. Martin, Project ImPACT, The University of Tennessee, USA, mmarti13@utk.edu
William Wishart, Project ImPACT, The University of Tennessee, USA, wwisharl@utk.edu
Thilla Sivakumaran, Project ImPACT, The University of Tennessee, USA, sthilla@hotmail.com

Abstract: Project ImPACT, a new PT3 awardee, contains several elements that are designed to systemically address the goal of producing technology-proficient teachers who can appropriately infuse technology into curriculum and instruction. Achieving this goal requires a collection of interwoven strategies within the preservice teacher education program. One such strategy, faculty modeling, is crucial for producing preservice teachers who possess adequate knowledge of educational technology applications, current educational technology standards, and effective practice. Project ImPACT includes a student-faculty mentoring component that provides one-on-one training and support to participating teacher education faculty (Thompson, Hanson, & Reinhart 1996) for the purpose of facilitating institutional change at the university level by promoting the infusion of technology into the preservice teacher education curriculum.

Professional development opportunities may not be widespread or individualized enough to meet the ongoing and specific needs of teacher education faculty (Bentley & Mumma 1999). Typically, universities' professional development strategies consist of offering faculty a variety of generic technology-related workshops; this model of professional development is not effective. First, faculty must see the relevance of the content as it applies to their area. Generic workshops often include participants from a range of subject areas and levels of expertise, and as a result, the content is targeted to meet broad needs of a general audience. Secondly, in order for faculty to take advantage of newly acquired technology skills, adequate follow-up support is critical. This support must be timely, convenient, and presented in supportive ways so faculty members are encouraged to continue taking risks. This kind of support is often lacking in a generic workshop format.

Project ImPACT’s mentoring component is built upon a foundation of collaborative learning and best practices in mentoring. It utilizes a team of mentors, comprised of graduate students from the department of Instructional Technology, Curriculum, and Evaluation, who possess expertise and experience in educational technology applications. Each mentor works one-on-one with three to four members of the University’s teacher education faculty. The faculty members represent a cross-section of content areas and mentor-faculty pairings are made with consideration to the knowledge and skills of the mentor and the specific needs of each faculty member. The primary purpose of this mentoring process is to facilitate the infusion of technology into teacher education courses. This work focuses on enhancing each faculty member’s ability to integrate relevant technology applications (Thompson, Hanson, & Reinhart 1996). The approach addresses two shortcomings associated with generic workshops by focusing on faculty needs that are relevant to their course curriculum (Zachariades & Roberts 1995) and providing continuous support (Levin & Buell 1999).

During the fall semester, each ImPACT Mentor and his assigned faculty members develop individual professional development plans. Each plan serves as a road map for developing and/or selecting professional development opportunities that are aligned with the needs of the faculty member. These opportunities are diverse in scope, ranging from individualized one-on-one sessions to small group training sessions focusing on specific technology applications.

Session content and format varies with the need of each faculty member. Some faculty members require short sessions of direct instruction on specific technology applications that integrate with course content to meet specific objectives. Examples of these include:
Other faculty members require series of sessions over time that focus on a variety of applications needed to achieve larger, long-term objectives. Examples of these include:

- Web-based and web-enhanced course development
- Larger scale digital video production
- Assistive technology course development

The mentoring component of Project ImPACT has produced a wealth of information that can be utilized in future systemic planning initiatives within the College of Education. Much of this information is documented within session logs that are maintained by the mentors. These logs serve as mechanisms for reflection and strategizing during biweekly meetings. Insights gained from these reflections can be categorized as follows:

- Perceived relevancy of technology applications
- Faculty commitment and prioritization
- Scheduling issues
- University support
- Issues related to mentoring roles and knowledge-base

While each mentoring relationship is unique and presents its own set of challenges, these areas provide a focal point for review of the mentoring process. In subsequent years, proactive strategies grounded in reflection will lead to continual improvement of Project ImPACT's student-faculty mentoring program.

Western Kentucky University's College of Education and Behavioral Sciences has received an Innovation Challenge Grant from the United States Department of Education. The project, called e-train express, is designed to implement programs and strategies that increase the number and quality of new teachers who are highly effective in using technology to facilitate, assess and communicate learning for all students.

Since only 20% of current teachers feel comfortable using technology in their classrooms and over two million new technology proficient teachers will be needed in the next decade, Western Kentucky University (WKU), along with partner schools [schools in the 28 districts of the Green River Regional Educational Cooperative (GRREC)], the Compass Learning Corporation and NetTango are implementing programs and practices designed:

- To ensure that all teachers who graduate from our teacher education program can use technology to increase student achievement;
- To ensure that all graduates can use technology to assess student learning;
- To ensure that all university faculty from both teacher education and the arts and sciences departments can model effective technology-assisted instruction for prospective teachers;
- To ensure that electronic portfolios are used as the primary means of gathering data used in the evaluation of teacher performance;
- To use technology to show K-12 students that teaching is a good career option; and
- To set up an electronic clearinghouse that will give teachers and teacher educators throughout the country access to exemplary technology-assisted lesson plans and assessments.

Western Kentucky University believes that technology has the potential to make teaching and learning far more efficient than in the past. Technology not only gives people access to new information, it gives them more opportunities to work together. The e-train express will enable WKU to integrate technology in teacher preparation courses and use technology to spread the best practices that develop from them.

During the first year, e-train has focused on faculty development. Faculty development began when thirty faculty members, called technology advocates, attended a day long institute. The plan was to excite, educate and obtain a commitment from the advocates who came from teacher education and the arts and sciences. During the institute, the advocates learned about the NETS standards from one of the co-authors and explored examples of the integration of technology into instruction. After a long day of work each
advocate was surprised when they received a PDA. Each PDA was labeled as belonging to an e-train technology advocate. This has had the intended effect of identifying them as a member of a 'special' group and increasing interest in faculty who are not yet involved. Finally, each advocate made a commitment to advocate the use of instructional technology, help their peers use technology in their instruction, model the use of instructional technology and participate in groups that investigate instructional uses of technologies. These groups focus on topics including:

- Personal Digital Assistants
- Web Design
- Presentation Software
- Digital Cameras
- Scanners
- Electronic Portfolios
- Web Quests
- Video Production
- Electronic Classrooms
- Online Classes
- Online surveys
- Ethical use of technology

The primary objectives relative to faculty professional development in technology centered on breaking the traditional mold of staff development characterized by one-shot, one-size-fits-all, trainer-driven presentations that lack follow-through. Studies show that most educators do not learn to use technology from taking courses, attending seminars or workshops, or through traditional professional development programs. Our training plan works on the premise that a team effort toward technology training can promote effective technology learning. The model of technology training we developed utilized the Project Director and the University Coordinator for the grant to act as coaches and facilitators, serving more to guide understanding than to follow pre-defined agendas. Instead, the people who attended the sessions defined the training agendas based on their needs and were active participants rather than passive listeners receiving knowledge from an "expert."

The training sessions were social in nature, yet very goal oriented. We limited the sessions to one hour and scheduled them frequently, either weekly or bi-weekly, with attendees deciding when the next session would occur. The sessions were inquiry-based as attendees set goals for the content of each session based on a "need to know" scenario. Trainees moved quickly from information synthesis, to application of the new technology skills as personal production tools, to integration of the new skills into coursework.

After the first six months, it was determined that the advocates were still excited about their roll and most had gained significant knowledge and enthusiasm. Individually or as a member of a group, all advocates have been asked to make a presentation at an e-train conference using instructional technology. The purpose of this activity is to transition
the advocates from learners to mentors and/or teachers, to build their confidence and to recruit new advocates.

Panel members include the Project Director, the University Coordinator, a faculty member from the Arts and Sciences, a faculty member from Teacher Education, a 'new' faculty member and a 'seasoned' faculty member. These members will present their perspective on the activities described above from varied points of view.

For more information about e-train express, please see www.etrainexpress.com.
**With a Little Help from Your Students: A New Model for Faculty Development and Online Course Design**

Punyashloke Mishra, Matthew J. Koehler, Kathryn Hershey, & Lisa Peruski
Michigan State University
punya@msu.edu, mkoehler@msu.edu, hersheyk@msu.edu, peruskil@msu.edu

**Abstract:** We describe an approach to faculty development that brings together senior education faculty and graduate students to design online learning environments. This approach forces course designers to confront beliefs about what constitutes good teaching, in conjunction with the roles of technology in effective pedagogy. Our experiences, supported by observation and interview data, show that faculty have explicitly considered pedagogical, technical, and practical aspects of course development; learned new technologies and their application to good education; considered the perspective of graduate students in ways they often do not in traditional courses; and reconciled their views of education in traditional classrooms with what they would be doing online. Likewise, graduate student co-designers learned new technologies; gained insights into how faculty design courses; and considered how pedagogical ideals get translated into specific features of the course.

**Introduction**

In order to prepare university faculty to meet the demands of teaching and learning in an online environment, institutions of higher education must find ways to develop the expertise needed to teach in the online world, while meeting several very real constraints (e.g., limited faculty time, limited college budgets, fear of technology, etc.). Faculty members who are to teach these courses are key to the successful implementation of these online courses. However, faculty development is often a difficult task particularly when it comes to technology. Research in the area of faculty development indicates that attitudinal issues, such as how people perceive and react to technologies are far more important than structural and technical obstacles in influencing the use of technology in higher education (Dillon & Walsh, 1992; Clark 1993). As one of the faculty members who was to develop an online course said:

"I don't know a lot about the technical stuff of the computer. I don't feel like I want to know that, or need to know that.... other people can do that. That's not what I want to do. I don't know how the telephone works either. Nor do I care."

Other obstacles include extensive investments of time for course preparation and development something most faculty find burdensome (Harris & DiPaolo, 1999; Loeding & Winn, 1999).

The standard approach to confronting these problems is to separate roles i.e. enlist the help of technical experts (e.g., web-programmers and designers) for the technical aspects of online course development, while leaving the development of course content to the faculty. The technology experts develop suites of tools, templates for course layouts, and then apply them to the content they receive from the instructors.

We see a variety of problems with this separation of roles approach. Most importantly faculty members do not have any ownership over the design of the course and the technology being used particularly if they are not intrinsically interested in learning technical stuff. This is in direct contrast with every day faculty experience with face-to-face courses where they have far greater ownership and control over the design of the course materials. In addition, the faculty members' lack of knowledge about the technology and its possibilities limit their ideas to those offered to them by the technology experts. Since form and function are intimately related, leaving these design decisions to technical experts can have a significant impact on pedagogy. Faculty members need to be the ones making these decisions rather than leave it to the technical experts, who may not have any background or expertise in instructional design and education. Ironically, the fact that faculty do not need to learn any technology is often touted as being the main value of this separation of roles approach.

Another consequence of this strategy is that it often leads to uniformity and an one-size-fits-all approach towards course development. In other words most online courses begin to look like clones of each other. Institutional practices get stabilized as producers present incoming faculty members with existing online
course designs and since the faculty do not know better, they continue to replicate what they have been told "worked before." This, once again, is in sharp contrast to the immense diversity we see in regular face-to-face courses. Courses taught face-to-face often differ drastically from each other when taught by different faculty members and even when taught by the same faculty member at different times. Instructors bring their personality, their individuality to the course, its presentation and its execution. However, in online instruction, the individual faculty member is often missing from the presentation of the course, or at the best delegated to a corner of the web site (the corner that contains the mandatory instructor's picture and bio).

Finally, the separation of roles approach treats faculty development as being the last stage in the process, i.e., faculty use the technology only when they get to teach it. First time is real-time, and this denies faculty members an opportunity to reflect on the process of online instruction prior to teaching it.

Our Design-based Approach

There are many different strategies that have been used for faculty development in higher education. Menges (1994) lists the different approaches that have been found to be successful. These are (a) workshops and seminars; (b) individual consultation; (c) grants for instructional improvements; (c) resource materials, such as books and newsletters; and (d) colleagues helping colleagues. Rather than use any single of these approaches our strategy of learning by design, incorporates all of the above and more. The design approach attempts to avoid the problems we listed above by developing the technical and pedagogical skills needed by the faculty members within the context of designing the online course. Instead of handing web-programmers a set of materials that worked in the face-to-face classroom, we advocate that expert teachers take a hand in the design of the technology to support the learning. We rely on the process of design to develop the necessary skills and relationships for understanding the nuances of integrating technology and pedagogy. Our emphasis on design has been informed by long-standing research on the use of design for learning complex and interrelated ideas (Dewey, 1910; Perkins, 1989; Blumenfeld et. al. 1991; Harel & Papert; 1990; Kafai, 1996; Mishra, Zhao, & Tan, 1999; Vyas & Mishra, in press). Design-based activities not only provide a rich context for learning, they also lend themselves to sustained inquiry and revision that we hope will help designers to come away with the deep understanding needed to apply knowledge in the complex domains of real world practice (Mishra & Koehler, in press).

At Michigan State University, this design approach is represented in an educational technology Master's level course taught by the authors. In this course, master's students design technology to help solve a problem of educational practice. That is, participants learn education technology in the context of real world problems. To accomplish our goals for developing skills in faculty members responsible for the development of online courses, we extended the course in design to include faculty members. During the Spring 2001 offering of the course, six tenured faculty were enrolled as "students" in the design course. Teams consisting of one faculty member and three or four master's students worked on designing an online course that would be taught by the faculty member in the following year.

There were various motivations for faculty and student participation. The faculty received a laptop computer and $1000 for developing the course. Graduate students were attracted to the opportunity to work with faculty members on an authentic project, as well as to learn about educational technology, specifically as it applied to online learning and teaching. For us, the faculty members teaching this course it was an opportunity to build on our research agenda on learning through design. It allowed us to take our ideas about technology proficiency and what teachers need to know and actually apply it (Mishra & Koehler, in press; Mishra, Zhao & Tan, 1999). This was also an important service that we offered to our college and university.

The major activities of the course consisted of readings, explorations with technology, prototyping of the online course, online and in-class discussions, and peer review and feedback. A typical class period had a whole class component that was used to discuss readings and issues that applied to all groups, and a working group component in which the design teams worked on their projects.

Data Sources

For this study we collected a range of data. We interviewed the faculty members about their experience. The average length of the interviews was around one hour. We also collected the final papers written by the students. In this paper students were asked to describe their learning and experience in this course. We also conducted a student email survey (after the grades were handed out). We combined this with our observations in class, postings made by faculty and students to the discussion groups as well as the artifacts created by the groups during the design process.
Outcomes for Faculty Members

Each of the six groups successfully designed an online course. Five of the courses have already been taught, and one will be taught during the Spring 2002 semester. More importantly, we believe that faculty members have learned a lot about designing online courses that they would not have using the traditional approach. First, faculty took control of over design decisions about when, why, and how to use technology. No longer were decisions about technology made by programmers who did not realized the pedagogical impact of those decisions. Also, faculty development happened before they taught the course— instructors thought about and used the technology before the class went live. Finally, the faculty learned about technology and developed skills that they would not have had they simply left the details to the technology experts.

Through an analysis of the interviews conducted after the course was over, postings to the online threaded discussion, statements in the class, and the courses developed by the design teams, we found that the faculty developed in a number of ways. First, because faculty had to talk out loud to their design team, faculty had to explicitly confront pedagogical issues in ways they have not had to in traditional courses.

“One of the most challenging and confrontive (sic) groups I ever worked with and that’s been very healthy and refreshing. I’ve confronted them about the way I want to do things and they’ve confronted me like ‘you can’t do it that way,’ or ‘it doesn’t make sense to do it that way,’ so that’s been very refreshing. It hasn’t been personal at all, … not challenging in a negative way but it’s been stimulating the group process”

Designing courses for a face-to-face environment was something that all faculty members had a lot of experience with. However, like most experts, firmly established work activities were characterized by automatic routines and tacit knowledge and practices. However, the introduction of a new context for course design, where the rules of face to face teaching do not necessarily apply, presented new challenges to established practices. It required the development of new procedures, new tools, and new artifacts to represent and teach content in new contexts. The faculty participants quickly realized this and sought new forms of support and collaboration required to support their solutions to these new problems. For example, a major concern of all faculty members was how to engage students with the text online. Faculty used their student group members to test out their ideas and make revisions as needed. One faculty noted:

“I was shocked because I had given everybody a sample chapter. I boxed it, bolded it, the things that I wanted to be salient. They still didn’t see it. So that told me it was only when we sat face to face and I said okay, here is a little pretest I’m thinking about, answer that one question and they couldn’t. And they didn’t even know they’d read it and they didn’t even know where it was. That was a very poignant test for me, it said, we have to think much more carefully about how we’re going to signal the students relative to what is really salient here.”

However, the struggle was not without merit—the instructors were able, through their experiences in the class, to successfully reconcile these differences between their past teaching experiences and the challenges posed by the new online environments.

Faculty also developed a broader understanding of technology. Teaching online courses requires a level of familiarity and comfort with technology that many faculty members lacked. Although faculty members were the “content experts” they typically were not the technology experts. Consequently, developing an online course required collaboration with individuals who are experts in technology (the course instructors and knowledgeable graduate students). Accordingly they not only became more knowledgeable about various technologies, their understanding of technology became realistic, and was more likely to inform the relationship between technical decisions and the impact on pedagogy. For example, one faculty member mentioned how the class discussions increased her knowledge of what is possible with technology: “I think there were applications I hadn’t seen before. I’d seen streaming video but I’d seen how it could be linked… used in a course so I kinda thought about them concretely for the first time. We spent some time almost every week talking about something technical and those were very interesting to me.”

Finally, the faculty members benefited from their interaction with the graduate students. The graduate students proved to be a valuable source of ideas. For example, one faculty member found:

“I think it’s… going to be simpler and clearer (for students) than I thought at the beginning and one thing that a couple [of] people (in my group) recommended to me is for those discussions, don’t leave them open ended. Connect them to a text chapter and have some very
focused items or, or questions or focus points for each web talk conversation.... In the past I would have tended to be more loose and students kind of pick up indirectly and maybe that's been one of the things that hasn't worked real well for me so that's an example of being very explicit in terms of today, based on this content, we're having this discussion."

Furthermore, by bringing to bear their own experiences as students, and by imaging themselves in the online class they were developing, the graduate students were able to give faculty members feedback about the likely effect the design would have on prospective students. For example, all faculty members commented on the value of the collaborative process of course design with students. One noted, "I think that was one of the most interesting things is that what was actually produced was largely their (students) work. I mean, they, they actually did the design, the graphics and all that stuff was all their work."

Outcomes for Graduate Students

In many ways, this design course was a typical graduate class experience for the students—they read articles, discussed ideas, and were responsible for meeting course deadlines. However, there were some important differences. Like faculty members, students learned a lot about technology—they were exposed to several technologies, they assessed their usefulness, and potentially used them in the design of the online class. In more traditional technology courses, students explicitly learn target technologies as part of the course (e.g. web design, digital video, etc). In contrast, the design approach made learning about technology implicit—students learned about technologies as they needed to in order to fulfill some desired feature of the course they were designing. However despite this "implicit approach" students were exposed to a range of different technologies and managed to focus their attention on particular technologies that were most appropriate for the task at hand. For instance, one student wrote, "This course was a wonderful experience for me, and I gained a lot of new knowledge and information that I found very useful for. The best thing that I learned from this course was about FTP and Digitizing Videos."

The task of designing an online course was a unique opportunity for most students. Most of their experience in graduate education has been as students in graduate courses. For those who had some experience teaching a graduate course, their experience was mainly limited to being a teaching assistant, or enacting someone else's ideas. None of the students had previously had the opportunity to design a graduate course from scratch. Opening up the process of graduate teaching for students gave them the chance to apply their knowledge of educational theory to a real context, and to further their own development as future lecturers, instructors, and professors. As one student said, "This class has been one that I will never forget. From how much work building, maintaining, and revising an online course is to learning how to work in a group again, this experience has been one that has reshaped many things that I have held to or thought about teaching."

Also, the chance to work with tenured faculty provided novel experiences for most of the students. Too often, graduate students' experiences with their professors seem opaque—they only get to see final products of their thought processes (e.g. research papers, courses they take, etc.). By working with expert educators, they got to interact with ideas in ways that they are seldom allowed—they worked over a whole semester with these ideas, got to influence the experts' ideas, and apply them to a real problem. As one student said, "Working with a faculty member, as a team to create an online class had been a wonderful experience to me especially in thinking about a particular course structure, it's syllabus, schedule, grading systems, forms, the layout of the web, video presentation about the course." Another said, "It was fascinating to see how the faculty thought about curricular design, teaching strategies, and student learning. As I was concurrently enrolled in HALE (Higher, Adult, and Lifelong Education) core course focused on teaching, learning, and curriculum, I learned a tremendous amount through listening to the faculty discuss their ideas and concerns." Most students reported that this course was one of the best courses they had ever had in their graduate program. Working on an authentic design problem, within a group led by a faculty member made the experience a unique one—one very different from most courses the students had been in before.

Conclusion

The design approach to faculty development has proved to be a fruitful lens for considering the many avenues of professional growth required to enter the world of online teaching and learning. Instead of turning over the development of their courses to web-programmers, the designers of these courses experienced something quite different. They worked together to design the courses themselves. Along the way, they not only
learned new technology skills, they also thoughtfully considered how the technology could be leveraged to accomplish higher-order learning goals for their potential students.

Did faculty develop? Consider the following quote we had offered at the beginning of the paper.

“I don’t know a lot about the technical stuff of the computer. I don’t feel like I want to know that, or need to know that... other people can do that. That’s not what I want to do. I don’t know how the telephone works either. Nor do I care.”

And a quote from a web programmer helping the same faculty member as she implemented the course having gone through the course:

[She] has been changing with that stuff all semester and it’s great, it’s been nice to watch when she first started she just changed text, now she puts in links, she adds papers up to the server and then links to them, she changes different html things. One of the things that she does is she records her weekly feedback to the students and then converts that to a real audio and puts it on the server. She doesn’t have to bother about sending it to me and then worrying whether I did it right or not and she can also do it while she’s on vacation or whatever.

Clearly, this faculty member had changed her stance about her own learning about technology and indicates what is possible in the design approach. As the same faculty member summarized her experience with this course “My goal was to really give myself, force myself the luxury of thinking critically about teaching in, in any other format. That was really a luxury of the course and that’s what I wanted and that’s what I got. I made that happen for myself.”

"Surviving" Web-based Professional Development (or, How Not to Get Kicked off the Island): Lessons Learned from the Inquiry Learning Forum

Julie Moore, Indiana University, US

Background
Organizations and institutions are increasingly offering online professional development opportunities to educators [Mather, 2000 #56]. This is especially true for teachers who must keep up with new teaching strategies, the latest professional standards, and constantly changing technologies. Coincidentally, new technologies promise to facilitate access to learning at times and places chosen by the learner. These web-based environments have the potential to transform teacher professional development through the use of new models of teaching and learning. They also have the potential to facilitate a culture of sharing, collaboration, mentoring, and support for K-12 teachers.

In the design of these web-based environments, there are not only technical challenges but, perhaps more importantly social and cultural challenges and norms which must be addressed in order for these new models to succeed. While initial attraction and interest may be high, establishing long-term, high-quality learning opportunities is a much more difficult goal to reach.

The Inquiry Learning Forum
The Inquiry Learning Forum (ILF) is a NSF funded research and development project that seeks to support a community of K-12 math and science teachers interested in inquiry-based teaching. The original research aspect of the project seeks to understand how to build and sustain an online community of practice. From a service perspective, we are trying to support teachers, pre-service teachers, administrators, and teacher educators come together in a resource and context rich web-based environment to explore, challenge, and expand their notions of inquiry-based teaching.

This paper and presentation will focus on the first two and a half years of the Inquiry Learning Forum project. Specifically, this presentation will address key design features based on a community of practice model, challenges consequent from both our original conception of the project and it's design, and how the project and the design of the website has evolved to meet these challenges.

The concept of "community of practice" has come out of sociology literature [Lave, 1991 #43], [Wenger, 1998 #40]. Barab, MaKinster, and Scheckler [Barab, in press #46]. define community of Practice as "a persistent, sustained social network of individuals who share and develop an overlapping knowledge base, set of beliefs, values, history and experiences focused on a common practice and/or mutual enterprise." The ILF was originally conceptualized as an attempt to create such a community through an online environment. When we approached teachers and asked them what they would most like to do for their own professional development, the answer we received overwhelmingly "I'd like to go see how that person teaches." With that in mind, attention focused on creating online "classrooms" - video-based examples of actual inquiry-based lessons that acted as anchors to discussions, teacher reflections, resources, connections to standards, lesson plans, and student work. The original thinking was that these resource-rich videos provided teachers with a mechanism for sharing their history and experiences, would provide a common practice upon which to discuss and challenge each others notions' about inquiry-based teaching and learning. The site launched in March of 2000 and seemed to be well received whenever shown or demonstrated.

The Journey
As time went by, however, the ILF project team realized that the type of interactions that were occurring were very superficial and not very sustaining. Groups using the system for workshops would be excited to use it, but not return and continue in any long-term conversations. Additionally, teachers who were featured in the videotaped classrooms were disappointed with the lack of critical dialogue around their classes that they had hoped would provide them ideas and avenues for improvement.

So why wasn't this working? As we examined the project at the end of year one we began to reach several conclusions. In many ways, we realized that we were battling more than the normal diffusion issues. We were battling long-held cultural conditions, a realization that the building of community requires
more scaffolding than we originally wanted to give, and the inability for the project in its current form to reach the person-to-person aspect that was needed.

First, while we sought to meet teachers' needs by providing the type of professional development they said they wanted, we were still fighting an uphill battle with regard to the culture of schools. To fully engage in a discussion around a classroom required a large chunk of time -- time their day didn't allow for. Also, while the web offers the promise of "anytime, anywhere" the reality of a teacher's day and the continuing lack of pervasive technology in teacher's classrooms makes this promise an illusion. Another cultural issue had to do with the way in which teachers traditionally interact with one another. Teachers traditionally work in extremely isolated situations, rarely get to see other teachers teach, and hardly ever engage in critical dialogue about one another's teaching. If they don't do this in their current situations, it was perhaps naive of us to expect them to do it in an online environment, where their words were captured for all to see -- forever!

Second, in our exuberance to have "community" evolve and blossom, we designed a space without much scaffolding for engaging in the space or in the dialogue. Discussions were distributed throughout multiple classrooms and general discussion areas. In our hopes for the notion of "inquiry" to bubble up out of the community, members were left to wonder, "what is inquiry, anyway?" Additionally, we did not provide any real mechanism for structuring people's experience with the ILF. They came to the website and were left to their own devices as to where to go and what to do. An aspect of the project that was overwhelming for many. Lastly, many users felt that the only way they could really contribute to the community was to contribute a video lesson - a daunting task for almost all. We did not have any low-cost ways of engaging in and contributing to the community.

Third, while we designed well for usability, we did little to design "sociability" into the ILF. It was difficult for people to "find" others with common interests. In our concern in protecting anonymity, we dehumanized many aspects of the site. In our attempt to build an online community, we failed to realize the importance of face-to-face, human interaction.

Changing our Course

We have attempted to meet all of these obstacles in a variety of ways. First, we have shifted our focus from "building online community" to "supporting community online." As such, we have developed group work spaces that allow pre-established, school-based, subject-based, or course-based groups to work together, build and share documents, and have their own private discussions. To address the issue of scaffolding, we have developed printable "guides" for the ILF as well as activities that utilize the features of the ILF to help teachers answer their own questions about inquiry-based learning. We have refocused the project and, quite literally, the site on inquiry-based teaching, putting our own stake in the sand as to what inquiry-based teaching is and how it can benefit students. We have tried to make entry into the community more accessible by providing lower cost ways of contributing and gaining from participation. The library, formerly a list of relevant links, is now a place where teachers can contribute and download lesson plans, the currency of the classroom. To reduce the overwhelming nature of the project, we have created a personal portal where members can store bookmarks to their favorite classrooms, lesson plans, discussion groups, and group spaces. To help encourage connections, we have developed personal profiles that are accessible from discussion forums, a members' list, and contributed resources. Members can now see, send email to, and leave guestbook comments to other members with common interests. Lastly, we have developed a model for bringing groups together to support one another in their common interests that focuses on both face-to-face meetings as well as online support.

Conclusion

While we can't say with complete assurance that we have "survived" the world of online professional development, we have certainly learned, and continue to learn a great deal. Breaking the mold with new professional development models is a very enticing challenge, but one that must be taken only with the proper respect for current culture and constraints.
Technology Committee Function: Holly Jolly Technology Folly

Betty Nelson, University Of Alabama At Birmingham, US
Lois Christensen, University Of Alabama At Birmingham, US
Jiang Lan, University Of Alabama At Birmingham, US
Karen Dahle, University Of Alabama At Birmingham, US

This session will be an interactive session in which panel presenters will discuss their functions on a technology committee and present the ways that they incite technology infusion and training with university faculty. Digital photos of two technology extravaganzas and the varied technological themes involved in both events will be featured in a PowerPoint presentation and accompanied by a description outlining committee endeavors. Conferees will interact and share some of the ways in which they enthusiastically provide technological professional development for university teacher education faculty.

Instructional Technology Support

John Spagnolo
spagnoloit@appstate.edu

Appalachian State University
United States

Abstract: The Technology Advisory Committee and the Faculty Development Committee of the college of education at Appalachian State University began a Faculty Technology Development initiative that involved faculty from across departments. This initiative had the following goals: (a) to have ongoing, sustained conversations on identified instructional technology issues within the college; (b) to create, promote and share a faculty vision on the role of technology in teaching and learning; (c) to collaboratively inquire into continuous improvement and sharing of what faculty were doing with instructional technology; and (d) to promote and share models of effective technology enhanced teaching and research. Funding for this effort is provided by the Appalachian Rural Teacher Technology Alliance, a PT3 grant from the U.S. Department of Education. This paper will include a discussion of the processes used by the Faculty Technology Development group to promote and support educating college of education faculty in appropriate technology integration into curriculum and will share lessons learned as well as the products produced to date.

Introduction

Recent national reports and research (CEO Forum Report, 2000; Uttendorfer, 2001; Carbonaro, Snart & Goodale, 2001) note that while computer technology is in place in higher education settings, the integration of technology into teaching lags behind. In K-12 teacher training programs, state boards of education have adopted technology standards for their teachers. North Carolina’s State Board of Education
mandated a set of basic and advanced technology competencies for pre-service and experienced teachers. As a result, faculties of education need to develop and strengthen their technology skills in order to model and facilitate these skills for pre-service teachers. Much research has been presented on the use of technologies in post-secondary learning environments in an effort to bridge the gap between available technologies and the integration of those strategies (Bohannon, 2001; Glennan & Melmed, 2000). Yet, little research exists on formative ways of training faculty to use this technology appropriately (Dutt-Doner, Larson, & Broyles, 2001). The focus of this paper is to present the work and lessons learned from a college of education Faculty Technology Development initiative.

This initiative began with six faculty members from across departments within the college of education in the fall of 2000, selected by the College’s Technology Advisory Council and the Faculty Professional Development committee. The group, the first of the Faculty Technology Development (FTD), had the following goals: (a) to have ongoing, sustained conversations on identified instructional technology issues within the college; (b) to create, promote and share a faculty vision on the role of technology in teaching and learning; (c) to collaboratively inquire into continuous improvement and sharing of what faculty were doing with instructional technology; and (d) to promote and share models of effective technology enhanced teaching and research.

Activities and Products

The faculty team initially used attendance at a national professional conference as a catalyst for meeting the FTD goals. The team met to select a conference to attend as a group, and to assess the current state of affairs within the college on instructional technology issues. Points, concerns and issues raised during these initial meetings became woven throughout the pre, during, and post-conference meetings. Pre-conference meetings included identifying key questions to be researched during the selected conference, establishing team and individual roles and goals, setting an overall team agenda for the conference, establishing travel arrangements, setting meeting times during the conference, and brainstorming post-conference dissemination activities to be implemented within the college. The team met during the conference to share experiences from different sessions attended, review goals and revise plans for future sessions, and raise new questions. Participant meetings during the conference were designed to connect the conference experiences to the college’s instructional technology issues. During post-conference sessions, the participating faculty discussed lessons learned, determined and planned additional dissemination activities, and planned for the next team.

Principles Guiding the Implementation of Instructional Technology (below) written by the participants on the first team has become an initial working document for the group as well as a statement for the college.

1. Above all we value effective teaching. We believe that technology can enhance effective teaching. Technology is fulfilling when it helps make us more effective teachers.
2. The learning curve and dynamic environment of technology don’t alienate or separate technology from teaching and learning or curriculum & instruction. All principles of pedagogy and learning apply to technology-based instruction as well.
3. The rate of change in the information age is immediate and the impact is dramatic. Long-term plans must be flexible. We must stay focused on our learning goals so that we don’t lose our way when new technology becomes available.
4. We believe that computer/telecommunications technology can improve the culture of the college. We must emphasize the importance of computer networks and what they offer. Interdependency via computers increases the importance of viewing ourselves as a learning community. Social-constructivist theory supports the use of technology to increase the levels of collaboration and innovation in our teaching. Computer networks are extensions of human networks. We must strive to include all our colleagues as well as our students in technological innovation.
5. We need to keep a clear understanding of the role of technology in activity construction; we also need a better understanding of when not to use technology in our instruction (Just because we can do something with a computer, doesn’t mean that we should. We must ask ourselves why we are using the technologies we are and how it will benefit our students.).
Often, we will need to resist technological innovation that is imposed from the outside (distance learning, for example) when the pedagogy may be compromised. Conversely, we must not blame the technology for bad pedagogy.

6. Integrating technological tools in instruction is tricky business. We must learn how to separate out real improvement in learning from temporary or illusionary learning. Instruction utilizing technology may make an activity fun, but may not actually accomplish learning goals. Technology innovation in instruction should take the following into account:

   The student may find the activity to be fun — but is learning taking place?

   The students may enjoy the novelty and excitement of the activity — but is it just because it’s something new or are students really learning something?

   The students may be engaged in the activity — but is the engagement because of learning or because of the excitement of the technology tool?

7. There are dual objectives in selecting technology tools in our teacher education programs:

   a. Using technology to enhance concept and content acquisition in the teacher education curriculum.

   b. Helping students learn and acquire skills in the use of technology as an effective part of the teaching act or other professional role for which they are preparing.

In addition, a second document, *Actions needed to Sustain the Growth of the Effective Use of Technology* (below) has been used to assist the planning process for creating new forms of learning environments.

1. Faculty members in Reich College of Education are already doing great things with technology. We must develop an awareness of the quality, types and levels of technology in instruction. We must be more conscious about the way we collaborate.

2. We should conduct research on our practice. We must think of new ways to capture what we are doing. Case studies, ethnographies, experimental design studies, and other research techniques can be applied. The current literature on researching technological innovation supports creative multiple approaches. We cannot know our deficits if we don’t know what we have.

3. We must acknowledge that we learn through our interactions with all people. While there are mismatches between people and developmental differences to take into account, it is crucial to recognize the worth and potential contributions of all of our colleagues.

4. We need to seek ways to sustain research, conversations, sharing, and explorations related to the use of technology in learning settings. How we reward effective work with technology and encourage the continued effort to explore and share the results of using technology will be critical to our efforts to prepare our graduates for the roles they will take on after completing our programs.

The first team of the FTD returned from their first conference experience and invited new members to participate in team activities. The new members joined some members from the first team to attend a second conference. This second team began by discussing the two documents above before attending a conference and then, at the conference, used their experience to expand upon the discussions and actions initiated at the first conference. Thus, the faculty team currently consists of new as well as previous faculty members.

A key recommendation of the team attending the second conference was to hold a retreat for the entire FTD group. This activity was held before the beginning of the fall 2001 semester. From the retreat several key activities emerged. Colloquia have been held to provide faculty opportunities to share their uses of technology with each other. Plans are being made to provide faculty with opportunities to visit K12 schools in which technology is being used effectively. And plans to develop resources to support case studies of technology use in the college are being formed.
The FTD will be expanded further this year with additional participants who will attend other professional technology/education conferences this spring to continue the foundational work started previously.

Lessons Learned

Retreats and conferences allowed faculty members to take time to learn about and discuss current issues and goals for this project. Out of this planned discourse came the realization that collegiality is an important factor for participation in this initiative. This coupled well with the concept of social constructivism that is the focus of our conceptual framework within the college.

The first team to participate in this effort quickly realized that a number of faculty members within the college of education were currently implementing state of the art technology in their teaching. After arriving home from the first conference, plans were discussed about how to more effectively share methods of instructional technology between colleagues.

Forming teams to participate in this project created a sense of ownership. From this sense came renewed feelings of belonging and commitments to attendance and further contributions toward common goals. Leadership also emerged in the form of school-based issues, policies, and politics on the use of effective technology in public schools.

Conclusions and Future Directions

Clearly, educating the professorate to understand the issues, tools, processes and products needed for a technology-based society is difficult at best. Transforming the faculty in our colleges of education who prepare our future teachers has proven just as challenging. This project has explored a model of professional development designed to provide faculty of a college of education strategies for investigating various technology-based learning environments. Experiences to date in developing and implementing this model support several conclusions:

1. Cross-discipline teams of faculties of education are very interested in learning about appropriate technology integration strategies for their programs.
2. Creating a college-wide vision of teaching and learning in technology-based learning environments is paramount in order to guide our future efforts.
3. Engaging faculty teams in asking appropriate questions concerning new technology-based learning environments is critical.
4. Opportunities to measure specific progress in our own college against that demonstrated within the national community are very useful in furthering faculty dialogue.
5. Planning specific small and large group pre- and post- activities is a necessary to insure continuity of purpose and dialogue.

As we continue to explore the implementation of this model, several future trends and directions are discernable within the faculty-teams.

1. Identifying and visiting exemplary technology-based instructional sites will serve as models for further discussions.
2. Collaborative cross-discipline research projects will be designed and implemented.
3. Additional faculty within the college will continue to be invited to participate in this program.

Technology Integration in Teacher Education: Changing the Way Learners Think About and Do Their Work

Jacqueline Peck
Mary Tipton
Kent State University

The Linking the Future to the Present PT3 grant at Kent State University is now in its third year of implementation. With a keen, questioning eye on our progress and insightful feedback from our evaluators, we are learning a lot about technology integration in our teacher education program. With this insight, we might simply say that in Year I we learned what didn’t work, in Year II we learned what did, and now in Year III we’re learning why.

Linking the Future to the Present supports faculty development of technology integration models by providing student assistants, consultants, materials and supplies, field visits to technology-rich learning sites, and stipends only in restricted instances; university conditions prevent our support through release time, which is the most frequently requested faculty incentive at our institution. During Year I, our incentives were apparently not attractive enough to generate the degree of faculty participation we originally expected. Also during Year I, faculty participation was limited to a triad structure, involving education faculty collaboration with liberal arts and sciences faculty; the idea of collaboration was not a barrier, but timing of courses and workload was. PK-12 collaborations were already in place for faculty in education and arts and sciences so that was never a challenge.

In Year II we expanded faculty opportunities to include individual and program-level projects. This successfully increased faculty participation so that by the middle of Year II we were on track with originally targeted numbers. We also found faculty could now better articulate how their technology integration was changing their students’ learning, and more importantly, their own. Concurrently, the evaluation feedback helped the project implementation team consciously recognize and attend to the role informal networks were playing in our complex process of innovation. Now that we have begun Year III, we are intentionally exploring, nurturing, and examining these networks; we believe a new model of faculty development is emerging. We too are changing the way we think about and do our work!

To effectively Link the Future to the Present, we situate our technology integration in the context of highly intellectual and compelling inquiry work for learners. We have chosen the research of Newmann, Secada, and Wehlage (1995, also www.consortium-chicago.org/acrobat/Intellectual%20Report.pdf) to frame this type of work for learners.

In this paper, we invite you to visit our virtual gallery of faculty technology integration models, listen to their commentary on how this integration is changing their own and their student’s thinking and learning, and hear our preservice teachers’ firsthand comments about the same.
The gallery includes work such as explorations of digital photography and language development in early childhood, critical examination of new literacies in middle childhood language arts, sophisticated imaging techniques in middle childhood biological sciences, case study in WebQuest format in early childhood intervention, authentic application of mathematical processes through inquiry into Rock and Roll Hall of Fame data, and examination of urban sprawl using real data in geography. These projects involve education faculty, liberal arts and sciences faculty, student assistants, and consortium partners.
Coaching Faculty for Technology Integration

Denise M. Peterson
College of Education and Counseling
South Dakota State University
United States
Denise Peterson@sdstate.edu

Abstract: This paper examines various staff development strategies used to integrate technology. This university received part of the statewide technology challenge grant referred to as LOFTI. Using this grant, both technology integration and change has been addressed through strategies such as intensive training sessions and coaching. This paper focuses on the bridge from intensive group training to a coaching mentality for technology staff development. The paper will also examine the potential effectiveness of coaching as a strategy.

Introduction

Faculty development is an important step in technology integration in higher education. Trying to keep faculty members updated in new technology developments and encouraging them to use technology in their teaching is a never-ending job. While staff development opportunities abound, there hasn't been an effort to make the opportunities relevant to individual faculty members. Thus, it may now be time to move into a "coaching" relationship with faculty members to encourage them to stretch their technology integration ideas.

Because South Dakota is currently in year four of a technology challenge grant, development opportunities have been numerous. The grant called Learning Organizations for Technology Integration (LOFTI) focuses on using technology as a change agent for the educational systems in the state through increased skills, knowledge and technology integration (Parry et al., 1997). As a representative of a local LOFTI group, the challenge has been to provide opportunities to faculty members without spreading myself and our other technology staff too thin as a resource. This session focuses on the opportunities provided and the realization that coaching may be an effective strategy for continuing the learning of university faculty members.

Past Faculty Development Opportunities

LOFTI has provided the funding for the College of Education and Counseling faculty members to learn about technology and determine how best they could integrate it into their curriculum. The goal of LOFTI for higher education has been to improve preservice curriculum to provide "in-depth, contextual learning opportunities for integration of content, pedagogy, and educational technology which incorporate engaged learner and process portfolio strategies" (Parry et al., 1997, p. 15). In order to do meet this goal of the grant, faculty members needed to model technology use in their teaching. Locally, it meant that faculty members needed to learn how to integrating technology effectively. The issues came with time and know-how amongst faculty.

In order to get faculty members to feel comfortable, a needs assessment was conducted the first year of the grant. In this assessment, faculty members indicated that they needed skills in everything from file management to web page design. In accordance with the expressed need, a weeklong intensive faculty development academy was designed providing opportunities to learn various programs applications and to grow comfortable with the computers in their building. This academy went a long way toward meeting the needs of faculty members who had little or no expertise in a variety of programs.

The second year was spent on reviewing some of the skills and taking more time with the integration tools available to our faculty members. Sessions during this weeklong intensive faculty training centered on distance learning using both interactive videoconferencing and internet, courseware products,
and brainstorming opportunities for integration of these tools. This session went well and built a community of faculty members committed to at least trying to integrate new technology. As the school year progressed, however, time and technology failures discouraged some of these faculty members.

The third year has been spent building a community atmosphere rather than focus on the various technology skills. Individual faculty members were granted money to develop curriculum for interactive video conferencing delivery and technology integration within courses. However, this was a loyal core developing the materials so another avenue had to be tried.

**Potential for Faculty Coaching**

As the third year progressed, the LOFTI coordinator had the opportunity to work with an individual faculty member to enhance her technology skills. Using some coaching strategies, the coordinator noticed a real gain in that individual’s abilities and confidence level. The stretch came from incorporating technology in a meaningful way not skill building for skills sake – this was an important discovery to the coordinator.

At about the same time, the coordinator began conducting coaching training sessions for business in the community as an independent project from the grant. Through the training sessions developed, the coordinator realized that coaching could be one strategy that may possibly be effective in working with faculty members. The concepts in coaching that would be useful include gathering information about the needs of individual faculty using surveys, and informal conversations. A second concept in coaching that is useful is dialogue with individual faculty members to determine what type of technology skills and integration projects can be useful to the department and the students they teach (Vella, 1997). Goal setting than could occur on an individual basis as faculty and their coach could set up some projects that move them to the goal of technology integrated curriculum. In this stage, the coach can help the faculty member to think and act differently as technology integration can require some redesigning of teaching practices. The last step is in following up with the coachee to assist them in reaching their goals by providing resources and helping them around barriers (Hargrove, 1995).

Realizing that this might become a possible model for faculty development, the coordinator has started formulating a plan to try using a coaching approach as faculty indicate a difference in needs. The plan consists of holding conversations with faculty to find out what they truly want in terms of technology integration and their curriculum.

**Conclusion**

The ultimate goal is to create opportunities for various faculty members to coach others that have the need for someone to help them stretch their technology goals. This can be completed through teaching other faculty coaching skills as well as encouraging continued growth in technology integration skills. The fourth and fifth years of the local LOFTI grant will be dedicated to this philosophy of staff development.

GRANT WRITING INFORMATION AND THE INTERNET: EFFICACY OF
STATE EDUCATION WEB PAGES

Susan Peterson, Ph.D., Associate Professor
Secondary Education and Foundations of Education Department
Slippery Rock University
Susan.Peterson@sr.edu
Slippery Rock, PA 16057

Abstract: The Internet can provide a valuable resource for teachers and others seeking information about grants and funding resources. Ideally, state department of education homepages should provide information to assist teachers and administrators who are interested in writing grants and finding education funding sources. This paper offers several state education homepages that provide easy-to-locate information on grant writing or unique features for those seeking information about grants. Chief state school officers should assist in making such valuable information easily accessible.

State education agency web sites are important tools for disseminating relevant information to educators and to the public residing within their respective states. A review of department homepages reveals many similarities. Generally, they contain some form of welcome or introduction from the chief state school officer, information about offices within the department, special initiatives or reforms; links for students, parents and administrators; recent news releases; and special links for those seeking employment or desiring information on state certification. Many sites use pull-down menus to help classify sub-categories of information, and most, but not all, have site search capabilities to help users locate specific topics or information that may be difficult to classify or otherwise uncover intuitively.

Ideally, state education web pages can, and indeed should, be powerful resources for educators and others interested in finding relevant information about education grants. In addition to providing information about public in-state grants, such sites should offer links to private and federal grants and offer tips and resources on the grant writing process specially designed for teachers who are novice grant writers. Grant information should be well maintained and up-to-date. Links should be available to such sites as the Foundation Center (www.foundationcenter.org) and the U.S. Department of Education at www.ed.gov ("Grants and Contracts").

Problems with locating state education grant information fall into several categories:

1) Grant information is easily located but is outdated (Once Upon a Time)
2) Information is found within various offices (Find Me If You Can)
3) No information exists (The Nil Factor)

All fifty state education departments and state jurisdictions now have active web pages; however, there is little consistency on the type and amount of grant information found within the sites. If the topic of "grants" does not have its own button on the homepage, under what category should information about this topic be placed? Unfortunately, information about grants is generally not easy to locate on most state education sites and is often buried under such headings as Programs and Services, Initiatives, or For Educators. Site search availability also varies considerably.

All state education department/agency sites are readily available at the Council of Chief State School Officers (CCSSO) site via a point and click map (www.CCSSO.org); however, few sites contain information that is easy to
locate, up-to-date, and useful to both the novice and experienced grant writer. A review of state education homepages reveals some state sites that could serve as models for those wanting to provide grant information that effectively reaches its intended audience. Examples of sites with useful information include:

**Texas**

The Texas Education Agency (TEA) homepage has a link to “Available Grants and Contracts” that is listed under the School Finance and Grants heading. Grants are accessed using a drop-down box on a page administered through the TEA Division of Grants Administration. The downloadable documents may be completed on the computer, another valuable tool. In addition to the grants and contracts, there are a number of other useful links: “A Grantseeker’s Resource Guide to Obtaining Federal, Corporate, and Foundation Grants,” “The Grantee Handbook” (a procedures manual for TEA grant recipients), “TEA Grant Process,” “Information Links” (federal and state links, including the Texas Register) and other TEA Grant Programs. The Resource Guide has a separate chapter on foundations, including information on starting a school foundation that would enable a public school to seek funding through a nonprofit foundation. Another positive aspect to this site is the “Join the Grant Announcements” listserv. Subscribers to this free service receive automatic notification of newly available grants and contracts. This means Texas educators who sign up for this service are getting notification of grant announcements delivered to their mailboxes regularly!

**Pennsylvania**

Unique to the Pennsylvania Department of Education grants page is the Peer Review Team Nomination Form, asking for parent, community member and educator volunteers to serve on grant review panels.

**New Jersey**

The New Jersey Department of Education Office of Grants Management and Development maintains an up-to-date web page with several unique elements. The site offers links to approximately 100 foundation-sponsored grants, which in turn provide direct links to detailed information about proposal submission for each foundation. In addition, there is a link to current federal discretionary grants. A unique element on the New Jersey site is an online survey for educators, asking for feedback on usefulness of information on the site.

**Alaska**

Listed under the obvious heading of *Forms and Grants*, the Alaska Department of Education provides a link to over forty topics of interest to teachers and administrators. Those using the site are encouraged to download the forms and fill out and return the forms electronically. Grants and special recognition programs are available from this site.

**Summary:** The Council of Chief State School Officers is a nationwide, nonprofit organization composed of the public officials who head departments of elementary and secondary education in the states and other jurisdictions. In 2000, the CCSSO announced six objectives, among which was to strengthen leadership at the district and school levels within each state. State school officers must realize that one way to strengthen leadership is to provide adequate and up-to-date resources using the Internet. States interested in encouraging a pro-active approach to grant writing should review and revamp their sites to make them user friendly to those interested in launching activities through grant writing. Billions of dollars in grants are available annually from thousands of funding agencies, but only a few select sites actually assist educators in uncovering information about them.
Despite the investment of time and money, it is not true that technology has reached its fullest potential as a tool for learning. To fulfill the promise of technology as a learning partner, three crucial issues must be addressed:

1. Teachers must be adequately prepared to use technology to assist student learning. This preparation includes appropriate content knowledge, understanding of and comfort with technology, and insight into student cognition.

2. Classrooms must be adequately supported. This support includes not only monetary support, but also support by knowledgeable people to assist teachers as they design, deliver, and evaluate instruction.

3. Curriculum materials must reflect the best understandings of content, cognition, and technology.

In order to address these issues, the Barat Program for Learning with Technology (BPLT) was established to provide a comprehensive approach to technology use for learning in classrooms. The goal of the BPLT is to improve student achievement in content areas, using appropriate state and federal standards for technology. In order to accomplish this goal, the BPLT will increase the readiness of teachers to use technology in the classroom by providing training and support, and create appropriate curriculum materials, including software, to aid student learning.

Increasing teacher readiness requires different approaches for pre-service and in-service teachers. Work is underway to change pre-service teachers' technology experiences. First, we are working with education and content area faculty to help them appropriately integrate technology into courses, thereby putting technology into a curriculum context. This is important because teachers teach as they have been taught. Second, a new lab has been constructed to help students experience appropriate uses of technology. In doing this, we are balancing between the current realities of technologies in schools and helping students realize what some of the possibilities are for technology use. A required course, EDU 212, has been repurposed to expose pre-service teachers to a variety of software typically found in K-12 schools.

With in-service teachers, our goal is to create learning communities that continue to evolve past the BPLT's involvement. We began with an assessment of needs and teacher abilities. We then, with the participating teachers and administrators, decided on appropriate emphases for our involvement, and began an initial design of our participation. Our efforts involve helping teachers develop action research projects so that they can assess the effectiveness of technology in their own classrooms. Our support for teachers includes graduate courses and other professional development opportunities, technology support, software development, and a lending library of software and hardware. Some examples of support include reduced-tuition graduate courses offered at local schools, technical support for teachers in classrooms, and loaner computers for teachers to work with at their homes. Special sections of EDU 525 and EDU 592 give in-service teachers both graduate credit and greater experience in integrating technology into their teaching.

So far, the program is involved with several different schools and school districts in northeastern Illinois, on projects ranging from early childhood language arts through middle school social studies to high school math and science. Both public and private schools are involved in this project. In all cases, we have found it important for curriculum needs to be generated by the teachers, and then work toward finding solutions, using technology where appropriate. All efforts are evaluated for effectiveness and to help guide future projects.

This presentation will present examples of our efforts, along with preliminary findings from some of the projects along with some of the early software development and online professional development offerings.
Abstract. This presentation outlines a three-level model of faculty development: workshops, support mechanisms, and consultations, and dissemination.

Beginning in the fall of 2000, the College of Education at the University of Florida recognized the importance of promoting technology integration throughout the college. Committed to doing more than simply paying lip service to the idea, the college hired an Assistant Director of Technology to develop and implement a faculty development program throughout the college. The first year began slowly, most of the faculty members had little or no motivation to attend these workshops, and consequently our faculty development initiative did not have a wide audience. However, the audience we had during this first year provided diffusion to the wider audience in the college and in this second year the program has expanded considerably. We believe that successful faculty development must include a variety of components such as workshops, continued support (physical and virtual), and individual consultations. We approach faculty development as a three-tiered model (figure 1).

![Diagram of three levels of faculty development]

Figure 1: three levels of faculty development

**Workshops**

Workshops (Level 1) are broken into individual modules rather than as a step-by-step cookbook-type approach to technology training. Workshops begin with a brief brainstorming session where participants are questioned about their particular objectives for the workshop. This approach makes each workshop context specific for the group of faculty in attendance, and consequently everyone leaves the
workshop feeling like they "got their monies worth." In addition, at the end of the workshop we probe further to determine which concepts should be expanded into online support elements. Each workshop is high energy where each person is both a participant and a contributor.

Support
In addition to these workshops we have an online support center which includes the workshop handouts as PDF downloads, tutorials that serve as prompts for concepts that might be forgotten after the workshop has ended, and frequently asked questions. We have learned that handouts, online tidbits, and downloadable documents contribute to the self-sustaining element of faculty development in the college.

Consultations
Once the faculty has gotten the basics from the introductory workshops, they may request additional time with a consultant (level 2). This element of our faculty development initiative has been very successful. When the consultants work with faculty the following issues are considered:
Context - All consultations occur in the professor's office using their computer and software.
Student teaching Teacher - Student consultants must remember that in this environment they are the experts and as such must understand how to effectively use their expertise to instruct their professors, through probing, modeling, patience, and practice.
Learner's goals - Prior to beginning a consultation the consultant discusses the professor's short-term and long-term goals. In addition, the consultant questions the professor to ascertain their current level of understanding.

As the consultants spend time with faculty a bond quickly develops between student technology consultant and faculty. This bond is dependent upon mutual trust and respect, and once developed, student and professor work together on many projects over time.

Faculty Modeling
The third level of our faculty development program is faculty modeling effective use of technology. We have found that once they learn how to use the technology, faculty are extremely innovative ideas for technology integration. Through college and university wide poster sessions we hope to share our faculties innovative uses of technology within the college of education community as well as the university community. It is our belief that faculty sharing ideas, strategies and techniques with other faculty motivate other faculty members to integrate technology in their teaching and research.
Facilitating Technology Integration In Teacher Education

Stephen Rose, University of Wisconsin Oshkosh, US
Thomas Fischer, University of Wisconsin Oshkosh, US
Penny Garcia, University of Wisconsin Oshkosh, US
Lenore Wineberg, University of Wisconsin Oshkosh, US

This paper session will present a description and analysis of an ongoing project that has facilitated faculty, students, and their cooperating teachers coming together to participate in a variety of projects that help them integrate technology into their teaching within a constructivist framework to promote powerful teaching and learning. Keys to this process are meeting the needs of post-secondary faculty to become proficient with the integration of technology into instruction in the teacher education curriculum at the University of Wisconsin Oshkosh, and having an effect on preservice teachers’ use of technology at field placements. The four part project: address faculty and academic staff skill levels with technology, have faculty develop technology-rich instructional projects, identify technology rich field experience placements, and collect information and data about faculty perceptions of instruction that utilizes technology to help promote powerful teaching and learning in the teacher education curriculum.

Faculty and academic staff technology integration workshops are offered to assist faculty to become skillful with, and model, a variety of electronic tools that can be added to their instructional repertoire to a) help students prepare for class, b) support students’ understanding of concepts through collaborative meaning making, c) promote resource-based problem solving, and d) model how theory translates into practice. Workshops also serve as a forum where faculty can reflect on shared concerns and collaborate in modeling the development of technology-rich instructional practices. Workshops are led by core team members, as well as other university professionals with technology expertise. Core team members also are available on an ongoing basis to provide one-to-one assistance to faculty members.

Electronic teaching portfolios are being developed to model authentic assessment strategies and to create linkages between the College of Education and NCATE standards, to contribute to preservice teachers’ professional development and lifelong learning, and to develop faculty and student technological skills.

Faculty instructional projects are the outcomes of the workshops on technology integration. Projects are examples of instructional innovations that employ a variety of technologies to promote greater student understanding of course material and to integrate technology via faculty modeling. Projects are developed by individual faculty for their courses and by teams of faculty associated with secondary learning communities.

Student teachers are placed with cooperating teachers who can facilitate the integration of technology into instruction at the PK-12 grade levels. Student teachers are to develop and teach technology-rich lessons collaboratively with their cooperating teachers. All student teachers submit at least one lesson plan featuring technology-rich instruction. Selected examples of technological instruction are collected and disseminated via CD-Rom to all cooperating teachers and preservice student teachers.

A College of Education symposium “Collegiate Classrooms in the New Millennium”, was held for faculty, invited student teachers and cooperative teachers so these related but diverse groups in terms of needs and experience could share and reflect on their instructional rich technology projects. Faculty/student teacher/cooperating teacher teams came together in table sessions to engage in substantive conversations about the instructional effects of their projects and changes they would make in the future. Student teachers demonstrated their lessons and faculty members discussed their technology-related projects.

Evaluation of the project involves collecting data and information about faculty who are in the process of changing their teaching to incorporate technology, gathered through both qualitative and quantitative methods. Faculty interviews were conducted about different elements related to integrating technology into their teaching. The research sought to understand the following propositions:
1. How are faculty using technology and how is it impacting their teaching?

2. Has the integration of technology in teaching resulted in students demonstrating an improved understanding of course subject matter, deliberation skills, and/or pedagogy?

3. Has the integration of technology change the way faculty teach?

4. Has the integration of technology facilitated preservice teacher’s deeper understanding of pedagogical knowledge?

5. How have faculty’s increased skill and use of technology impacted their personal view as self as teacher?

6. What are faculty perceptions of the climate in the college of education toward the use of technology in instruction?

Faculty teaching projects also are evaluated to determine the range and sophistication of uses of technology.

Quantitative data collection concerning faculty change over time in attitudes toward teaching methodology and acceptance of technology involve pre and post – assessments that utilize the following instruments: Stages of Concern Questionnaire, University of Texas; Computer Anxiety Scale, Sears; Computer Thoughts Survey, Weil; and Teaching Styles Survey, Norton. Data retrieved from these instruments will help determine the quality, effectiveness and appropriateness of integration of technology into their teaching.

This presentation will discuss what the information and data indicate are the effective components of facilitating technology integration in to teacher education and those areas in need of further modification.
Staff Development: A Tale of Two Programs

Catherine C. Schifter, Ph.D.
Associate Professor
Temple University, College of Education
Philadelphia, PA, USA
Catherine.Schifter@temple.edu

Abstract: Over the last decade or more, large amounts of money have been invested in establishing school based computer labs, classrooms with Internet connections, and at least one Internet ready computer per classroom. Research indicates that staff development is the key to whether these investments are successful. This paper presents two staff development programs from one large urban school district with different outcomes. As school districts continue to spend scarce resources on technology innovations, learning how to predict sustainable change is important.

INTRODUCTION

In the last decade extensive amounts of money have been invested in establishing school based computer labs, classrooms with Internet connections and at least one Internet ready computer for every classroom. Conferences are dedicated to discussing the impact and importance of computers in education (e.g., SITE, Ed-Media). The proceedings from these conferences offer tips on how to integrate technology into teacher education programs, staff development tips, specific topics related to teaching math and science, and comparisons of technology implementations between countries. There are journals dedicated to technology in education, again with examples of implementation programs, uses of the Internet, and more. The key to effective impact of technology in classrooms, however, lies in whether the teacher knows how to use the computer, Internet, and/or software in pedagogically appropriate ways for her students.

Current technology training for teachers is insufficient. While the U.S. Department of Education recommends spending 30% of school technology money on training, the reality is that only 12-18% is used for training (Giordano, 2001). The fact that many teachers do not use technology in ways other than for games for reinforcement is not shocking. Most public school teachers were not taught by teachers who used technology, so they have no model from which to work. Rogers (1995) theory of "diffusion of innovation" explains that only when the innovation is seen as better than current practice, among other characteristics, will it be embraced. The ACOT studies (Fisher, Dwyer, and Yocam, 1996) demonstrated that teachers need time to reach the point where the technology is truly one more tool in the toolbox. And, while there are numerous studies that indicate positive outcomes from technology infused teaching and learning, technology is one more intrusion into classroom activities, often seen by teachers as something to take up time. This paper compares two teacher development projects designed to help teachers learn how to appropriately use technology to improve literacy, and attempts to predict which will more likely provide sustained change.

BACKGROUND

As part of a Technology Literacy Challenge Fund (TLCF) Grant received by a large urban school district (e.g., over 200,000 students district wide), several projects were developed to help teachers learn how to use technology to impact reading and writing abilities of children in grades PreK-8. One of those projects was designed to teach 4th through 8th grade teachers how to use technology as part of project centered learning (PCL). Another project created a mentoring process coupled with both face-to-face and online training to teach Kindergarten through 3rd grade teachers how to use technology in their classrooms more effectively. These two projects had the same overall goal using two different approaches.
The school district contracted this author to assess the implementation of the grant. My objective was to assess how each project was implemented and the impact on teachers in classrooms. This paper presents a comparison between two of the staff development approaches to help teachers use technology to improve literacy. A sample of teachers who participated in the two projects were interviewed and observed in their classrooms after completion of the training programs, or participated in focus group discussions of their experiences. This qualitative data was used to compare teacher response to the two programs and to provide guidance for future program development.

PROJECTS

The developers of the first project adapted an established teacher development course in PCL for infusion of technology into PCL. The course lasted 15 weeks, and teachers received a Mac computer for their classroom upon successful completion of the course. The course taught the basic principals of PCL and how to design a cross-curriculum project. In addition, the course taught the participants how to effectively use specific software, and how to use the Internet. The course was delivered through community technology centers to selected teachers selected. The trainers were oriented to the course two weeks prior to the first implementation to ensure comparability of delivery across trainers. The PCL project director did not participate in delivery of the course. Approximately 500 teachers started the course, and 450 completed it.

The second project involved identifying teachers who were successfully integrating technology into classroom activities (mentors), and teachers who wanted to learn how to integrate technology into their classrooms effectively (mentees). This project was initially developed through another grant, and the director both developed the program and taught most of the face-to-face classes.

The mentees initially attended 3 face-to-face classes where they learned how to use a laptop computer, to use specific software, and to use the Internet. They were introduced to an online discussion forum, where they would have five online modules for the program, assignments and a journaling area. These teachers were loaned a laptop computer throughout the program to do the online assignments either at home or at school. After the face-to-face sessions, the mentees were paired with a mentor, whose classroom they visited over two days. During this time, the mentors modeled infusion of technology. The mentee was to "soak up" as much information as possible and return to his classroom to implement technology into literacy activities. There was follow-up over the next three months by the mentor and a district technology person. One hundred and sixty eight teachers completed the mentoring program.

DISCUSSION

These two projects were very different, even though they had the same goal. The first had a project director who helped write the curriculum, helped train the trainers, and then went on to new projects. The second project had a director who was intimately involved with curriculum development and out in the field with the teachers in the classrooms. The first project depended on many sites and instructors to implement the course, while the second brought all the participants to a central location for training with a small consistent group of instructors that included the project director. The teachers in the first project only had access at the training centers to the new software they were learning and received a classroom computer upon successful course completion. The second project provided laptop computers for the teachers throughout the training and then replaced the laptop with a Mac computer for the classroom. Training received in the PCL course depended on the trainer, while formal training in the mentoring program was centralized and scripted. The only variant for the mentees was to which mentor they were assigned. The first project had no follow-up activities or support, while the mentoring program had 3 months follow-up technical support and ongoing support through the project website.
The full impact of these two projects cannot be assessed in a short time, no matter what teachers say upon interview. According to the ACOT studies, significant change in teaching with technology takes years to accomplish, not weeks or months. Obviously, this paper cannot report which project achieved definitive change. However, using the literature on diffusion of innovations and on implementation of innovative educational programs as a guide, there are elements in the two project descriptions that can be used to predict sustained change. Rogers (1995) suggests five sequential stages in the process of adopting an innovation: knowledge of the innovation, forming an attitude toward the innovation, decision to adopt or reject, implementation, and confirmation of decision. The ACOT (Dwyer, Ringstaff & Sandholtz, 1990) studies also suggest teachers go through five phases toward technology integration: entry, adoption, adaptation, appropriation and invention. Fullan & Pomfret (1977), in their review of research on curriculum and instruction implementation, posit five dimensions of implementation in practice - changes in materials, structure, role/behavior, knowledge and understanding, and value internalization.

One of the most comprehensive studies of educational innovation was the RAND Change Agent study of implementation of the ESEA Title III, Bilingual Education, Right-to-Read, and Vocational Education programs of the late 1960s through the mid-1970s. They reported that well-implemented reforms had a strong training component, practical workshops and locally available technical assistance. Effective follow-up support must address teacher's specific problems in implementing the strategy in their classrooms: "Classroom changes were most apparent where the projects provided teachers with some form of classroom support, which complemented the training and/or materials development phases of the project" (Berman & McLaughlin, 1975, p. 45).

Using this literature as a lens on the two projects, one could argue that the participants made it through the technology integration entry phase and were working through the adoption phase. They had received training in, what was for them, innovative ways to use technology to affect literacy. Both projects provide knowledge of the innovation, an opportunity to form an attitude and to adopt or reject, and to implement new skills in the classroom. Participants were provided materials, examples of different classroom structure and teacher/student roles, and opportunity to develop knowledge and understanding of infusing technology into teaching literacy. However, only one of the two projects provided the follow-up support back into the classroom. Previous assessment of success of educational programs for change indicates that one predictor of success is ongoing support after teacher training programs. The mentoring project described has ongoing support for the participants, initially through classroom visits, and then through the online discussion at the website. The PCL project offered training and technology with no follow-up. One can predict that as these teachers are re-interviewed in the new academic year that teachers who took the PCL training may continue to implement the principals of PCL using technology, but that the teachers who took part in the mentoring project will more likely continue to use both the technical skills and resources acquired.

CONCLUSIONS

School districts are obligated to provide teacher development programs of all kinds. Some training has greater impact than others. Overall, behavioral change is difficult to accomplish. In the case of the two technology-related projects described, support beyond the training program may be the key to sustained change. This paper presents only the first year of looking at the implementation of two programs intended to change teaching behavior, however, long term impact may be predicted. As school districts continue to spend scarce resources on technology innovations, learning how to predict sustainable change is important.

REFERENCES

Abstract: The paper describes a professional development project which has the aim of promoting and supporting pedagogically sound use of Information and Communication Technologies (ICT) in a faculty of education in a university. The professional development project, called the eChange Project, focuses on pedagogy first and technology second and supports the academic staff of the faculty in their development of appropriate strategies for use of ICT in their subjects. The paper focuses on the experiences and issues concerning the use of ICT which arose in the teacher education part of the faculty. It explores the layers of support that are required in the use of ICT in teacher education and analyses some of the issues concerning professional development projects with teacher educators. An evaluation of the success of some of the strategies used and a discussion of future directions for the project are presented.

Introduction

Recent literature on the use of Information and Communication Technologies (ICT) in education indicate that most education faculties are not using the technologies to their full potential and that academics in these faculties often exhibit a lack of confidence about ways of implementing such technologies in appropriate and authentic ways. Many teacher educators are uncomfortable with the use of ICT in their subjects, either because they do not see any value in using ICT with their students, or because they, themselves, lack skills in the area (Cuban 1998). Further, it appears that beginning teachers and student teachers often do not see themselves as computer literate and, because of their belief that computers will remove opportunities for highly valued face-to-face interactions, they are not motivated to use computers themselves in their teaching (Foley & Schuck 1998).

It therefore becomes apparent that there are two areas in which support for appropriate use of ICT is needed in teacher education institutions: firstly to encourage teacher educators to start using ICT in ways that both enhance their teaching and promote their students’ development of the required skills for using ICT effectively and secondly, to show prospective teachers how to use ICT appropriately in their future teaching. A two-layered approach is therefore necessary in any professional development of teacher educators.

Further, if the transformational potential of using ICT is to be recognised then more must be done in professional development projects than merely teaching a few skills. New conceptualisations of ways of using ICT in teaching and learning need to be considered (Carroll 2000). New content can be covered in ways that could not be done previously. Therefore the “what” of learning can change as we have access to simulations, tools and techniques for understanding content differently (Cuban 1993, Pea 1998). However, Pea (1998) goes further in this discussion and adds that the technologies will not be the panaceas on their own. All such tools are mediated by human goals, beliefs and activities. Consequently, professional development in this area must consider the learning context and beliefs of the teacher educators and has to take these into account. The literature on professional development in general suggests that professional development must be sustained, ongoing and intensive and supported by collective problem solving around specific problems of practice (CERI 1998). It must be experiential, and able to provide opportunities for teachers to engage in teaching, reflection and discussion that contributes to the process of learning and teaching (CERI 1998). These understandings of professional development and the use of ICT in teacher education led to the creation of the eChange Project.
The eChange Project

The eChange project is an ongoing professional development project based in the Faculty of Education at the University of Technology, Sydney (UTS) located in the state of New South Wales (NSW) in Australia. The Faculty of Education at UTS has responsibility for two major areas: adult education and teacher education. The eChange Project is a professional development project, coordinated by the author, for faculty staff to develop and support their use of information and communication technologies in appropriate ways in their teaching. The project started in 1999 and is ongoing. This paper will focus on the particular challenges and context of the Project in the teacher education area.

At the start of the project academics in teacher education in the Faculty of Education, UTS, appeared to fall into two major groups: the first was a group of academics who had been early adopters of new technologies and who frequently experienced frustrations in their attempts to either incorporate these new technologies into their teaching or to transform their teaching through the new technologies. Administrative structures, policies and practicalities often posed barriers to the developments initiated by this group.

The second group were academics who in general, had little knowledge of how to incorporate new technologies into their teaching in effective ways and who lacked confidence to explore possibilities with ICT. Their major use of ICT was for their own email and internet usage. This group did not see value in the use of new technologies for their teaching or were quite unfamiliar with them. As the faculty was undergoing a large amount of change with respect to its staffing, resistance to new and seemingly untested uses of technology, and to the accompanying time demands was high.

A contextual factor which highlights the importance of professional development for teacher educators in the appropriate use of ICT is that the major employer of graduates of the teacher education programs, the NSW Department of Education and Training, requires certain competencies in ICT from graduates that they employ. Further it is assumed that these competencies will be embedded in the subjects in which they are appropriate. This requirement points to an urgent need for teacher educators to be able to use ICT appropriately in their teaching, and importantly, to teach their students how to incorporate ICT into their teaching.

The eChange project consequently offers two major areas of support:
- firstly, to assist early adopters of new technologies to have a forum in which to reflect on thoughtful use of the technologies and to remove barriers limiting their progress,
- secondly, to encourage, support and facilitate appropriate use of ICT by faculty members who are not doing so.

The first challenge for the project was to convince teacher educators from the second group that using ICT might enhance their teaching. There are four major professional development options that tend to be used for this sort of purpose. These are central support, faculty mentoring, technical support in the faculty and the use of external consultants. While our university does offer excellent centralised support, most people in the faculty were not availling themselves of it, possibly because they felt that as educators they could learn little from people outside the faculty, and possibly because the encouragement to use that support was not targeted specifically at the faculty. Technical support in the faculty, another option, was not used because many of the faculty staff were unfamiliar with the jargon often used by those familiar with new technologies and staff also needed to be convinced of the pedagogical value of the use of ICT before being interested in learning the skills. Having an external consultant who might be technically expert but would not have a good understanding of the context of the faculty was also rejected. In developing the idea for the project, the Dean of the faculty became convinced that the best way to get staff to embrace ideas of change in their teaching was to have two teacher educators in the role of coordinators of the eChange Project. The two coordinators were selected from the academic staff. We were teacher educators who were interested in exploring the new technologies and had used them in various ways in our subjects. We were not technical experts but rather academics with a keen interest in enhancing our practice.

Towards the end of 1999, we were appointed in the role of eChange Coordinators. We were given time release from part of our usual workload from January 2001. The project has been running since then and is ongoing. My colleague who had worked on the project with me from 1999 retired in July 2001. In 2002 two other colleagues will have roles in the project to support the work that I do. In our first year of the project we developed a number of strategies to get the project running. These continued in 2001 with a few additional activities and strategies. A discussion of these follows.
Strategies for the eChange Project

Working with the Early Adopters

Due to the different requirements of the two groups of academics described above, it was necessary to have a two-pronged strategy to launch the project. We needed a way of encouraging the early adopters as we saw them as a valuable resource for the faculty in leading the way in transforming teaching and learning. We therefore wanted to identify the problems they were having and also to investigate their ideas for transformational practice. Our way of achieving these two goals was to form a committee of early adopters. Membership of this committee was by invitation. We invited those academics who were engaged in interesting and innovative ideas for using ICT in their teaching, the faculty technical support person, and a member of the faculty management committee and we coordinated the running of the committee as part of the eChange Project. The mix of people on the committee was helpful in that it allowed the sharing of ideas. The technical support person could advise us of the potential of the available software for the new ideas that were proposed, the management committee person would take suggestions back to that committee for resourcing and would also suggest ways forward that fitted with the strategic initiatives of the faculty, and the remaining members of the committee would brainstorm ideas that they had for innovative implementation.

In that committee we resolved to have a faculty web development server for experimental and developmental purposes and this was set up for all faculty members to use as required, but with the main intention of supporting the developments of the early adopters. We also supported a plan for two members of the committee to develop a CD-ROM for teaching purposes and investigated ways of encouraging other staff to develop their thinking in the area. The committee has had a few changes of membership since its inception but remains an active and dynamic source of ideas for ICT usage development in the faculty.

It is our intention in the coming year to have members of the early adopter committee work with their close colleagues and act as mentors for their colleagues in small groups. This strategy should help us develop a critical mass of users of ICT who are interested and committed to enhancing their practice. The increase in innovative use of ICT will encourage those who are not participating to join in the developments.

Encouraging New Users

Our strategies emphasise collegiality, pedagogy, warmth and acceptance. We discuss the pedagogy first and then suggest ways of using ICT to implement those pedagogical strategies. The project focuses on how the technology would enhance teaching and learning rather than on what the technology could or could not do. Technological jargon was not used at all, and the coordinators and the academics shared a common language.

One of the first initiatives we implemented was to hold a forum in which teaching and learning ideas could be discussed as a way of preparing the ground for developing new approaches using ICT. We discussed new ideas for teaching and learning and illustrated with a few suggested models. We then had a group session in which people could talk about the major program in teacher education in the Faculty, the Bachelor of Education which prepares elementary teachers. One of the benefits of this session was that people were able to share their ideas and plans across disciplines, and get an idea of what others were doing in the program.

Following this forum, we offered individual support to staff members to use a Virtual Learning Environment (VLE) which is supported centrally in our university. We worked with staff members on ways of setting up the environment so that it would enhance their teaching and we were on hand if they needed support with their use of the VLE.

After a lengthy period of working in this way with different staff members, we had a two day preparation session, in which we suggested that staff members come with particular subjects in mind and work on leaving at the end of the two days with a product that they could use the following semester. Ideas on "blue skies" development were shared, subjects were planned with use of the VLE incorporated, and discussions on teaching practice were held.

A successful strategy has been to team teach with others in various subjects and to incorporate use of ICT in rich ways into these subjects, thus supporting the other team members’ development of knowledge in the area and providing them with contextual evidence of the value of such incorporation.

This year another initiative we have offered has been a reading group. In the reading group, those interested are sent relevant papers dealing with the issues arising in education concerning ICT. We meet and discuss these issues about a week after the participants have received the papers. These meetings are held monthly and a group of about six to eight academics and support staff attend them. These discussions allow
staff members to reflect on and raise issues about the use of ICT in their teaching and to discuss these in an intellectual manner, supporting arguments from a research basis.

Successful Examples and Remaining Challenges

The major factor contributing to the success of the project has been that the coordinators have been academic staff and not technicists. Those who do not feel confident about their use of the new technologies have appreciated the fact that I am not a technical expert and am prone to making errors and learning on the job. This alleviates any reluctance to expose their ignorance which some staff might have felt in working with a technical expert. Also I have a good understanding of the context as I am a teacher educator and this allows appropriate suggestions and support to be offered. Staff who had little knowledge of the technologies but were very informed about good pedagogy appreciated the emphasis and direction that I gave the professional development.

A project that was piloted this year and hopefully will be developed further next year occurred with one of the academics who had not previously done any online work with his students. The academic was aware that his students needed to work with schools to get clearer ideas of how to develop a teaching program. Beginning teachers often would tell us that the area they struggled most with when starting their teaching careers was this one. However, because of the very contextual nature of programming in schools, it was difficult for staff to give the students the experiences they needed. So an online assignment for the students was developed which used a partnership with school teachers. Students were put into working groups headed by teachers and would discuss their programs online with the teachers and each other. In this way, they could obtain practical advice from their teachers to merge with the theory. The students were enthusiastic about this project in their evaluations but a limitation was the number of teachers who actively engaged in the project. When the project is repeated when the subject is next offered, the lecturer intends to give more support to teachers so that they find participation easier.

Another project with the teacher education students had the aim of challenging their beliefs about mathematics. Students were placed in pairs and given a statement to debate with another pair. Mathematics educators from around the world were invited to respond to these statements. Their responses were placed in the communication site and students would use these responses and recommended readings from the library and from websites to compose their position. The intervention was useful in challenging the beliefs about mathematics teaching and learning that the students had held (Schuck & Foley 1999).

A mentoring project in which beginning teachers and experienced teachers interact online is ongoing. Beginning teachers find that they get valuable support from the mentoring network and the experienced teachers learn about the experiences of beginning teachers that they might otherwise have not heard about.

Other projects done in teacher education included an email project where first year teacher education students interacted with teacher education students in New Zealand and shared experiences of learning in their respective teacher education programs; and using a question and answer forum in a discussion board to develop student teachers’ understandings of mathematics and of science. So we have a number of areas in which teacher educators are using new technologies in authentic and appropriate ways to develop learning. However, there are still many staff who are either reluctant or have not yet had the opportunity to rethink their subjects in terms of what they might now be able to do with new technologies that they could not do formerly.

The challenges therefore that lie ahead are many. It is apparent that having forums, whether regular or irregular, is not sufficient for getting staff to develop new ideas and use ICT consistently. There is an increase in expectations of employers of teacher education graduates with regard to their ability to not only use ICT skillfully but also to use it effectively in their classes. Teacher educators can no longer afford to choose not to use ICT in their teaching nor can they limit their use to presentation uses. They need to be aware of how students can incorporate ICT into their teaching and into their future students’ learning. So a challenge is to encourage all staff members to embrace the need for professional development in this area. An allied challenge to this one is one concerning time factors. Staff are already overburdened with the intensification of academics’ work and it takes great commitment to be prepared to devote more time to subject development. This extra time is undoubtedly necessary as in any reconceptualisation of subjects, contrary to the rhetoric which suggests time is saved by working with ICT.

Another aspect of professional development that needs to be considered is student access to computers. Students are all given access to computers on campus and can work in one of the many computer labs where necessary. However, those who have computers at home and have internet access are advantaged by having ready access to such facilities. Implementing projects at schools during students’ field experiences
would enhance their learning as they would be using ICT in context. Unfortunately, often students are not
given the opportunities to implement such projects due to practical constraints at the schools.

The major obstacle to be overcome is that of the beliefs of many of the teacher educators and student
teachers. If they can be shown that use of ICT is enhancing their practice they will be far more committed to its
use. Therefore projects such as the eChange Project need to work in context and suggest ways that practice can
be enhanced. This is a major strategy of the eChange Project.

Conclusions

The eChange Project has had a number of successes in supporting authentic and appropriate use of ICT
in teacher education. More staff are now online and have incorporated ICT into their teaching in useful and
effective ways. Others are making inquiries and starting to think about how they can use new technologies in
their teaching. However, sustained and targeted support is necessary to continue the process. One of the
important aspects of my role in supporting staff is to develop open relationships with them in which they feel
free to ask for help in any aspect of their work.

One of the great opportunities for the eChange Project is to act as a catalyst in promoting reflection and
reconceptualisation of practices, and encourage the sharing of ideas from which all teacher educators would
benefit. Thinking about new ways of teaching and learning for whatever purpose is always a useful exercise
which prevents stagnation of ideas. Having forums to share ideas which are centred around practice with ICT
encourages the sharing of other ideas simultaneously and provides the opportunity to debate teaching and
learning issues about which little discussion has occurred. Consequently, the professional development
opportunity allows for greater thinking about teaching than might occur otherwise.

Our future directions involve looking at developing a whole program project such as an electronic
portfolio which will have aspects of each subject contributing to it. Students will then have a product to take
with them when they seek jobs and different aspects of the portfolio could be developed in different subjects,
thus encouraging staff to incorporate appropriate ICT into their areas.

A panel of three Instructional Technologists, a Media Services Librarian, and a member of the faculty will present the history, trials and tribulations, disasters and successes of faculty development at this small liberal arts college in suburban Pennsylvania. Topics covered in this panel discussion will be the history of faculty development, the development of an Instructional Technology team, the move from technical workshops to project-based faculty development, the collaboration between Media Services and Instructional Technology, and a brief presentation of a project developed during project-based faculty development.

The history of faculty development began with desk-top applications workshops designed for faculty and staff where the basics of the application were taught by computing services staff. The workshops were taught out of context with no relationship to their application to teaching; faculty and staff received the same training.

The development of an Instructional Technology team led to changes in the focus of faculty development. Faculty still looked at workshops as being “techie-oriented” and it has been an ongoing struggle to change their perceptions.

The addition of the Media Services Librarian (with faculty status) to the IT team led to the collaborations between the library and the Instructional Technologists. The Librarian’s familiarity with the faculty provided insight into the attitudes that were affecting the success/failure of faculty development. We needed faculty allies!

After a year of providing workshops with few attendees we developed a new plan. With the help of “early adopters” of technology we presented a panel, “Exploring the Possibilities of Teaching with Technology”. Four faculty members served on a panel and briefly described their successful incorporation of technology. They answered questions by the faculty concerning the time involved in learning the technology and the development of course materials, the benefits to the students of technology incorporation, the assistance available through the IT team. At the end of the panel we advertised our new approach to faculty development, project-based faculty development opportunities, and asked for proposed projects from individual faculty members.

Shortly after the end of the Spring semester we held our first Technology Exploration. Ten professors with specific ideas for technology integration into their courses attended our three-day hands-on Exploration. Multiple workshops were designed specifically to meet the needs of the individual faculty projects. Time was given for work on individual projects with one-on-one assistance from the instructional technologists as well. The Technology Exploration ended with each professor presenting his technology project.

One of these professors will give a brief presentation of the multimedia, web-based project he developed and is using with his classes. Included in his presentation will be his impressions of the new approach to faculty development.

Time will be given throughout the panel to questions from the audience.
Evidence for Campus Transformation Through Instructional Technology Faculty Development

Michael Rodgers, PhD
Associate Professor of Chemistry
Southeast Missouri State University
Cape Girardeau, MO 63701

David Starrett, PhD
Director, Center for Scholarship in Teaching and Learning
Southeast Missouri State University
Cape Girardeau, MO 63701

Southeast Missouri State University is a public regional comprehensive Master’s granting institution enrolling 8000 students. Founded as a Teacher’s College, the University still provides a quality teacher education program and graduates a large class of K-12 teachers every year. At the dawn of the Internet revolution in the mid-1990s, the University found itself at the trailing edge of instructional technology adoption. Faculty interest in computer-based instructional technology was limited, technology investment was poorly funded, and technology infrastructure was inaccessible to large segments of the campus. Recognition of our weakness in instructional technology coincided with a growing awareness of the need to enhance access to education in our service area, and increasing concerns that online instruction offered by universities outside of our service region were beginning to compete for the undergraduate students that have traditionally been Southeast’s clientele.

The University responded to the IT implementation gap with a comprehensive and inclusive strategic planning process. A University-wide Information Technology Committee (ITC), representative of all constituencies in the institution, developed a coordinated campus-wide technology plan that included a strong faculty development program. Teaching, Learning and Technology roundtables for faculty identified academic goals and priorities for integrating information technology with learning. Technology Associates, consisting of a faculty member from each college and school of the University, were charged with developing and implementing a Technology Serving Learning (TSL) program (the TSL Institutes) to develop faculty expertise needed to integrate IT with learning. All of these actions were supported by the University’s 1995 Strategic Plan, which recognized the need to significantly upgrade technology for student learning by devoting one of the Plan’s six Priorities to the problem. Two of the Priority’s six Goals stated that the Priority would be met by extending "access to information technologies to faculty ...by providing training opportunities and support", and extending "distance learning opportunities via technology."

Strategic planning resulted in creation of a comprehensive support structure for faculty seeking to effectively integrate technology into instruction. Permanent funding was procured, and the Office of Instructional Technology (OIT) was established within the Center for Scholarship in Teaching and Learning (CSTL) to support faculty. Faculty instructional technology training was delivered informally through the CSTL/OIT, and formally through the TSL Institutes. Those involved in planning and implementation opted not to act defensively, seeking merely to develop expertise in a few Southeast faculty sufficient to give the University an Internet presence. Rather, the planners sought a campus-wide transformation of IT use
through the TSL Institutes, believing that many faculty – even those with little previous
computer experience – could benefit from mastery of basic IT skills. By achieving a “critical
mass” of faculty interest and expertise, Southeast might become a leader in IT application and
innovation: the Internet was a new frontier to all educators, and therefore, offered opportunities
even to IT newcomers. Through use of the Internet to improve instruction, Southeast might
well blaze trails that other institutions could follow in an emerging field that had few
established leaders.

The TSL Institutes were launched in 1997, and since that time, 279 of the 380 full-time
faculty on campus (73%) have attended at least one Institute session. The Institutes were
organized through collaboration of the CSTL, the OIT, and the Technology Associates.
Inclusion of the Technology Associates in the collaboration gave the Institutes a distinctly
faculty-driven aspect. Adoption of a continuous-improvement approach allowed both problems
and new opportunities to be quickly identified and addressed in ways that befitted rapidly
evolving technology, growing student familiarity with computers, and changing faculty
attitudes. As a result, the Institutes moved in 1999 from a short course format to single-day
sessions. The change better leveraged previous faculty experience, and improved access by
faculty who had time conflicts that made commitment to a five-eight day Institute impractical.
To improve the balance between technology and pedagogy, the single-day sessions became
part of a two-tier model, in which a mandatory pedagogy session was followed by choice of
twelve or more applications sessions over several weeks. To serve a wide range of faculty,
from early adopters to those harboring deep fears of computers, Institute offerings were
reorganized and expanded into a five-track program, featuring multiple sessions on Basic
Computer Skills, Instructional Design, Basic Web Design, Advanced Web Design, and
Teaching on the Web. Further improvements included online sessions, such as "Teaching in
the Online Environment", and Web page development with our Online Instructor Suite (OIS)
course management software. Follow-up support in the informal, comfortable work
environment of the CSTL continued beyond the Institute sessions, with hardware, software and
human resources all available to faculty.

Many at Southeast Missouri State University have claimed that Southeast has moved
from the trailing edge of IT adoption to the leading edge of development and implementation.
Further, the change has amounted to a transformation of the campus culture. To give credence
to these claims, we have sought evidence in a variety of forms. This presentation will focus on
how 20 items of evidence were used to evaluate the state of instructional technology at
Southeast, with suggestions for adapting the list for use at other institutions. The 20 items are:

1. Evolution of Institute
2. TSL Institute attendance numbers
3. Declining recruitment budget for the TSL Institutes
4. Evaluation instrument completed by Institute participants
5. Number of Institute participants who later became Institute Facilitators
6. Number of online courses offered
7. Enrollment in online courses
8. Number of faculty IT server accounts
9. Number of course sections supported by Websites
The evidence supports the claim that Southeast has indeed undergone an IT transformation. The ability to support such claims can have important implications for planning by teaching and learning centers, and funding of technology-related programs on many campuses.
Adjunct faculty: Prepared to integrate technology into their curriculum?

David Stokes, Westminster College, US
Betsy Price, Westminster College, US

The Campus Computing Project has conducted the largest continuing national study of the role of instructional technology in higher education since 1990. The Project’s 2000 national survey reveals that 59.3 percent of college courses now utilize electronic mail and 42.7 percent use Web resources (Green 2000). These numbers are consistent with what we see on our campus and what we have learned from peer institutions. These observations indicate that faculty have made strides in the use of technology, but those strides have been primarily in the areas where technology supports traditional teaching methods. Educators must now capitalize on those features of technology that allow them to change what they are able to do in the classroom, not just how they do it.

This phenomenon in colleges appears to be similar to what is happening in the pre-college classes. Recently T.H.E. Journal (May 2001) presented a summary of their State of the States survey on technology funding and use in the public schools. While funding across the country for technology and technology innovations in the classroom continues to rise, particularly in the area of professional development, the growth in teacher proficiency remains a challenge. According to survey results from the 20 states reporting 60% of all elementary school teachers, 75% of all middle school teachers, and 80% of all high school teachers have demonstrated average proficiency in integrating computers into the curriculum (p.50). This may appear encouraging yet these findings suggest that many educators have yet to become fluent with technology or to use technology fluently to the learning advantage of students.

The inability of numbers of teachers to engage technology critically for learning may not alone lie at the door of school districts, state funding, or teacher education programs. While it has been determined that the success of integrating technology into curriculum depends upon the computer skills of teachers (Gallo & Horton, 1994), many preservice teachers remain unprepared to teach with computers. While federal funds infused through PT3 grants are beginning to change the way higher education views the need for technology integration into curriculum, perhaps even inducing the paradigm shift in investment from hardware to brainware Farenga and Joyce (2001) call for, recent changes in this funding pattern may well set back technology for teaching initiatives.

Instructional technologies engage students in more active learning while accommodating diverse learning styles (Smith & Kolosick, 1996). Yet resource based learning, inquiry, and other powerful teaching strategies are largely dependent on faculty’s ability to effectively utilize new technologies (Taylor & Laurillard, 1995; Brace & Roberts, 1996). The presence of technology is not sufficient to create change. Faculty need time and support to incorporate new technologies into teaching and learning. Assisting faculty in the meaningful integration of instructional technologies into curricula is one of the greatest challenges facing higher education today. Faculty at institutions of higher education may still struggle in advancing technology integration into the curriculum (Isaak & Ward, 2000). Though technology has made changes in faculty thinking about teaching, it has not changed how faculty teach.

In many instances computers are still being used in higher education for little more than communication and administration (Green, 2000). This may be particularly so for adjunct faculty who may not have the access to technology or means to learn how to integrate technology into their curriculum. This comes at a time where many colleges are increasing their dependence upon adjuncts to fill key teaching roles nationwide. The ability of this group of educators to teach with technology has never been more necessary. Many adjunct faculty teach in content areas central to obtaining teaching licenses. If adjuncts do not have access to knowledge and training in how to incorporate technology into their curriculum it is difficult for them to model technology teaching practices for future teachers. The trickle down effect of this upon future teachers ability to “see” the need for such integration must cause problems for teacher education programs and the potential of technology proficiency of future teachers.

Westminster College in Salt Lake City has been successful in obtaining two Preparing Tomorrow’s Teachers to use Technology grants. These grants have greatly impacted teacher education faculty who now regularly integrate technology into their curriculum. This said the grants have had little impact upon faculty who help prepare teachers in content areas not taught by School of Education faculty and even less impact upon adjunct faculty across campus. With the advent of a Teagle grant on campus in 2000 efforts have been made to provide adjunct faculty access to technology.
workshops with an objective for them to gain knowledge and experience in integrating technology into their teaching and curriculum. Specifically this paper reports upon the results of a survey of these adjunct faculty who teach in the School of Arts and Sciences, Nursing, Education and Business with suggestions as to how to improve their teaching with technology skills and knowledge.

Method
Surveys were sent to all 139 adjunct instructors on campus seeking their input upon their various uses of computer based technologies, 77 responded. Issues reported upon include:

- percentage of class time spent with different teaching methods
- percent of class time spent with different teaching methods by rank
- teaching methods used in the different schools on campus
- percentage of class time adjuncts use material supports (chalk, PowerPoint, overheads, pictures, stories, Internet etc.
- number of workshops adjunct faculty have taken
- use of home email
- use of campus email

Results are analyzed and compared to Green’s (2000) assessment of the use of computing in colleges. From this data comparisons are drawn between the effectiveness of faculty training and adjunct training with technology applications. Suggestions of further means to improve adjunct training are provided.

Discussion
Adjunct faculty at Westminster College begin their tasks with a campus wide orientation that in part provides a “how to” for use of the campus computer network. Adjuncts are provided with a network computer account, an office often shared with other adjuncts, a brief working knowledge of their teaching environment, and sometimes a regular faculty mentor to help overcome the hurdles of “settling in”. With access to the computer network comes extensive data storage capacity on a server, a full array of word processing, statistical, and graphic software, a website, and email. Adjuncts were also informed that they could contact the IT Department to meet them in their classroom to learn how to use the presentation equipment. Finally, for those who may not have computers or compatible software at home, adjuncts could checkout laptop computers from the library computer lab.

To assist adjunct faculty to better understand the possibilities of teaching with technology, a regular once a semester workshop was created and adjuncts encouraged to attend. For the past 2 years, as the college created a Faculty Technology Center (FTC), adjunct faculty were increasingly directed to the center for one-on-one instruction. More recently hired adjuncts are immediately brought to the FTC where qualified instructional technology staff provides individual assistance at a level of comfort compatible with the adjunct faculty members’ skills. Additionally, beginning computer workshops are offered two or three evenings or weekends a semester. The content of the workshops focuses upon the perceived needs of those who attend. Technologies taught are in the main, PowerPoint, email applications, webpage creation, and a sprinkling of WebCT applications. Discussions on the general or specific role of technology for teaching and/or learning were conducted at a novice level. Adjunct faculty’s pedagogical understandings of technologies for teaching and learning at their time of hiring, their technology knowledge and skills, were never recorded if in fact they were asked for. Thus the survey as a data source.

In contrast to the above, full time faculty in the School of Education not only have access to all that available to adjunct faculty, but have been 3 year participants in a Preparing Tomorrow’s Teachers to use Technology (PT3) grant shaped to provide intense levels of professional development in the pedagogy and practice of teaching and learning with technology. Included in the broad goals of the grant are a goal to improve the quality of instruction in science math, language arts, reading, social science and creative arts methods courses through technology enriched curriculum on campus and in field placements.

At the beginning of the PT3 project faculty had a dawning understanding of the power computer based technologies provide for achieving instructional gains but perhaps not learning gains. Faculty came with a growing recognition that computer based technologies, particularly multimedia, bring to their teaching real-life examples that provide a context central to learning (Brown, Collins, & Duguid, 1989). Though it was understood by faculty that access was available to many forms of technology aids, videos, audio, statistical data and lesson plans, they felt considerably underexposed as to how best to use these technologies in their own instruction to benefit preservice teachers’ cognitive and practical skill development. The notion of anchored instruction (The Cognition and Technology Group at Vanderbilt, 1990) that is the capability to demonstrate real world applicability of knowledge was less prevalent than hoped. Research findings that
suggest computer-based learning environments reduce learning time significantly with higher achievement levels (Kulik & Kulik, 1991) were not known or ignored. Although all content method faculty at Westminster College are in philosophical agreement with Piaget (1969) that students learn better when they can invent knowledge through inquiry and experimentation rather than through acquiring facts presented by teachers, they did not understand the role computer-based technology and particularly multimedia, web applications and online learning can have upon instruction and learning practices. In short faculty had not yet come to understand that “Technology is not a collection of machines and devices, but a way of action” (Muffoletto, 1994).

Over the course of the last three years School of Education faculty (12) have each experienced extensive one-on-one training by competent instructional technology staff funded by the PT3 grant. These staff regularly visit faculty, while faculty teach, making careful suggestions of technologies capable of extending instruction and learning. Workshops are held for several hours each month to provide group training on new technologies of interest to faculty e.g. video editing. Additionally, several hours are effected each month for forum discussions on the general and specific efficacy of teaching and learning with technology. Faculty share their successes and failures, read articles exploring pertinent issues, and discuss the ramifications of technology upon the School of Education program and preservice student learning. Issues developed in these forums become subject matter for School of Education faculty meetings often resulting in programmatic changes.

To date faculty have received training to a measure of competency in:
- PowerPoint
- Dreamweaver
- Smartboard
- Mimio
- Digital cameras
- Software applications
- WebCT
- Eboards
- Streaming video
- Various online research databases

Outcomes of this training and educational project include: ready support of faculty for the creation of an education teaching with technology lab/classroom; numerous examples of curriculum revision, program changes that provide a richer immersion into technology-rich learning environments for preservice students; and "more effective instruction" (Van Ert, 2001).

Competition for technology resources is now the issue of discussion by regular faculty.

**Survey outcomes**

Despite the discrepancy between training offered to regular faculty in the School of education and adjunct faculty the results from the adjunct faculty survey are encouraging. Seventy six percent of respondents report taking at least one technology workshop. These respondents tend to be newer adjuncts more likely to have taken a workshop and to engage with technology in the classroom. The newness of the adjunct reflects how we orientate and work with our new adjuncts. During their orientation they are introduced to the instructional support services and asked to report to the FTC for a one-on-one session with staff. This activity parallels the colleges’ recent efforts to provide better workshops and support for adjuncts. In this the college feels some success. Unfortunately, the emphasis on new adjuncts has resulted in the college not successfully inducing veteran adjuncts to attend the FTC or to integrate technology, with the exception of email, into their curriculum.

Email use by adjuncts has risen dramatically with much use being generated from their homes. This may indicate a need of adjunct faculty to generate lessons and pedagogy at times convenient to them, times not necessarily convenient to access to on-campus facilities. In contrast regular faculty use more diverse means of communication including eboards, and most particularly threaded discussions on a routine basis.

<table>
<thead>
<tr>

<th>Fall 2001</th>
<th>Home email</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Email</td>
<td>51%</td>
<td>68%</td>
<td>89%</td>
</tr>
<tr>
<td>Seldom use or never use</td>
<td>48%</td>
<td>32%</td>
<td>11%</td>
</tr>
</tbody>
</table>
Further survey results suggest that email is the dominant form of out of the classroom communication between adjunct faculty and their students. This suggests an increasing awareness of the advantages computer based communication technologies have over more traditional means. This result was not expected. Regular faculty (11 of 12) as expected, use email almost exclusively for out of classroom communication.

### How Adjuncts Connect with Students

<table>
<thead>
<tr>
<th>% of time</th>
<th>Email</th>
<th>Phone</th>
<th>Set office hours</th>
<th>Appointment</th>
<th>Casual meeting on campus</th>
</tr>
</thead>
<tbody>
<tr>
<td>29%</td>
<td>27%</td>
<td>21%</td>
<td>12%</td>
<td>6%</td>
<td></td>
</tr>
</tbody>
</table>

Other survey results suggest that the provision of technology workshops was a popular choice for adjuncts. As the level of sophistication of the workshop increased so did the number of attendees. This suggests that adjunct faculty are very interested in learning basic computer skills leading to much deeper understandings as to why use technology in the classroom as well as to best time such use. They understand the need to be current in their field and this includes technological innovations.

As the FTC became more fully equipped and staffed and thus better able to serve adjuncts the survey revealed large numbers of them seeking one-on-one assistance in developing their curriculum. This has resulted in increasing numbers of adjuncts seeking multimedia classrooms in which to teach. Regular faculty report regular use of the FTC along with in-house support and training on issues of interest or concern.

### Number of workshops adjuncts attended

<table>
<thead>
<tr>
<th>Year</th>
<th>None</th>
<th>One to Two</th>
<th>Three to Four</th>

<td>7%</td>
</tr>
<tr>
<td>2001</td>
<td>9%</td>
<td>61%</td>
<td>15%</td>
<td>15%</td>
</tr>
</tbody>
</table>

A further surprise is the manner of use of technology in the classroom. More adjuncts report regular use than anticipated. This is tempered by indications that the technology use may be in the form of simply replacing another teaching medium than any measure of substantive change to Muffoletto’s “way of action” (1994).

### Use of computers in the classroom.

<table>
<thead>
<tr>
<th>Use computers in class</th>
<th>% of classroom time</th>
<th>Specific Software</th>
<th>PowerPoint</th>
<th>Internet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sometimes to everyday</td>

<td>26%</td>
<td>21%</td>
</tr>
<tr>
<td>Hardly ever to never</td>
<td>46%</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Prior to the grant, the college ran large group, one-size-fits-all workshops. Each workshop featured specific software. All the attendees went step by step with the IT instructor. We wanted faculty to use discipline specific software and to use it into the classroom. To accomplish this we followed the suggestions of Green and other researchers who indicated that a new way of teaching was needed.

<table>
<thead>
<tr>
<th>FTC attendance</th>
<th>WebCT</th>
<th>FTC</th>
<th>Workshops</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>1</td>
<td>13</td>
<td>29</td>
</tr>
<tr>
<td>2001 (Fall only)</td>
<td>7</td>
<td>70</td>
<td>0 (not offered)</td>
</tr>
</tbody>
</table>

However our survey also indicated that lecture continues to be the dominant teaching activity.

### Types of teaching styles adjuncts use.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Lecture</th>
<th>Small Group</th>
<th>Problem Base</th>
<th>Questions</th>
<th>Large Group</th>

<td>12.1</td>
<td>17.1</td>
<td>11.8</td>
<td>29.4</td>
<td>17</td>
<td>11.7</td>
</tr>
</tbody>
</table>
This said it is interesting to note that when use of lecture method is assessed by school, education adjuncts appear more likely to use diverse teaching methodologies. This is both pleasing, perhaps not surprising, yet still difficult to explain. Only one adjunct faculty in the school of education regularly took part in the PT3 promoted project described previously, thus the overall effect of that technology program had little influence upon the practices of the majority of School of Education adjuncts. These adjuncts shared no benefit in training with technology over those in other schools across campus. Most importantly this finding is in line with regular faculty uses of lecture for teaching. The difference is that regular faculty are much more likely to use manipulatives and multimedia in concert with lecture.

<table>
<thead>
<tr>
<th>Percent of Time Lecture is used by School</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business</td>
</tr>
<tr>
<td>Lecture</td>
</tr>
</tbody>
</table>

Overall adjuncts report a more varied use of technology in the classroom and a deeper use of email as a communication medium than expected. This said email was rarely used as a device to move along pedagogy. Adjuncts continue to use lecture as the primary source of instructional medium and to use technology as a replacement tool for now outmoded technologies rather than to fundamentally restructure their modes of teaching.

Conclusion
The suggestion that Green and other researchers had made that teachers need a different type of instruction than large computer classes, worked at Westminster. Although we are still a year away from the end of the Teagle grant and our results are not conclusive, we believe that we are making strides at bringing technology into the classroom as a pedagogical tool. This is being accomplished through our efforts to individualize computer instruction with an emphasis on discipline specific software and uses.

While our survey results are promising there is a need to reflect upon the outcomes and to build upon the successes of the adjunct training programs now in place. Adjuncts seem to be more technologically literate than expected but lack knowledge and skills that would allow them to reinvent their teaching using technology aimed at improving student learning gains instead of as an instructional medium. Overall adjunct teaching with technology as instructional aids is not much different to regular faculty use across campus. This said their teaching to learning gains, perhaps best exemplified by bringing the world to the classroom through computer based technologies is far behind that of faculty in the School of Education. To close this gap the following are under consideration:

- Extend the hours that adjunct faculty have access to support in the FTC
- Introduce adjuncts into the FTC prior to their teaching so that they have the opportunity and encouragement to use technology for teaching
- Treat the FTC as adjuncts’ personal and professional development expecting that they will build skills and expertise the longer they are at Westminster
- Reconsider the role of workshops to focus more upon technology education than technology training. That is educate adjuncts on the means to explore technology as an instructional and learning tool rather than a communication medium or a replacement tool for older instructional technologies like chalk or overheads
- Provide short sharply focused workshops for small numbers of adjuncts to learn specific pedagogical applications of technology or develop technology skills in collaboration
- Provide access to classrooms that model exceptional teaching and learning with technology practices
- Help adjuncts to understand the need for careful time management as they further engage in integrating technology into their courses
- Provide key technical help, at short notice, in setting up and perhaps operating various technologies as adjuncts explore the medium
- Need to find the means to help veteran adjuncts to want to consider integrating technology into their courses given their history of long service for mediocre pay and spotty curricular support
- Finally, though our survey provided much needed information on adjunct actions, there is a need for greater knowledge of specific technology and teaching skills adjunct faculty bring with them as they enter service, and how the college community could help them fulfill their crucial but often voiceless roles.

Abstract: Recognizing technology as an essential tool for teaching and learning in the 21st Century, the University of Missouri-St. Louis established a technology and learning center within the College of Education to fulfill its vision for technology integration. While the center is a physical facility, it is also the springboard for a variety of faculty development activities. Among other change management programs, a study was undertaken to assess the integration of technology by faculty college-wide. The collection and analysis of faculty survey data and the corresponding results are presented.

Introduction

Beginning in 1996, a process of renewal and change began at the College of Education (COE) at the University of Missouri-St. Louis, under the leadership of a new dean. This “futures” planning process established four pillars of the college’s shared vision: 1) more field-based student work, 2) technology as an essential learning tool, 3) life-long learning for all educators, and 4) community collaboration. Attaining the goals set forth in this visionary process required change, both at the individual and the institutional level. Recognizing technology as an essential tool for teaching and learning in the 21st Century, the COE’s E. Desmond Lee Technology and Learning Center (TLC) was established to fulfill the “futures” process vision for technology.

While the TLC is a physical facility, it is also the springboard for a variety of faculty development activities. One of these change management programs is the PT3 project. The goal of PT3 is to have faculty model technology integration in their courses. This is accomplished through one-on-one and group meetings, providing opportunities for planning and reflection. By its nature, the PT3 program supported the implementation within the TLC of several data collection initiatives to assess its impact and guide future work. PT3 evaluation, including student portfolios, case studies and self-assessments is a data collection and analysis task set.

In addition to PT3, the TLC is collecting data regarding the overall numbers of users served by the facility and its staff and equipment. During the first year of operation, from May 2000 to September 2001, there were 47,000 visits recorded (each time an individual comes to the center, one visit is recorded). There were 28,613 visits by students, approximately 56% were undergraduate students and 44% graduate students, 1200 visits by...
guests, and 1098 visits by faculty. In addition, 27 individual faculty members have held classes in which technology was integrated into the learning process and 60 faculty members have received instruction at the TLC. These numbers demonstrate a promising degree of use of our facility and services but we are working to extend the research conducted by the TLC regarding the benefits derived from its service offerings.

The third area of data collection is aimed at assessing the integration of technology by faculty college-wide. Toward this end, a study was undertaken to determine faculty technology competencies. This study used a self-assessment competency-based survey to gather information regarding faculty's knowledge and use of a variety of computer technologies. With the recently approved National Standards in Education, came specifications for the inclusion of technology education in pre-service teacher preparation programs. Three sources were referenced in the development of the technology skills survey items, the International Society for Technology in Education (ISTE) Standards, National Education Standards, and the Missouri Show-Me Standards. The survey questions ranged from skill-based questions, such as opening, saving and deleting files, to application questions, such as developing online courseware. In general, the survey questions addressed the use of hardware and general software applications available within the TLC.

This survey assumes faculty members are able to fairly and adequately assess their own level of skill in the use of various computer technologies and tools. Skill tests were not conducted to verify the responses given. Faculty were not required to disclose their identity, however they were given that option so the researchers may potentially conduct follow-up interviews and further skills investigation with willing survey participants.

The scope of this project is two-fold: (1) to reduce the number of factors in the survey instrument used and (2) the investigation of the underlying data structures that permit the grouping of faculty based on personal and professional descriptors and self-determined computer technology skills. The intent is to develop characteristics that describe faculty who are well versed in the use of technology tools and their application in academic instruction as compared with those who are lagging behind. If these attributes are identified, the education technology faculty can develop a plan to involve more faculty members in technology preparedness programs.

Method

The data set used in this study was collected at the University of Missouri- St. Louis and contains survey responses from 20% of the estimated College of Education faculty population, or 33 faculty participants. These faculty members were full-time or adjunct instructors. They were asked to participate in the online survey via an e-mail memo from the Dean of the College of Education to the entire college faculty population. The survey was available to faculty online through Internet access to Flashlightonline, an academic survey instrument available through the Center for Teaching, Learning and Technology at Washington State University – Pullman, Washington.

The survey results were anonymous, unless the respondent chose to complete an optional section including name and/or additional comments. Upon review of the data, it was noted that 18 of the 33 faculty members who responded completed the optional sections. All 33 participants responded to the 16 survey items that reflect demographic data (items 1-6) and provide a measure of technology use and tool-based skills (items 7-16). Each skill-based question was a simple check box on the survey form, with a check indicating an affirmation that the respondent possesses the skill and a blank box indicating a negative response. The first six questions determine the respondent's position, years in that position, academic area of emphasis, gender and age. Since the purpose of this study is to investigate relationships among faculty descriptors and familiarity with computer technology tools and resources, the demographic information was selected based on criteria for describing and discriminating between different faculty members. These 33 subjects' responses were used for the data analysis conducted.

The data report generated by Flashlightonline was downloadable to MS Excel as a spreadsheet. The analysis of this data was conducted using SPSS software (© SPSS, Inc.). The raw data was modified such that each technology skill sub-item on the survey (each check-box) was a nonmetric categorical variable with a value of “1” or “0”, with “1” representing a checked box and “0” an empty box. The demographic data points are either
nonmetric categorical (such as gender) or nonmetric ordinal variables (for example, respondent’s age). A review of the data indicated four invalid technology questions. Every respondent answered these four items affirmatively. Thus, these data points were removed from the data set. The frequency plots for the technology questions are a good indicator of the “easy-to-do” (general and introductory) performance tasks and the “hard-to-do”, or more advanced skills. The correlation matrix indicates some collinearity among the technology item variables. For factor analysis, this is desirable.

Although it is recommended the researcher use a sample size of at least 50 observations with the factor analysis technique, this study was conducted with the data collected. The factor analysis resulted in identification of 15 component factors for the complete data set. The 15 component factors are described as:

<table>
<thead>
<tr>
<th>Factor No.</th>

</tbody>
</table>

Table 1: A Description of Component Factors

According to the Total Variance Explained table generated, these 15 component factors account for 88.2% of the total variance.

After reducing the data set from 57 variables to the 15 component variables derived in the factor analysis, a cluster analysis was performed to identify distinguishing characteristics for grouping respondents. The demographic items were introduced in the cluster analysis. The Proximity Matrix for these 33 observations indicates all data points are distinct and are separated by at least 4 units in Euclidean distance. The smallest squared Euclidean distance value is 16.162 and it relates to the similarity of observations number 27 and 30.

The results of the cluster analysis on the data set indicated the significant differences in the demographic data overshadowed any differences in the technology skill levels of the participants. Thus, the demographic data was removed from the data set and a second cluster analysis was conducted using only the 15-factors for the 33 data points. A review of the Agglomeration Schedule for the cluster analysis indicated an increase in the difference in the percent change values at the transition from four to three clusters. Therefore, the four-, three-, and two-cluster solutions were investigated. Next, a one-way ANOVA was conducted on the 15 factors using the Ward’s method variables resulting from the cluster analysis as factors (for two-, three- and four-cluster solutions).

For the three-cluster solution, the ANOVA results indicated the significance level of the F-test is < 0.05 for the latent variables identified as: Factor 1 (Significance = 0.014319), Factor 7 (Significance = 0.0000114), Factor 11 (Significance = 0.000000146), and Factor 13 (Significance = 0.014046). This indicates group differences on the skill areas of general computing skills, file access, e-mail attachments, and e-mail reply.

The final step was the K-cluster analysis. The results for the two-cluster, three-cluster and four-cluster trials were reviewed. Based on the analysis of the observation groupings and the ANOVA results for the three
alternatives, the three-cluster solution was determined to be an appropriate grouping of observations. This cluster solution provides groupings with significant differences on four factors without isolating any single observation as its own group. The remaining task was the interpretation of the clusters.

To develop cluster profiles, an interpretation of the three clusters was attempted using the raw data responses. By comparing the observations using both their technology skill data and their demographic data it was possible to develop the following attribute information:

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Observations in Cluster</th>
<th>Characteristics of Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster 1</td>
<td>1, 3, 7, 9, 12, 14, 17, 18, 19, 10, 13, 14, 17, 18, 30, 31</td>

</tr>
</tbody>
</table>

Table 2: Cluster Definition for Three-Cluster Solution

The research indicates there are significant differences among the faculty members with regard to computer technology skills and classroom application. The three groups that have been identified are distinct in their use of the TLC resources, experience with online courses and spreadsheet, database and e-mail skills. In addition, those with more advanced computer technology skills (clusters one and three) tend to be newer to their current university positions, predominantly male and in the fields of Educational Technology, Educational Psychology and Teacher Education (the areas occurring most frequently in clusters one and three). However, there is a split in this group that is related primarily to their reported general computing skills levels and their use of the TLC resources. The faculty members with lower average scores in the skill areas of spreadsheet, database, and advanced Web skills tend to be young, predominantly female and in fields such as Educational Administration (the area occurring most frequently in cluster two). This group reported lower skill levels than the other two in the factors described as general computing skills, classroom technology and dealing with e-mail attachments.

Discussion

In addition to information provided by this study regarding the current technology integration status, it provides a baseline for future studies. Thus, the goals of the faculty data collection are to assess both status and change in technology integration in COE courses.
The survey data collected was analyzed using two statistical methods, factor analysis and cluster analysis. The primary purpose of the factor analysis was to reduce the data set to a smaller number of parameters. The fifteen components identified by the factor analysis were used in the cluster analysis. The resulting groups of participants were differentiated by their level of technical skills, academic specialization, and the number of years in their current position at the university. Part of the analysis was conducted to enable changes to the survey instrument itself. Thus, the reduced survey will be used to conduct future investigations of technology integration in faculty courses. Further research will assist in the verification of current results and will begin to capture the change perspective among faculty participants with regard to technology integration.

Abstract: Standards delineated by the Council for Exceptional Children (CEC) include competencies in technology that promote teacher development of a supportive technological learning environment for students with disabilities. Personnel preparation programs must demonstrate in courses and field experiences that technology use is incorporated in the learning environment. This study presents preliminary analysis results of a survey to determine faculty technology use in educator preparation courses. The data presented are part of a larger study of technology learning environments in a teacher preparation program. Results indicate that faculty do not model all types of technology use within the learning environment of educator preparation courses.

Introduction

The National Council for the Accreditation of Teacher Education (NCATE) adopted technology competencies as a required component for training all teachers. Standards delineated by the Council for Exceptional Children (CEC) include competencies in technology that promote teacher development of a supportive technological learning environment for students with disabilities. Personnel preparation programs must demonstrate in courses and field experiences that technology use is incorporated in the learning environment. Gillingham and Topper (1999) discussed four possible delivery approaches to preparing teachers for technology use in classrooms: single course, technology infusion, student performance, and case based. Ludlow (2001), in a review of the literature and discussion of technology and teacher education, notes that research indicates a need for better training. This need is based on research and reports that indicate (a) preservice program faculty do not model the use of technology, (b) faculty do not facilitate its implementation in activities and coursework, (c) future special educators are more likely to use technology competently if it has been embedded throughout their coursework and field experiences, (c) technology competencies are often “add ons” rather than integrated into coursework, (d) few faculty members have the expertise to develop complex technology mediated instruction, (e) faculty lack the skills for troubleshooting technical problems during instructional interactions, (f) research in the area of making informed programming decisions related to technology is lacking, and (g) systematic training procedures to assist faculty and students in using new technologies have yet to be developed.
Edyburn (2001) delineated 197 articles that have contributed to an emerging knowledge base on special education technology research and practice. Content analysis identified several themes but most relevant to this study were the areas of implementation issues, preservice teacher education, and technology integration. In a review and discussion of instructional technology and personnel preparation for early childhood special education, major issues were identified within the context of higher education. Illustrations for faculty to examine their own instructional strategies within technology use were presented. Self-examination areas included online materials, electronic reserve, electronic mail, listservs/reflectors, online forums, electronic presentations and face-to-face instruction (Hains, et al, 2000).

Method

Using a survey of education personnel preparation faculty, the investigators addressed the question: Do faculty model technology use in the courses they teach? Faculty were invited to complete the survey at the end of a program area meeting. A script describing the study was read by one of the investigators requesting that surveys be completed after the meeting and returned anonymously.

Participants

A total of 26 faculty members at an upper division university in the Southeast region of the United States constituted the sample for this survey. Response was 100% of faculty attending program area meetings. Participants were all full time faculty members in an education personnel preparation program.

Measures

This study used the Technology Integration Survey for Faculty (High Plains Regional Technology in Education Consortium, 2001). For the purposes of this study, only the first 16 items were analyzed. These 16 items are designed to gather information on the degree of technology integration the faculty is incorporating into their teaching and are directly related to the question of whether faculty model the use of technology in their courses. Responses are evaluated on a 4-point Likert-type scale with the following labels: (1) strongly disagree, (2) somewhat disagree, (3) somewhat agree, and (4) strongly agree. The following is taken from the directions on the survey:

Directions: This survey is designed to gather information on the degree of technology integration you are currently incorporating in your teaching. The statements address what you are actually doing, rather than what you can do.

Use the following scale to gauge the degree to which each statement is true of you:

1 Strongly disagree (You have never tried this, either because you are not comfortable with the technology or because you believe it is not appropriate in your teaching situation or because you don't have access to the necessary technology.)

2 Somewhat disagree (You've tried this once or twice but it has not become a consistent part of your instruction.)

3 Somewhat agree (You do this consistently to some degree but it is not an integral part of your instruction.)

4 Strongly agree (This is a consistent, integral part of your instruction.)

Results

The results of the study are similar to those identified in the literature: faculty (a) are incorporating software packages into the teaching of their subject areas; (b) are using assistive technology (e.g., scanner, digital cameras, video cameras, voice recognition) to develop and deliver instructional units in their
teaching areas; (c) are using technology (e.g., video conferencing) to teach students; (d) are using the internet to gather resources (e.g., lesson plans) for teaching in their subject areas. However, faculty are not using projection devices with a computer to develop and deliver instructional materials in their teaching areas. The following table summarizes the results of the study.

### Table 1: Samples of Faculty Responses by Technology Use

When the participants answered whether they use a variety of software packages to teach in their subject area, 38.5% of the participants stated that they do not use software packages. Similarly, 53.8% of the surveyed faculty stated that they do not use spreadsheet application when teaching. When asked about their use of a scanner to develop and deliver instruction, 76% of the participants answered as not doing so. Of those surveyed, 84.6% stated that they do not use digital cameras to enhance their teaching. Similarly, 92.3% of the participants indicated not using video cameras to develop and deliver their teaching. In relation to the use of assistive technology to promote learning for students with special needs, 88.5% of the participants indicated that they do not use such technology. Of those surveyed, 80% indicated that they do not use technology for distance education and 92.3% stated that they do not use video conferencing to teach in their subject areas. When asked about their use of projection devices, word processing, and use of multimedia, 53.8%, 88.5%, and 69.2% of the participants, respectively, agreed to incorporating them into their teaching. Similarly, 88.4% of the participants agreed to using the Internet in an informed manner and 69.3% agreed that they used lesson plans and other resources published on the web in their teaching.

Convenience sample, sample size, and the use of self-report data limit the findings of this study. However, results are consistent with research findings that preservice program faculty do not model the use of technology and that faculty therefore do not facilitate its implementation in activities and coursework. This lack of technology use is contrary to recommendations that future special educators are more likely to use technology competently if it has been embedded throughout their coursework and field experiences.

### Discussion

Technology integration to provide a supportive classroom learning environment has been discussed as an evaluation tool of an educator's ability to address the individualized needs of students (Crawford & Martin, 2001) as well as a critical component in the success of learners with disabilities (Seever, Crawford, & Martin, 2001). University faculty teaching personnel preparation courses should be modeling the integration of technology for their university students. Research has indicated that effective technology integration may be critical to producing educators who use technology competently to meet the needs of their students through a supportive classroom environment. Additionally, implications related NCATE recommendations and CEC standards for providing a supportive learning environment for students remain an area of concern.
This study used a survey questionnaire to determine whether faculty model the use of technology in educator preparation courses. It measured faculty use of technology not faculty knowledge of technology. It is possible that there is a discrepancy between knowledge and use of technology. Faculty may know more technology than they incorporate into their education personnel preparation courses. Results of this study indicate that some faculty (a) are not incorporating software packages into the teaching of their subject areas; (b) are not using assistive technology (e.g., scanner, digital cameras, video cameras, voice recognition) to develop and deliver their instructional units in their teaching areas; (c) are not using technology (e.g., video conferencing) to teach to their students; (d) are not using the internet to gather resources (e.g., lesson plans) for teaching in their subject areas; and that some faculty (e) are not using projection devices with a computer to develop and deliver instructional materials in their teaching areas. Additionally, the use of the survey questionnaire may have resulted in faculty self-assessing their use of technology in educator preparation course.

Conclusion

In light of faculty responses to the survey, further consideration pertaining to faculty professional development opportunities and curricular integration is imperative. After all, "Computerized electronic technology makes possible not only the wide and rapid distribution of information, but its manipulation, analysis, synthesis, and recombination as well. Through these operations, new knowledge is created that helps us understand ourselves and our world in new ways" (Gibbon, 1987, p. 2). Technology provides the opportunity to expand the realm of the curriculum, but only with faculty time and effort, as well as support of the institution, will appropriate and successful integration occur.

Perhaps consideration should be allocated toward the philosophical framework through which the faculty view their own pedagogical behaviors. A traditional mode of interaction within a classroom environment is one that is supportive. However, a supportive environment that celebrates the successes of the faculty may be described as one in which innovative approaches to teaching are perceived as inventive and appropriately rewarded. "A combination of essential conditions is required for teachers to create learning environments conducive to powerful uses of technology. The most effective learning environments meld traditional approaches and new approaches to facilitate learning of relevant content while addressing individual needs: (International Society for Technology in Education, 2001, paragraph 1).

As university faculty shift toward an integration of technology within their university courses, the modeling of technology use for university students will contribute to the production of education personnel who are competent technology users. This shift may provide the supportive learning environment necessary for education personnel to understand the importance of not only having pedagogical expertise but also of modeling its use through technology (Crawford & Martin, 2001).

Abstract: A number of factors have been shown to influence the acceptance of new technologies in education. Research indicates that training and support are critical factors in the adoption of instructional technology by higher education faculty. This paper is a report on one solution that has shown potential in solving a problem of providing faculty development in instructional technology on multiple campuses with a small development staff at the Center for Teaching and Learning with Technology.

Introduction

With ever-increasing pressure from college administrators, faculty members are being encouraged to embrace technology as a way to increase the number of students served, improve the quality of their instruction, better prepare students for the workplace and reach students not previously served by traditional classroom instruction (Green, 2001). The initial review of the research examined factors reported in the literature as causes of college faculty reluctance to use technology as well as factors that help promote its increased use.

As indicated in Okpala & Okpala (1997) and Spotts & Bowman (1995), while the use of technology is rapidly increasing in the business world, the use of technology in academia is still not widely accepted. Additional evidence in Green (2001) shows that only 14.7% of colleges and universities in his study used course management tools for their online courses and only 30.7% used web pages for class materials. With the need to expand the use of technology increasing, it is important for colleges and universities to recognize the critical issues that impede growth in the use of technology by instructors and address them if their goals are to be met. Identifying incentives and motivational factors that will help expand the use of technology by college faculty will be beneficial to institutions of higher education (Chizar & Williams, 2001). Understanding the need for support systems will assist colleges and universities in planning for the infusion of technology in teaching. Providing adequate user support and assisting faculty with integration of technology in instruction were reported by Green (2001) as two of the most critical issues in on-campus computing for the next two to three years.

The literature review established a foundation for planning and implementing faculty development programs at the New York Institute of Technology's Center for Teaching and Learning with Technology (CTLT) in the use of technology as a tool for instruction. Understanding how faculty use technology, their concerns about technology and factors that help produce positive acceptance by faculty members are keys to successful instructional technology implementation and expansion projects.

The Role of Training

Faculty training is a critical component to successful integration of technology in higher education. The Center for Teaching and Learning with Technology at the New York Institute of Technology (NYIT) was formed with the expressed purpose of providing technology training to the college's faculty.

In recent surveys, Milliron and Leach (1997) and Green (2001) reported that the training structures for developing the technology skills of faculty members are still not in place and yet training is viewed as an essential ingredient in keeping their faculty current. Chizar & Williams (2001) also reported similar findings in their faculty survey.

For a staff development program to meet the needs of the faculty, it is critical that the trainers understand the specific types of technology being used by the faculty and which new technologies may also be useful for them. Gandolfo (1998) and Inman & Mayes (1999) suggest that training programs must be designed...
to allow for multiple training experiences. They found that as faculty become more familiar with technology, their need for additional training in other technologies is likely to increase.

Inman & Mayes (1999) also suggested that there should be a distinct separation of general computer literacy education and basic hardware training from advanced training in more sophisticated technologies. Dusick & Yildirim (2000) also found the need for separation of users and nonusers in training. Experienced users were focused on improving their existing skills through specific training. Nonusers preferred short personal training sessions or small group training sessions (Carey & Dorn 1998). Wilson (2001) also reported that faculty preferred one-on-one or small group training to traditional classroom training settings.

Dusick & Yildirim (2000) and Wilson (2001) found that computer competency and prior computer instruction were significant predictors of the use of computers for instructional purposes by faculty. It is evident from the study that training is an important positive factor in expanding faculty use of computer technology.

Candiotti & Clarke (1998) and Dusick & Yildirim (2000) also found that on-going technical support for faculty while they are learning new technology is critical. Both studies suggested that a modest investment in support staff yields far higher returns in increased faculty use.

**Using Technology to Teach Technology**

Ongoing training and support for faculty also plays a critical role in the expansion of technology use. Trainers must be aware of the types of technology that are available and in use in order to create training programs that will be useful to faculty (Inman & Mayes, 1999; Dusick & Yildirim, 2000).

Green (2001) reported that the single most important information technology support issue for institutions of higher education over the next three years will be assisting faculty to integrate technology into instruction.

Recently, NYIT adopted a new course management system for delivery of the college's online courses. It was selected because of its ease-of-use and intuitive interface. However, the organization of lesson materials in the new system required training for each faculty member using the online delivery system. Over 100 faculty members needed to be trained in a very short amount of time.

Many of the research articles cited the time factor as a deterrent to faculty adoption of technology. Training can only be effective if faculty take advantage of it. It became part of the training plan at CTLT to produce online versions of the training programs for the course management system, online web editors and general best practices for online teaching and learning.

Providing training that is available to faculty online has great potential for increasing faculty participation. Faculty members do not have to manage already tight schedules to attend sessions. They can take the training courses at any time of the day or night when time permits. The ability to work independently also has the potential to alleviate some of the reluctance to attend large group training sessions where their lack of certain technology skills may become more apparent to others.

Online faculty training appears to be a solution with a great deal of potential to provide much needed training while avoiding many of the disadvantages of traditional classroom style training sessions. Although group training sessions are still be offered by the Center, this additional delivery option has provided a way to reach many more faculty members in more different locations.

**Tools that Facilitated Online Training**

Rapid development of online training with a small faculty development staff required tools that were easy to learn, provided flexibility in formats and supported the types of training needed at the Center for Teaching and Learning with Technology. The writer investigated a number of tools designed for online content development and selected a set of web tools from Macromedia (http://www.macromedia.com). They proved to be quite powerful, worked well together, and yet were very intuitive and relatively inexpensive.

The primary tool used was Macromedia Flash 5. The writer was able to create a few simple templates that facilitated the technical training required for a variety of faculty needs. The files created in Flash were remarkably small and required no special plug-in to be viewed on the web. Action scripts built into the software allowed the designer to easily add interactivity that allowed the learner to control the pace and sequence of the instruction. It was possible to import screen captures from programs that the faculty wanted to learn, such as Blackboard or Dreamweaver, and provide step-by-step instructions and guided animations using the actual
displays from the program. Being able to see the screens and read or hear the instructions at the same time proved to be a useful strategy based on initial feedback from the faculty.

Another part of the Macromedia "Web Design Studio" package was another product called Fireworks 4. This graphic manipulation tool allowed the writer to compress the screen captures to reduce the download time without substantially reducing the quality of the images.

Macromedia's Dreamweaver 4 was used to develop and maintain the Center's web site where these tutorials were made available for use by faculty (http://iris.nyit.edu/~ctlt). Dreamweaver's built-in file transfer protocol (FTP) feature made file transfer and updating a relatively easy process.

Initial Results of Faculty Satisfaction

Although the results are quite preliminary at this writing, the initial data, gathered using an online survey instrument, indicate a high level of satisfaction with the use of online technology to assist faculty in learning technology. One of the major factors mentioned by numerous faculty members who used the programs was the convenience of being able to use the training programs anytime and anywhere. This convenience factor may encourage more faculty members to participate in technology-based educational enhancements to their traditional instruction when regularly scheduled training sessions offered by the Center for Teaching and Learning with Technology do not fit their busy teaching schedules.

References

The integration of ICT in teacher education is one of the priorities of Dutch educational policy. Much money is already invested in computer hardware, and although less, in specific software for teacher education. However, the investments in professional development activities for teacher educators in order to integrate this software in their programs pay far behind.

This proposal is about an arrangement for professional development of teacher educators in elementary science. This arrangement aimed at familiarizing teacher educators with multimedia cases. Working with multimedia cases implies a double innovation. The first innovation is about the change in pedagogy of teacher education. Case-based learning in teacher education means a more profound place for classroom practice in the programs. The second innovation refers to the use of ICT for student learning purposes. Both intertwined innovations have implications for the knowledge base of teacher educators, and hence for their professional development. This proposal describes an explorative study on teacher educators learning about multimedia cases. In the next sections an outline is presented of the context of this study followed by brief a description of the methodology and a summary of the main findings.

The MUST-project

The study described in this proposal in part of the MUST project. The acronym MUST stands for Multimedia in Science and Technology. This project is a joint venture on behalf of three Teacher Education Colleges, the National Institute for Curriculum Development and the University of Twente in the Netherlands. The project aims at developing multimedia cases and investigating their impact. At the core of every MUST case is an interactive video-clip of elementary science classrooms. Hyperlinked to this video all kinds of information are added on a CD-ROM, such as comments on the video, facts about the school and the class etc.

Teacher education programs are frequently charged with being irrelevant, overly theoretical and out of touch with the realities of teaching 'on the front lines'. However, situating teacher learning in classroom practice may have as drawback that the kinds of teaching advocated in reform proposals are non-existent in real settings. Case-based learning is perceived as a means to overcome this theory-practice divide and cherish the innovative aspirations of curriculum change. When combined with computer technology, the educational potential of case-based learning may even be enhanced. Multimedia applications add the power of computer technology to approaches of case-based instruction, because these applications can stimulate more than one sense at a time and in doing so, may get and hold more attention (Jonassen & Reeves, 1993, p. 703; Cennamo, Abell, George & Chung, 1996)

"Case methods are expected to be more engaging, more demanding, more intellectually exciting and stimulating, more likely to bridge the chasms between principle and practice, and more likely to help neophytes to learn "to think like a teacher" (Shulman, 1992, p. 1).

Although the advantages of case-based learning is well-documented in literature, empirical studies on their use by teacher educators is scarce. This study tries to make a contribution to fill this gap.

Methodology

The research reported about in this paper was guided by the following two questions:

- Which images do teacher educators associate with the implementation of MUST cases by teacher educators?
- How do teacher educators evaluate their competencies of the different knowledge domains necessary to integrate MUST cases in their curriculum?

Fourteen teacher educators (3 women and 11 men) participated in this study. They all followed a short trajectory of professional development in order to get familiar with the MUST philosophy and products. This trajectory consisted of a one-day workshop, activities with MUST cases at their teacher education college and a finalizing workshop of 5 hours.

The following data have been collected:

- After the first workshop the teacher educator wrote down their impressions of the MUST cases. Their responses were stimulated by expressions such as "What is on your mind when thinking about using MUST cases?"
- Subsequently, the responses are collected per expression and grouped in the following categories:
  - Implications MUST cases from a curriculum perspective;
  - MUST cases and future teachers;
  - MUST cases and teacher educators;

Fourteen teacher educators (3 women and 11 men) participated in this study. They all followed a short trajectory of professional development in order to get familiar with the MUST philosophy and products. This trajectory consisted of a one-day workshop, activities with MUST cases at their teacher education college and a finalizing workshop of 5 hours.
Technical implications of MUST cases.

After the last workshop the teacher educators were asked to evaluate aspects of their knowledge and skills on a 14-item list. They could rate themselves from 1 to 10. (In Table 1 the results are summarized.)

**Results and conclusion**

*Images*

Most remarks were related to MUST cases and the curriculum at the teacher education college (37%). The teacher educators saw good opportunities to integrate the multimedia cases in the existing curriculum at their college. They did not perceive the cases as a springboard for curriculum reform. This is not surprising, because all participants had redesigned their curriculum profoundly in the recent past. The participants express as a major point of concern the lack of time within the curriculum. Multimedia cases capitalize on in-depth information processing. So, from a perspective of content coverage cases are rather in efficient. Teacher educators were afraid that other important topics would get less attention when much time was devoted to the topics in the cases.

About 25% of the remarks were about the anticipated reactions of students on the cases. The teacher educators expected that working with the cases would a motivating experience for their students, especially because of the video-clips of elementary classrooms.

Remarks (20%) were on the technical implication of working with multimedia cases (installation on the computer network and so on.)

18% of the remarks were about the role of the teacher educator, especially how to guide student learning while working with a multimedia case.

*Competencies*

At the end of the second workshop the teacher educators filled out a self-evaluation form.

**Table 1: Knowledge domains in relation to MUST cases**

</tbody>
</table>

N=14

Not unexpectedly, the teacher educators rated themselves highest on their "core business" (science in teacher education). Remarkable is the high rating of the technical competencies to work with multimedia cases, because after the first workshop the participants expressed concerns on this point. Informal conversations with the teacher educators indicated that the first in-college experiences with the cases did not cause any major technical problems.

The teacher educators do not have much insight in the ICT competencies of their students or in the role of ICT in elementary science. This implies that they cannot take a leading role in innovation in elementary science in which ICT plays a significant role. The participants do not feel very comfortable as far as teaching with multimedia cases is concerned. Teacher educators particularly perceive the use of multimedia in interdisciplinary courses as beyond their reach.

**In conclusion:**

The workshops and in-college activities with MUST cases have raised enthusiasm amongst the participants. But the implementation of multimedia cases in an innovative way requires more long-term support and collaboration. Especially the rational behind case-based learning needs more thorough attention, otherwise multimedia cases may be viewed as an interesting and motivating "extra" in a already heavy loaded curriculum.
From a simple PowerPoint™ presentation to a complete online course, technology now allows educators unprecedented freedom to create, modify, and disseminate their own instruction; however, this same freedom also offers unprecedented opportunities to create and disseminate ineffective or poorly designed instruction. Ineffective technology-based instruction often stems from neglect of the basic principles of effective instruction. This paper describes four non-technical tips educators can use to enhance the quality and effectiveness of technology-enriched instruction. They include (a) identifying instructional objectives, (b) understanding the target audience, (c) organizing the content, and (d) preparing for instructional delivery.

Introduction

It is no longer surprising to see P-12 teachers and college or university faculty with the technical ability to create multimedia-rich PowerPoint™ presentations, develop and maintain their own course Web sites, or, with no technical assistance, setup and operate a wide variety of computer-based equipment. As educators, we are rapidly becoming more technologically savvy. Fortunately, many of us are learning to embrace this change and are enjoying the unprecedented freedom technology offers us in our ability to create, modify, and disseminate instruction, however, this same freedom also offers us ample opportunity to produce ineffective or poorly designed instruction. In allowing us to personalize and package the instructional messages we convey to our students, technology also gives us much latitude to miss the mark, and that is precisely the issue raised in this article. Perhaps we need to be reminded that, as we run to jump on the technology bandwagon, we must not forget to bring the basics of good instruction along with us.

Most of us have endured PowerPoint™ presentations with font sizes so small that we could not possibly read the information being presented or lectures by professional educators who stood with their backs to the audience as they read paragraph after paragraph from the information projected on the screen. In these and many other situations, technology, in all its capacity to enhance instruction, only served to impede the dissemination and reception of the intended message. It is with this in mind that we offer a few reminders on how, as professional educators, we can reduce the chances of getting blindly caught up in technology’s enticement and instead, capitalize on its potential to support effective teaching.

Identifying Instructional Objectives

In simple terms, objectives are specific descriptions of what we want the learner to know or be able to do as a result of instruction. Whether we are using PowerPoint™ in the classroom or delivering our instruction online, it is critical that we make the effort to identify specific instructional objectives, even if it requires a considerable amount of time. Surprisingly, many of us spend more time selecting background colors and clip art, digitizing video clips, creating endless lists of hyperlinks to online resources, or toying with any number of technology’s fun and often
frivolous features than we do identifying and incorporating objectives into our technology-based instruction. While technology's bells and whistles or its ability to expedite our productivity should not be neglected, our first priority should be to identify and incorporate instructional objectives in the design and development of our instruction. Determining and writing good objectives is not always, if ever, a quick and easy process. Taking the time to determine instructional objectives, refining them, and then developing content and evaluation methods around them can be a very detailed and time-consuming process. This stands in direct contrast to the expectations we may have of technology and its ability to assist us in rapidly creating a finished product. While convenience and expediency are enticing attributes, as educators, surely we are not willing to trade them for quality and effectiveness.

Understanding the Target Audience

In a traditional setting, when teachers walk into a classroom to teach a lesson or deliver a lecture, they are in direct, face-to-face contact with their audience and can react, make accommodations, and modify the information they are presenting and the way in which they present it based on audience reaction and response. Trained educators know this ability can greatly improve the effectiveness of instruction. Unfortunately, technology, if we allow it to, can easily separate us from the learner.

As many of us have already discovered, our efforts to understand and accommodate our audience often tend to lead us away from the rigid and inflexible presentations that can be so instructionally ineffective and instead, toward the development of presentations that simply support the information we wish to convey. For example, rather than creating a presentation that contains slide after slide of the exact content being presented, forcing the instructor to follow the pre-developed content precisely, we instead find ourselves more often creating presentations that merely contain supporting electronic artifacts such as charts, graphs, maps, photographs, video clips, or a few talking points. By simply augmenting a lecture or presentation with technology instead of letting technology dominate it, we help create an instructional environment that is much more responsive to our audience.

Organizing the Content

The appropriate organization of content is crucial when conveying information or providing instruction. The clear articulation of the content order reduces the chance of misinterpretation or confusion by the learner while assisting him or her in establishing important and necessary associations between the elements that make up the content and between prior knowledge and current information. Fortunately, content organization is often made simple by the content itself. For example, the order in which a step-by-step task such as creating a new slide in PowerPoint is presented is very sequential and straightforward. On the other hand, some content is more open ended and much more complicated to organize. Imagine having to organize the content for a presentation on how to deliver a persuasive oral speech. This type of content could be effectively organized in a wide variety of ways.

It is in the delivery of this open-ended type of material that it becomes crucial for educators to give careful attention to the appropriate organization of content. Unfortunately, as we now find ourselves with the technology-enhanced ability to create our own instruction, we must often assume the responsibility of organizing our instruction ourselves. To do so effectively, we must have a strong understanding of the content itself, of our target audience’s existing skills and knowledge, and of the desired learning outcome we wish to achieve. Based on these, we can begin to organize our instruction or information in clear and appropriate ways.

Preparing for Instructional Delivery

This is perhaps the simplest but most overlooked aspect of delivering effective technology-based instruction. Simply put, make sure everything works before getting up in front of your audience. Audiences or students are no longer tolerant of our lack of preparation and consideration when we don't know how to operate equipment. In addition to being familiar with the operation of the equipment, we must also be familiar with our presentation and its content. Were not suggesting that hours of rehearsal and practice are required in order to deliver a polished and professional presentation, however, adequate steps must be taken to ensure that, as the presenter or teacher, we are familiar with what we are presenting and with the equipment used to present it. Anything less runs the risk of seriously jeopardizing the instructional effectiveness of our presentation. This is a big price to pay for failing to take a few extra minutes to make certain we are prepared.
New Instructional Technology and Faculty Development:
Negotiating the Titanic Through the North Atlantic

Dr. Wanda Bunch, Chief Curriculum Officer, Pitt Community College, Greenville, North Carolina, wbunch@pcc.pitt.cc.nc.us

Dr. Phyllis J. Broughton, Dean of Academic Affairs and Student Services, Martin Community College, Williamston, North Carolina, pbroughton@martin.cc.nc.us

Introduction: What does the Titanic have to do with new instructional technology and faculty development? As we are well aware, the Titanic was an extremely large ship that had to negotiate dangerous icebergs in the North Atlantic. The Titanic was promoted as an unsinkable new ship, guaranteed to deliver its passengers safely and for them to have a most enjoyable trip while moving from one shore to another.

For faculty, technology is that new ship. Like the Titanic, it is not unsinkable. Icebergs can wreck any project. There just has to be good navigation through the icebergs that will inevitably appear in the North Atlantic or in projects that execute change. A point for the navigator to remember is that icebergs are moving objects and hard to chart so what seems like smooth sailing may have some surprises along the way.

Methodology: To execute our plan, three phases were instituted. Phase 1: Recruit interested faculty on PCC campus, provide training in the Blackboard software and offer time, technical guidance and funding for on-line and web enhanced course development during the summer. Phase 2: Seek grant funding to provide released time or technical support to allow faculty time to devote to learning new technology. Offer training to PCC faculty first but invite regional community colleges to participate in the training, as well. Provide guidance and support for faculty interested in going “beyond PowerPoint.” Phase 3: Seek additional grants to develop an E-Mentoring program to have faculty assisting faculty.

These phases were based on faculty needs assessment and again, like the builders of the Titanic, available innovations and demand.

Original Project Objectives:
- Assist faculty in transition to more technology use
- Provide learning in a non-threatening environment
- ‘Incent’ faculty to try new technology
- Increase internet and web enhanced classes across the curricula, to feeder institutions, to other institutions and to the global market

Faculty Involvement: Some faculty are adventurers – ready to try anything new and different; some see the move to incorporate more technology in the classroom and in on-line courses as an imposition on their academic freedom, their personal time and their teaching competency; some feel that the adventurers can try it first, get the kinks out, then they “just might” get on board if someone helps them. The course of action is to
find the incentive for each type of faculty member and use that to ensure their participation. Some types of incentives which can be used are recognition, released time, new equipment, opportunity to be first and "know more," travel and presentation options, leadership opportunities, and the ever popular, cash.

**Funding Sources:** Businesses build incentive programs into marketing and training plans. In most cases, educational institutions, especially ones funded by tax dollars, have little or no ability to start or market new programs without taking funds from some other internal source. As with Pitt Community College, grants and gifts are usually the major outside funding sources but there are other internal sources available, as well. For example (1) lapsed salary funds which must be spent on faculty salaries or be returned to the state can be used for extra contracts for faculty technology skill and course development, (2) Grants with a technology “twist”, (3) partnerships with industry or universities (4) faculty initiative.

### Navigating Faculty Using E-Mentoring for Creating Online Courses and Marketing Materials

**Welcome to E-Mentoring:** A major concept for navigating the Titanic was through team work, with everyone having a major part to play for the success of the trip. Navigation for faculty was through a new technique called “E-mentoring,” also referred to as telementoring or online mentoring. The role of the e-mentor is one of an esteemed educator who has already been down the path of learning technology and gained experience and knowledge to share upon a worthy e-mentee (one who is learning). An E-mentor is compared to the captain of the ship, one who been trained and understands the dangers of currents and plots the course for a successful trip.

With the year 2000, the Internet and technology has improved the way of doing business with the working world. The traditional role of mentoring has expanded and evolved as well. Technology has allowed up to alter the traditional method of mentoring, allowing the workforce and education to tap the career advice of a mentor from virtually anywhere in the world.

**Goal:**
With the use of E-Mentoring, the goal of this project was to provide a means for creative and interactive learning that involved significant and continuous participation among faculty as a team to develop online courses or marketing materials.

**Objectives:**
1. To use new tools and technologies to extend educational access to faculty for communication and online development.
2. To implement technology to improve the quality of teaching in face-to-face classrooms, web-enhanced courses, and online courses.
3. To change the nature of the teaching-learning interaction to involve learners more direction, support, and guidance in creating effective learning environments through the use of technology.

4. To develop marketing materials for CDs and/or web applications.

What is E-Mentoring? E-mentoring is an interactive relationship between a mentor and a mentee through the use of the Internet, e-mail, information highway, discussion groups, chat rooms, etc. For our training, e-mentors are the pioneers who have already designed, developed, implemented, and evaluated online courses. The e-mentors possess a wealth of knowledge and experience in technology and course design. They have the knowledge of “what works” and “what doesn’t work.”

E-Mentoring is a Team Effort: Developing online courses is a team effort and everyone brings a certain about of expertise to the team. In this project, the following roles and responsibilities were as follows:

- Faculty mentors: The faculty member of instructor assumes the role of the instructional or content expert. He or She is responsible for planning, implementing, and evaluating instructional materials. The Faculty Mentor also assists in locating resources and course materials appropriate for course content. He or She assists in helping Faculty Mentees solve problems related to organizational structure and policies.

- Technology mentors: A Technology Mentor assumes the role of assisting with instructional and graphic design and the logistics of structural design. This person is responsible for assisting the instructor in selecting software and hardware appropriate for specific course results. This person assists in designing specialized graphics; visuals and print materials; web-based materials; and audio, video, and digital requests. The Technology Mentor is also responsible for equipment setup, network connections, testing, and troubleshooting course design applications. This is a critical role in that the Technology Mentor advises the instructor how to develop course content and learning strategies to blend with software and hardware capabilities. Technology Mentors may be on your campus or at a distance. FTP (File Transfer Protocol) can be used for Technology Mentors off your campus.

- Faculty Mentees: The Faculty Mentee assumes the role of the learner by researching and working closely with a Faculty Mentor and Technology Mentor in course development. Faculty Mentees tasks include:
  - communicating frequently with Faculty and Technology Mentors
  - preparing and following a timeline
  - developing course content and learning strategies
  - obtaining copyright approvals
  - developing contingency plans
  - taking care of program logistics
  - preparing course resources ahead of time
  - providing feedback to learners
About the E-Mentoring Project.
This e-mentoring project is funded by the North Carolina Community College system’s grant. The grant is available from September 2001 to May 2002. This project is also unique because the e-mentoring took place between two community colleges. Martin Community College is located in Williamston, North Carolina, and Pitt Community College is in Greenville, North Carolina. Pitt Community College provided the Technology Mentors for Martin Community College.

The mentoring project included synchronous and asynchronous communication and learning.
- Synchronous communication is when mentors/mentee are online at the same time. This includes brainstorming, role playing, and discussing course content in real time.
- Asynchronous interaction is communication that takes place outside of real time. Mentors and mentees participate at times that are convenient for them. This delayed interaction allows mentors/mentees time to reflect and pace themselves and to check resources and references before contributing to online discussion.

Summary:
A series of training and application were conducted throughout 2001-2002. Approximately 123 faculty from 13 other community colleges participated in the training. Technology funds provided training and travel opportunities for faculty during a period when there were severe budgetary constraints with the community colleges. Funding provided release time for faculty, technical personnel to assist in software and hardware needs, and specific training and resources for course design. A web page was maintained for convenience for participants for information and updates.

Upon completion of this project, faculty will showcase marketing CDs (Commercial Refrigeration and Welding) and online course development. Materials developed are available for other colleges to share and use as resources.
Evolution of Faculty Web Page and Video Skills: A P³T³ Case Study

Abstract A primary mission of staff working with the Purdue Program to Prepare Tomorrow's Teachers to Use Technology Project (P³T³) is to train faculty members in the School of Education to use technology and serve as mentors during the learning process. This study was initiated to investigate how select faculty members evolved as they integrated technology into their work, how they perceived technology integration, and how effective and efficient their strategies were to use technology in their teaching. In addition, existing problems in faculty training, and inefficient processes in technology integration were investigated. The authors provide tentative solutions to these problems and suggestions for possible early intervention in an effort to prevent similar problems in the future.

Introduction

Among other goals, the Purdue Program to Prepare Tomorrow's Teachers to Use Technology (P³T³) is designed to prepare pre-service teachers to demonstrate fundamental technology competencies, and prepare teacher education faculty to teach pre-service teachers in technology-rich environments by modeling approaches that future teachers should use themselves. In order to achieve this goal, P³T³ incorporates a comprehensive faculty development and mentoring program, which is the focus of this paper. P³T³ combines workshops, training sessions, and one-on-one mentoring. Workshops, which are conducted at the beginning of each semester and during summer breaks, consist of a two-day "start-up" session followed by three or more days of focused skills development. In the first two days participating faculty members engage in problem-based learning activities involving technology integration. This is followed by previews of technology skills development workshops and consideration of models of technology integration in education. At the conclusion of the "start-up" sessions, faculty members develop and share personal technology integration plans. Based upon the technology integration plan, a graduate student — skilled in the appropriate software/hardware to meet the goals of the faculty member — is assigned to provide optimal mentoring throughout the integration of technology into teaching during the following academic year. Subsequent sessions include workshops on WebCT, PowerPoint, FrontPage, and Dreamweaver, and "how to" sessions focusing on the use of digital video, digital photography, HTML programming language, and Purdue's career account system (supporting centrally managed storage for files and web pages).
Through workshop and personal mentor training provided by the P3T3 graduate assistants, some faculty made great strides in the development of technology skills. Others attended the same workshops but encountered major struggles and challenges as they attempted to incorporate technology into their courses. A few faculty members chose to continue their curriculum in the same manner as it always was – without the addition of new technology. What are the reasons for this broad spectrum of use? Why did some faculty members perform exceptionally well? Why did some find the challenges so overwhelming? And why are there still faculty members who choose not to use technology?

Theoretical Framework

Considering the rapid pace of development in educational technologies, coupled with innovations in teaching and learning, utilizing technology is high on the list of priorities of educational managers, administrators and operatives. Sandholtz et al. (1997) noted the use of technology is recognized as a valuable tool – making technology more common while developing it to enhance teaching and learning. However, Brand (1998) found that despite increased access to computers and related technology, educators are experiencing difficulty in combining technology into classroom teaching practice. Training and mentoring provide two major incentives in aiding faculty to successfully integrate technology in teaching (Dusick, 1998; Dusick & Yildirim, 2000).

Methodology

This research relied on case studies conducted by two of the authors. Both of us are proficient technology users and work as graduate assistants in the P3T3 program. We serve as mentors for the faculty members and have been involved with the project since its inception in the summer of 2000.

Through an interview process, we videotaped or tape recorded responses from three faculty members and a teaching assistant. Two additional faculty members included in this paper were not interviewed, but information was recorded from interviews with the P3T3 assistant assigned as their mentor. Completed faculty projects were also used as a source of information for the subjects – websites and edited video projects provide evidence of faculty involvement with technology. Subjects were selected to include those who successfully learned and integrated technology and those who chose not to make changes. The faculty members have been teaching from 10 to 37 years in K-12 and higher education. One faculty member was proficient with technology, but the others were at various developmental stages of computer skills. For the purposes of this study, they were categorized into two groups: those who used web design software to develop websites, and those who attempted to incorporate video into their curriculum or course presentations. We conducted the interviews to explore faculty member attitudes toward technology integration, the strategies they used to learn the technology and integrate it into their teaching, and to determine the challenges they faced as they incorporated the new skills.

Website Integration

Three faculty members were interviewed about website integration. Two had no prior experience with website development but the third was familiar with website design, as she maintains her own website.

Successes

Dr. F. has been a professor in the School of Education for more than 10 years. After attending the faculty workshops, with the help of her P3T3 mentor she created her own web pages and a separate website related to her research interests. Professor F. stated, "There are several people I work with that use web pages... It's very convenient for me to get information. Web pages look like the information source. The assistance I get from P3T3... definitely impacted me to have my own web page. I don't have the technical skills to do
it, but after I went to the Dreamweaver workshop, I know what I can do.” Dr. A. had been an administrator in the K-12 school setting for more than 30 years. He has been a Professor in the School of Education for three years. Like Dr. F., he created his web pages with the help of his P^3T^3 mentor after attending the faculty workshops. Dr. A. stated, “I use the web a lot in my work area…this university is a highly-technology involved university. Both of these are motivations for me to create a website for myself.” Dr. E. has more than 5 years of experience as a professor in the School of Education. Recognizing the value of the web as a communication tool for her students, her associates at other universities, and the outside world even before the P^3T^3 project began, she employed a graduate assistant to create her own website. After attending the P^3T^3 workshops, he was excited about converting her designs from FrontPage on a PC operating system to Dreamweaver on the Macintosh platform. With positive reinforcement from her P^3T^3 mentor and technical help when she needs it, she has plans underway to transfer the pages to the new format rather than recreating the pages in a new website.

Challenges

Some challenges were more easily solved than others. Dr. A. was faced with the introduction of web-editing software that was different from the one he had originally learned. He stated, “The changing of the software forced me to learn the new technology. However, it’ll be a long process for me to learn and update the new software.” Dr. F. stated, “Faculty’s time is very tight.” Dr. E. agreed and also stated that she is a Mac user; however some web design software, like FrontPage, is just for the PC. Her need for P^3T^3 assistance occurred when she found a need to update her current site. She approached a P^3T^3 assistant and together they experienced a great deal of difficulty making edits, even when working on the platform used to create the pages. Because the grad student who made the original site was no longer available for advice about specific programming, editing was neither efficient nor easy. After unsuccessful attempts to edit the pages in a manner the faculty member could understand and duplicate, the P^3T^3 mentor recognized the faculty member’s confusion and frustration. The mentor chose to work on the site alone, read the HTML coding, identify the problems associated with the programming, and save new documents. When the mentor and Dr. E. met again, Dr. E. successfully updated the new documents. The mentor’s decision to work on the project alone prevented Dr. E. from becoming frustrated to a point of choosing not to make future changes. If she had faced the problems alone, they may have been overwhelming. By finding the problems and creating documents that could be more easily edited, the mentor helped the faculty member gain experience and confidence. Currently she needs little more than occasional help for her updates.

Impact of P^3T^3

Professor F. stated, “Without the assistance of P^3T^3, I don’t know if I would have created [a site] or not. I got hands-on experience, and specific handouts in the workshop; I get back and use it. After the workshop, I got individualized help from P^3T^3. P^3T^3 provided me encouragement, support, a sense of ‘can-do’ confidence.” Professor A. stated, “The P^3T^3 assistant has been indispensable for me to put that [site] on. [She] helped me a lot. It would not be on so quickly, in such a quality without [her] help. I really appreciate [the] help.” In contrast, Professor E. stated, “I went to a couple of FrontPage workshops, but they didn’t get to the level and skills I needed. They just start teaching how to create a new page, how to insert graphics.” P3T3 one-on-one mentoring provided the required help.

As P^3T^3 mentors work with faculty, we must strive to help them determine the correct software before their projects begin. When projects are already underway, we must recognize when faculty members become frustrated and find ways to minimize the frustration and provide alternatives to motivate the faculty to continue making personal technical advancements. We must also meet the needs of faculty who already have some expertise but desire to learn skills beyond those taught in beginning workshops.

Video Editing

Several faculty members showed interest in adding video to their coursework after viewing a demonstration using iMovie on a Macintosh to make a video clip from a digital camera. Four faculty members subsequently purchased digital video cameras with a stipend provided from the P^3T^3 project. Others
decided to use one of 14 cameras already available in the department. A variety of results occurred from the purchase of these cameras and the incorporation of digital videos. One faculty member and one teaching assistant were interviewed for this case study, as well as two P^T^3 assistants working as a faculty mentors.

Successes

Teaching Assistant Mrs. L taped an interview with a Master Teacher in a K-12 classroom and desired to edit the tape prior to introducing the teacher to her students. She was immediately provided with personnel resources and training to complete the work within her timeline. The result was a teaching assistant with a new skill, and a polished final product that succeeded in meeting her objectives. Dr. E. first became involved with video through a 3-year project she headed in the Educational Technology Department – a few years before the P^T^3 project began. Although she had extensive experience with video, she took a more personal interest in adding it to her curriculum when she saw the ease of digital video editing as presented in the P^T^3 workshops. As a direct result, she purchased a digital camera and began working with it herself without the aid of her mentor. Soon she was editing the videos and she currently has plans to incorporate video in her classroom in the future.

Challenges

Even though Mrs. L. is a new teaching assistant in the School of Education, she set her project into motion with a set of clearly defined goals. However, she didn’t realize the amount of video-editing time required to meet her goals. With her new responsibilities and minimal free time she was overwhelmed with the task she needed to accomplish. Professor G, a 17-year faculty member at Purdue, wanted to use video to document his research, but he became disinterested when he found that he could not use his video camera to download still photos to his Macintosh due to platform issues. Professor C, a Visiting Professor in the School, attended a P^T^3 faculty workshop session designed to build computer skills through the use of hands-on training but experienced difficulty during the sessions. She commented that she did not learn skills when she was guided through each “point and click.” Even though she wasn’t comfortable with her own use of the technology, she realized its importance to the students so she added a video assignment to her undergraduate course curriculum. While this project had great potential, neither she nor her course instructors had the skills to support the activity. When it became clear that P^T^3 staff would be unable to provide support for more than 400 students since the P^T^3 project concentrates on faculty development, Dr. C. changed the assignment and made it clear to P^T^3 staff that her teachers were too busy teaching course content – that “they don’t have the time to teach technology.”

Impact Of P^T^3

Each instructor had different reasons to use video – personal research, interviewing guests, curriculum enhancement, and challenging students. Professors G and C do not have plans to continue using video at this time. Some of their setback lies in their lack of research and quick decision-making. Dr. G purchased a camcorder before realizing it did not fit his needs, and Dr. C assigned a student project before verifying resources for support. Ms. L. was overwhelmed by the amount of work necessary to edit the tape, and didn’t plan enough time to do it by herself, but she communicated her needs effectively and P^T^3 was able to obtain help so she could meet her goals. Each of these instructors had limited experience with technology. On the other hand, “Dr. E.” is technology proficient and realized she needed to take time with a camera and learn to use it prior to adding the component to her classroom, choosing a slower path without the need to discuss it with her P^T^3 mentor.

It is easy to become motivated to learn a new skill when opportunities arise, and experienced P^T^3 assistants make the technology appear simple. However, learning a new skill takes time; two of the faculty members lost motivation when they learned that their goals had a price that was too high (in time and/or the requirement to learn and teach a new skill). In the future, as P^T^3 introduces new technology, we can learn from the two faculty members who were successful. We need to recognize signs that instructors are
planning unattainable goals and try to more effectively communicate the time and resources necessary to integrate new technologies so that the instructors have a better chance of success in developing realistic goals in the future.

Outcomes

The study shares successes for some faculty, but more importantly it identifies problems for faculty that include frustration during “point and click” hands-on workshops, platform-dependent issues, lack of awareness of the scope of some technology-integration issues, and a need for better pre-planning. Workshop instructors and mentors must analyze their audience/mentees and strive to meet their needs rather than assume all learners need basic skills. For example, let the participants bring questions and specific needs or challenges to the workshops. Help them understand what they can achieve at the end of their training. When tasks appear to be as simple as a “point and click” PT3 staff must be capable of explaining the learning curve necessary to become proficient with the software and hardware. Most of the workshops are conducted on PC computers, and skills may not translate easily to Macs. Although many software programs are seamless today, there are issues when older versions of software are used, and these issues should be addressed. Mentors have an obligation to give faculty confidence in themselves by helping them determine realistic tasks using reasonable time and effort while using the appropriate equipment to meet their goals. Faculty must be able to practice and use their new skills in their own time on their own computers so they are motivated to continue to increase their skills and become independent users of the technology who no longer need assistance. With the new skills, they will develop their curriculum to include technology designed for teachers of the future, and those of us involved with the PT3 project will have met our goals.

SECTION EDITOR:
Bernard Robin, University of Houston

For those of you who have been involved in technology and teacher education for a number of years, you may remember the days of the text-only Internet. It was less than ten years ago that there was no World Wide Web (do we even call it that anymore?), there were few if any pictures to access electronically, and multimedia files being available online was but a dream of futuristic things to come. What a difference a decade and a couple of billion web pages make! Today's Internet users are bombarded with an almost endless stream of images, animations and ever more sophisticated multimedia resources. And the prediction is that we have only seen the beginning. According to the Consumer Electronics Association, the DVD is the fastest-growing consumer electronics product of all time. Digital cameras are being sold in record numbers and in the US., digital television sales are estimated to exceed 10 million within the next five years. Recent surveys indicate that almost one fourth of the U.S. population over the age of 12 has downloaded music from the Internet and the number is growing.

Since the first graphical web browser became widely available in 1993, the text-only Internet has become increasingly less useful and less interesting. Emerging technologies, rich with media of all types and description, are converging in numerous and unanticipated ways that capture our imaginations and engage all types of learners. The opportunities for educators interested in taking advantage of these technologies are likewise growing but many challenges will arise for teacher education programs that understand that they cannot ignore the technological revolution that is part of our world.

With this year's SITE conference, a new strand has been added to showcase the convergence of the art education, technology and teacher education. With this addition, we hope to begin a series of dialogues and encourage an exchange of ideas on issues related to the coming together of art and music education, museums, technology and teacher education. With this first attempt, we focus primarily on educational projects involving museums of art. Museums in general, and art museums, specifically, are already enthusiastic technology users and providers of educational content on the web. In 1995, only about 120 museums had a web site, but by 1997, that number had increased ten times to 1200. Today, just about every major museum in the world has some type of online presence but the work now has shifted to adding quality and not just quantity. Museums are participating in partnerships with other organizations and collaborations with schools and universities are helping shape the use of new technologies to support teachers, students and all learners. Projects that have already been developed from such partnerships include the creation of virtual exhibitions, the writing of lesson plans that use museum content and the implementation of programs that bring teachers and students to museums for workshops, seminars and special projects.

The number of articles in this section is understandably small this first year but already, they reflect the diversity of programs already underway. We feel certain that in time, the convergence of the arts, art education, technology and teacher education, in all of its possible variations, will expand to include even more components. We hope to bring together art and music educators, museum education staff, technology specialists and teacher educators who can help re-design existing programs and create innovative new ones. We invite all others interested in these ideas, including K-12 teachers, researchers, and other community partners, to join us and share our excitement as we announce this new section for SITE.
Expanding the Boundaries of the Music Education for the Elementary Teacher Classroom with Information Technology

Dr. Cheryl Jackson  
Music Education  
College of Education  
Eastern Kentucky University  
United States  
Cheryl.Jackson@eku.edu

Abstract: This paper is a report on how information technology is used in a music methods course for elementary education majors. The National Council for Accreditation of Teacher Education (NCATE), the National Association of Schools of Music (NASM), and the Kentucky Department of Education: New Teacher Standards call for teacher educators to address issues of teaching with technology. Information technology is incorporated into the Music Education for the Elementary Classroom Teacher course, especially through the use of Blackboard 5. Each student enrolled in the course has access to the course syllabus, project guides and other important information. To be able to use Blackboard, each student must be familiar with the Internet, email, and simple word processing. Effective uses of technology are modeled as sources of information, aids to effective teaching and learning, and a starting point for knowledge and the advancement of pedagogical skills.

Introduction

The Music Education for the Elementary Classroom Teacher course is required of all elementary education majors at Eastern Kentucky University. The trepidation of some of the students in the music education course is evident. Some are fearful of the music class, in general. Some are fearful of using the web-enhanced component of the course. Many of the elementary generalist education majors in the music education course are non-traditional students. Therefore, some of them have not had a great deal of experience in using computers. The author can understand this fear. Several years ago when the author began teaching in the public school system, the audio system that was used to play recordings, or an electronic keyboard, or other electronically amplified musical instrument were considered as using technology in the music classroom. The definition and scope of technology in the music and general classrooms has been significantly augmented. The National Council for Accreditation of Teacher Education (NCATE), National Association of Schools of Music (NASM), and the Kentucky Department of Education in the New Teacher Standards direct teacher educators to address issues of teaching with technology. Due to the importance of music and technology in the curriculum, future teachers must have many opportunities to develop and strengthen their skills in both areas.

A review of literature yielded very few articles that specifically addressed the use of technology with music education methods courses. As stated in the summary of agreements made at the Housewright Symposium on the Future of Music Education, held in Tallahassee, Florida, September 23-26, 1999, "Societal and technological changes will have an enormous impact for the future of music education." It is imperative that all persons are enabled to “participate fully in the best music experiences possible (National Association for Music Education, 1999).” Kimberly C. Walls’ article (2000) presents some ideas for addressing technology competency in music education courses. Typical music education courses must include a great deal of information in a very short period of time. Therefore, the content of the course can be extremely condensed. This fact is especially true of the Music Education for the Elementary Classroom Teacher. The fundamentals of music are presented during the first half of the semester, leaving the remainder of the semester for elementary classroom instrument music performance skills, music teaching techniques, and other culminating activities. Information technology should enhance the course objectives rather than merely adding to them. As suggested by Walls, technology may be easily integrated into a music education methods course through the use of email assignments and on-line course materials (19).
Perhaps one of the most attractive features of using the web-enhanced component of the music methods course is the ability to access assignments and course documents from one's own home or computer laboratory any time day or night. Many of the music education students in the current report would agree with one of the subjects in the Bauer study, "I like being able to access course materials at a time that suits my own schedule and preferences." Bauer's study also addressed the attitude of the students toward web-enhanced learning experiences. "The degree of accessibility to Internet resources, along with the individual characteristics of students who use these resources, may be related to student attitudes toward this instructional methodology (Bauer, 1999)." As the web-enhanced component becomes user-friendlier and as the students' skills are strengthened, the attitudes toward the web-enhanced assignments may become more positive. On the other hand, as stated in the Bauer and Daugherty 2001 study, "Students indicated that they would not like to take a course that was conducted entirely over the Internet" (32). The course content of the Music Education for the Elementary Classroom Teacher would not lend itself to being taught entirely on-line. The success of many of the activities and assignments relies upon on-site classroom instruction with face-to-face communication to achieve some of the course objectives.

Blackboard

At Eastern Kentucky University the use of Blackboard has increased since it was placed into service. Since the music methods course includes a great deal of hands-on activities, one may not realize the benefits of an on-line component upon first glance of the course. However, the incorporation of Blackboard has enhanced the course objectives and has proven to be a great classroom aid to the students and the instructor. "Blackboard 5 is a comprehensive and flexible e-Learning software platform that delivers a course management system, and, with a Level Two or Level Three license, a customizable institution-wide portal and online communities." (Blackboard Inc. 2001).

The course syllabus, course calendar, and project guides are all posted on Blackboard to which each student enrolled in Music Education for the Elementary Classroom Teacher course has access. Each student may access the information from the comfort of his or her own home or from one of the computer laboratories on campus. To be able to use Blackboard, each student must be familiar with the Internet, email, and simple word processing. The following features in Blackboard are used for the music education course: (a) Announcements, (b) Syllabus, (c) Assignments, (d) Communication, (e) Discussion Boards, (f) Digital Drop Box, and (g) Online Gradebook.

The Announcements page is the opening page. When the instructor needs to communicate an announcement to all students enrolled in the course, then the message is posted on that page. As previously mentioned, the Syllabus section includes the course syllabus, course calendar, and project guides with scoring rubrics. The students are enabled to retrieve these important documents at any time during the semester. The on-line availability of the course documents serves as a timesaving and cost-effective method of distributing materials to students.

The Assignments page is used to post coursework that needs particular explanation. For example, one of the requirements of the course includes each student teaching a mini music lesson in a mock elementary setting to his or her peers. A comprehensive Peer Teaching Lab informational packet is posted to the Assignments section. The Communication section is handy for sending messages to individual students about exemplary projects or missing projects.

The Discussion Board provides a forum for students to pose questions to their peers or the instructor. The instructor may set up a forum based on a particular topic. Many of the students in the music education class have had no, or very little, musical training. The Discussion Board allows the students to ask questions about the fundamental elements of music, and then, it allows their peers who have had musical training to answer their questions, thereby providing them with teaching moments.

The Digital Drop Box allows students to send their written projects to the instructor, and it provides a place to store their projects. The students have the option of sending written projects to the instructor via the Digital Drop Box instead of via email attachments. Sending the material by means of the Drop Box is more practical than filling the email inbox with a large quantity of messages. Many of the students at Eastern Kentucky University commute long distances; therefore, the ability to deliver written reports via Blackboard's Digital Drop Box proves to be very handy. The Online Gradebook allows the students to check their grades at any time. It enables the instructor to organize the Gradebook entries and weight the various entries.
The web-enhanced component allows the students to take ownership of the course documents and information that is posted to Blackboard. Use of this component is a most efficient way of communicating with the students. The flexibility of anonymity or working with peers online serves as a very attractive feature.

Inconveniences with Blackboard

Although the Blackboard software has many advantages, a few inconveniences exist in the system. For example, some students have problems using the Digital Drop Box. When a student uses word processing software other than Microsoft Word, then the file may not come through at all. Word Perfect files will work, but the formatting may be changed. Also, the student must remember to add the file, and then to send the file. Often a student will not complete the final step. They also receive no confirmation that the file has actually been sent.

Three to four sections of the music education course are offered. One major drawback to the Online Gradebook is that it provides a single alphabetic listing of all the students. The students’ names are not separated into individual sections. Each section may have from twenty-five to twenty-eight students. The creation of groups is tedious for sections of more than about ten students.

Entering large documents such as the course syllabus, for example, requires a very rudimentary knowledge of HTML. When first getting acquainted with Blackboard, importing documents can be somewhat problematic.

Eastern Kentucky University has updated the current version of Blackboard 5 to Blackboard 5.5. Some of the new features include the following: (a) weighting grades in the Gradebook; (b) displaying Announcements; (c) Setting Release Dates; and (d) Setting the Entry Point for the course. “Weighting grades in the Gradebook” needs no further explanation and has been discussed earlier. Concerning the displaying of Announcements: in the older version, the instructor had to mark an announcement as “permanent” to have it show on the opening tab. Otherwise, the announcement would only be visible for one day. In the newer version, the Announcement is automatically displayed for one week. The “Setting Release Dates” feature allows the instructor to choose a period of time that the document will be available to the students. As previously mentioned, the Announcements panel was the opening page in Blackboard 5. In Blackboard 5.5, an instructor may select the area of the course to appear as the opening page.

Additional Strategies

In the Music Education for the Classroom Teacher course, the students design and construct a Music Materials Notebook. The project is a collection of music related materials that the generalist teacher may use in his or her classroom. Students are encouraged to search the Internet for songs, bulletin board ideas, lesson plan ideas, and many other items for use in the Notebook. One of the sections of the Notebook is a personal entry. The students are encouraged to use their creativity in including a comprehensive section that is of special interest to them. The following are among the choices (found on the Internet) that students have included: a list of web sites that relate to music instruction, music games, music worksheets (crossword puzzles, word search, fill-in-the-blank, etc.), or piggyback songs (new words to “old” tunes).

As previously mentioned, each student designs and implements a mini lesson that includes music in a mock elementary class setting. The Peer Teaching Lab allows each student to practice many of the acquired musical skills with his or her peers, as well as enables the student to practice teaching techniques discussed in class. Students are encouraged to retrieve ideas for lessons from various sources including the Internet. In addition, they are required to use technology in their mini lessons. Moreover, students have used compact disks that they have created to provide accompaniment or listening examples.

Special Education majors, who take the music education course, are encouraged to survey the National Association of Music Therapy Website for relevant information. This particular site is kept up to date and is very helpful not only for the Special Education majors, but also for the elementary education majors.

Conclusion
The students' skills are strengthened through technology-enhanced assignments. Moreover, the assignments will prove to be useful in the future teachers' classrooms. As a teacher of teachers, the instructor is expected to model effective uses of technology as sources of information, aids to effective teaching and learning, and a starting point for knowledge and the advancement of pedagogical skills. Therefore, the students will best be served by incorporating authentic and relevant technology-enhanced assignments.

Those teacher educators incorporating technology into music or other fine and performing arts methods courses should be sharing their insights and experiences. If we are to truly expand the boundaries of our methods classrooms, then strategies and technology-based activities must be reported and documented.

Sara Wilson McKay, University of Houston, Art Education Program swilsonmckay@uh.edu
Sara G. McNeil, University of Houston, Instructional Technology Program smcneil@uh.edu
Donna Odle Smith, University of Houston, Instructional Technology Program odlsmith@uh.edu

Abstract: The focus of this panel discussion is to examine how art museums are creating partnerships with schools, universities, and teachers to design and develop technology-based instructional resources that can be used by students, in-service teachers, pre-service teachers, and the general public. Education specialists from the National Gallery of Art and the Museum of Fine Arts, Houston, along with educators from the University of Houston and George Washington University, will describe the programs they are creating and discuss the benefits, challenges, and lessons learned from these collaborations. The panelist will explore the role of museum educators and their institutions as they embrace and utilize technology as part of their mission to work with teachers and schools. University faculty and students will also discuss the challenges involved in creating and taking graduate level courses that utilize museum content and resources.

The National Gallery of Art's Project: 2001: A Cyberspace Odyssey
Phyllis Hecht, Web Manager, National Gallery of Art
Julie Springer, Coordinator, Teacher Programs, National Gallery of Art
Natalie Milman, Assistant Professor, George Washington University

This education initiative at the National Gallery of Art was the first of two annual programs designed to explore online technologies as tools for studying and teaching art. Open to teachers nationwide, participants began to plan and develop online programs that will integrate K-12 curriculum content, constructivist learning theories, and the art collections of the Gallery. The technology initiative was the most recent incarnation of a professional development seminar, The National Teacher Institute, that has been offered every summer at the Gallery since 1989. The Institute was established with the belief that the best teachers are those who make time to renew their skills and rededicate themselves to lifelong learning.

The goals of the 2001 program were two-fold: to strengthen teachers' skills and comfort levels using online technologies and to help them develop Web resources that they or their students could use in the classroom or during independent research. A select number of the final projects will be edited and published on the National Gallery's Web site for use by the online community of K-12 educators.

A major challenge was how best to establish certain parameters for the content and design of the projects, while allowing for the inventiveness and creativity of individual teams. We also wanted to ensure that finished products met teachers' specific curriculum and instructional needs, while constituting useful resources for the wide variety of K-12 educators who would be accessing them through the National Gallery's Web site (http://www.nga.gov).

We also realized that many of the teachers selected to participate, although experienced in writing lessons or curricula, would not have sophisticated skills writing or designing for the visually-based, dynamic
medium of the Web. The six-day program was thus framed to facilitate understanding of effective Web use, and good Web site design and writing. We began by introducing teachers to the collections of the National Gallery by showing them how to use the Gallery's Web site search engines in order to find the best objects to support their curriculum projects. Reading assignments and critiques of select Web sites done prior to their arrival in Washington helped prepare them for selecting the best activity structures and design features for their projects. Armed with these insights, teams were then asked to refine or refocus their original proposals for brief presentations at week's end.

Another challenge was how to support teachers once they left Washington and keep them motivated and working once they returned to teaching full-time. Each team was assigned two mentors with whom they could brainstorm and problem-solve through e-mail and phone communications. One mentor was qualified to advise on the content development of their project; the other on the technology and software issues faced in building their projects. A listserv was established to facilitate communication among the teams and Gallery staff members. A password-protected Web site was also established to allow easy reference to project guidelines and deadlines, links to educational resources and software tutorials, and to provide work spaces to build their individual projects.

Recommendations from the Museum of Fine Arts, Houston Education Department
Beth B. Schneider, Education Director, Museum of Fine Arts, Houston

Since 1997, the Museum of Fine Arts, Houston (MFAH) has collaborated with the Program in Instructional Technology in the College of Education at the University of Houston (UH) to design a series of Web site components. These include the Bayou Bend Web site for the Bayou Bend Collection and Gardens (http://www.bayoubend.uh.edu), the American decorative arts (1640-1880) wing of the MFAH; a temporary traveling exhibition Web site for The Grandeur of Viceregal Mexico: Treasures from the Museo Franz Mayer (http://www.fm.coe.uh.edu), a private art museum in Mexico City (March 2002 launch); an online catalogue and order form for materials from the MFAH Teacher Resource Center (online spring 2002); and a prototype Web site for kids. The Bayou Bend and Grandeur of Viceregal Mexico sites were each developed over several semesters by graduate students enrolled in Web design and multimedia classes. Each semester, a different group of students enrolled in the course. For the online catalogue, a staff member in Instructional Technology and a graduate student, took a printed catalogue and, using Cold Fusion, created an online catalogue from which teachers in Texas can order free loan materials from the museum. In another project, middle school students participated in a four-session enrichment experience called "Multimedia Masters." Each session lasted a full day, with part of the activities taking place at the MFAH and others taking place at the university. The Spring Independent School District had collaborated with UH on this activity in the past, and in the fall of 2001, focused the class on a kids' Web component for the MFAH. Through these various partnerships with UH graduate students, faculty, and staff, the MFAH education team has learned valuable lessons about collaborating on Web site development with universities.

For all of these projects, the people developing the Web sites had to learn about the technology and also about art, a new topic for almost all concerned. Graduate students, most of whom worked full time while attending school, had to acquire new technological skills and learn content from a very unfamiliar field of study: art and art history. The enthusiasm of the museum staff and UH faculty for these projects, meant that each project was overly ambitious – although all were completed as planned. The deadlines inherent in an exhibition Web site are much more demanding that those for content focusing on art in the museum’s own collections. Finally, the MFAH had a rather small and inadequate Web site that, until late in 2001, did not have the same sophisticated level of design and content as did the MFAH’s traditional publications. The museum does not at this time have a full-time Webmaster.

For other museum’s planning collaborations with local universities in the development of Web site components, some of the lessons learned from the MFAH/University of Houston partnership are described below:
Focus on your permanent collection and on those works of art which have been published, have been the focus of research, for which you have images and curatorial expertise. The great challenge of working with temporary exhibitions is that text and images are often not available far enough in advance for students to have enough time to develop the site.

Begin with projects that do not have definite time restrictions. An exhibition Web site has to be ready to launch a month or so before an exhibition opens. A component of the museum Web site focusing on an aspect of the permanent collection often has greater flexibility and the museum can respond to the needs of students developing the site.

Be realistic in the scope of your initial projects. The Bayou Bend Web site was developed from three existing brochures focusing on Bayou Bend's collection, founder, and gardens and architecture. Students had access to abundant research and images. The Grandeur of Viceregal Mexico project had little advance scholarship accessible in English; few texts on the specific objects; few images until well into the project.

Be prepared to spend a significant amount of time working with faculty and students. MFAH project director and education director, Beth Schneider, attended the weekly 3-hour meeting of the Web design class; facilitated the student group working on the exhibition introduction; and was the conduit for all content information, images, and text approvals. The project also required frequent meetings with faculty and curators.

Be aware that not all projects are appropriate for students. The online catalogue was first assigned to a graduate student who was just learning Cold Fusion and this provided less than hoped for results. The most efficient solution to this problem was for the museum to pay a UH staff member expert in Cold Fusion and a graduate student who was learning the program. Together, they were able to complete the project on time and with significantly greater expertise.

Student learning is the focus of the classes. In a classroom setting, the museum is not a traditional client and university faculty and students are not traditional contractors. Learning to work with actual clients is a part of that process, but not the only important part. The museum staff members involved in the project need to balance the educational needs and goals of the students and faculty and the needs of the museum in creating a final project. This can be a very delicate and sensitive process.

Overall, the MFAH-UH collaboration has been a great success. Everyone involved in the project has learned a great deal. MFAH staff members look forward to future collaborations with the Program in Instructional Technology at the University of Houston and discussions have already begun to determine what projects will come next.

Recommendations from the University of Houston Instructional Technology Program
Bernard Robin, Associate Professor of Instructional Technology, University of Houston

Two graduate Instructional Technology courses at the University of Houston (UH) use content from the Museum of Fine Arts, Houston (MFAH) as the raw material for technology-based projects that student teams design and develop. The first course to be discussed is CUIN 7330: Project-Based Web Design and Development. This course focuses on the planning and creation of web-based educational resources that enhance works of art and decorative arts that are on display at the museum. Each student in the course is part of a team that includes other students, a university facilitator, and a staff member from the MFAH's education department. The teams are each assigned different project components that together make up a large-scale project that may last for several semesters or even several years. A more detailed discussion of the course and its workings may be found in A Model for Creating an Art Museum-University Partnership to Develop Technology-Based Educational Resources (Robin, McKay, Schneider, McNeil, & Smith, 2002.)
The course is now in its fifth year and the relationship with the MFAH, as the content provider, continues to evolve. Based on our experiences, the following recommendations are suggested for other educators who would like to create similar partnerships with art museum partners.

- **Make sure the students understand the expectations for their work.** Working with real clients with real deadlines gives students an understanding of what they will face when they finish school. In this course, we do not operate under the philosophy that “this is only a school project.” If the work is good it will be considered for going on the web; if it’s not good, it will not. Clear expectations about the quality and specifics of student work should be articulated by the client and the faculty members. In this collaborative setting, students learn to critique their own and other students’ work in a non-personal, non-threatening manner. Through a series of such critiques, not only will the quality of the work improve, but the students’ understanding of the design process will increase.

- **Make sure the museum staff understands that student learning is the most important component of the course.** This concept is often stated but is worth repeating. It is the job of the university educator(s) to make sure that student learning remains the most important component of the course. The opportunities afforded by working with an art museum are many, but the opportunities for learning are the reason students enroll in a course. A willingness on the part of the client and the faculty to be open to student ideas will increase the potential success of the partnership.

- **Make sure that university educators understand basic museum policies and procedures.** Even though student learning is the focus of the course, educators must not forget that the client’s needs are almost as important. If the student work does not meet the client needs, or if the faculty do not work within the policies of the museum, the partnership will suffer and ultimately, may dissolve.

- **Use additional university and museum experts as project component facilitators.** We have learned that in large-scale projects, student teams benefit from a university or museum expert who is willing to work with the students. These individuals provide valuable guidance and expertise and help the teams determine which parts of their design and development meet the needs of the client.

- **Try to recruit students from other disciplines outside of the Instructional Technology Program.** We have also found that the course can be strengthened by having students from other programs besides IT enroll in the course. Students with backgrounds in other areas such as art, art history, and social studies can add depth and meaning to the projects that are created. Since there will almost certainly be other team members who possess technology skills, not every student in this technology course needs to be a technology expert.

- **Provide opportunities for in-depth research.** Students interested in using these projects as the basis for thesis or dissertation work find a great opportunity for research. The museum benefits from scholarly research that focuses on their exhibitions and students benefit from a wide array of possible research topics and a large population of potential participants.

- **Prepare for changing expectations of the clients.** Finally, be aware that as design and development of technology-based resources progresses, the client’s expectations may change. Rather than treat this as a negative occurrence, we view this as a predictable and necessary consequence of such a partnership. Students learn first-hand that no matter how meticulously they plan their projects, modification of their work will be needed as their clients see their work and begin to adjust their expectations of what is possible.

For the Project-Based Web Design and Development course, a critical factor for success has been the ability of the university educators and the museum education staff to adapt to change. Over the last several years, we have continuously made changes to the course and to the projects that students create. In addition to the recommendations already mentioned, being flexible will almost certainly enhance a successful, long-term outcome in a museum-university educational partnership.
Other Critical Factors for Success
Sara McNeil, Associate Professor of Instructional Technology, University of Houston
Donna Odle Smith, University of Houston, Instructional Technology Program

The second course, Collaborative Design & Development of Multimedia, is a two-semester course sequence of planning and creating interactive multimedia resources. These students also work in teams with content facilitators, but the products from this class are destined to either function in stand-alone multimedia kiosks, or to deliver web-enabled multimedia content. The deliberately interactive nature of this type of product requires a unique approach to content design, organization and delivery.

Several themes that emerged from data gathered from both the students and the client that are representative of the current literature in the field of educational technology development are shown below.

- **Preparation and Shaping Expectations**
  Students need to completely comprehend the steps of the process before they begin the actual design phase. The process of designing and developing multimedia courseware is complex and often difficult to understand when it is built only on a theoretical and technical framework. If both the students and client understand that there are often periods of indecision and questioning and possibly redesign, then perhaps the process would proceed more smoothly. Students should also realize that every team is different and that flexibility is a critical factor for success.

- **Dedicated Client-faculty Member**
  The client must be willing to work with students in a variety of roles from content matter expert to the user of the materials and must become active participants in the process. The client must be accessible at times other than class periods and flexible in their thinking about the possibilities for design.

- **Time to Build the Large Community with Adequate Time for Reflection and Meetings**
  The teams and the learning community in which they function, needs to be established as quickly as possible. Other opportunities for developing team skills and communication should also be provided throughout the design and development process. Teams should have time during class to meet, but should also expect to communicate either face-to-face or in person between classes.

- **Good Problem and a Variety of Approaches**
  The instructional problem should create a balance between challenge and frustration for the teams. The process should support a variety of solutions and opportunities for creative and original discoveries.

The multimedia projects that resulted were the results of a small team of students working together part-time with limited interaction and limited resources. Even with those limitations, the four modules developed displayed a remarkable level of creativity, imagination, innovation, and mastery of both instructional design principles and application of technology for online learning. It is not hard to visualize the level of quality that might be achieved by those teams working under different circumstances where more time and resources were available.

The Convergence of Teacher Education, Art Museums and Instructional Technology: Goals, Insights, and Recommendations
Sara Wilson McKay, University of Houston, Art Education Program

The following section includes some thoughts about collaborative efforts among teacher education programs, specifically in art education, art museums, and instructional technology:

**Collaboration: A Definition**
In any collaborative effort, a laying bare of several key aspects must occur. Players in the collaboration must each honestly assess their strengths and be forthright about what benefits they hope to reap from the collaborative process. Also a genuine willingness to co-labor is imperative: true collaborative work (vs.
cooperative work) recognizes that each participating party comes to the table with goals and agendas, but there is an openness and an expectation in collaboration that these goals and agendas will change and be improved through the process. To emphasize co-laboring is to admit that any truly collaborative endeavor is indeed a difficult and delicate task requiring the utmost in trust from all parties.

Correlated Communication
The Art Education program at the University of Houston has collaborated with several area arts organizations of varying size and structure, before now becoming involved with the MFAH. Attempting to add Instructional Technology components to already conceptualized collaborations that students in the Art Education program have developed as their real-world projects has so far most often occurred as an afterthought—e.g. a video project was conceptualized to support the orientation information for teachers for the university’s Mobile Art Quest (MAQ); at the time during the class, the realization of this idea was not a possibility, but this project has now been adopted by IT Program’s video class as a potential project, yet it could have been a much richer project if it had been conceptualized in a collaborative way from the outset. However, now that frequent and open communication has become more of a stable feature between IT and Art Education, we expect that the very conceptualization of the projects with area arts organizations will change for the better.

Real-World Projects
In addition to open and on-going communication, the next key feature is the opportunity to work on real-world projects in pre-service teachers’ classes. Future art educators, when working with their client, begin to see their efforts in a whole new light. They conceptualize education in a much larger way than what occurs in the K-12 classroom—the end-user is not a generic 10-year-old who is imagined during the creation of endless lesson plans. Rather, the end-user of their educational efforts is someone they can imagine who has specifically had certain experiences in a museum or on a web-site. Specifying the beneficiaries of their efforts concretizes the pre-service teacher’s transition from student to teacher in that they become cognizant of the importance of their role as teacher. They see, anticipate, and plan for direct results of their educational efforts. Obviously, there is overlapping benefit in students broadening their thinking about education in a non-school environment that impacts their eventual performance in the K-12 classroom.

Linking Pre-service to In-service
In bringing together IT, art museums and teacher preparation programs, one of the goals is to prove the usefulness of both technology and museums (and other learning sites) in students’ future teaching endeavors. If teachers experience instructional success with technology and view museums as important educational places in their pre-service work, they will take these beliefs and these skills into the schools where in turn they will have influence not only on their own students but also on their colleagues. It has been said that improving the quality of education happens one teacher at a time pointing to the impact quality teachers have on their students, but this does not acknowledge the large impact innovative teachers also have on their colleagues and on school climates. Forging the link from pre-service education to in-service education is one of the things a convergence of museums, technology and teacher preparation does best.

References
The appropriate and successful integration of technology into today's diverse learning environments remain a predominant theme of importance within the areas of graduate and inservice education. Research focused upon face-to-face, Internet-enhanced and Internet-based learning environments has expanded imperative theoretical, research-related and application-based discussions. The appropriate and successful integration of technology within the learning environment is the focus of the majority of outstanding articles within this section. The authors within this section offer the latest research and theoretical issues through which the future of face-to-face and distributed learning environments will emerge.

Professional development is a growing area of interest within the world of instructional technology. The integration of technology into the learning environments over the previous ten year period has left a significant gap between the amount of technology available and the support for teacher candidates and inservice educators towards appropriately and successfully integration technology into the learning environment. As such, a renewed interest in and focus upon professional development is occurring within the world of graduate and inservice education. Emphases upon managing change, action research, integrating technology into the teacher candidate and inservice educator's learning environments, as well as Internet-enhanced and Internet-based professional development opportunities are discussions emerging as predominant themes.

Learning environment instruction is a vital element within graduate and inservice education, with the essential aspects focusing upon learning environments, learner-centered and instructor-centered instruction, collaborative technology integration into learning environments, interactive activities, project based instruction, content-based instruction and case study-based instructional environments. Learning environments emphasizing the latest research and theoretical issues pertaining to face-to-face, Internet-enhanced and Internet-based instruction are in its infancy. As well, the integration of technologically focused enhancements for the learning environment is accentuated. Instruction pertaining to scaffolding of knowledge, multimedia resources, instructional design and development, and the integration of moral development theory maintain interest; further, a triadic collaboration that enhances instruction through technological integration is discussed. Interactive activities associated with Web-based conferencing, videoconferencing, francophone networks, and other related information communication technologies are discussed with opportunities to communicate points of interest. Finally project-based, content-based and case study-based teacher education and graduate level learning environments are highlighted.

Student-centered learning environments focus upon engaging students outside the classroom environment, multimedia and handheld technologies. Engaging students within real-world environments, outside of the four walls of a classroom environment, offers innovative aspects towards enhancing learning objectives. Multimedia learning environments enhance the student-centered opportunities towards further understanding, with emphases upon linear and nonlinear multimedia programs; further, cognitive learning theory and instructional design models are appropriately incorporated and presented as aspects of the design and development process. Lastly, handheld technologies have become elements of interest, as standards, assessment and accountability are presented as prevailing movements within the learning environment.

Teacher candidate instruction is a continual area of focus within instructional technology. As such, focusing upon developing master instructional technology educators within graduate and inservice learning environments. One project that emphasizes the development of master instructional technologists is Project MITTS (Developing Master Instructional Technology TeacherS) that focuses upon technology-rich field experiences as well as professional development opportunities that emphasize standards, best practices, mentoring and the utilization of technology. A second project is
one that emphasizes the partnership between institutions of higher education, surrounding school districts, public libraries, hardware manufacturers, software designers and manufacturers, local community organizations and telecommunication companies. Each of the organizations associated with the partnership emphasize a systemic educational reform through professional development opportunities.

Certification, accreditation, evaluation and levels of competency are areas of continual concern. The importance of national accreditation and certification standards towards the appropriate and evolutionary evaluation of teacher preparatory units and instructional technology programs emphasize a continual formative progression towards appropriate and successful level of expertise expected so as to enhance the preparation of teacher candidates and further enhancing the standards of inservice educators. Instructional technology competencies of graduate-level teacher candidates, graduate students and inservice educators offer elements of expertise and reflect the encouragement and promotion of information technology through the development of portfolios as a reflection of information technology competency.

Graduate and inservice education theoretical discussions and research that impact the learning environment are imperative to the ever-expanding conceptual framework. Pertinent theoretical issues surrounding graduate level, teacher candidate educational opportunities and inservice teacher professional development must be carefully considered and are imperative as technologies become more available and viable within learning environments. The authors within this section have presented rigorous research, contemplative theoretical discussions and thoughtful reflections that exemplify the cutting edge of the world of instructional technology.

*Caroline M. Crawford is an Assistant Professor of Instructional Technology at the University of Houston-Clear Lake. She can be reached at crawford@cl.uh.edu.*
GIS in Teacher Education: Notes from the Field II

Marsha Alibrandi
Shannon White
Rita Hagevik
Barbaree Ash Duke

Over three years of an experimental course entitled GIS in Education, we have consistently engaged student participants as collaborative co-constructive partners in designing instruction. With a class website that facilitates communication between students and instructors, and by incorporating former students as instructors, a number of new components have been added. With a goal of sustained GIS integration, we have conducted follow-up studies of in-service Instructional technology teachers’ use of GIS across the curriculum. GIS projects designed by the participants and the results of follow-up studies are presented.

In an experimental course offered to M.Ed. candidates in Instructional Technology, course design, the design of the course itself is coconstructed with student participants. Given the uniqueness of a GIS in Education course, there is opportunity to discuss with students the value, placement and design of such a course as part of their Instructional Technology experience.

Through web and email feedback, reflections, discussions and quizzes, students have provided useful insights into their learning and how a course of this kind can best meet teachers’ needs. Aduet and Paris and Audet have both discussed the prolonged period between teacher introduction to GIS and its implementation. In various studies, we have investigated what factors contribute to what we have called GIS ‘uptake.’

Working with prior students to understand what helped them most to learn toward implementing those suggestions in future iterations, we found that the addition of a virtual lab component, books that discuss GIS use in both communities and schools, and a community partnership component were all contributing factors to learning and using GIS in concert with existing curricula. In the state of North Carolina where high stakes testing has greatly impacted classroom teacher practice, the integration of technology must meet curricular goals.

Elementary, Middle and High school teachers all found applications across a wide range of curricula. Of a dozen graduate teacher education projects, there were three main subject areas: Social Studies, Language Arts, Business Education and Earth Science or Geology See Table 1.). Additional projects by other students were not related to K12 curriculum, but to other issues.

With a goal of both temporal and curricular ‘uptake,’ we promote a methodology of collaboration. At least two of the teachers integrated interdisciplinary curricula with GIS. The Techno-book project was based in the language Arts curriculum of student reading “journey books” that tell the stories of journeys. The Instructional Technology specialist
designed a project in which students would map the journey using a GIS (ArcVoyager), would relate historic, weather and economic information to provide context for the story, and would present these in a Power Point presentation.

With Instructional Technology specialists central and working across disciplines, we hope to see increased lateral 'uptake,' that is, uptake of GIS by teachers other than the initial GIS user. In subsequent meetings of Instructional Technology specialists, presentations on GIS are planned to develop interest and support of GIS integration.

Among international GIS educators, there was debate about the location of GIS in the curriculum; whether geography, the natural sciences or instructional technology were the most appropriate home bases for school GIS. It has been our assumption (with inadequate evidence to project) that uptake in Instructional Technology might result in more lateral uptake across disciplines. One issue involved in the lateral adoption of GIS is that when one person concentrates his or her energy on GIS without reaching out to collaborate across disciplines, that GIS could essentially be lost to an entire school population if that one teacher moves or retires. Our assumption is also that instructional technology specialists can more easily integrate any technology across disciplines, so that GIS would simply be one more of those technological skill sets that could be transferred from one discipline to another, thus enhancing transfer learning.

As the course continues and if teachers tend to avail themselves of in service GIS opportunities, we will investigate these possible expansions of school GIS application. By SITE 2002, we will have additional data to report regarding integration by schools who have participate din various GIS offerings.
Professional Development Kit (PDK): Multimedia Resources for Instructional
Decision Making
by Kelly Hunter Limeul and Janet Smith
National Center on Adult Literacy
University of Pennsylvania/Graduate School of Education
3910 Chestnut Street
Philadelphia, PA 19104-3111

The Professional Development Kit (PDK) is a multimedia resource for adult educators
that utilizes print, video, CD-ROM, and the depth, flexibility, and complexity of the web.

The CD-ROM contains over 10 hours of Quicktime™ video that is accessed from within
the computer's CD-ROM drive as one navigates through the different organizational
elements of the PDK web site. The videos are also available on conventional VHS tape
for viewing in group or classroom settings. Within the 10 hours of footage are authentic
classroom investigations centered around particular topics, as well as commentary from
professionals working within the field of adult literacy. The centerpiece of the kit is the
PDK Guide, which provides ideas and resources of how to use the accompanying CD-
ROM and videotapes in the professional development of adult educators.

The submitted video "Margarita: Narrative" follows an ESL teacher as she attempts to
engage students in reading, writing, speaking and listening through the use of a dialogue
exercise. The taping took place over a two week period in an authentic high functioning
ESL classroom in Bethlehem, PA. The final 15-minute piece was culled from over 15
hours of raw footage.
The Maze of Re-Certification and Accreditation

Abstract: Education in America is currently receiving prominent attention in the public forum. Efforts to strengthen the quality of education have included more rigorous student and teacher standards, creating the necessity for reforms and revisions in teacher preparation programs. This paper describes the process involved in applying for New York State Re-Certification and NCATE Accreditation of a Masters Program in Educational Technology. The focus is on the challenges that a small college faces in complying with the requirements of various organizations. Problems, solutions and a sample curriculum are provided.

Introduction

One of the goals of the Goals 2000 legislation passed in 1994 was to provide teachers with opportunities for lifelong enhancement of professional skills. As a nation, we have fallen short of this goal (Senate Committee on Labor and Human Resources 1998). The turn of the century has witnessed a renewed interest in the state of education in America, as evidenced by its prominence in the 2000 presidential election. Parents are concerned about the quality of education their children are receiving. Our nation's leaders are calling for accountability as they seek to close the gap between our system of education and that of other industrial nations around the world. Concern appears to be focused on the lack of competent teachers, laying the problem directly at the feet of teacher preparation programs. One response has been the establishment of stricter standards. But the solution begins with the consideration of the students' needs and growth. Once we establish what our students need to know and be able to do, we can develop programs to prepare teachers to meet student objectives. Teacher standards must flow from student standards. However, setting standards is only the first step; of far greater importance is developing assessments to meet the standards (Galluzzo 1999). Almost every state has released more rigorous learning standards for students. Since research has shown that teacher expertise is related to student achievement (Darling-Hammond 1997), we must now focus our attention on teachers and the programs that prepare them. States are rethinking their certification procedures as well as their policy of requiring accreditation of teacher preparation programs, thus putting organizations like the National Council for Accreditation of Teacher Education (NCATE) in the foreground of the educational reform dialogue.

Iona College's MS Program in Educational Technology

Iona College has offered a graduate program in computer technology in education since 1983, when the College's MS program in Education Computing became the first of its kind to be approved by the New York State Department of Education. The program was offered at both the main campus in New Rochelle and the branch campus in Rockland County. It was designed for teachers, administrators and
other school personnel, whether they were computer novices or experienced computer users. The goals were to enable them to provide leadership in the field for schools and industry, to integrate educational computing into the school curriculum, to be teachers of computer literacy, to write educational software, and to conduct research and evaluation in the field. Because the program was placed within the Department of Computer Science rather than the Department of Education, there was a strong technical computing orientation that included programming. Students who completed the MS program were eligible for permanent certification in elementary education and the secondary subject areas, provided they met the other state requirements. The degree was considered by the state to be "functionally related" to all these certification areas.

As originally offered in 1983, the program had a common core of 9 credits, three areas of specialization (Elementary Education, Secondary Education, and Educational Software Design), each with 12 specialization core credits. The specializations required programming in an appropriate language: LOGO for elementary education, BASIC for secondary education, and a commercial language for software design. There were 9 credits in general electives, and 6 credits in a culminating experience (thesis or project). When the program was revised in 1991, the goals remained the same but the specializations were eliminated. The core was changed to 15 credits, with 15 credits in general electives and 6 credits in a culminating experience.

Because of changes in the undergraduate preparation of teacher candidates, the Department of Computer Science undertook a major revision of the program in 1993. As the College was educating the community about its mission statement, the department identified the mission of the program: To provide students with the knowledge, skills, and experiences to become successful practitioners and leaders in the field of Educational Technology. At that time we changed the name of the program to MS in Educational Technology. The student population was identified as teachers, administrators, corporate trainers, and others who wish to enhance their knowledge of emerging educational technologies. The program remained open to both computer novices and experienced computer users. Linked to the mission of the College and the department, the program goals were defined to enable graduates to: provide leadership in Educational Technology for schools and industry; participate in the integration of Educational Technology in the learning environment; conduct research and evaluation in the field of Educational Technology; develop a foundation for continuing education and growth in the field of Educational Technology.

The curriculum changes included adapting an existing course, Introduction to Software Packages for Education, as a transition course that would not count towards the degree. The core consisted of 12 credits, with 18 elective credits, and a 6 credit capstone in research methods and a research project. The department committee's proposal was approved by the department and the college committees and was sent to the State Education Department, where it was also approved and went into effect in September of 1999.

**New York State Certification Requirements**

In 1996, after New York State adopted new performance-based student learning standards, the Regents Task Force on Teaching was established to address the teaching crisis in the State. They found that too few teachers are prepared to incorporate the more rigorous student standards and assessments and that too few teachers are able to sustain a high level of standards throughout their career (Teaching to Higher Standards: New York’s Commitment 1998). The findings of this task force led to immediate action by the State. In September 1999, the Deputy Commissioner for Higher Education in the State of New York sent a letter to institutions offering teacher education programs stating that the Board of Regents had adopted new standards for teacher preparation programs. Among the objectives of these new standards are to ensure that: teachers would receive rigorous preparation in the content areas they would teach; these new teacher standards would coincide with the performance-based student learning standards that had been adopted in 1996; teachers would have experiences with diverse student populations; education faculty would collaborate with faculty in the arts and sciences, local schools, parent and community groups.

**Seeking New York State Certification**
The State also issued revised methods of obtaining both Initial and Professional Certification for teachers. When Iona received notification of these changes, the first decision we faced was whether to revise our program to offer Initial or Professional Certification. Since Initial Certification had traditionally been the province of baccalaureate programs, it seemed appropriate to offer our students the opportunity to attain Professional Certification. The State described numerous ways to achieve Professional Certification but those we considered were: 1) A Masters degree plus 12 graduate credits in a candidate’s undergraduate major and 2) A Masters degree that includes 12 graduate credits linking pedagogy and content in English Language Arts, Mathematics, Science and Technology, and Social Studies. We rejected the first option because the completion of at least 40 graduate credits appeared to place too great a burden on students. We decided on option two because we believed it would better meet the needs of our student body. While Iona already had courses that addressed the linking of pedagogy and content, none did so explicitly in each of the three areas. Therefore, this decision necessitated the development of three new courses to replace some of our current courses.

These courses were designed to enhance the teaching of these three content areas utilizing the most current and appropriate software. The new courses were entitled Integrating Technology into the English Language Arts Curriculum, the Mathematics, Science and Technology Curriculum, and the Social Studies Curriculum. The courses emphasized the creation and delivery of a variety of lessons to afford the students practical experiences using software most appropriate to the specific content areas (e.g., desktop publishing, spreadsheets, database management systems). Faculty members from the Departments of English, Mathematics, Biology, and History at Iona provided guidance and suggestions to ensure the required linkage of content and pedagogy. These courses accounted for 9 of the 12 credits needed. The final 3 credits were accommodated through an existing course where students engaged in an independent research project involving the integration of technology in the classroom.

Once the curriculum had been revised, the next step was to complete the New York State application for certification, which placed a strong emphasis on the preparation of faculty teaching in the program. The State was most interested in their degrees held, their areas of expertise, their specific courses assignments, their knowledge of the problems of high-need schools and diverse student populations, and their recruitment from underrepresented groups. As a small college, we rely heavily on adjunct faculty with considerable experience in K-12 education to complement the technology expertise of our full-time faculty. We were concerned that this situation might weaken our application.

NCATE Accreditation Requirements

To further ensure the quality of teacher preparation programs, New York State also set a deadline of the end of 2004 for institutions to achieve accreditation. NCATE was then, and is now, the only organization ready to grant accreditation. Recognized by the U.S. Department of Education, NCATE sets standards of quality by which teacher preparation programs are judged. In the forefront of the recent national call for educational renewal, NCATE has revised its standards and recently released NCATE 2000 Unit Standards with its focus on performance-based standards and assessments. Research studies indicate that students of NCATE-accredited institutions have demonstrated superior classroom performance when compared to their peers at non-accredited institutions (Brown 2001, Nweke 2001, Wise 2001). Iona College made known its intention to apply for NCATE accreditation to comply with the New York State directive.

Among the initial steps in the NCATE accreditation process is the creation of a curriculum portfolio submitted to one of the NCATE Constituent Members, professional organizations that establish discipline-specific standards approved by NCATE. The International Society for Technology in Education (ISTE) is one of the technology organizations that establishes guidelines by which educational technology programs are evaluated. Procedures for ISTE accreditation can be found at http://www.iste.org/standards/ncate/advanced.html.

Seeking NCATE Accreditation
As mentioned earlier, the Masters Program in Educational Technology at Iona College differs from most programs of its kind in that it is offered through the Department of Computer Science rather than through the Department of Education. The Education faculty had the responsibility of completing the NCATE application; our first responsibility was the completion of the ISTE portfolio. The most significant part of the portfolio was the matrix of performance indicators and experiences to fulfill the guidelines along with a set of course syllabi with the mapped indicators.

A committee was formed to complete the matrix and syllabi. An ISTE consultant provided invaluable assistance in explaining the requirements. For each performance indicator in the matrix, we were required to indicate the specific objectives, topics and assignments in our courses that verified that students had met the indicator. To cross reference the matrix, we were required to map each indicator onto the objectives, topics, and assignments of our course syllabi. Since our program offers a masters degree, ISTE advised Iona to complete the matrix for Advanced Programs consisting of the Educational Computing and Technology Literacy Endorsement Matrix as well as two sections for Educational Computing and Technology Leadership.

It became obvious from the start that compliance with ISTE standards would entail drastic changes in our program. The first problem we encountered was how to meet the over one hundred indicators within our current courses. ISTE requires each graduate of the program to meet each of the performance indicators in the matrix, implying that all the indicators must be met in core courses that are taken by every student. As explained above, New York State requirements necessitated the development of three new courses in the core. On the other hand, there were certain courses that we strongly believed should be part of our program, such as the programming and research courses, and were reluctant to eliminate. In light of all these requirements, our committee had no choice but to expand the core from its existing 18 credits to 30 credits. This left only 6 credits of electives for our students. We were concerned about the lack of diversity in our students' course of study but there were no other viable alternatives.

Each committee member took responsibility for a group of core courses and revised the syllabi and assignments to meet the appropriate indicators for the course. We met periodically to ensure consistency and completeness. The initial feedback from our consultant on the first three sections of the matrix revealed other problems in our procedures. Many indicators had several parts and we had not been sufficiently attentive to each and every one of them but rather addressed the general intention of the indicator. We learned the importance of using the language of the indicators in our syllabi. Another problem that surfaced was our misconception that merely addressing an indicator in class was sufficient evidence that it was met. Our consultant made us aware that performance indicators could only be properly satisfied through specific assessments such as examinations, assignments, and projects. This realization forced us to revisit each of our syllabi to provide compliance with the indicators through performance-based assessments. We also encountered difficulty in completing all of the indicators to our satisfaction. Some of the indicators required equipment that we do not have and that we might have trouble acquiring. Other indicators could only be properly met in an extensive field experience that we are unable to provide at the current time. By the end of this iterative process, we added another new course to the program (bringing the total of new courses to four) and significantly revised four others. Iona College submitted its ISTE portfolio to NCATE in August 2001. A complete description of the revised program can be found at http://www.iona.edu/cs/gradreqs.htm.

Implementing the Program

We have already achieved one of our goals: New York State has registered our newly revised Masters Program in Educational Technology. We were gratified that the State recognized the strength of our program and implicitly acknowledged that our use of adjuncts in the program did not detract from but rather enhanced the students' experiences. After approval by the state, the next challenge was to implement the new program. A three-year projected schedule had to be revised to reflect the changes. The scheduling was complicated by several factors, including the stipulation that all core courses had to be offered on both campuses within a reasonable cycle. Students already in the program, who had matriculated under the old curriculum, were given the option of completing their existing program plans or switching to the new requirements. Most opted to complete their old plans, making substitutions where necessary. A summary of the changes was prepared and distributed prior to registration for fall of 2001 for all new and non-matriculated students. New requirements could also be found in the college catalog and the department website. The more structured program required scheduling additional advisement hours to
explain its effect on the students' programs. The adjunct faculty teaching in the program had to be brought up to date on the changes, and made aware of the revisions to their course outlines, which they were no longer permitted to modify. In general, they were pleased with the specificity of the outlines, and they adjusted their teaching accordingly. Collection of assessment materials became more crucial, and the department is still experimenting with methods of collecting and storing those assessments. Electronic portfolios are being developed for each offering of the courses.

Conclusion

We discovered that the new courses the State required us to offer were well received by our students. Our K-12 teachers are constantly looking for effective ways to integrate technology into their classrooms and they found these courses most beneficial to them and their colleagues.

At the time of writing, we are still awaiting a response from ISTE on our curriculum portfolio. Although the first round of the ISTE accreditation process was long and arduous, it yielded some positive outcomes. Perhaps for the first time, the committee examined each course in minute detail to reduce duplication of course material, and to eliminate areas that were outdated and replace them with more meaningful, relevant and current topics and assignments. This purposeful "house-cleaning" can have a cathartic effect. Our program has been invigorated with the latest theories in educational technology and, as such, is a more challenging but rewarding program. With its emphasis on performance-based assessments, we are convinced that our revised Masters Program in Educational Technology will better prepare our students to meet the challenges they will face in their own classrooms.

How Graduate Teacher Education Students Addressed Timely Teaching and Learning Issues Through the Construction of a Website for Their Colleagues

Dr. Candy Beal, Department of Curriculum & Instruction, College of Education, NC State University, USA  
<candy_beal@ncsu.edu>

Dr. Lisa Grable, Department of Curriculum & Instruction, College of Education, NC State University, USA  
grable@unity.ncsu.edu

Abstract: This research paper examines a unique curricular design project that demonstrates the value of recursive learning. A curriculum integration project completed and reported on last year, Wetlands 2000, was thoroughly explained and used as an example of taking curriculum integration theory to practice in a larger project that examined the value of using a curriculum integration approach to teaching and learning. A website on curriculum integration was built in support of colleagues' who question the value of teaching solely for recall of discrete facts and who are frustrated by education's pressure to move in this direction.

As educators, we teach and learn about a spiraling curriculum. The first step is to introduce and explore a basic idea. After students are able to understand what we have taught, we then cycle back and expand on the original idea. This method helps develop new dimensions of thought and information. The time spent in discussion and development of the idea is Vygotsky's (Vygotsky, 78) interpersonal processing which shifts to intramental processing as students internalize the information and seek to make meaning for themselves.

Educators are constantly using the spiraling curriculum method of teaching. For experienced educators it may be so routine that they may not spend time reflecting on the process itself. This paper describes how a curriculum integration project implemented in a technology enabled environment and reported on last year became a component of an even larger technology project for preservice and graduate teacher education. In other words, we spiraled back to the original learning and deconstructed that project to illustrate the process of curriculum integration, the subject of the new learning.

The Wetlands 2000 Project was a curriculum integration/service learning project that was reported on at last year's SITE Conference in Orlando, Florida. It involved one hundred 8th graders and their teachers and demonstrated the power and scope of learning that is possible in a technology enhanced learning environment. The project demonstrated classic curriculum integration. Students asked about, researched and reported on big issues of social/environmental injustice using technology applications as diverse as GIS, spread sheets, PowerPoint presentations and online research sites. The eighth graders did action research at the wetlands site and made a public/university-wide presentation of their project findings. It was a highly successful, exhilarating, exhausting process and, once it was completed, the class moved on to other learning opportunities. Who would have known that this project would play a major role in another, larger effort involving graduate students studying and building a website about curriculum integration?

The graduate students selected the topic, curriculum integration, to support their argument that children learn best when differentiated instruction is used to fully engage them in issues of personal and global interest. They sought to demonstrate that testing for knowledge of discrete facts alone does not indicate true reflective knowledge. Their frustration was borne of our country's mania for using standardized testing as the sole measure of learner achievement. Their audience was others like themselves who were struggling with the question of whether to teach the children or teach the test.

They based their website work on James Beane's (Beane, 97) study of curriculum integration and their own experiences using curriculum integration in the classroom. They deconstructed the theory and process of curriculum integration and then build a website to inform colleagues about curriculum integration's application to middle school education. Components on their website (<www.ncsu.edu/chass/extension/ci>) included:

$ a thorough, user-friendly study of curriculum integration
$ an explanation of how curriculum integration, based on the needs of early adolescents, applies to teaching and learning in the middle school classroom
$ a one hundred year time line with drop down information that traces the development of curriculum integration in the context of the history of education and
a section on evaluation and assessment, highlighting both formal and informal methods to examine students' progress.

Graduate students determined that the most critical part of the website would be an example that demonstrated how curriculum integration could be used in an actual class project. Having heard about the Wetlands 2000 Project undertaken by their undergraduate preservice colleagues, they decided that highlighting that project would be a way to show the actual application of curriculum integration theory. In an effort to offer a unique approach to learning about Wetlands 2000, the students chose to fictionalize the actual story. They called it Pam's Story.

In Pam's Story, the reader meets a new teacher and follows her through the first semester of her first year of teaching. Readers are introduced to the members of her team, become familiar with the issues teachers face on a daily basis, and join her team as they develop and implement a curriculum integration project, Wetlands 2000. Photographs and sketches from the actual project appear throughout the chapters of the story. Graduate students included all of the teaching and learning approaches that were employed in the real project. They related theory to practice in all aspects of implementation of Wetlands 2000. Pam's story ends with the team celebrating its success by visiting a global issues museum. In the final chapter, the teachers and students find themselves addressing a new concern that will require building yet another curriculum integration unit. The graduate students cleverly provided a link to another website, SwimDog, that was developed by undergraduates as a curriculum integration resource. The teacher education class also included a forum in the site to enable all teachers to discuss issues regarding curriculum integration. It joins a resources and references section that can be used to learn more about curriculum integration.

This project demonstrates that learning in a technology enabled environment makes it possible to fully access information and activities previously undertaken and currently archived. Past projects can be recycled into other contexts. Time and energy that was devoted to previous learning activities becomes value added when it is used as the foundation on which to build new knowledge. Students see that learning is a dynamic, recursive process, the results of which can be more readily shared through technology.

Abstract: This paper is a description of how pre-service and in-service secondary mathematics teachers use a web-based professional development tool to examine, reflect on, and discuss classroom practices. The teachers are engaged in a professional development project in which they work in teams with each other and with mathematicians and mathematics educators to collaboratively plan, implement, and reflect on mathematics lessons. The web-based environment supports their work by providing discussion areas and document building capability. The web site also contains video clips of lessons and lesson artifacts that can be used to stimulate discussion about teaching and learning. Ultimately, video of the lessons developed through the project and artifacts from these lessons will be included on the web site. Research related to this project will examine the interactions among the team members and the ways in which the web-based forum may be used to support teacher education.

Introduction

We present how technology has been used in two intersecting innovative teacher education activities. In particular, we describe how we have provided a rich context for pre-service and in-service mathematics teachers’ professional development through the use of information technology in the form of a web-based professional development tool (the Inquiry Learning Forum (ILF)). The ILF website has been used in both a professional development project (the Collaboration for Enhancement of Mathematics Instruction (CEMI)) and in a secondary mathematics methods course at Indiana University.

The Inquiry Learning Forum (ILF)
The ILF, hosted at Indiana University, "is a web-based professional development tool designed to support a community of in-service and pre-service mathematics and science teachers creating, sharing, and improving inquiry-based pedagogical practices" (Barab, Makinster, Moore, Cunningham & the ILF Design Team, in press, p. 3). The virtual facilities for the community include classrooms that can be visited, various types of meeting rooms, a library, and "workrooms" that provide "an on-line space for groups to form working circles, or sub-communities, to facilitate collaboration on a particular project, product, or goal" (Barab, Scheckler & Makinster, 2001, p.7). Thus the ILF creates a comprehensive web-based professional development community through which the participants connect with each other and participate in interactive construction of professional knowledge (Barab, et. al., in press).

The CEMI Project

CEMI seeks to engage teams of middle and high school mathematics teachers, university mathematicians, university mathematics educators, and pre-service secondary mathematics teachers in an activity that is inspired by Lesson Study, a form of professional development that is widely used in Japan. In Japan, an entire school has a general theme for the Lesson Study and each lesson study group develops a lesson that relates to the theme. Study lessons are then taught in regular classrooms. An implemented lesson is observed by many teachers in the school and is followed by a public discussion of the lesson with the planning group. This cycle of meetings and lessons is repeated several times during a year.

CEMI Lesson Study Groups also work through cycles of planning, implementing, and reflecting on individual lessons. Responsibility for planning and reflecting on lessons is shared among participants. The classroom teachers are responsible for implementing the lessons while other group members observe and take notes. The CEMI project is not simply trying to engage U. S. secondary mathematics teachers in Japanese Lesson Studies, but rather to adapt this model of professional development for several purposes. These include providing professional development for all of the participants in the project and creating an extensive community of people with diverse perspectives with the common goal of providing secondary students with quality mathematics education. The evaluation/research component of the project seeks to understand these activities and their impact on the participants and the participants' classroom teaching.

The CEMI project conducts many of its activities through the ILF website. Lesson Study Groups regularly meet face to face, but the actual writing and co-construction of lesson plans occurs on ILF site through the use of a document builder tool. Discussion of the plans and reflection after teaching also occurs both face to face and on the ILF. Ultimately, video of the lessons developed through CEMI activity and artifacts related to these lessons (e.g., student work, teacher reflections) will be included on the ILF site. Through the ILF, the work of each Lesson Study Group is made available to others in the project and will eventually be visible to all ILF members. CEMI participants have recently decided to take a break from the development of new lessons and spend 2-3 months more intensively reflecting on the lessons that have been developed and taught over the past 18 months. In addition, participants will read and discuss books and articles related to the teaching and learning of mathematics. These reflections and discussions will take place in both face to face meetings and on the ILF.

The Methods of Teaching Secondary Mathematics Course

It is a goal of every teacher educator to stimulate meaningful discussion about issues related to teaching among their students and to help students become reflective about their own and other's teaching. The ILF is used by Indiana University's secondary mathematics education students for both these purposes. Students in the secondary mathematics methods course are participants in CEMI Lesson Study Groups, but they also use the ILF in other ways. Students are required to virtually visit mathematics classrooms on the ILF. This provides a common classroom experience for all students. Available for each lesson are written plans and video clips of implementation, student work and teachers' own reflections, connections to state and national standards, and references to related resources. Discussions of these visits occur on line and in class, enabling students to use real classrooms as a basis for developing concepts of teaching and learning mathematics. Students also use the ILF document building tools to create and revise their own lesson plans, making the process visible to both instructors and other students. The ILF library contains web-
Research Components and Issues

Research related to the ILF, CEMI, and the secondary methods class has several foci including (a) the role of the ILF in helping mathematics teachers, mathematicians, teacher educators, and secondary methods students develop "communities of practice" (as defined by Wenger 1998); (b) the integration of Japanese Lesson Study methods into U.S. teacher professional development and the ways in which the ILF enhances this process; (c) the characteristics of face-to-face and on-line discussions and the ways in which the ILF can be used to support reflection on teaching and learning; and (d) the roles of teachers, education students, teacher educators, and mathematicians in Lesson Study Groups and on-line and face-to-face discussions. Wenger (1998) identifies four characteristics that define communities of practice: negotiating meaning; preserving and creating knowledge; spreading information; being a home for identities. Because we believe these are important characteristics, we are beginning to examine data to determine the extent to which the Lesson Study Groups and the methods class exhibit these characteristics.

Conclusion

The ILF provides a technological tool that provides opportunities for professional growth for pre-service and in-service secondary mathematics teachers as well as other mathematics educators. Our use of the ILF in the CEMI project and in the secondary mathematics methods class is only in its second year, so conclusions about its value must be tentative. However, we are convinced that the ILF is helping us introduce pre-service teachers to reflection on practice in ways that were previously unavailable and that are valuable. Similarly, the ILF provides a mechanism for engaging in-service teachers and other mathematics educators in collaboratively constructing and examining practice in new and powerful ways. Whatever terms are used to describe what is developing — discourse community, community of practice, collaborative, or something else — the bottom line is that through the use of the ILF we have people talking with each other and working together who have not previously done so.

Building an Educational Technology Masters Degree Program with ISTE/NCATE Standards as the Foundation

Cathy Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, USA. ccavanau@unf.edu

Terry Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, USA. tcavanau@unf.edu

Abstract: The NSDC 2001 staff development standards and ISTE's 2000 standards for educational computing and technology programs served as the foundation for a new Educational Technology Master's degree program at the University of North Florida, designed to lead educators in the region toward the innovation stage of educational technology integration. Program development began with a thorough review of existing courses and their alignment with national standards. A team of professors created a matrix of course objectives and standards in order to identify gaps in the existing program. Existing courses were restructured, and new courses were designed to meet needs.

Preparing teachers to teach with technology

In the rapidly changing world of the information age, it is more critical than ever that all teachers be lifelong learners, and that they collaborate to continuously improve their practice and their results with students. A priority of the US Department of Education is preparing prospective teachers to use technology as a tool for teaching and learning and to work effectively with diverse students (US DOE 2001). Lack of professional development for technology use is one of the most serious obstacles to fully integrating technology into the curriculum (Fatemi, 1999; Office of Technology Assessment, 1995; Panel on Educational Technology, 1997). "The transformation of classroom technology from hardware, software, and connections into tools for teaching and learning depends on knowledgeable and enthusiastic teachers who are motivated and prepared to put technology to work on behalf of their students," states the CEO Forum on Education and Technology (1999).

Jamie MacKenzie (1993) indicates stages of technology mastery for teachers, from survival through innovation. The needs at each stage are different. Studies have outlined four stages through which teachers may pass in learning and applying new technologies in their teaching: (1) Survival-- struggle, teacher-directed, (2) Mastery-- coping, confidence, (3) Impact-- tech-enhanced, learner-centric, (3) Innovation-- restructures learning.

Leading educators toward the Innovation stage requires effective professional development experiences. The National Staff Development Council revised the Standards for Staff Development in 2001 to better meet the needs of today's teachers and students. The National Staff Development Council revised the Standards for Staff Development in 2001 to better meet the needs of today's teachers and students. The NSDC standards guide professional development of teachers in all facets of education. As a guide to staff development in technology, the International Society of Technology in Education has provided standards for Professional Preparation in Educational Computing and Technology Literacy (NCATE 2000). The two sets of standards have many parallels, and served as the foundation for the development of a new Educational Technology Master's degree program at the University of North Florida, designed to lead educators in the region toward the innovation stage of educational technology integration.

Educational technology master's degree program development

Prior to the development of the new Educational Technology Master’s degree program, UNF had four technology-centered “tracks” in its Master’s catalog. The tracks were minors within elementary education and secondary education majors. Both the secondary and elementary education programs offered tracks in instructional technology and in computers in education. The four technology tracks were developed at different points over the last decade and for various purposes, but the result was program profusion and confusion. Beginning fresh on a new
program would have several benefits: students would join one clear program, the program would be extensively updated, and the program would reflect current standards not in existence when the original programs began. The names and descriptions of the new courses better reflect current practice, and together they meet new standards implemented at the state and national levels.

The new program is outlined below:

College Core courses in Foundations of Education Research, and Education in America.
Curriculum and Instruction Core courses in School Curriculum and Models of Teaching.

The process of developing the new program began with a thorough review of existing courses and their alignment with national standards. A team of instructional technology professors created a matrix of course objectives and standards in order to identify gaps in the existing program. To streamline the transition from the existing program to the new one, existing courses were restructured, and new courses were designed to meet needs. The most significant new course is the capstone Educational Technology Issues course, which includes a strong field-based project. The field project requires the Master’s students to work with children in classrooms on innovative technology-based experiences, and to create and deliver professional development experiences to teachers. UNF’s new program addresses each of the NSDC 2001 staff development standards and ISTE’s 2000 standards for educational computing and technology programs.

The Learning Schools Programme:
an analysis of teachers' professional development and
pupil gains in a lottery-funded ICT training programme
for in-service teachers

Dr John L Chatterton  j.chatterton@shu.ac.uk
Head of IT
Sheffield Hallam University
School of Education
Collegiate Crescent Campus
Sheffield S10 2BP
England

Introduction

In the UK, the New Opportunities Fund of the National Lottery has provided funding of £230 million
($330 million) to train teachers, not in the basic skills of computer use, but in the much more complex
areas of the use of ICT in teaching and learning, planning and assessment and in the continuing
professional development of teachers. The expectation is that all teachers will at least meet the ICT
competences laid down for the training of new teachers in all subject areas and over all phases of
education. Lottery funding provides not more than half the cost of the projects it supports, so schools
are expected to contribute teacher-time for the training as their 50% of the funding. At the same time,
the government is spending some £500 million ($700 million) on provision of hardware for schools
and every school is gaining a broadband connection to the internet, with a nationally supported
school-web structure — every school has a web address and every teacher and pupil is to have a
personal email address.

Standards for the training were set out by the government and would-be providers of the training were
asked to submit their programmes for approval. The approval process resulted in a mixture of
provision: some subject-based, some taking a whole school approach; some providers worked within
a defined region, others worked nationally.

The Learning School Programme, with which this paper is concerned, is a national provider which
takes a whole school approach, while providing specialised materials for the various subjects and
phases. The Learning Schools Programme was formed from the co-operative efforts of the Open
University, the largest provider of open and distance learning courses, and RM plc, a major supplier
of ICT systems and software in the education sector in the UK. The author is currently co-ordinating
the delivery of the programme to more than 2500 teachers across a large area of England.

As we pass the half-way point of the programme, which is due to finish in 2003, evidence is
beginning to accumulate about teachers reactions to the programme, changes in their professional and
classroom activities and their perceptions of the consequent impact on pupil motivation and
attainment.
Teachers and ICT

The Learning Schools Programme begins with a needs analysis undertaken by the individual teachers and covering the four basic areas of planning, teaching, assessment and reporting and personal professional development. Teachers are guided through an examination of 44 professional tasks covering the four areas and, using the professional development record, they devise an individualised programme according to their needs.

The teachers are supported during their training by a mixture of face to face tuition, books, multimedia CD, videos, online support and computer moderated conferences: further details will be provided in the paper.

During the training period, the teachers build up a portfolio documenting the work they have done and the changes which have occurred in their planning, teaching etc. A senior member of staff in each school takes responsibility for organising the school-based part of the training and s/he is responsible, with the support of the Learning Schools Programme's School Adviser, for assessing the portfolios and monitoring the progress of the staff. At the end of the programme, each teacher is expected to plan and teach a series of lessons involving the use of ICT and to evaluate its effectiveness in terms of the subject-based objectives / lesson outcomes. On completion, the teacher completes an evaluation of the programme and a personal development plan for furthering their use of ICT.

The data provided by the programme mechanisms has been supplemented by interviews with the teachers to provide a rounded picture of the progress made and the changes occurring in the classroom. These demonstrate a wide range of outcomes and show how these outcomes are dependant, inter alia, on the underlying attitudes of the teachers and on the rapid changes in hardware provision which have been concurrent with the training programme.

847
Conclusions

The data so far have been very positive, with the great majority of teachers reporting that the programme has helped them to raise their awareness of the possibilities of the use of ICT in subject teaching and has given them the confidence and encouragement necessary for them to begin to use ICT in the classroom. Virtually all the teachers on the programme were making significantly increased use of ICT for professional purposes by the end of the programme.

Where progress was slower, it was generally linked to staff having limited access to ICT facilities within the school — caused in no small part by the rapid increase in demand for the ICT facilities the school had. This was particularly true of the early entrants to the training, where the investment programme had not taken full effect.

Integrating technology into teaching: exploring a teacher learning community for teacher professional development

Haojing Cheng, Doctoral candidate, Michigan State University
Mary Ann Robinson, Technology Outreach Coordinator, Mecosta-Osceola Intermediate School District

Abstract:
The push for integrating technology into k-12 curriculum from social and political forces has exerted tremendous pressure on schools and education support institutions to provide adequate professional development opportunities for teachers beyond just fundamental technical training. According to OTA (1995), less than half of American schools provide teachers with training on basic computer skills, let alone the training on instructional uses of computers. It is not a surprise to see not many teachers actually use technology regularly in their teaching (OTA, 1995; McKinsey, 1996). Such conflicts between the call of the reforms and the reality of the teachers’ work require teacher learning opportunities that directly address the emergent problems that teachers confront in their practices.

The importance of learning communities for professional development is much discussed in literature (Schwab, 1976, Lave and Wenger, 1991; Hallwa and Lindy, 1999, Putnam and Boko, 2000). In the past 10 years, the calls for a commitment to alternative means of inservice teacher professional development have increased exponentially. This is considered as the key to any and all educational reform (Wilson & Berne, 1999).

This paper intends to examine the role of a teacher learning community in relation to teacher learning for technology integration and professional development. By focusing on the content and conditions of teacher learning through this teacher support group, this study will deepen our understanding of the role of teacher learning community for professional development of inservice teachers.

This paper explores the benefits to all stakeholders when student mentors are used within a graduate course in educational technology. Stakeholders include the university professor, thirty-four practicing K-12 teachers working toward an M.Ed. in Educational Technology, and three eighth grade students proficient in using some of the software used in the graduate course.

The purpose of the course is to develop graduate students' skills and sophistication with a variety of multimedia tools appropriate for K-12 teachers. In addition, these students produce an electronic portfolio that provides evidence of their expertise in educational technology. Students use Inspiration, PowerPoint, HyperStudio, iMovie, and a variety of graphics editing programs.

This study incorporates Dennis Harper's Generation www.Y model of training K-12 students to assist teachers with technology use and curricular integration. The Gen www.Y students developed technology skills, collaboration skills, and presentation, teaching, and leadership skills during training sessions throughout the school year. Their training included an in-depth exploration of iMovie as well as numerous opportunities to collaborate with peers and present their ideas and work to large audiences. During the summer, these Gen www.Y students assisted graduate students as they learned to use iMovie.

This paper discusses benefits to the university professor, the graduate students, and the Gen www.Y students. Data sources included observations, open-ended surveys, and focus groups. The paper also delineates the details of the partnership between the university and the K-12 school district where the Gen www.Y students attended school.
A WEB-BASED GUIDANCE SYSTEM WAS IMPLEMENTED FOR THE LIVING TECHNOLOGY TEACHER

Chao, Shih Van. National Kaohsiung Normal University Of Taiwan.
Department of Industrial Technology Education
jim@controller.nknu.edu.tw

Abstract: The purpose of this study was to identify a junior high school technology student teachers' remote teaching guidance model through Internet. A Web-based guidance system was implemented for the beginning Living Technology teacher.

This system included seven communication paths, which were WWW, E-mail, BBS, Chat Room, Videoconference plus E-mail and Mobile phone/BBCall and mobile short messaging to support the guidance for beginning teachers. This system was mainly used to establish communication among student teachers, guidance teachers, and guidance professors.

Network connection Method Of Remote Teaching Guidance

A survey instrument was design to collect data from all three groups for evaluating the system. Statistical analysis result was discussed. The network resources used in the system were also presented.
The researcher found that WWW and Email were most used by professor and beginning teachers and they worked very well. They were seem not used to communicate with each other by real time communication tools such as CuSeeMe or Chat even though there was no network problems. Beginning teachers were ask question directly to their colleague—senior teacher instead of professor. Therefore, focus on senior teacher’s guidance skill was important to guide a beginning teacher.

Beyond the Classroom:
Using technology as a tool to engage and empower students outside of the classroom

David Michael Cobb, Jr.
The Oakridge School
Arlington, Texas
mcobb@mrcoobls.net

Abstract: As American schools increasingly invest in technology for schools and classrooms, recent research has demonstrated that increases in infrastructure are not equating to increases in technological integration in the learning process. Much more than infrastructure development must occur for computers to be integrated into the curriculum and used in sophisticated ways to engage students. Teachers must be given the training and confidence must be developed to encourage infusion of computer technology into their teaching. Additionally, some teachers who are using technology may not use it to its fullest advantage and with the most efficient means. This guide will focus on methods to engage students and increase contact hours virtually through the integration of technological tools. Four methods of technological integration will be discussed for expanding curriculums beyond the classroom: web page publishing, computer mediated communication, online lessons and activities, and portable curriculum resources.

Introduction

History of Computers in United States' Schools

In 1967, Sir Eric Ashby referred to a “revolution in education” that would occur as a result of evolving technologies in the area of electronic media (Ashby, 1967). Ashby and his contemporaries could not have imagined the realities of the revolution that have occurred since the 1960s. Since that time there has been much enthusiasm, anticipation and conjecture with regard to the role and impact of new technologies and what effects they would have on education in our schools.

In the mid 1970s a few select High school students were using computers as part of their studies. The few students that were exposed to computers in schools were probably involved with elementary computer programming exercises in a language like Fortran, or supplied raw data to be used within a simulation program run on the machine. Generally there was no direct access to a computer in their school. Students from across the country would send special cards marked with code to be entered into a distant computer. Everybody hoped that the results arrived back at school in time for the next lesson but it could be more than a week before students got to see how their efforts fared. It was bad luck for a student sending in work for a Fortran exercise if the only error made was, for example, to forget a backslash or semicolon in a line of code. The role of the teacher in these circumstances remained unaffected. These exercises only served as supplementary lessons to a busy mathematics curriculum. The technology did not help achieve the existing mathematics curriculum it simply added to the curriculum (Campbell-Kelly, 1996).

Yet by the end of the 1970's, microcomputers began to increasingly appear on the consumer market. Machines like the Apple II, Tandy TRS-80 and Commodore were successfully marketed to household consumers. Early on few made it into schools and even fewer into classrooms. The beginning of the 1980's also saw a few primary school teachers taking an interest in microcomputers and their use in classrooms. In most cases, early teachers using technology were enthusiasts or computer hobbyist. However, computing as such was still seen by the majority of educators to be the exclusive domain of computer scientists, mathematicians or businesses. For one reason, microcomputers were extraordinarily expensive and out of the fiscal reach of most schools (Campbell-Kelly, 1996).

By the beginning of the new decade, computers were acknowledged as effective and efficient tools in business. Schools began to be asked questions about possible educational applications of computers in schools. Yet, the cost and availability of computers made the questioning merely philosophical. In 1981, IBM introduced their version of the personal computer (PC) for use in home and schools. The Apple Computer Corporation responded to the growing competition with an offer to assist schools with breaking into the technological age. Many schools gladly leaped into the new realm with the offer of a 64K RAM Apple II+ computer, with a 128K capacity floppy disk drive and color monitor for free or at a very low price. This helped set the scene for educational computing to take off in both primary and secondary schools. All of a sudden, just about every school community began to see computers for their students as a goal. In 1983, the release of the less expensive and more powerful Apple Ile and Commodore 64 models increased the already piqued interest of politicians, administrators, parents, and teachers on possible educational benefits (http://www.digitalcentury.com/encyclo/update/comp_hrd.html). As the computer market exploded in the 1980s, schools increasingly moved computers into schools and classrooms. The number of personal computers in use in homes and schools more than doubled from 2 million in 1981 to 5.5 million in 1982 (Office of Technology Assessment, Teachers and Technology: Making the Connection [OTA, 1995], 1995).

As the technology infrastructures were being constructed in schools across the country, a new vehicle for technology integration was being developed. The Internet traces its history back to a U.S. Department of Defense research project called ARPANET started in 1969. However, the resources of this computer network were not opened to non-military users until the 1970s,
and big universities were the only early takers of the newly termed Internet. Yet in 1989 Tim Berners-Lee, a physicist working at CERN, the European Particle Physics Laboratory, was developing a collection of “hyperlinked” pages of information distributed over the Internet. The information would be distributed via a network protocol called HTTP (hyper-text-transfer-protocol) in what Berners-Lee termed the World-Wide-Web (Web). With the new advances with computer hardware, software, and now the Web, schools and districts began to allocate more of annual budgets to increased numbers of computers as tools for student retention and as a quantifiable demonstration of advancement. The Web has made the benefits of the computer and the Internet so much more readily seen. In the 1992-1993 school year, the National Center for Education Statistics estimated that public and private elementary and secondary schools spent over $280 billion on technology infrastructures (Digest of Education, table 33). Through the early 1990s schools endeavored to develop technology plans and programs. In 1992 the number of computers in schools had surpassed 3.5 million and more growth was occurring (OTA, 1995). In 1994, the Clinton Administration set a goal of connecting every classroom and library in the country to the Internet. As this goal was announced only 35 percent of schools and 3 percent of classrooms were connected to the Internet. By 1999, 95 percent of all schools, and 63 percent of all classrooms had been connected to the Internet, with one instructional computer with Internet connection for every six students (Orszag, 2001).

Since the turn of the century, educators have begun to explore with more constructivist technological integration programs. Constructivist theory argues children actively construct their knowledge. Rather than simply absorbing ideas spoken at them by teachers, or somehow internalizing them through endless, repeated rote practice, constructivism proposes that children actually invent and develop ideas through active learning (Forman, 1988.) Thousands of schools have invested in laptop computer labs and classroom laptop sets. Over 500 high schools across the nation have gone to full laptop learning environments. In a full laptop environment, each student has his/her own laptop for school and home. These innovative schools are on the cutting edge and complete research has not been done on the eventual effectiveness of this type of endeavor. However, early results show great promise in engaging, empowering and transferring ownership of learning to the students. Several studies suggest educational benefits related to laptop use. Specific benefits noted include increased student motivation, a shift toward more student-centered classroom environments, and improved school attendance (Stevenson, 1998). In the 1998 Stevenson study of a laptop pilot program in Beaufort, South Carolina students with laptops demonstrated a “sustained level of academic achievement” as opposed to students not using laptops who tended to decline during the same period. The study also states that academic benefits were most significant in at-risk student populations (Rockman, 1998).

Research into the educational use of laptops has only begun; laptops have not been in place long enough to generate complete studies of their impact on student achievement.

Integration of Technology In Schools

Since Ashby’s prophetic prediction of a “revolution in education” we have seen incredible advances in computer technology and technology availability for schools. Unfortunately, during the great infrastructure build up of the 1990s the needs of teachers with regard to professional development went almost entirely ignored. Increasing numbers of computers found their way into many schools with little planning for integration to improve existing curriculums. Unsure of what they could do with these computers, or lacking confidence to use them or time to learn how, many teachers simply ignored them or left it to the “computer teachers” to use the equipment. So although through the years of tremendous increases in computer hardware and software availability in schools, few teachers have kept up with the technology to enhance an engaging learning environment (Hunt & Bohlin, 1995). Yet, research clearly demonstrates the potential worth of computers as a part of student learning and national, state, and local educational standards have named computer implementation as a primary goal (National Center for Education Statistics [NCES 1995], 1995). Recent research has given strong evidence that technology brings incredible educational benefits. John Cradler, Technology Director for the Chief State School Officers of California conducted a study entitled “Summary of Current Research and Evaluation Findings on Technology in Education” for the Far West Laboratory, an education think-tank. The study’s findings clearly indicate that technology has important benefits to curriculums, students, and teachers. The following is a list of outcomes for students and teachers with effective technological integration in curriculums.

For Students:

- Increases performance when interactivity is prominent.
- Increases opportunities for interactivity with instructional programs.
- Is more effective with multiple technologies (video, computer, telecommunications, etc.).
- Improves attitude and confidence especially for “at risk” students.
- Provides instructional opportunities otherwise not available.
- Can increase opportunities for student-constructed learning.
- Increases student collaboration on projects.
- Increase mastery of vocational and work force skills.
- Help prepare students for work when emphasized as a problem solving tool.
- Significantly improves problem solving skills of learning handicap students.
- Improves writing skills and attitudes about writing for urban LEP students.
- Improves writing skills as a result of using telecommunications.

For Teachers:
- Less directive and more student-centered teaching.
- Increased emphasis on individualized instruction.
- More time engaged by teachers advising students.
- Increased interest in teaching.
- Interest in experimenting with emerging technology.
- Teacher preferences for multiple technology utilization.
- Increases administrator and teacher productivity.
- Increased planning and collaboration with colleagues.
- Rethinking and revision of curriculum and instructional strategies.
- Greater participation in school and district restructuring efforts.
- Business partnerships with schools to support technology.
- Increased education involvement with community agencies.
- Increases in teacher and administrator communication with parents.

One of the top reasons teachers give for low level of technology inclusion is lack of training (Bosch & Cardinale, 1993). A large amount of reports and studies have revealed that both beginning and veteran teachers feel inadequately prepared to integrate technology into their curriculum. In a 1995 survey, the Office of Technology Assessment found less than 10 percent of new teachers felt prepared to implement technology in an effective manner (Abdal-Haq, 1995). Yet the nation is embracing technology at an incredible pace. A January 2000 report from the White House stated that more than half of all American households now use the Internet, with “more than 700 new households being connected every hour.” In a 1995 study over eight in 10 families were planning a PC purchase in the next year and cited “children’s educational use” as the reason for the purchase. With all the recent research pointing to the benefits and proliferation of computers in education and American homes the need for effective technological integration has never been greater (Schacter, 1999).

While advances in the technology have made computing much more accessible and user friendly, many teachers still lack a clear starting place to begin integration. It has been estimated that secondary school students spend only 25 percent of their computer time doing productive learning with technical assistance (Becker, 1993). And many teachers who have begun integration lack direction on how to continue to build critical thinking and student based learning through the use of technology. But what they are missing out on is an opportunity to experience first-hand the benefits of a cooperative learning environment where teacher and student can expand learning objectives. Teachers need to be able to fall back on a readily accessible support mechanism for those times when confidence and direction are challenged and threaten to frustrate their efforts and waste valuable time (Johnson, 1997).

Despite the difficulties to study the ever changing field of technology and its effects on education, the majority of recent research gives evidence that computers offer great educational benefits (Orszag, 2001). A recent study conducted by the Miken Institute concluded that effective computer integration into curriculums greatly improves student performance. However, the study also cautions that for effective integration to occur, computers must be used to engage students and encourage critical thinking. Implementing tools that shift focus to student-centered learning have been found to have the greatest possible effect. Many available technologies allow teachers to engage students with the curriculum while empowering them with choices in the learning (Schacter, 1999).

Abstract: OSU Extension, as the outreach arm of The Ohio State University, has traditionally addressed the need to enhance teaching skills among its program personnel via face to face in-service training. With approximately 900 educators located in 93 field offices, the OSU main campus and at numerous research centers, providing training to meet individual needs at a teachable moment is challenging. Through the development of an experientially based multi-media program Enhancing Teaching and Learning Dynamics, the authors intend to individualize instruction. This paper session will share the development of the program and highlight how instructional technology was used in conjunction with localized coaching and feedback activities to develop a skill enhancement program.

Introduction

To remain viable in today's high touch informational society, formal and non-formal teaching in higher education must incorporate computer-based instruction. Educators must keep up with the technological revolution that has restructured how people access knowledge. Teaching effectiveness and instructional strategies take on new dimensions when teaching via distance education methods. Those who are comfortable teaching in face-to-face environments are facing challenges requiring new approaches to teaching and learning. Teaching strategies highly effective in group settings may not enhance learning when the learner is sitting in front of a computer in the comfort of his/her home or office.

The Extension Employee Development Network at The Ohio State University provides training for employees on effective teaching as well as assisting with teaching components for undergraduate/graduate classes on teaching strategies, adult learning, and incorporating critical thinking into learning environments. The OSU Extension faculty who are major recipients of the Employee Development Network's teaching are hired for their subject matter expertise. These employees may not have education degrees or experience in teaching, yet their major role is that of educator/teacher. Therefore, it is imperative that these 900 plus employees receive effective teaching training so they in turn can teach learners throughout Ohio.

The Employee Development Network has traditionally taught effective teaching courses/modules in face-to-face group settings. Four members of the Network decided the time had come to revamp this teaching experience in alignment with high tech teaching strategies. A multi-faceted approach was used in the development of this individualized "effective teaching experience". The "experience" includes a computer-based training/teaching module (web-based or a CD), on-line learning partners, concept
integration through teaching and facilitated learning, coaching and observation, and advanced training and in-service offerings. The experientially-based multimedia resource CD includes video references, text information, hyper-linked text, video/text/audio examples of implementation methods, pretest/posttest evaluation instruments, comparison log template, and application exercises.

The quality of teaching and learning cannot be compromised when using computer-based training. Teaching and learning principles and theories are just as critical in high tech dissemination of information as it is in high touch learning environments.

Constructivist Learning Theory and Instructional Design

The authors have focused on "constructivist learning theory" as a theory appropriate for guiding instructional design projects that are computer-based. According to Bencze (1999) constructivism emphasizes the mental building learners seem to do when they learn. The theory relates to the gestalt way of thinking that the whole is more than the sum of its parts. In the field of management this idea is referred to as synergism. Learning, from the bringing together of various input from different parts of our lives, suggest the need for active versus passive learning.

The authors of this paper were also the designers of the aforementioned multi-media experience on effective teaching. Their operational definition of constructivism was:

...a philosophy of learning that subscribes to providing learners with active learning processes that provide experiences, collaborative activities, shared discourse and reflection that encourages the learner to assemble, build and/or construct their own and a shared knowledge base. Thus, providing the learner an opportunity to take the knowledge gained through these active learning processes and extend it beyond what was presented. (Bencze, 1999)

Following are critical instructional design principles that support a constructivist learning theory. These support the writings of Rosenberg (2000).

* educational goals must motivate and compel the learner;
* program activities/exercises must focus on learning by doing;
* learners need to perceive that the educational environment is one in which it is safe to fail;
* coaching and feedback strategies are a critical component;
* examples of modeling by experts are provided as part of the experience;
* authentic case studies and scenarios are furnished for a realistic perspective;
* the product affords opportunities to apply/reuse information after learning occurs;
* interacting with the program sets the stage for the learner to bridge "real life" experiences with the learning.

Experiential learning theory is compatible with active learning and constructivism. Kolb’s (1984) four components of experiential learning include:

1. Concrete experiences including sensing and feeling
2. Reflective observation also referred to as watching
3. Abstract conceptualization involving thinking
4. Active experimentation or stated also as doing.

Whether teaching credit courses, providing in-service training for extension faculty and staff who teach community-based non-formal courses, or conducting effective teaching workshops for college professors or graduate teaching assistants, faculty must be on the cutting edge of technology. With every passing year, many learners arrive with more and more high tech literacy. The younger generations in the workforce are described as “cyber literate” and “techno savvy” (Salopek, 2000). Training programs and learning experiences must catch the attention of those who grew up with the glitz and glamour of videos, MTV, computer games, and learning from high tech/interactive toys.

The higher education students/learners of the future who will have entirely grown up in the digital age will have a tremendous edge on information technology. Alch (2000) said in reference to the net generation “they’re comfortable with changes brought about by new technologies and e-
commerce...they’re conversant with a communications revolution transforming...education...and every
other institution" (p.32). Are teachers of higher education ready to teach this new generation?

Dunerstadt (1999,p.12) would say that if we are not ready, we had better get ready. In Katz’s
book Dancing with the Devil, Dunerstadt says:

The classroom itself may soon be replaced by more appropriate and efficient learning experiences.
Indeed, such a paradigm shift may be forced on faculty by the students themselves. Today’s
students are members of the “digital generation”. They have spent their early lives surrounded by
robust, visual, electronic media...unlike those of us who were raised in an era of passive broadcast
such as radio and television. They approach learning as a “plug-and-play” experience...inclined
to plunge in and learn through participation and experimentation. Although this type of learning is
far different from the sequential, pyramidal approach of traditional college or university
curriculum, it may be far more effective for this generation, particularly when provided through a
media-rich environment.

Enhancing Teaching and Learning Dynamics Program Overview

The authors of this paper have applied constructivist theory and experiential learning models to
design a multi-faceted, individualized “effective teaching experience” called Enhancing Teaching and
Learning Dynamics: Individual Support for Extension Educators. Starting with the concept of a single
computer-based training CD, we have now expanded the package into a full-scale training module
consisting of a set of interactive multimedia CD’s and four other fundamental components. These
components include coaching activities facilitated by experienced Extension educators, an on-line learning
partners web-site, concept integration through teaching and facilitated learning within the responsibilities of
an Extension educator, and advanced in-service offerings. Each CD within the resource set contains an
introduction and a menu of its contents so that an individual may create his/her own path of exploration as a
self-determined learner. The CD also includes video/text/audio presentation of content, printable text-
based materials, hyper-linked text of key terms and concepts, examples of implementation techniques, tips
on concept integration, evaluation instruments, a journal for self-reflection, interactive application
exercises, checklist and form templates, reference lists, and a link to an on-line resource site. Figure 1
illustrates the relationship of each program component to Kolb’s (1984) experiential learning theory and
Rosenburg’s (2000) instructional design principles. (Figure 1 attached)

Best Practices for Effective Educational Design

One of the side benefits from the creation of the computer based program on effective teaching is
knowledge gained relating to the “how to’s” of designing educational experiences that are computer or
web-based. The authors offer the following advice to other educators who are ready to accept the challenge
of designing a computer-enhanced learning experience:

Make it a team effort that brings together expertise in the subject matter being taught, expertise in
educational design and expertise in computer-based programming. If any of the three areas of
expertise is missing, the quality of the end product will be compromised.

Learn from others’ experiences by accessing other educational computer programs. Try out the
activities and make a list of the techniques/strategies you like and dislike. Have colleagues
interact with the program and make a list. Compare the lists of likes/dislikes and then decide
which would be appropriate for your project.

Engage the assistance of a “sounding board” comprised of people who are representative of the
end users. Have them continuously interact with the evolving program and give feedback as a
type of formative evaluation.
Include a variety of learning activities that meet the various needs of your learners. Ask yourself if the training is tailored to different learning styles, or are you trying to make one size fit all (Goldberg, cited by Salopek, 2000).

Stonecipher (2000) poses the question and answers it—"will the introduction of new technology present any threat to traditionalists? Of course it will...we need to make sure that we are on the winning side of new technologies" (p.3).

A Challenge to Educators

Many in higher education are indeed traditionalists. Some educators will feel threatened but many will rise to the challenge of integrating new technology strategies with their current teaching methods. For those who do not rise to the challenge, they may retire from the "ivory tower" never having 1) provided feedback to a student via e-mail; 2) given a grade to a graduate student they have never met; or 3) engaged in a debate through a chat room with students from nine states and four countries. The time is right for experimenting with learners. Higher education must rise to the occasion.

Collaboration between University and Schools in the Appropriate Use of ICTs in Teaching and Learning.

Jolanda Bueno de Camargo Cortelazzo
Doctor in Education, Teacher in the Pedagogy Course and in the Graduation Program in Education and Researcher on ICTs use in Education at Universidade Tuiuti do Paraná, Brazil
jolanda.cortelazzo@u tp.br icortel@attglobal.net

Abstract: This research investigates what teachers think of and how they use ICTs in their teaching practice in Higher Education and proposes collaborative projects to make teachers more prepared and updated to optimize their students learning through the appropriate and effective use of ICTs. But this research does not focus only the operational aspects of ICTs. On the contrary, it starts from the point that the knowledge of the history of technology and the appropriation of the use of ICTs can permit teachers to understand the impact ICTs have on their actions, on their own development, on students learning styles and process. Since ICTs are intensively present in the society in which teacher and students live, both in Higher Education have to discuss how ICTs affects society and think of ways to control and regulate them in favor of a sustainable life for the human kind.

Introduction
In Meetings, Conferences and in teacher empowering courses, you become aware that there are a number of graduated professionals from Human Science and Teacher Colleges working in a different area not related to the courses they had attended. Many continue in the same function they had occupied before taken their Higher Education Courses. Others are unemployed. One of the reasons they present is that they do not correspond to the labor market need either because they do not have experience or because they do not master the Information Communication Technologies, ICTs.

Recently, private educational institutions and the human-resource departments in the companies, in any level, have been more demanding in choosing new employees for training functions as well as for teaching, administration and coordination. They demand competence and proficiency in the use of ICTs either as distance or face-to-face instruction,

On the other hand, there are many non-academic courses that teach just operational instructions in the use of computational applications and systems as if all ICTs were just operationally relevant. There are no care with the orientation of how, when and why to use the ICTs in Education and in the professional development at school, at the University or in-service. There is no study of the history of technology and as it outcomes from specific political and economical issues. There is no reflection on the use of ICTs as collaborative technologies that promote collective intelligence, creativity and teamwork. They do not prepare teachers to the use of ICTs in Distance Education, favoring the relationship among peers and the interaction among students beyond the school walls. They do not even preview negative consequences which could come from the inadequate use so they could prevent or minimize them.

On the other side, state and city public schools receive principals, coordinators and teachers selected in public contests which do not preview the competence verification neither in the use of ICTs nor in the collaborative work. Therefore, most of the school professionals do not have competence and proficiency in the use of ICTs and they do not know how to introduce them or implement their use in their schools. Most of these professionals use them as tools individually, without realizing their potentiality as collaborative tools enhancing creative and efficacious team work, besides optimizing their individual work, their research and their personal development.

Based on the project “Quality in public teaching and teacher formation”, at USP, São Paulo and on my own experience in teacher development courses, besides the production of knew knowledge in the field, this research can bring relevant contribution for the Pedagogy curriculum to improve teacher development, to satisfy the needs in this professional field as well as to fulfil a social function in the community.
Theoretical Fame

The teacher responsibility in the construction of a communication society can not be limited to the acceptance of the technological determinism that technology will master more and more the society, restricting its liberty, making it automated and controlled. Teachers must see the ICTs as mind extensions which can enhance the human creative, sensorial and cognitive capacity.

Large computerized databases permit information storage, classification, selection and retrieval in ways which were impossible to be manipulated by human being’s memory. The simulators amplify the imaginative capacity while the virtual reality amplifies the perception, enabling the virtual manipulation of dangerous experiments.

Telematics, integration of telecommunication and informatics, decreases space and time barriers and permits the development of a creative collective intelligence (Lévy, 1996). It creates conditions to access virtual libraries and the realization of projects with partners of institutions in other regions of your country and/or abroad. It also enables teachers and students from public schools to share projects. Finally, telematics optimizes the existing technological infrastructure if teachers are well prepared to its appropriate use.

Artificial Intelligence permits people to work with enormous databases and elaborate projects taking decisions much more rapidly and accurately.

We, teachers, are responsible when we make up our minds to act, or not, to develop in our students a criticism in using ICTs, putting them to the service of the society through a collaborative collective action to produce new social scenarios and new humanizing knowledge.

Instead of seen them just as tools which substitute or make human beings slaves, we can “make them tools and instruments which give freedom to people and social groups” (Martin, 1997:14). Autonomy and competence to search and retrieve information in communication networking will permit teachers and students to experience the permanent exercise of communication and information.

This experience, done through the manipulation of the ICTs, must be integrated to the curriculum not as a simple operational action, it must be embodied as a resource, as study object and as educational agents.

Lévy (1998), Martin (1999), Postman (1996) point out the danger of people to be drown in an information ocean if they are not prepared to look for information with selection and value criteria. As Postman says (2000:170), schools have to be worried with those psychological, social and political effects technology impose. Thus, it is urgent for us, teachers of teachers, to prepare a “technology education” and to organize our courses with time and space for reflection so we can develop, in our teacher-students, concepts, attitudes and skills to analyze both the use of ICTs and if the collected information ethic they work with is true, relevant and.

It is essential for students and teachers to realize that people can be emitters, authors and agents and the ICTs are media for them to learn, work, have fun, create, communicate and collaborate interactively.

When teachers become effective and reflecting ICT users, they will realize they can help to improve student learning efficiency. It is not enough to introduce activities mediated by different technologies, it is fundamental that teachers experience technology in their own development as a mediator of information search, selection and retrieval and in the communication with their peers, their students and the community where they live in. Using ICTs as other means to do research and to communicate, the teachers will certainly be able to work with them, awake their students interest and guide them in the mastering and controlling process of ICTs for their own growth.

Research

This research is an experimental action research in the sense that it tries to produce new knowledge from the investigation of a present situation and proposes an educative action from the results of this investigation getting along with it and assessing its process and outcomes.

At first, the investigation diagnoses if the 1998-2001 graduated teachers from UTP Teacher College have enough knowledge of the ICT educational and teaching potential as well as it collected data to characterize the social contexts and the teaching contexts where they have been working. They answered a questionnaire and attended a lecture “ICT Mediation in Education” to sensitize those who were still resistant to ICTs and to bring updating information to those already familiar with them.

This research investigates also the functions which the 1998-2001 graduated teachers from UTP Teacher College have been carrying out using ICTs, their competence in using them as collaborative tools, or other educational uses people make of them.
Teachers graduated in the years 1998, 1999 and 2000 did not have any preparation to use ICT in education during their under-graduation course. "ICTs in Education" as a discipline in the Pedagogy curriculum was introduced at UTP Teacher College in 1999 (those classes graduate in 2001). So it is possible to compare their competence, to know if they had any kind of instruction in using TIC in their professional life and how it works in their teaching practice.

Collected data will permit to plan and execute a 60-hour empowering course aiming to the reflecting teacher formation, adopting the collaborative educational action approach with individual projects interlaced with community and school collective projects. The teacher-students in this course will write a brief history of technology and work with ICTs as different forms of representation and communication and as mediators of a renewed and transforming education for a society with more equity and solidarity.

Since most in-service teachers cannot come back to University to study, a Distance Education program can provide them an environment to learn, discuss and reflect on the collaborative use of ICTs in education. The research also brings necessary information to improve the curriculum of Pedagogy at Teacher College so that under-graduate students can experience ICTs, collaborative team work along their course as well as transfer what they will have learned to their teaching practice.

Partners

In parallel, ICT companies have been contacted to start a partnership with the University to promote a support to teacher continuing education in the use of ICTs. It is a trend to bring the enterprise to develop partnerships with schools to fulfill their social function. The research contributes with new knowledge on the use of ICTs that can be shared in the companies. It is a multiple-way partnership. The research gets funds, the enterprises get knowledge, schools get qualified teachers, teachers become competent and proficient and their students, in consequence, have better teaching.

Conclusion

Finally, this research has as basis that the focus must be on the students learning, never on the ICTs, but the teachers go on being the key for teaching and learning. Then, for the success to happen in education, dedicated and true teachers must be empowered by both studying and updating their knowledge as well as their use of ITCs. As they transfer their knowledge to their practice, a constant discussion and evaluation have to be held. As a parallel outcome, a new experience in working with face-to-face and distant courses will be created and evaluated as it goes on.

Web-based Multimedia for Educators Course

Caroline M. Crawford
University of Houston-Clear Lake
United States of America
crawford@cl.uh.edu

Abstract: The instructional design that is imperative towards the design and development of a Web-based course environment is of primary consideration when a graduate-level course is the focus of attention. Further, a multimedia course that incorporates the theoretical as well as hands-on elements that must be consistently focused upon and updated is of further concern. What is the most productive way to constantly maintain the most recent knowledge within the multimedia genre, as well as offer a wide scope of multimedia environments through which to offer the learner a full scope and sequence of curricular events? The analysis, design, development, implementation and evaluation of two significantly distinct Web-based learning environments will offer a clear progression through the initial instructional design phase, clear feedback offered by the learners which drove the second instructional design phase, and the results of the second implementation and evaluative efforts pertaining to the course.

Introduction

Within the revisionist's redesign of the course, the curricular scope and sequence shifted, the access to the knowledge and interactive elements shifted, the flow of the course significantly changed and the learner's feedback on the newest course structure is intriguing. Educators must have the opportunity to delve into the graphic design basics, pertaining to textual layout as well as the importance of using type styles within distinctly different environments, have a clear understanding of instructional design basics, focus upon flowcharting and storyboarding a multimedia product, remain sensitive to human/computer interface issues, and remain closely tied to the formative and summative evaluation stages of the development stage. Further, a shift in the Web-based mentality impacted the outcomes of the learner's level of understanding throughout the course; this Web-based versus Web-enhanced structural shift offered opportunities to the learners that eased self-regulation issues as well as community-building concerns.

History of the Multimedia for Educators Course

The graduate-level Multimedia for Educators course had historically been taught by adjuncts within the specialization area; therefore, there was no significant standard in place for the course's instructional design. When the author became a member of the Instructional Technology team and took the responsibility to standardize and maintain the course, a significant shift towards meeting the International Society for Technology in Education (ISTE) standards (International Society for Technology in Education, 2000; International Society for Technology in Education, 2001) was continuously integrated, implemented and updated.

As the standardization process for this course was under way, the university developed a plan of action towards the support of the World Wide Web-basing of coursework. The instructional technology specialization area was one of the areas focused upon as an initial area of focus; therefore, the Multimedia for Educators course was one of the initial courses chosen to Web-based. As such, the course structure was as follows:

- Course Introduction
- Unit One: Introduction to Multimedia
- Unit Two: Developing Multimedia – The Basics
- Unit Three – Designing with Images
Each of the course units maintained their own separate unit objectives, which directly identified with the course objectives that were previously identified through the Texas Essential Knowledge and Skills (TEKS) (TEA, 2001) and ISTE standards (International Society for Technology in Education, 2000; International Society for Technology in Education, 2001).

The course interface created a metaphoric representation so as to aid the learner towards the conceptual framework development and understanding. A metaphor surrounding the creative artist metaphor was decided upon, as multimedia is an artistic form of expression that integrates instructional design, imagery, designing with type, video, audio and numerous other interactive entities. Following is the initial interface for the course:

The artistic metaphor was simulated from the home page of the Web site. As the course was developed using a packaged course development software, the iconic representations were integrated from the course development software. Further, the course metaphor was further integrated through out the course structure as image maps simulated in the unit overview section of the course:

The course layout was one wherein all the textual and graphic information was scripted using HyperText Markup Language (HTML) so as to fit within the confines of the packaged course development software, as well as take advantage of the interactive activity capabilities available. Each of the seven Units of Instruction, as well as the Introduction and Syllabus sections, consisted of seven to fifteen pages of
instruction that the learners needed to access. Within the pages, there were numerous hypertext links to either interactive activities or outside-of-course hypertext links to Web sites of importance.

**Concerns With Original Instructional Design and Layout**

The feedback from the learners was mainly positive, as the Web-based course was given to numerous hours of thought and planning before any specific design or development was undertaken. Following are the aspects that the learners noted as being positive within the course structure:

- Course metaphor
- Units of Instruction were color-coded
- Navigation
- Unit of Instruction overviews
- Unit objectives
- Unit Summaries
- Table of Contents at end of Unit of Instruction
- Clearly delineated assignments
- Clearly delineated assessment rubrics for each assignment

However, there were a few areas within the original course that the learners noted as being either difficult or negative aspects:

- Amount of information that the learners needed to review
  (As an aside, the learners printed out every Unit of Instruction page for ease of review)
- Some hypertext links to outside Web sites were “dead” links

As these negative aspects were serious considerations for the course instructional designer, the course was revised the following semester.

**Revisions to the Course**

Revisions to the Multimedia for Educators Web-based course were undertaken over a semester’s time period. Several significant shifts in the instructional design and interactive layout were to occur and a significant period of time was necessary in order to accomplish this. Following are the changes that the course embarked upon:

- Shift the Units of Instruction
- Revise the Online Quizzes
- Change each of the Unit of Instruction’s Layout
- Integrate the instruction within each Unit of Instruction into a downloadable Portable File Document (PDF)
- Integrate audio downloads
- Integrate video downloads
- Integrate PowerPoint presentation overviews for each Unit of Instruction

Following are short explanations of the above revisions to the Web-based course, so as to further emphasize the necessary elements under consideration.

**Units of Instruction Shift**

The instructor desired to integrate a more advanced multimedia software package into the course which, therefore, mandated a shift in the instructional design of the course. Following is the revised course structure:
Some of the previous course elements were integrated into one Unit of Instruction and additional Units of Instruction were added, such as Unit 6: High-End Multimedia Environments. Further, the knowledge-level online quizzes for each Unit of Instruction were revised to reflect the shift in subject matter.

Unit of Instruction's Layout Shift

The layout for each Unit of Instruction was meant to allocate more space to the areas of greatest importance within each Unit, as the majority of the instructional information would be included within the Portable File Documents (PDFs) for each of the Units. Following is a simplistic layout example for a generic Unit.

![Unit Layout Example]

Each of the Units of Instruction included each of the elements included in the layout delineated above. Therefore, the significant difference between each of the Units of Instruction would be the color allocated to each Unit of Instruction, as well as the Unit Downloads and Unit Activities made available. Further, the Unit objectives and Unit assignment and assessment rubric would be available for the overview of each Unit of Instruction. As well, each of the Unit of Instruction slide show presentations, audio and video downloads would be appropriate to the Unit in question.

Portable File Document (PDF) Instruction Access for each Unit of Instruction

Each Unit of Instruction consisted of its own portable file document (PDF) that organized the unit knowledge into an appropriate instructional design format to emphasize the materials to be integrated into the learner’s knowledge base as well as to designate the interactive activities that would offer the opportunity towards higher order thinking skills. The PDF format was chosen due to its portability factor and the ability to designate a page layout for each presentation of the content. The content contained within
the PDF document offered an ease of instructional shift for the faculty member due to the lack of HTML scripting that was previously necessary. Quickly changing the document, saving it as a PDF, and uploading the file to the server was all that was necessary to revise the course content.

Integrate PowerPoint Presentation Unit Overviews, Audio and Video

Each Unit of Instruction offered a PowerPoint presentation as a Unit overview, as well as audio and video files of the instructor stating the main objectives of the Unit. The audio and video files were meant to test the perceived learner-instructor relationship that occurs within a face-to-face course yet may not occur to as great an extent in a Web-based course learning environment.

Learner Feedback

The new layout of the course was tested the next semester, with student feedback noting significant elements of interest:

- The High-End Multimedia Environment integrated into the course, although significant support information was available to the learner, was overwhelmingly disliked due to the steep learning curve over a short allocation of time. The learners noted a desire that a high-end multimedia environment with a less steep learning curve be considered as a replacement.
- The students stated their approval towards the PDF documents for each Unit of Instruction. They noted that it was easier to print out the information, if desired, as well as the portability factor was desirable when they moved from computer to computer throughout their daily activities. They disliked accessing the course Web-based site constantly for other courses and enjoyed the ability to manipulate their learning environment through the portability of the PDF documents for each Unit of Instruction.
- The students noted a lukewarm attitude towards the slide shows available for each Unit of Instruction, although they all noted that they reviewed each one available for each Unit. The audio and video files were not available at the time of review, so the learner feedback was unavailable for the audio and video file level of success.
- The students stated that they strongly supported the "cleanliness" of the Units of Instruction. The layout was easy to access and review, as well as printing out the information available aided them in their motivation and time allocation.

Conclusion

The instructional design that is imperative towards the design and development of a Web-based course environment is of primary consideration when a graduate-level course is the focus of attention. The interactive elements of a Web-based course is also of significance throughout the instructional design process with the focus being allocated towards the learning environment, the ease of information and activity access, and the clear layout of each Unit of Instruction.

Online and Onsite Action Research:
A State Wide Professional Development Model

Abstract: This paper is a description of a collaborative state-wide action research professional development program. The program centers around an action research course that employs a variety of distance education delivery strategies, including a newly developed and innovative online course. The purposes of this paper are to: 1) outline the local action research program and its instructional and collaborative principles, 2) illuminate the state-wide collaborative efforts and organization, 3) describe the distance education delivery strategies, 4) outline the online course, and 5) discuss preliminary findings.

Action research or teacher research is a form of reflective practice based on the principles associated with systematic inquiry of one's own educational practice. Historically, action research was embedded in social action and critical perspectives required to illuminate issues of curriculum and the social structure of schooling. Throughout the decade of the 1990s, action research, and its various forms of participatory inquiry began to emerge in graduate programs and higher education focused professional development endeavors. However, in recent years, action research has become an increasingly popular form of K12 professional development (Licklider,1997; Lytle and McGuire,1993). Its popularity can be noted in K12 staff development guides, school reform efforts, and workshops (Halsall,1998; Harris, 1998).

The popularization of action research has created challenges for educators who believe that this model of professional development is, by its very nature, different from the more traditional forms of training, workshops, and inservice education. As action research has expanded into the arena of district promoted staff development (Kochendorfer, 1997; Lytle, 1996), there is a tendency to reduce its conceptual, instructional, and contextually-driven frameworks into more discreet packages of “how to” or “tidy tips” approaches demanded by overworked and highly-pressured classroom teachers. Furthermore, there is the tendency to promote locally driven, collaborative and successful programs to a larger audiences. The challenge here is to keep to the pedagogical and collaborative tenets vibrant as more distance education strategies are employed in the ever expanding dissemination process.

It is within this changing world of professional development and action research, that a local and collaborative action research program evolved into a large dissemination project. The question before the developers of a local action research program called ULEARN (Utah-Local Educators Action Research Network) was, how do you deliver a state-wide professional development program and maintain the instructional quality and collaborative nature that framed a successful local program? The purpose of this paper is to: 1) outline the local action research program and its instructional and collaborative principles, 2) illuminate the state-wide collaborative efforts and organization, 3) describe the distance education delivery strategies, 4) outline the online course and 5) discuss preliminary findings.

The Local Effort and Guiding Principles

Building upon years of instructional and evaluative knowledge about the role and design of a successful graduate action research program (Crow, Stokes, Kauchak, Hobbs, and Bullough,1996), a professional development effort was initiated in 1994 by four teacher educators from the University of Utah, Davis, Granite, and Salt Lake City School Districts. The teacher educators represented one full-time faculty member and three University/District Liaisons (half-time at the University of Utah and half-time in their respective district’s Staff Development Offices). The goal of this collaborative venture was to design and implement a high quality professional development course for K12 educators using an action research model (Crow, Adams, Bachman, Peterson, Vickery, and Bernhardt, 1998). The subsequent course and
U-LEARN (Utah Local Educators Action Research Network) program was developed and infused with six guiding principles that grew out of the work by Judith Warren-Little (1993). U-LEARN principles are:

1. Professional development should be educator-centered and context-specific.
2. Professional development is sustained within a community of learners focused on studying and discussing teaching and schooling practices.
3. Professional development should allow educators the opportunity to generate meaningful and passionate questions and pursue those questions within an atmosphere of support and knowledge of the action research process.
4. Action research should encourage a variety of "ways of knowing" that are useful to each educator.
5. Learning the action research process requires sustained instruction by competent teachers, application of knowledge and skills by interested educators, and a community of learners involving participants and instructors.
6. Action research is both exciting and painful. There are no right, common or easy answers. The process is "messy" and intriguing. The teacher empowerment is breathtaking.

The first course was taught in 1995 to 30 K12 teachers and administrators in the three participating school districts. Taught onsite in various schools, the participants and instructor met for 90 minutes every week during a seven month period. Taught every year, participation in the six-credit semester course grew rapidly to 80 educators in 1998. By 1998, a consortium of seven rural school districts in central Utah called CUES (Central Utah Education Service area) approached the U-LEARN instructors with a proposal to provide the same course to their educators. The CUES course employed the state’s two-way audio and video conferencing system (EDNET) to create weekly teaching sessions broadcast to five rural districts locations. Additionally, the course implemented four onsite teaching sessions in two locations. In September of 1998, the CUES distance education program was delivered to eight selected educators who then became onsite facilitators for future CUES action research courses. By May, 2000, the CUES course had successfully taught an additional 35 educators in these rural school districts.

State-Wide Collaborative Efforts and Organization

By late 1999, the four University of Utah teacher educators/course instructors were approached by representatives from the Utah State Office of Education and, a large K12/higher education consortium called the Brigham Young University Partnership. In a series of meetings, a state-wide action research professional development program was developed called the Action Research Initiative.

In order to create a locally and contextually driven program directed by collaborative efforts and centered in communities of learners, the Initiative organized the state of Utah into seven regional areas (see www.ed.utah.edu/ulearn). Each of the seven areas were represented by a local regional director (K12 administrator), one of the four University of Utah (UU) instructors, and a cadre of urban and rural assistant instructors called Lead Instructors. The coordination needed for recruiting participants was lead by the regional director and supported by the UU instructor. Financial resources were supported from Goals2000 Grants, directed by the UU instructor, and housed in the region’s school district.

Presently, five and of seven regions are active participants in the Initiative efforts. The five regions include eighty percent of the urban Wasatch area (two regions: BYU Partnership and Utah Education Consortium consisting of the University of Utah and five local school districts) and three rural consortiums (including 20 rural school districts).

Distance Education Delivery Strategies

From the beginning of the U-LEARN program in 1994, the four University of Utah (UU) faculty members framed their efforts and course instruction with the guiding principles of action research and coupled them with the following instructional quality indicators: sound theoretically framed content, high
instructional touch, classroom relevance, teacher empowerment, and appropriate academic rigor. The challenge of the Initiative program was to keep these guiding principles and instructional indicators front and center while employing more distance education and technologically-based approaches. To do so, the foci of the distance education delivery strategies were high tech and high touch. In order to achieve these goals, several key distance education strategies became integral Initiative program elements.

The first element was the instructors. Each region was directed by a University of Utah instructor. Each instructor worked with 3-6 Lead Instructors. The Lead Instructors were selected from K12 educators who had either completed a Masters degree with an emphasis on action research or completed years of U-LEARN course participation. Furthermore, Lead Instructors were selected because of their ability to work with adult learners, demonstrated proficiency in the action research process, and work in their own K12 classrooms. The UU and Lead Instructors worked with regional participants during the onsite teaching sessions and acted as “online course coaches” to those same participants.

The second distance education element was the onsite teaching sessions. The sessions were taught in each regional area. Because of the large geological area, two teaching sites were designated within each region. While the four onsite sessions covered content represented in the online course, the sessions also provided an opportunity for instructors to meet with participants. Personal contact was important for several reasons. Firstly, most participants were new to the online course environment, therefore, anxiety and confusion were high, particularly during the initial months of the class. Secondly, the action research process was a new venture for educators, requiring them to systematically study their own teaching and classroom practices. As a result, the action research process can be considered, a “messy” venture involving ambiguity, questioning, and methodological refinement. These unsettling perspectives often require high touch strategies. Therefore, the onsite teaching sessions became a salient aspect.

The third element was the online course. The online course was developed as a self-sufficient, stand-alone course. However, for the Initiative efforts, the course became a significant enhancement to the four onsite teaching sessions.

The Online Course

Prior to the 1999 call by educators for a state-wide action research program, the University of Utah instructors believed that an online course component was needed to encourage their distance education efforts for the ULEARN program. The online course built upon the curriculum, instructional strategies, and evaluative feedback gained from years of onsite course implementation. The four UU instructors secured funding to design the course with a corresponding website from a 1998 Goals2000 Grant. With grant funds in hand and a curriculum ready for online enhancement, a UU agency dedicated to technology driven applications, called Media Solutions was hired to migrate the course to Learning Space. It should be noted that Learning Space was selected for this project because it was already available to the course designers at no further cost. Additionally, the grant paid for Web Server maintenance through the College of Education and technical support staff.

The online course was designed to teach and apply the action research process to educators’ professional lives by linking the online instructional experiences to their classroom activities. The course was activity-based and field focused. The course employed asynchronous instruction along with directed field assignments and projects, links to the relevant resources, threaded discussions, reflective assignments, journal entries, regional threaded discussion groups, “study-buddy” pairings, links to database reference systems, chat room, and collaborative learning space interactions.

The online course curriculum organization is nested. There are 11 Units. Within each Unit are Modules. Finally, within each Module are Activities. Each Unit and Module is composed of an Overview Statement that introduces the participant to the upcoming content, goals, expectations, and instructional activities.

Media Solution personnel created an online version as well as a hard-copy Participant Guide that served as a “how to” module able to teach beginning and advanced Internet users about: accessing the
Internet, navigating the website, accessing asynchronous activities, and participating in electronic conversations.

Preliminary Findings

September 2001 signaled the start of the pilot year for testing the program organization and the distance education strategies, including the newly developed online course. Presently, there are almost 60 participants located in urban and rural Utah. The course is lead by four University of Utah adjunct faculty members and 17 Lead Instructors working in potentially 30 school districts. The start dates for the course varied by region. One region (CUES) began in September 2001. Three other regions started October/November 2001 (Central Wasatch, NUES, and SEDC). Finally, the BYU Partnership started January 2002. All course participants will complete their action research projects in time for the 1 May 2002 ULEARN Conference. At the conference, participants will share their action research projects with other course participants and invited guests.

Based on observations, informal interviews, field notes, and document analysis our preliminary findings focus on four major themes: 1) the online course development, 2) overall course development and implementation, 3) Lead Instructors, and 4) collaborative process.

Online Course Development: Developing an online course that stayed true to our original, course pedagogical and content principles were a challenge. Most online course software packages are not designed to be activity-based, content applied, and field focused. Most online courses are designed around reading the content, participating in threaded discussions, using the chat rooms, and completing written assignments. Our action research course was and is based on immediately applying learned principles to the field settings of the K12 classroom or school. Furthermore, action research and the inquiry process requires sustained application, reflection, revision, and re-application through instructional directed activities and coaching. Much of the "learning" of the action research process occurred because participants and instructors worked together and through ambiguity and frustration. Designing an online course environment to facilitate and lead participants in a field-driven and applied learning seemed daunting at times, yet always a necessity. The Media Solutions personnel were extraordinarily bright and creative as they adapted a rigid software into an activity-based learning environment.

Overall Course Development: Using the online course as an enhancement to the onsite teaching sessions has helped to create and maintain the sense of community, lessen participant anxiety, and ensure instructor comfort. The onsite teaching sessions became invaluable in introducing the participants to the technology, the action research process, and instructional personnel. While the online environment assisted in developing personal contact through a somewhat anonymous medium, the face to face interactions added a much needed warmth and connection our K12 educators were accustomed to through their more traditional professional development classes.

Lead Instructors: Facing the prospect of teaching and traveling to the entire state of Utah meant that the four, already full-time employed instructors would need to be working two full-time jobs. This was not acceptable nor possible. Therefore, the conceptual formation of the Lead Instructors and actual selection of them made the Action Research Initiative possible. Furthermore, the Lead Instructors formed an additional, and important layer to the community of learners created by the four instructors. As a group, all the instructors struggled with and learned the Learning Space software. Moreover, the Lead Instructors became a valuable feedback resource as the course was designed and migrated to the online medium. The Lead Instructors' feedback guided the development and content needed for the Participant Guide.

Collaboration: Collaboration was messy and difficult, at best. Every aspect of the ULEARN program, Action Research Initiative, and online course was the result of collaborative efforts. The original U-LEARN program and onsite course were developed by personnel forming a university-school district partnership. The program was created to serve the needs of K12 educators, district staff development, and higher education. The state-wide Action Research Initiative was developed through partnership endeavors on the local, regional, and state levels. The Initiative required state leadership and resources while the program implementation was driven by local concerns. Finally, the online course was developed from
several perspectives, including; the four university faculty designers, Media Solutions online and web expertise, and feedback from Lead Instructors as well as participants.

While the collaborative piece sounds neat and tidy, it was not so. Collaborative efforts required detailed planning and fluid philosophies to accommodate shifting stakeholder needs. The best of intentions were often met with changed agendas. Concerning the online course, close and continued interactions, evaluative feedback sessions, and shared development time was required between the primary course designer and software migrator. As a result, the online course development timeline moved from an initial estimated three months to over 20 months.

While the online and onsite course began a few months ago, work on the state-wide Action Research Initiative has been ongoing for over two and half years. Much has been learned, refined, changed, enhanced, and eliminated. The endeavors throughout the process has focused on creating and sustaining meaningful collaboration, empowering educators through the action research process, enhancing distance education strategies, and providing academically appropriate professional development. Embedded throughout the journey was the challenge to consistently stay true to the program and instructional principles.

Integrating Inquiry Based Learning into Project Based Methodology Using a Constructivist Approach

Terry H. Daniels  
Department of Education  
St. John's University  
Wm. E. Grady High School  
New York City Board of Education  
United States  
crtstringer@pobox.com

Abstract: The problem faced in many K-12 classrooms is that teachers have access to computers but don't know how to infuse technology into their instruction. The goal of this paper is to set forth a plan to imbue in these teachers how to use computers in their classrooms and to use instructional technology to augment their teaching. The solution applied to the problem was treated through the implementation of project-based constructivist methodology. Each step in the process was reinforced through the use of hands on projects, which in turn were reinforced in the ensuing steps of the process.

Introduction

The National Education Association (NEA) (2001) has stated that technology is changing how faculty teach and how students learn. Administrators and faculty need to understand the role of technology in the classroom and how it complements the educational experience. Shaw (1999) cites a survey in which 13 percent of 1500 new and veteran teachers stated that they were well prepared to use technology in their teaching. Thirteen percent of veteran teachers versus eight percent of new teachers stated that they were not prepared at all to use technology in the classroom. The International Society for Technology in Education (ISTE) (2000) stressed that it is essential for teachers to create a learning environment through the powerful uses of technology. Technology should not be taught in isolation, but combined with traditional methodology to create new approaches to teaching curriculum while addressing individual needs. The National Council for Accreditation of Teacher Education (NCATE) (2001) contends that in the preparation of today's teachers, technology must become an integral part of the teaching and learning process in every setting.

Discussion

It is apparent that teachers in today's classrooms need support and training to learn how to use technology from the preservice to inservice levels. Shaw (1999) believes that the impact of teacher usage of a computer in every classroom will not become apparent until the class of 2004 graduates from college. Moore and Engeldinger (2001) discuss the need for preservice teachers to have a vision for the integration of technology into their classroom curriculum. This vision must precede the formation of the skills required to become competent users of instructional technology. Huffman (2001) considers what constitutes a successful technology-based learning environment. He stresses the importance of training the teachers who deliver instruction. A search of the literature revealed how to use technology in education, but no overall schema for training teachers to transfer this knowledge into the classroom. Teachers need a model to show them how to integrate technology into their curriculum, not how to use technology as suggested by Frances-Pelton, Farragher & Riecken (2000).

Implementation

A course of study evolved at two large northeastern institutes of higher education between September 2000 and June 2001. Twenty-five postgraduate inservice K12 teachers in an Instructional Technology Master's program and 45 postgraduate inservice/preservice teachers/students in a stand-alone computer course
in a reading and writing program were exposed to a structured instructional technology course of study. Both courses of study used the same methodology and learning skills. Once learned, the basic skills of saving graphics, finding curriculum based Web sites and e-mailing attachments, were integrated into a project-based unit using inquiry-based learning (IBL).

The first step in the process is the development of the Scenario. This is similar a lesson plans motivation. The Essential Question and Foundation Questions called the Task, follows. This section is used to engage students in either decision-making or the development of a plan of action. The plan of action uses the previously learned skills to enhance the project with graphics and list resources and to create activities. The Product designates how the material gathered from the Task will be disseminated. The construction of an Assessment tool is the final unit. After the IBL unit has been completed, it is ready to be presented to students as a project-based thematic unit.

Conclusions

It is important in any course of study where instructional technology is used to have students become engaged in meaningful hands on projects from the onset of classes. Milbrath & Kinzie (2000) contend that teacher self-efficacy and attitudes must become positive toward the use of computers and technology in order for students to model them. Albion and Gibson (2000) observed that if teachers are to become successful at adapting technology into their curriculum, they require an understanding beyond that of being confident in using computers in their daily lives. Herrington and Standin (2000) discuss the use of real-life situations when designing a program. The use of PBL is authentic learning and adds meaning to coursework through the use of situations found in the daily lives of students. By connecting technology with active involvement in learning, Kommers and Mizzoguchi (2000) believe that teachers create a knowledge base that is described as a key issue by constructivists.

Abstract: This report is a composite of findings related to the use of the computer in selected schools in Northeastern Ohio. Separate data bases are combined to present an answer to question of "are we there yet" in relation to the use of computers in educational environments. These areas include teacher use, student use, and perceptions of use.

Introduction

The introduction of the personal computer in 1975 launched a great prediction that the computer would revolutionize the way we teach and learn. The adoption of computer technology into American schools spread so rapidly that Ward and Zullo (1982) had declared that the movement was already an established order. While the predictions of the early 1980's were that by the year 2000 schools would be totally immersed in computer technology, the adoption of this technology may not have advanced at the predicted rate. By 1986 data relative to the rate of adoption and use of computer technology in schools was available (Daulton, 1987). For more than two decades there has been stated need for teachers to be able to use computer technology in their classrooms. The implications of not having and using computers to teach our children include that children who are not learning via the computer will be disadvantaged. Colleges and universities have struggled with the best teaching practices for preparing teachers to work with technology in the schools. Parents have questions the value of ways computers are used for teaching and learning. Schools, public and parochial, have experienced differences in acquiring the hardware and software for their teachers and students. Differences in teacher skills and attitudes toward using computers have impacted what has happened in the teaching and learning experiences. Four teachers who desired to learn more about the adoption and use of the computer in their schools have also attempted to answer the question of "are we there yet" in relation to the use of computers. While the answer to the question could easily be "not yet," a picture of where we are with computer technology and education can be presented. This picture may help to guide administrators, teachers, parents, and teacher educators in helping make computer technology an appropriate and effective educational resource.

The Study
This report is a composite of four studies and independent observations designed to answer the above question of where we are in use of the computer technology in certain schools. Schools of all levels have made great strides in acquiring the computer hardware and software needed for education. Experiences for teachers to learn to use the computer for effective teaching have been provided in many forms and levels. Most students in many schools have the opportunity to use computers for learning experiences. The presence of computers in homes has also impacted the student's use of computers for learning experiences. While the use of the computer as a tool in effective teaching is readily accepted, the goals remains that all students and teachers have full and easy access to computer technology for effective learning and for classroom management. To answer the guiding question of where we are with computer technology in education, the researchers designed surveys and collected appropriate data to answer the following questions:

1. Are there differences in availability of computer technology in public and parochial schools?  
2. Do parochial and public schools have teachers adequately trained to use computer technology?  
3. Is there a difference in how public and parochial teachers use computers in teaching?  
4. How does the availability of computers at home affect students of all abilities including gifted and learning disabled?  
5. How does the availability of home computers impact teacher use of the computer at school?  
6. Does the teacher's perceived level of computer skill impact the teacher's use and the student's use of computers in the classroom?  
7. Does computer assisted instruction provide students with a positive learning experience and higher test scores?  
8. What are implications from this data for schools and colleges in designing learning experiences for teachers as part of in-school and graduate education experiences?

Findings

Detailed answers to the above questions will be presented in the composite picture at the SITE conference. This summary includes only limited findings from the data and observations.

There are differences in the availability of computer technology in public and parochial schools. At the time of data collection, the public schools seemed to have more access to computers in classrooms and computer laboratories. This may have been a result of grants available to public schools through state and federal funds that the parochial schools have not had. While there seemed to be a difference in availability of computer technology in parochial and public schools, teachers from both systems have been provided with educational opportunities to learn to use the computer in classrooms.

Computer availability at home does have a significant impact on how teachers and students perceive use of the computer for educational purposes. More gifted students reported having computers at home than other students. Fewer students with special needs reported having computers at home. Teachers and students with home computers also reported a higher use of computers in their classrooms. The initial critique of the data collected regarding the use of computer assisted instruction indicated that this process could improve overall grades and test scores. However, the researchers would be in error to say that the academic gains were strictly a result of the addition of computer assisted instruction.

Conclusions

The data collected helps to tell us how far schools have come in the use of computer technology. As rapidly as changes occur within this technology it is impossible to report a complete picture of where we are. However, from the data collected and from observations about teacher needs and requests we must continue to design graduate education courses in computer technology to meet the needs of all teachers. Early in the introduction of computers for educational purposes, many experienced teachers said they would retire before they were required to use the technology. That is no longer true. All teachers need to know about computers and are willing to learn if we provide the proper levels of training. Advanced technology courses and workshops provide experiences for teachers who have advanced beyond basic skills. While we would like to think that all entering the field of teaching are leaving undergraduate
education prepared to use computer technology, we cannot be certain. Frequently, teachers ask if workshops or courses that introduce the teacher to basic computer skills can be offered. These courses in basic skills for teachers fill easily and include recent graduates of teacher education programs as well as more experienced teachers, indicating that inservice and other in-school training has not provided teachers with the skills or confidence they need. Are we there yet? We have come far, but we are not there yet for all teachers and all students.

References

Abstract: We have developed a training tool to fulfill the important training requirements emerging from teachers' new roles and practices. Built around a web application, this tool makes a strategic use of a collection of videos to foster teachers' ability to translate inservice training into new classroom practices. A characteristic power of this tool rests on its flexibility by allowing trainers operating in different contexts to build specific training paths online.

In January 2001, we have initiated the creation of a Canada-wide network of French interveners involved in training and supporting teachers. The goal for developing such a community was to create a space wherein we could exchange about innovative practices through using videos of teachers that typified good examples (David & Cantin, 2001).

In Canada, as in several other countries, the educational system has been transformed in order to help pupils develop the higher learning competencies they will need in the twenty-first century. The curriculum reform, based on higher learning competencies, has dramatically modified teachers' roles. In order to evolve in such a context, teachers must develop new teaching competencies: managing a complex classroom, integrating technologies and exploiting different resources, managing collaborative work, organizing knowledge and trying to evaluate in ways consonant with this new context (Perrenoud, 1999).

More than ever before, important training needs emerged from these changes concerning the teachers' new roles and practices. Fortunately, videos can play a significant role in this context. They allow showing good examples of what is expected from the teachers in terms of higher teaching competencies in new learning environments. Under certain conditions, video will also help developing observing competencies. The teacher's ability to identify important elements within a learning sequence is usually the first step to appropriate intervention. Ludlow believes that the video tool fosters the acquisition of professional competencies because it brings together teachers, training and the reality of the profession (Ludlow & Duff, 1997). Ensuring a greater impact in the classroom of preservice and inservice training is also a challenge. By providing many significant indicators, the use of video can have an important impact on the teacher's capacity to achieve higher teaching competencies (Copeland & Decker, 1996; Mottet, 1997). The use of technologies also entails giving teachers support when it is most needed and thus allows individualized training paths.

All these reasons explain the high interest for training environments based on the observation of videos. Therefore, we have collected over a dozen projects such as InTime (Plakhonik, 2001) or CLICK (Chambers & Stacey, 1999). To this day, these projects are mostly closed templates developed so as to meet the specific needs of a university or a region.

The Project

As stated before, French Canadian communities are often small and the training programs as well as trainers vary from one province to the other. Our first goal was therefore to develop a web application to index all the videos produced across Canada and to classify them according to teaching competencies and characteristics of learning situations. Then we wanted people to be able to use this video collection in order to build their own training sequence.

The system we have developed is composed of six units designed so as to achieve the goals described previously. The first unit allows the selection of videos. It is a powerful indexing system which makes it possible to search through the video database and to select sequences on the basis of multiple criteria. The second unit makes it possible to build listening guides. This unit allows the trainer to target precise elements before, during and after the video in a learning situation. For example, it can be a text asking the learner to pay attention to an aspect of the training situation, in order to analyze the impact of transfer (Aubé and David, 2000).
or to compare the pupils and the teacher’s point of view (Rand, 1998). The trainer can also use this unit to insert short video sequences such as the comment of an expert.

The third unit is oriented towards the integration of interactive elements aimed at supporting a reflexive practice. It could be multiple choice questions, open questions or elements making it possible to develop the observation competencies. With this unit and the two previous ones, the trainer can create case studies such as suggested by Merseth (1994). The fourth unit, much simpler, is based on an inventory of necessary teaching competencies. In a training situation, it allows the trainer to identify the competencies that are targeted and the learner to organize his or her professional development. In the same line of thought, the fifth unit allows the learner to build his own journal which contains the list of the observed videos and a repertory of targeted competencies. The sixth unit is a simple discussion group offering the possibility to exchange around case studies.

These six units allow to create diverse training paths in order to fulfill different needs. To complete this tool, we are actually initiating a unit that proposes situations to experiment competencies developed during the process. These learning situations are mostly WebQuests describing projects realized in classrooms.

Helping In-Service Teachers Facilitate the Use of Information Technology During Pre-Service Teacher Field Experiences

JoAnna Dickey
College of Education
Eastern Kentucky University
United States
JoAnna.Dickey@eku.edu

Abstract: The results of a study completed by the author and two other colleagues inferred that student teachers reported a significant difference between their perceived ability to use and the actual use of information technology during their student teaching experience. Although pre-service teachers perceived themselves as being able to use technology for teaching and learning, they reported little use of these skills during student teaching. Based upon the results of this study, a project was launched during the Summer 2001 session. The goal of the project was to have in-service teachers (K-8) develop information technology application ideas and materials that could be shared with cooperating teachers. In turn, these ideas and materials could then be used to facilitate field experiences with visiting pre-service teachers. This paper will briefly explain the results of the initial study, project development, and project results.

Study and Results

The emphasis in the ability of teachers to use technology in the classroom for teaching and learning is a nationwide trend. In-service and pre-service teachers are expected to meet technology standards designed by the International Society for Technology in Education (ISTE, 2001). In Kentucky, a standard with performance criteria for technology knowledge and use has been established as part of the initial and renewal teacher certification process (Kentucky Education Professional Standards Board, 2001). This state standard is closely aligned with the ISTE National Educational Technology Standards and Performance Indicators.

Because the use of technology skills is an integral part of initial teacher certification, teacher educators Dickey, Long, and Reehm (2001) developed a study to explore student teachers' competencies in relation to the Kentucky technology standard for new and experienced teachers. Eastern Kentucky University student teachers in elementary, middle grades, secondary, and special education certification areas were asked to complete a survey designed to rate their perceived ability and use of technology during their spring semester 2001 student teaching experience.

Survey participants (elementary N = 43, middle grades N = 26, secondary N = 59, special education N = 10) rated their performance on 27 criteria in each of four different performance areas. Participants rated their performance on a Likert scale (range 1 - 5) for: (1) ability, (2) frequency of use, (3) opportunities to use technology as a student teacher, and (4) observation of the cooperating teachers' use of technology.

Mean scores for each group of survey participants were computed and analyzed for all 27 criteria in each of the four performance areas. Results indicated that: (1) all groups met a high majority of the criteria in the area of ability, and (2) the number of criteria met by each group differed among the four performance areas. A series of t-tests computed to analyze these differences revealed that student ratings were significantly higher (p< .001) for ability than for the other three areas.

A regression analysis was computed to analyze students' ability, frequency of use, and cooperating teachers' use as predictors of technology use during student teaching. Results indicated that the frequency of use and cooperating teachers' use were significant predictors (p< .001) of opportunity to use technology by student teachers, while ability was not a significant predictor.

Although correlation does not determine causation, the findings in this study have important implications for teacher preparation programs. One implication is that students may feel that their ability to use technology for teaching and learning is extensive but a specific effort may have to be used to...
assure that these skills are actually used during field experiences, and in particular, student teaching. Another implication is that cooperating teachers may need assistance in facilitating the use of information technology during pre-service teachers' field experiences.

Project Development

The implications of this study indicated that there was a need to provide in-service teachers with information to help them facilitate the use of technology with visiting pre-service teachers during classroom field experiences. In order to help meet this need, a four-week workshop was developed for K-8 classroom teachers during the 2001 summer session at Eastern Kentucky University. Five elementary, one special education, and six middle school in-service teachers from at least nine different school districts participated in the workshop. After a series of self-assessments in operating system terminology, literacy terms, copyright regulations, and computer ethics, the workshop participants reviewed the Kentucky Education Professional Standards Board experienced teacher standard for the knowledge and use of technology (Kentucky Education Professional Standards Board, 2001). Based upon their self-assessment results and the review of the Kentucky technology standard, the participants were then asked to develop a professional improvement plan to expand their knowledge and use of technology for teaching and learning in the classroom. This professional improvement plan included a declaration of plans to develop a minimum of four portfolio artifacts that demonstrate classroom use of technology for teaching and learning. The goal of this workshop was to compile ideas and materials for elementary, middle, and special education teachers to share and use with field experience pre-service teachers. Therefore, the “sharing of ideas and materials” was an integral part of the workshop. Other activities included: (A) the development of an annotated bibliography; (B) three different field trips to school technology laboratories; (C) at least one software review; (D) at least one web site review; and (E) the participation in at least five presentation and sharing sessions.

Four weeks was a very short time period to assimilate and develop new skills, but all of the participants made dramatic changes in their ability to use technology for classroom teaching and learning experiences. The range of participant technology expertise ranged from novice to well developed. All participants were required to share their knowledge and creative ideas, therefore, those participants who needed technology assistance often contributed creative ideas and those participants that had some experience working with computers helped other students use the computers. A comfortable learning environment was established where mistakes and adventures could be made. The participants were asked to think of this experience as a “think tank” to develop ideas to share with other in-service teachers to help them facilitate the use of information technology during pre-service teacher field experiences.

Project Results

The participants went through several adaptations to be able to work with the software and equipment that was available at the workshop site. Some of these adaptations included the use of provided hardware and software that may have been different than those provided by their school districts. They quickly discovered that the use of digital images, color, or graphics increased file sizes. This factor made files difficult to save and transfer to their home site. All of the participants experimented with the use of color, graphics, sound, animation, and hyper-linking. When presenting their projects, they quickly discovered that a simple project could better introduce information without distracting movement or sound.

The artifacts that the participants developed for their portfolio and contributed to this project could be classified into six categories: (A) lists of favorite web sites for teachers; (B) word process projects with graphics; (C) tables and charts; (D) spreadsheets; (E) electronic slide shows; and (F) web pages. The web site lists contained sites where teachers could get information about lesson planning, unit development, content area, materials, assessment tools, electronic field trips, and “kid” learning sites. These web site lists also contain favorite search engines, government offices, state information, and professional organization sites.
Word processed artifacts usually included the use of graphics. Participants preferred to use color graphics. Ideas covered a wide range of classroom activities. Materials included: a classroom newsletter with a class picture; a school event flyer; a dress code brochure; an achievement award; and a series of reward coupons or passes for behavior management. The artifacts that focused on the use of tables and charts were developed for a variety of purposes. These materials included: a summary of student debit and credit accounts for purchases chart; a multiplication table; a student weekly work log; a weekly lesson plan table; a student behavior checklist chart; a school math curriculum chart; a work station assignment table; and an observation daily point sheet table. Several artifacts used spreadsheets during a content area study. Examples of these materials were: a spreadsheet listing the characteristics of volcanoes; a career study spreadsheet that lists the average salaries earned in various occupations; and a spreadsheet to report the results of a study in the number of blue or brown-eyed students in a class. Some of the content study spreadsheets were incorporated into electronic slide shows. The electronic slide shows that were developed also contained a wide variety of purposes. Some slide shows were developed to help parents learn about the teachers, classroom or school during parent-teacher conferences or school open houses. Other slide shows were developed to be used with the students to: introduce procedures, rules, or teachers; provide fact and content information during a unit of study; and prepare the students for a field trip.

The most challenging type of artifact for participants to produce was the development of a web page. One of the factors that contributed to this challenge was the adjustment that many of the participants had to make because their school district used a different software program than the one supported in this workshop laboratory. Some participants never had the experience of working with HTML. Therefore, there were several learning curves to master before being able to develop a web page. Information that was included on these web pages included: the teacher's name and contact information; the teacher's philosophy about how children learn; units of study for the year; classroom or school rules; helpful tips for parents; school activity announcements; and class projects.

Conclusions

The study conducted to explore student teachers' competencies in relation to the Kentucky technology standard for new and experienced teachers brought an awareness to the investigators that field experiences should be monitored to assure that the pre-service teachers experience the use of information technology. There was also an awareness made that cooperating field experience teachers may need assistance in acquiring information that will help them facilitate such experiences. Different delivery systems may be used to provide this assistance. Workshops, seminars, distance learning, and on-site training sessions can be developed to help prepare in-service teachers to facilitate the use of information technology when working with visiting pre-service teachers.

During the described workshop, participants expressed an appreciation for the risk-free environment; the cooperative and sharing atmosphere; and the time to experiment, develop and create useful materials. These in-service teachers especially liked the field trips to other school technology laboratories where they got to observe new ideas and discuss projects with fellow classroom teachers. Although this experience was offered as a short term workshop, each participant demonstrated growth in the use of information technology for teaching and learning by completing a professional improvement plan and contributing selected artifacts to the class project.

Plans to disseminate these contributed ideas and materials include: (A) providing demonstrations at school district professional development workshops; (B) sharing the project results with university professional laboratory associates; (C) present project information to educators at professional meetings; and (D) publish information in professional journals. There is a similar workshop scheduled for the spring 2002 semester.

Teacher education programs are always seeking ways to enhance the clinical training of graduate students. They desire to capitalize on the experiences provided from within the walls of the public school systems. In the areas of counselor education, educational psychology and speech-language pathology, this may include the need to supervise students during clinical training experiences. In addition, university programs are seeing a rise in the number of non-traditional applicants. These people are often seeking a career change and have other life responsibilities that make obtaining a degree as a full-time student impossible. With the increased availability of distance learning opportunities, applicants from outlying geographic areas now have access to higher education that they may never have had before. This presents a unique set of problems for programs that require numerous clinical training under the supervision of qualified professionals.

It was in direct response to these issues that the Communication Disorders Program at the University of Virginia began to investigate alternative means of student supervision. After much investigation it was decided that videoconferencing technologies would afford the program the ability to provide two-way interactive supervision to students at geographically distant sites. It allowed the program to expand in allowing students to participate in a masters degree program while maintaining their jobs in the public schools.

The program has developed and implemented a protocol that incorporates the use of videoconferencing technologies into an interactive, efficient and effective model for supervision. This model has greatly reduced the costs and loss of productivity associated with supervision of students in off-ground placements. Students report decreased stress and an increased feeling of independence when supervised using videoconferencing. The technology allows the supervisor to control the video image and provide audio feedback to the student without disrupting the session. This model of supervision has been readily embraced by administrators and technical support personnel within the public schools; thereby fostering relationships between the university and the public schools.

A videoconferencing unit and television were placed in the therapy room of the student clinician. The other unit was placed in the office of the clinical instructor on campus. The videoconferencing unit connected to the television monitor requires minimal space on a desk top or table surface. The most complex aspect of this endeavor was establishing adequate Internet connections to allow for the transmission of the audio-video information between the sites. This was worked out on a case by case basis with the technology personnel at the school. The student clinicians were responsible for obtaining the permissions for observation and videotaping. After the Internet connections were configured and permissions were obtained, a schedule of supervision of the student clinician was undertaken. The clinical
instructor was able to remain in her office while conducting supervision of student clinicians in the public school setting. The videoconferencing units allowed for two-way, interactive communication between the clinical instructor and the student clinician. The clinical instructor adjusted the camera throughout the therapy session allowing for excellent viewing capabilities. The instructor could provide audio input to the clinician through personal ear monitors without disruption to the therapy session. Feedback was provided to the student clinician at the end of the session through videoconferencing or as written feedback sent through email. It was possible for the clinical instructor to make video-recordings of the sessions for later review.

This presentation will address the key elements in implementing videoconferencing in the supervision of graduate students. A discussion about the specific equipment and technical support needs will be addressed. The discussion would include information and resources regarding issues of connectivity, administrative concerns and feedback from student clinicians. Participants would be encouraged to participate in a discussion regarding the benefits and perceived drawbacks of the model. Additional applications will be proposed.

A demonstration of the model will be conducted using portable videoconferencing units and personal ear monitoring system. Participants will be able to observe a clinical training session incorporating the use of videoconferencing. There will be an opportunity for the participants to engage in dialogue with the supervisee.
Collaborative learning environments and scaffolding provide cognitive supports to assist knowledge building in academically demanding situations. In such environments, participants work together to solve problems, develop solutions, negotiate meanings, and challenge ideas. Scaffolding facilitates knowledge construction by providing supports that guide, model and cue higher order processes involved in thinking, knowledge construction and problem-solving.

In the past decade, information and communication technologies (ICTs) have become widely recognized as valuable educational tools, yet, meaningful adoption of relevant technologies across curricula has been limited, even in schools that are well resourced. Clearly, teacher educators have an interest in fostering teacher professional development that will strengthen applications of information and communications technologies in classrooms so that student teachers can gain relevant pedagogical understandings, attitudes and skills.

Rethinking educational pedagogy

In recent years there has been considerable interest in developing environments in which learners work together to construct knowledge, seek new solutions, meet goals, and develop shared understandings about issues, processes and outcomes. The cognitive processes generated in these contexts are first manifested at an external level, and then gradually internalized to become part of the learner's independent repertoire of competencies (Bonk & Kim, 1998; Pea, 1987; Salamon, 1990; Vygotsky, 1978).

These interactive contexts require a new role for the teacher-as "facilitator" of learning. The idea of "facilitating" has been around since the mid 20th century. Today, we have new insights into the importance of a facilitator as a mediator, strategist, and collaborator in learning, on the interactive nature of cognitions and social behaviors, and on the key roles of technology in education (Elliott, 2000; LaFrenz & Friedman, 1989; Pea, 1996; Rogoff, 1990; Scardemalia & Bereiter, 1996; Wertsch, 1991).

Purpose of the study and research context

This paper reports on a study of teachers' in-service experiences as they used the knowledge creation system, Zing™ (www.anyzing.com) to rethink their role as teacher in a technology rich learning environment. Teachers focused on the ways pedagogy must change if children, and teachers, are to become knowledge creators. As teacher beliefs are formed through processes of enculturation and social construction, and as beliefs are strong mediators of behavior (Mandler, 1975; Nisbett & Ross, 1980), teachers' understandings about ICTs in classrooms are important mediators of their practice. Teachers' skepticism about the role of ICTs in learning often stem from beliefs formed from their own negative experiences of technology, together with long held beliefs about the nature of teaching and learning (Elliott, 2000).

During the teacher in-service sessions examined here, 30 participants worked through activities supported by Zing™ to develop new understandings of ICT pedagogies and of their roles as facilitators of learning. Zing™ helps structure an environment in which participants orchestrate their own change processes in an authentic professional context.

Zing™ was developed in Australia and originally used for facilitating group-based decision making in the corporate and higher education sectors. Using one computer, a multiplexed set of twelve keyboards, and a cluster of monitors (or a shared projector screen) Zing™ sessions are customized to suit participants' learning goals and outcomes. Sessions have a built-in etiquette with times allocated to discussion, response, review and synthesis.

In the present study, Zing™ provided the framework and platform to help teachers examine their beliefs about ICTs and learning and to transform their pedagogy to use ICTs as knowledge creation tools. The mediational influences of the software-generated supports, together with facilitator scaffolding and participants' collaborative efforts, enable joint construction of shared knowledge about issues (Callan, 2001).

Sessions were designed for groups of between 6 to 20 teachers and were of about 12 hours duration. Participants were experienced teachers from both primary and secondary schools. The data reported here draw on transcripts of thirty teachers' responses during sessions. They document teachers' journeys to better understanding pedagogical issues relating to computer use and their roles as teachers in this new environment.

Participants worked collaboratively to examine their attitudes and beliefs about using ICTs in classrooms, and to develop specific facilitation and scaffolding techniques suitable for a classroom context. In the Zing™ environment participants are immersed in the learning and facilitation process through observing, modeling, rehearsing, evaluating and finally creating their own facilitator model. As each participant works through the activities and contributes to the discourse, his or her content is transferred (published) from an individual space to a team space where it becomes public property. Each participant contributes individually to the learning and knowledge
development process, and concomitantly contributes to the shared construction of knowledge. Zing™ enables all written responses to be stored on activity logs and archived. In addition, participants undertake a critique of each other’s learning and the performance of the facilitator.

Results and discussion: Changing conceptions of ICTs

Analyses of participants’ contributions to the sessions indicated clear shifts in their conceptions about the role of ICTs in the classroom. Initially, it was apparent that teachers’ views of computer use were confined to traditional computer activities, such as drill and practice, word processing, information seeking, calculating and publishing. Participants’ conceptions of themselves as teachers tended to be shaped by historical images of teaching and schooling.

At the conclusion of the sessions, when ICT and facilitation practices had been brainstormed, modeled, scaffolded, and acted, teachers had developed better understandings of ICT pedagogies, including ways of “scaffolding students’ learning”, “modeling changing pedagogy”, “be(ing) active learners with the students”, “maintain(ing) flexibility of learning styles and Activities”

When reflecting on their experiences over the sessions, teachers commented that using the Zing™ system in this collaborative and scaffolded sense ensured that each and every voice was heard, that discussions were focused, and that all views were considered and valued equally. Teachers’ changing views about techniques afforded in the Zing™ environment indicate new understandings about ICT pedagogical practices as illustrated below:

Importantly, teachers developed new understandings about facilitation through scaffolding and collaborative efforts. They were particularly interested in techniques of modeling, rehearsing, and brainstorming. Techniques to “capture everyone’s thoughts and ideas”...”in an organized and systematic way”... “without evaluation from others” were seen as particular strengths to transfer to their own teaching. Equally, experience in actively using the technology and seeing each technique modeled, then rehearsing and later facilitating others’ use of strategies were important in internalizing new ways of thinking about effective ICT use.

For teachers, the interactivity within the sessions resulted in information becoming part of a network of beliefs about teaching and learning in technology rich contexts. From this should evolve new beliefs and cognitions and that will, hopefully, be translated to classroom practice. Participants indicated that use of the technology enabled them to make sense of ideas and to construct new understandings of pedagogy. They believed that they would change their classroom pedagogy.

Concluding comments

Results from the present investigation have shown that a guided, mediated, and collaborative environment, which takes teachers through a process of observing, constructing and facilitating can shape new understandings about the role of ICTs in learning and ICT pedagogies. As mentioned earlier, beliefs about teaching develop through processes of enculturation and social construction and are changed by internalizing new conceptions and experiences. Hopefully, the apparent changes in teachers’ beliefs about ICT pedagogies, because of their origins in positive and concrete experiences within a knowledge building context, will be strong enough to ensure concomitant changes to classroom practice.

Books vs. Technology: Bringing Technology 
into the Children’s Literature Course

Candace Figg
College of Education
University of Louisiana at Lafayette
United States
cfigg@louisiana.edu

Abstract: Although the student-learning goal of the Children’s Literature Course is to provide students with knowledge of a broad range of quality children’s literature, this paper outlines the perceptions of students in a Children’s Literature class that utilized technology to support their learning experiences and discusses appropriate use of technology to enhance learning for courses requiring focus on print media.

Introduction

Although the dust surrounding the debate between print media and electronic media has settled, students in courses whose purpose is to provide a broad knowledge base of types of literature, such as Children’s Literature, should be able to benefit from the support that computer technologies can provide in enhancing the learning experience. Because the research indicates that learning to use and incorporate technologies into daily practices relies upon training that incorporates “hands-on integration, training that extends over time, modeling, mentoring, and coaching, and posttraining access” (Roblyer & Erlanger, 1998-99, p. 59), providing skills to students without overwhelming them and deterring from the learning required to support course objectives, (e.g., reading vast quantities of literature and developing evaluative and comprehension tools for understanding the literature) becomes a challenge. This study investigates participant perceptions of the value and relevance of the inclusion of technology into the learning experience of participants in a Children's Literature course, and would be of interest to those who wish to use technology to enhance learning for courses requiring a deep focus upon print media.

The Study: Method of Inquiry and Data Sources

Due to the complexity of the learning environment and the multiple perspectives of the individuals participating in this study, this exploration of the perceptions of technology-based activities that students deem valuable within their learning experiences was conducted using Naturalistic Inquiry, the “investigation of phenomena within and in relation to their naturally occurring contexts” (Schwandt, 1997, p. 101). The study design allows the findings to "emerge" from the data as the value systems of the researcher and informants "interact in unpredictable ways to influence the outcome" (Lincoln & Guba, 1985, p. 41). The phenomenon is documented as it emerges through the use of certain procedures for data collection and analysis, as described by Lincoln and Guba (1985) and Erlandson, Harris, Skipper, and Allen (1993). Included in these procedures are the selection of a purposive sample, development of a “Person as Instrument” statement and maintenance of the researcher's Reflexive Journal, preparation of case studies, and collection and analysis of data from which the working hypotheses emerge. Further naturalistic techniques, including member checking, peer debriefing teams, and triangulation of multiple sources of data, were utilized to ensure trustworthiness of the study.

The 25 female participants who served as the purposive sample for this study ranged in age from twenty to fifty-two years of age, with technology skill levels varying from little or no technology skills to novice. All participants entered with the ability to do basic word processing of assignments and had an e-mail account, but may or may not have used e-mail. During the semester of course instruction, participants utilized e-mail on a consistent basis to submit work and ask questions of the professor, conducted Internet searches for information and possible resources for inclusion in a thematic bibliography, experienced posting to the Blackboard discussion board on three occasions, participated in two online quizzes provided by the textbook publisher, and reviewed coursework assignments and work of other students on the course website. Little class time was dedicated to skill instruction, but was available from the professor via e-mail or fellow classmates who were taking the basic technology class simultaneously with this class. At the conclusion of their experience, they were asked the general question, “What are the technology-related events and/or experiences in this class that you believe were valuable to your learning experience? In addition to the data collected from the interviews,
data also collected from student portfolios, journals, and informal comments (made by students during the class sessions and e-mail conversations with the professor), as well as the reflective journal of the professor served as data sources. Analysis was conducted using the constant comparison method as described by Erlandson, et. al. (1993). Rigorous member-checking with participants and review of emerging themes by peer debriefing teams were also conducted in order to balance bias in interpretation. The emerging themes that resulted from this process are the findings of this study.

Findings

These findings are preliminary as the final interviews are still being member-checked, but three main themes (subject to refinement as the data collection/analysis continues) have emerged:

Theme 1: Students perceive technology training as invaluable to their learning process. Regardless of skill level, participants expressed the idea that technology is becoming so interwoven within the fabric of society that it is important for them to acquire as much knowledge about technology as possible. In addition, the use of technology to make their work easier (e.g., sending assignments via e-mail, locating course assignments online after missing class, or acquiring another copy of course documents stored online) was deemed valuable.

Theme 2: Inclusion of technology that students perceive as an authentic part of assigned classwork is valued. Students perceived three technologies: the use of e-mail to deliver assignments via attachments, the use of websites that provided course information and assignments as well as a forum for publication of their work, and the collection of information and resources from Internet sources as the most valuable of the tools used in the class because each of these tools was learned as a part of completing a required assignment.

Theme 3: Regardless of skill level, students valued technologies that they were able to successfully master. As students participating in the study began the course with beginning technology skills and class time devoted to skill instruction was minimal, ease of skill acquisition was important to the participants. E-mail, searching the Internet, and using the class website were easily explained via e-mail or by fellow classmates. Technical problems with some of the other technologies left participants frustrated and unable to participate.

Conclusions

Although the purpose of this inquiry was not to provide findings that are representative of all students, but to explore the perceptions of these 25 students as they reflect upon the value of technology in their learning experience this fall, the findings will provide the reader with a glimpse into the world of these participants thereby providing meaning and insights that might be valuable to the reader’s own teaching and learning experiences. Thus, the lessons to be learned from the research presented in this inquiry are generally decisions that remain the responsibility of the reader, but the findings may suggest possible consideration in various contexts of incorporating technology to enhance learning environments of courses requiring a deep focus on print media. These considerations include provision of the following in course development as a means of assuring that students will view the inclusion of technology into their learning experiences as valuable:

- Just do it! Students are eager to use technology and view the learning of technology skills as important to their success.
- Include assignments in which the technology is an integral part of the assignment. For example, in the Children’s Literature class, the students were required to create a thematic bibliography consisting of several book and non-book resources. Adding website resources to the requirements necessitated the need for students to locate, review, and apply the same criteria of quality evaluation to the website resources as to the other resources. In addition, the creation of weekly book annotations was a course requirement modified so that annotation files were submitted via e-mail attachments for inclusion in the online database.
- Design these assignments around the basics: e-mail, websites, Internet searching or provide class time for students to acquire necessary skills to successfully complete additional assignments.

Demonstrating The Use of Instructional Technologies in Enhancing Effective Teaching Skills

Warren Flood, Ohio State University Extension, US
Nikki Conklin, Ohio State University Extension, US
Jo Jones, Ohio State University Extension, US
Linda Kutilek, Ohio State University Extension, US
Walter Warkus, Ohio State University Extension, US

This session will demonstrate instructional technology products that were designed by Ohio State University Extension to aid extension educators in enhancing their teaching effectiveness. The presenters will showcase a CD-ROM package for individualized learning. The following abstract describes the program.

As the outreach arm of The Ohio State University and with its organizational mission, To help people improve their lives through an educational process using scientific knowledge focused on identified issues and needs, it is imperative that the program personnel of Ohio State University Extension (OSU Extension) be skilled teachers. Many of OSU Extension’s program staff are hired for their subject matter technical expertise. These staff members may or may not have a preparation in education and/or experience in teaching while incorporating experiential learning strategies.

OSU Extension has traditionally addressed the organization’s need to enhance teaching skills among its program personnel via in-service programming that covered the basics of the teaching and learning exchange. With approximately 900 program staff members housed on the OSU Columbus campus, at research centers, and in 93 field offices across the state, providing in-service programming to meet the individual needs of the staff has proven challenging. OSU Extension employs roughly 50-75 new program staff members throughout the year, making the scheduling of a single in-service for all new hires difficult. In addition, experienced employees often indicate a need to refresh or renew their teaching skills.

The development team consists of four professionals from Ohio State University Extension. We also enlisted the help of a multi-media specialist from the College of Food, Agricultural and Environmental Sciences Communication and Technology Unit. Our roles included providing for the training and development of program staff of OSU Extension. Because our audiences teach non-formal educational programs in local communities, we are committed to providing a role model of experiential training methods to be used with both adults and youth. The experiential learning aspect of our research programs make them unique compared to programming efforts offered by other community-based organizations.

Through the development of the Enhancing Teaching and Learning Dynamics Program, members of the Employee Development Network intend to individualize the instruction of the teaching and learning exchange. What started as a single computer based training (CBT) interactive multimedia CD has now evolved into a full-scale training module. The program includes a resource CD, coaching for experienced Extension educators, and a set of in-service workshops. The single interactive multimedia resource CD has now become a set of three CD’s. Each CD in the set contains the introduction to the set so that the individual learner may determine their own path for using the set.
The experientially-based multimedia CD component of the Enhancing Teaching and Learning Dynamics Program will serve as a resource for the staff member, providing video references, text information, still images and audio examples, hyper-linked text, video/text/audio examples of implementation methods, "pretest/posttest" evaluation instruments, comparison log template, and application exercises. The Enhancing Teaching and Learning Dynamics Program has been designed to be used jointly by the coach, the employee, and the Employee Development Network as a training resource within OSU Extension.
Triadic collaboration: A three-sided approach to technology integration

Amy Gibbons, West Texas A&M University, US
Kathy Burleson, West Texas A&M University, US

Abstract

Triadic Collaboration: A Three-Sided Approach to Technology Integration

Societal expectations for the use of technology in schools continue to increase, reinforced by expectations of federal agencies (Department of Education), educational organizations, as well as national and state agencies. Institutions of higher education have developed a variety of approaches to respond to these pressures, primarily with the inclusion of a separate educational technology course in the pre-service curriculum (Thompson, Schmidt & Hadjiyiani, 1995; Thomas, 1996; Zachariades & Roberts, 1996). However, pre-service teachers are graduating feeling inadequately prepared to effectively integrate technology into the curriculum (Byrum & Cashman, 1993; David, 1994; Dradowski, Holodick and Scappaticci, 1998). In addition, in-service teachers indicate their greatest obstacle to the integration of technology is the understanding of how to use it in instruction (Stuhlmann, 1998; Vannatta, 2000).

To respond to these situations, this study investigated a three-sided approach to modeling the integration of technology in daily teaching. University faculty, pre-service, and in-service educators were given information and demonstrations for modeling appropriate technology use in the classroom. Each of these three groups was given a needs assessment which consisted of surveys to find out what they already had knowledge of and were able to do in the classroom. Each group was also asked informally what they thought they needed to know more about to be able to successfully integrate technology into the classroom. Faculty development workshops that targeted technology implementation strategies were designed based on the needs of each group. These workshops were delivered throughout two semesters to each group separately so their needs could be met.

When workshops were completed, surveys were administered again to each group to perceive the impact of the workshops on the group and the use of technology in the teaching day. Observations of classrooms were made where appropriate to help monitor the types of technology integration that were applied before and after the intervention.

Online Professional Development – lessons learned

Melanie Zibit Goldman, Boston College, US

"The [online] process has extended my classroom allowing me to have professional dialogue with other teachers. Today's schools are not structured to give teachers the needed time to discuss concerns or just to share innovative ideas. I now have an endless support team. Online discussion allowed me, and in many cases forced me, to rethink how I teach and what I teach. Because it was technology based it also forced me to better use technology as a tool for learning. .... I am now looking at how to use online discussion and collaboration with my students and their parents. (7th grade science teacher --MSTelementoring teacher)

"MSTelementoring", funded by the National Science Foundation, is an online professional development project for K-12 teachers in central New York State's Syracuse and Onondaga-Cortland-Madison Board of Cooperative Educational Services region. It provides sustained support for teachers as they work to change their practice to more inquiry methods in math and science, fosters the integration of the Internet into existing curriculum, and provides an online mentoring group for sharing and learning. Teachers use the Internet during (and after) school hours to find out what each other is doing, to share meaningful personal reflections on their practice, to seek suggestions for solving problems or new ways to do a curriculum unit.

Over the three years of the MSTelementoring project we experienced success as well as difficulties fostering online learning with inservice teachers. This paper/presentation will share what we have learned about:

• Desgining online learning so that it helps teachers grow as professionals
• Facets and constraints of online discourse
• And strategies to get teachers to exchange reflections, ideas, issues, and potential solutions

I. Designsing online professional development:

It is important to go beyond the conception of professional development as "training." Professional development needs to be defined in ways that include "formal and informal means of teachers to not only learn new skills, but also develop new insights into pedagogy and their own practice, and explore new or advanced understandings of content and resources" (Miles Grant, 1997, p 72) Changing one's practice is not something that can come about by attending an isolated week long workshop but is an ongoing process that must evolve over time and in the context of a teacher's daily work. Overtime, teachers need the support to experiment, reformulate their ideas, change their beliefs, and realize they are the best qualified to challenge themselves and direct their own learning. The key facets in the design of MSTelementoring professional development are:

1. Make professional development relevant
   In MSTelementoring teachers take ownership of their growth and collaborate on the direction of the project. As teachers become part of an ongoing learning community, they grow in valuing themselves as a community of professionals, begin to feel more empowered to decide what is of value to them and find a voice to shape their own learning and the project.

   What this means for the design of MSTelementoring is that it must be flexible to shift with the changes and needs of its teachers. Through discussion with teachers and monitoring teachers' progress, the project staff design agendas and experiences that relate to where teachers are developmentally and guide them to new skills, content, practices and beliefs.

2. Include a mix of online and face to face
   A mix of face to face and online learning worked best to build a strong community. The face to face allows teachers to get re-acquainted, to deepen their relationships, and to enjoy the energy of brainstorming and discussion during the sessions. The face to face has also brought learning of new skills and content that fed into what teachers use and discuss online once back in the classroom. Teachers value the online for anytime, anywhere collegial sharing and support, particularly those who are isolated or in rural districts. Although 86% of the teachers said that online communication was very useful or somewhat useful, teachers still favored the face to face.
3. Teachers formulate a blueprint for their own learning
Every year we have had teachers create Professional Development Plans at the end of the summer session. The development of Professional Growth Plans involves teachers reflecting on what they would like to accomplish over the year related to changes in inquiry-based practice, new math and science curricula, integration of technology, and leadership in their community. Around mid-year we asked teachers to revisit their plans to see what they have accomplished and rethink their priorities going forward. At the end of the year we ask them to again think about where they have been and what they have accomplished.

II. Facets and constraints of online discourse

Online learning takes time, self-motivation, and a focused cognitive process of reading and reflection with the text-based medium. Online discussion requires concentrated blocks of time to read, think and respond. The usual rapid-fire approach we associate with communicating face to face does not work. Thus, with teachers’ workloads increasing, it is difficult for them to find time unless it is in the evening or on the weekend.

1. Self-motivation:
The online environment differs from face to face instruction in that it is all computer-mediated. Participants have to read between the lines to compensate for lack of sense cues and a participant’s self-motivation to keep involved must be that much greater. The participant must develop a "cognitive language" that makes the ideas expressed in computer text come alive with meaning and excitement. This is a very difficult endeavor considering that teachers spend their days in face to face classrooms, interacting with their students. It also requires self-motivation to read and catch up on ones own when a participant has been absent from the online for a length of time.

2. The environment in which teachers teach
The factors we found inhibiting teachers from making the kind of progress we would hope include: (B. Hunter 1999, the 1997 NSN Survey Report H Becker).
- lack of time for experimenting, training, planning and implementing
- unstable technical infrastructure
- little local control over resources
- lack of administrator's understanding and support
- no sustained or long term professional development program
- shifts in school system priorities and curriculum
- teacher workload
- lack of equipment access

III. Strategies for engaging the teachers

1. Online environment
Easy to use technology is essential! New possibilities in online learning platforms opened up in the course of the three years so that in this last year, we moved to Blackboard courseware. This turned out to not only facilitate online discussion and sharing of material within the project, but served as a catalyst for innovation in teachers’ classroom practices.

2. Teams play a critical role
There are many factors that make one teacher team work together more successfully than another. These factors are 1) individual teacher motivations, e.g., desire to be connected to other teachers or interest in growing professionally; 2) the relevance of the tasks and discussions to his/her needs, 3) easy access to technology, 4) release time, compensation, or support within the school for participation, 5) the degree of isolation of a teacher’s situation; 6) having common interests; 7) maintaining a critical mass of exchanges. When we were able to match members in terms of their motivation, desire to contribute, and access to technology we have seen healthy discussions.

3. Moderators are key to success
Facilitating in the online environment is quite different from face to face. Conversation is mediated through the virtual environment where the challenge is to overcome the absences of sense cue and personal presence. Moderators play a critical role in overcoming this lack of cues to build a sense of trust and openness in an online environment. A successful moderator is in touch with individual teachers through personal email exchanges and phone calls, monitors who has not participated, follows up to find out why and finds solutions, and models posts online that are characterized
by openness and depth of reflection. Just like your classroom environment, engaging in discussion that moves from short brief answers to deeper meaning and reflection online takes skill and practice. It is critical to have moderators who have expertise in the content of the professional development, are good "listeners", and are experienced or willing to learn how to facilitate online discourse.
Introduction

This presentation analyzes the reasons and motivations of the Portuguese Information Society, its origins and characteristics, and the importance that this new society can have in education. Computers and digital networks have proven to be the best way to access information and knowledge that is essential for the development of a country. In order to prevent the info-exclusion of those that can’t have access to these technologies at home or at work, it is crucial that computers and networks become accessible in public places like schools and libraries. We will describe the Portuguese government initiatives in relation to this question, which intend to generalize access, improve education and also create jobs.

The Study

Portugal began to define a policy for development in the area of what would become the Information Society in 1995. The Mission Statement for the Information Society and its National Initiative were first created and staged in March 1996.

The National Initiative sparked widespread national debate about the Information Society (which I will hereon refer to as IS), out of which was developed a set of guidelines that would accelerate and democratize the use of modern technologies. The debate also gave wing to the Livro Verde para a Sociedade da Informação em Portugal (which I will refer to as the Green Book), which serves as the essential reference for correct and sustained implantation of IS and its notoriety in Portugal.

With governmental support for the Green Book, various guidelines and vectors of orientation were structured into a clear plan of action, which resulted in projects including:

- Science, Technology and Society Network (RCTS'); Internet in Schools Program; Computers for Everyone Initiative; Digital City Program; National Initiative for Electronic Commerce; National Initiative for Citizens with Special Needs.

Following the publication of the Green Book and all of the initiatives that grew out of it, policies and measures for the development of information technology were defined and applied in order to guarantee the success of the Portuguese IS.

National Initiative for the Information Society

The National Initiative for the Information Society constitutes an important cornerstone in the implantation of IS in Portugal. In fact, this Initiative played a fundamental role in the accelerated and democratic diffusion of the use of modern information technology, sustainably integrating the old and the new, knowledge and know-how. It also identified barriers of a technical, organizational, social, cultural or economic nature, problems which could interfere with the full development of an informed, democratic and open society, as the Green Book points out.

This Initiative was founded on the awareness that educating citizens begins in school, which translated into the following measures in which new information technology played an extremely important role, namely:

1. The Well-Informed School, including computers and Internet access in every school (K-12) through RCTS;

---

1 RCTS: Rede Ciência Tecnologia e Sociedade – initial in Portuguese for Science, Technology and Society Network
2. The Open Government, including computer access to governmental services and forms, in an attempt to minimize bureaucracy and improve efficiency, which meant installing computers in libraries and public archives;
3. The Well-Informed Citizen, creating ties among city halls and local interests;
4. Accessible Culture, guaranteeing libraries, museums, youth centers, archive and documentation centers, and research and development information on-line;
5. The Well-Informed Firm, motivating and creating incentives for the use of e-commerce;
6. Health First, computerizing health services and, consequently reducing costs and inefficiencies of the current system;
7. Handicapped Program, encouraging integration of these citizens in the use of information technology.

It was through these objectives that equality of access for all citizens who could benefit from IS was established.

In fact, in current society, knowledge is one of the most important components of development, making it necessary to create structures which contribute to a rapid and efficient spread of knowledge among the most diverse sectors of society, giving particular importance to sectors in which the creation and absorption of information could have a significant multiplier effect. In this vein, the following objectives were defined:

1. Expand RCTS to all K-12 schools and institutions of higher learning, libraries, museums, youth centers, archive and documentation centers;
2. Promote the creation of a network of Internet servers, to enhance the accessibility of cultural issues throughout the Portuguese and Portuguese-speaking communities around the world;
3. Develop support programs for the creation of multimedia projects with cultural content;
4. Promote the computerization and digitalization of historic archive and cultural patrimony;

The Well-Informed School

Of the sectors of society, education probably benefits the most from the use of new information technologies, since it is based on knowledge acquisition, actualization, and use. Within the education system, the following measures were defined:

1. Install computers, as previously explained;
2. Promote the development of educational and cultural content, of support for teacher activities and initiatives, and the educational process, all in ways favoring the use of information and communication technology;
3. Create teacher training programs, for all levels.

Science, Technology and Society Network (RCTS)

The creation of the RCTS reinforced the network connecting Universities, Polytechnic Institutes, and R & D Institutes, really becoming the national “backbone”, as cited in the document “Portugal in the Information Society” (my translation), from the Ministry of Science and Technology. This reinforcement allowed for the growth in bandwidth to 4 Mbps. In addition to this growth in national connections, international connections also grew from a bandwidth of 512 Kbps in 1995 to 34 Mbps in 1999. Further to the growth in bandwidth, the objective of installing a digital infrastructure in schools was accomplished and 15 Points of Presence (PoPs) were installed, primarily in institutions of higher learning and R & D institutions all over the country.

The RCTS has also permitted the growing development of communication between scientific, technological and socio-cultural communities, creating conditions for equal access among teachers, students, or library users to new information and communication technology.

Beyond this infrastructure of equipment and logistic support, Internet sub-domains were created, making e-mail addresses and space for publishing pages on the World Wide Web (WWW) available for all connected institutions, as well as a set of Internet tools and services, related to e-mail, chat rooms, and content production for the WWW.
Internet in Schools Program

The Internet in Schools Program, through RCTS, brought Internet connection to all schools, both public and private, from the fifth to the twelfth grade, comprising multimedia computers in school libraries and/or school media centers. This has facilitated students’ recourse to Internet research and expression and CD Rom publications.

Although the program initially planned on connecting only high schools to public libraries, it was expanded to include fifth grade on and Teacher Training Centers in 1998 in two phases, in cooperation with local authorities. In September 1999, 1700 schools (with students from the 5th to 12th grade), 220 schools (with students only in the 5th and 6th grade) and 80 additional clubs of a cultural, scientific, and educational nature were connected, in addition to 250 public libraries and 15 museums.

Throughout this time, hundreds of thousands of students and teachers have been sensitized, systematically and practically, to the pedagogical potential of the Internet:
1. more and faster information research and recovery systems;
2. more autonomy and democracy in information access and communication among schools and with society;
3. student familiarity with technology and technological processes which could be encountered in their professional future.

The Internet in Schools Program is a project of the Support Group for the Educational Telecommunications and Computer Network (uARTE2), in collaboration with the National Scientific Computation Foundation (my translation), with the participation of other entities, such as Regional Government, Citizen Groups, and Municipalities.

Graph 1: Illustrates the growth in access subscribers to the Internet between 1997 and 2000. The data shows an increase of approximately 182% in the last three years (www.cisi.mct.pt).

Operational Program of the Information Society (POSI3)

The IS has been defined as a national priority. Its plan, entitled “Towards a Society of Knowledge and Information, 2000-2006”, comprises two operational programs:
1. Science, Technology and Innovation, which in the mid-term hopes to bring the country up to speed in science, reaching the average level of the European Union;
2. Information Society, which should build the bases needed for sustained implantation of the Information Society in Portugal.

Operational Program of the Information Society (POSI3)

The IS has been defined as a national priority. Its plan, entitled “Towards a Society of Knowledge and Information, 2000-2006”, comprises two operational programs:
1. Science, Technology and Innovation, which in the mid-term hopes to bring the country up to speed in science, reaching the average level of the European Union;
2. Information Society, which should build the bases needed for sustained implantation of the Information Society in Portugal.
Graph 2: Illustrates the percent access in 2001 by different places in Portugal (www.cisi.mct.pt).

POSI, following on the heels of the Green Book, has come about as a sign of government support for the continuing and growing importance of the Information Society; it has successfully stimulated access and guaranteed a dynamic development and experimentation related to the social use of new information technology in all areas of development. A set of measures has been delineated to reinforce the importance attributed to this growth, namely:

1. Promote the generalized use of the Internet - Internet Initiative;
2. Increase the number of home Internet connections by four;
3. Generalize the availability and use of email and Internet for the entire Portuguese population through the creation of public access areas, like cyber-cafés and media centers;
4. Free access for all educational institutions;
5. Increase the number of Portuguese content sites by one thousand;
6. Create a national training and certification process of basic competency in information technology;
7. Link a diploma of basic competency in information technology to the level of obligatory education (ninth grade);
8. Make all information published by public entities available on the Internet;
9. Carry out the National Information Highway Plan, stimulating offer, interconnectedness, use and regulation of the bandwidth of networks
10. Create an R & D program in the area of IS;
11. Create an R & D program in the area of IS aimed at developing Portuguese language content.

This program is part of the European Community, englobing an investment of approximately €625,035,000, distributed evenly over the years of execution.

The expansion of the Internet in Schools Program gave rise to the signing of a protocol between the Ministry of Science and Technology and the National Association of Municipalities on the 26th of February, 2000, which established the end of 2001 as the final date for connecting the 8,600 schools in the nation. Currently, 9,448 institutions, excluding those of higher learning and research, are connected to the RCTS, distributed as follows in graph 3:
Conclusions

We defend that youth population must have access to the information available in digital networks, and also to the powerful instruments of the Information Society. They must have the possibility and the ability to process text, image and sound in order to create collective or individual work without any frontiers. We believe that only with these creations, is it possible to concretize a cyberspace that guarantees an efficient and fast access to information for all. Universities, as a key element, must contribute as essential entities within digital networks, using both as resources to transmit scientific and cultural knowledge, giving support to professors and schools creating thus the appearance of new electronic means like Internet.

The potential of information technology is ideal to serve the objectives of education. In this context, we believe the Information Society will give rise to new perspectives in education and new forms of study, which will increase the global level of literacy.

The future of Portuguese youngsters should be paved via two components: the Information Society and the information technology, in a way that allows for the creation of new skills for the successful development of the country.

Managing change: Critical considerations for IT professional development for practicing teachers

Jennifer Jenson, York University, CA
Brian Lewis, Simon Fraser University, CA

For the two years our research has examined the implementation of computer technologies in schools across Canada, focusing on the problem of managing change within what we see as a transitional period in education. This paper will report on one significant portion of our findings -- the disparity between professional development programs' purported skills training using computers and teachers' actual "uptake" and use of that training in their own classrooms.

We have identified and clarified some of the more pressing questions arising from the implementation of computer-based technologies. These questions involve technological, infrastructure, human resource and learning policy issues, including teachers' professional development; questions of sustainability; and questions of public policy in an increasingly technocratic and commercial education environment.

Each of these issues speaks to the need for strategies designed to address how and why choices are made, who makes them, and with what effect, both intended and unintended. Too often the reverse happens: technology changes rapidly and decisions are made in a more or less ad hoc fashion, as administrators scramble in response to the initial promises of technology. Then these same administrators, as well as teachers, students and parents, must face unforeseen problems and demands triggered by its implementation.

Public Policy: A Global Shift
There is a critical need for a reflexive approach to the implementation of technology in our schools that responds to issues of policy, organizational culture, politics, and decision-making practices. These issues are of particular importance as Canadian public policy in all areas has become concerned with the country's transition to a "knowledge society" -- a transition which has brought increased attention to education, as a primary "resource" in the development of a "knowledge economy" infrastructure.

In Canada, among other countries, policy-makers have largely shifted their focus away from cultural protection and protection of the public sphere -- in any traditional sense. The Canadian government's commitment to a globally- oriented, privately-developed, market-based regulatory framework has thrown into question the nationalistic communications policy framework of the past several decades. As a new communications infrastructure is being established, an entirely new policy framework is developing as well.

In justifying their policies, governments have employed idealistic and simplistic visions of what the "information revolution" will mean. In their rush to remain competitive with the United States and the rest of the world, few policy makers are asking traditional, yet fundamental social questions about the risks and changes these new policies will shape. The "education revolution" has become a small but critically important part of a more general information revolution, and subject to similar policy changes. Policies addressing the implementation and use of new technologies within education have become firmly entangled within overall information and economic strategies and objectives. It is as if a major fault line has shifted -- social activity has come to be increasingly judged and evaluated through economic objectives and priorities. Education is central to this shift. Education, long a "goal in itself," a "public good," has become more purely a means to the end of a more efficient and competitive economy and workforce, immutably situated within the notion of the "knowledge economy."

"Investing" in Education: New Technologies
One significant result of this broader policy shift has been an added emphasis on information technology in Canadian public schools. Information technology is a tempting answer to education's perceived shortcomings in preparing students for the knowledge economy. Computer technology provides a tangible link between the world of education and the world of work.
In the past few years there has been an extraordinary amount of interest and investment in the deployment and use of computers and computer networking in Canadian public schools. The 1998 federal budget, for example, committed $205 million over three years to Industry Canada's “Community Access Program” and “SchoolNet.” As the number of computers accessible to students and teachers in classrooms and labs has increased, there has been a corresponding emphasis on “integrating technology across the curriculum.” Teachers' effective use of computers in their classrooms, however, remains an elusive goal. Researchers have identified numerous barriers to teachers' use of computers in their classes, such as limited equipment, inadequate skills, minimal support, time constraints and the teachers' own lack of interest or knowledge about computers (see, for example, Bryson & de Castell, 1998; Berg, Genz, Lasley & Raisch, 1998; Clark, 2000; Ertmer & Addison, Lane, Ross & Woods, 1998; Hadley & Sheingold, 1993; Laferrière, Breuleux, Baker & Fitzsimmons, 1999; Macmillan, Liu & Timmons, 1997; NCES, 1999; Schrum, 1994, 1997, 1999).

Teachers and Technologies: the question of professional development

Rightly or wrongly, teachers have come "under fire" as insufficiently skilled to make use of promising new technologies. Meanwhile, substantial funding resources continue to be dedicated to the purchasing of hardware and software while neglecting the human part of the equation: teacher support and development.

Governments, faculties of education, school districts, schools, communities and individuals have belatedly come to understand the need to give teachers access to training and development in required information technology skills. In British Columbia, for example, in 2001, the Ministry of Education earmarked $1.6 million for professional development in the integration of technology into classroom instruction for 1,000 teachers of grades 6 to 9.

While programs for providing professional development have varied widely and have been examined in detail in a number of U.S. based studies (see, more recently, Hoffman & Thompson, 2000; NCES, 1999; Sorg & Russell, 2000; Schrum, 1999; Swain, 2000; Walbert, 2000) and a Canada-wide study (Laferrière, Breuleux, Baker & Fitzsimmons, 1999) we have looked at three examples of professional development in Canada, each enacted at a different administrative level (faculty of education, school-district and school-based), and each employing a different strategy for professional development.

We have used several methods for gathering data in our work: documentary research, on-site visits, workshop observations and semi-structured interviews with teachers, project developers and administrators. Through these techniques we have identified a common range of issues encountered when teachers' participate in large- and small-scale professional development programs.

Of significance for each of the examples we chose to explore is how teachers and administrators respond to and speak differently about the programs in which they are involved. There exist striking disjunctures between what, from their particular subject positions, teachers identify as salient and relevant professional development, and what the professional development program itself purports to accomplish. Administrators and teachers have divergent perspectives on these issues mapped largely onto their positions within the institutional structure of schooling.

Abstract:
A graduate/pre-service education course was redesigned at the University of Nevada, Reno. Course instructors believed that students would better grasp the course objective of creating a WebQuest for target classrooms if this activity was modeled for them. Therefore, the course's entire content was transformed into a WebQuest. An evaluation was conducted at the end of the semester. Results suggest that students perceived that they learned new technology skills for the purpose of creating their WebQuests while master teachers perceived that the WebQuests created by the students were useful tools for their teaching.

Currently, there is much discussion about how to successfully integrate technology into the classroom (Maddux, Johnson & Willis, 2001; Geisert & Futrell, 2000; Jonassen, 2000; Bitter & Pierson, 1999; Alessi & Trollip, 2001). Many educators believe that there are many benefits to integrating technology into educational environments. New technologies, computers specifically, can teach ideas and concepts in exciting, enjoyable and efficient ways (Maddux, Johnson & Willis, Geisert & Futrell, 2000; Jonassen, 2000; Bitter & Pierson, 1999; Alessi & Trollip, 2001). However, bringing computers into classrooms is expensive, both financially and in terms of the time and effort required. Therefore, it is essential that computers contribute to the achievement of important, rather than trivial educational goals. One means that may contribute to the accomplishment of this goal is the use of a Web-based, inquiry-oriented activity called a WebQuest (Dodge, 1995).

A graduate/pre-service education course that traditionally covered computer telecommunications skills and concepts as well as methods of integrating information technology into the classroom was redesigned. It was reasoned that if the WebQuest approach to emphasizing the use of the Web in learning was a good idea for K-12 students, it should be a good idea for pre-service educators and graduate students. Therefore, a WebQuest was designed to encompass the entire course's content. The major course project became the task section of the WebQuest that required each student to design, build, and conduct a WebQuest in cooperation with an in-service teacher. Most of the correspondence and cooperation between the student and the in-service teachers was done over the Internet via e-mail. This approach has two advantages. First, it models information technology in the curriculum. Second, it provides students with a real-time learning opportunity in using the Internet and World Wide Web to enhance teaching and learning.

Course Design and Procedures
The 18-week course was designed to model a WebQuest so that students would experience WebQuests as students before designing a WebQuest for target students. The course WebQuest was uploaded onto the university server so that students had access to the site from any computer with an Internet connection (Johnson & Vidoni, 2001). Students completed four miniquests—or lab-based learning exercises that covered the basic computer skills necessary to create a WebQuest—and submitted their assignments to the instructor via e-mail. Links to journal articles related to course content were also linked to the course WebQuest and in-class discussions were conducted on the readings so that students would critically evaluate issues related to educational technology.

Students designed WebQuests that were used by teachers in real classrooms. Master teachers participating in a PT3 Grant at the university were paired up with most of the students. Some students preferred to work with university faculty and were encouraged to do so. Although many of the master teachers lived over 100 miles away from the university, students whose master teachers lived in the local area made site visits to their master teachers' classrooms. Students made three presentations during the course. The first presentation was made during the sixth week of the course for the purpose of discussing project ideas with classmates. Students received critical feedback from instructors and fellow students that they used to modify their WebQuests. The second presentation occurred during the tenth week of class once students had completed their WebQuests and just before they posted them on the Web for target students to use. A final presentation was made for the purpose of reporting the results of their project.

**Evaluation Results and Suggestions for Improvement**

All nine master teachers and 9 students completed evaluations. Most narrative comments were very positive. Students and master teachers rated all 5 statements of the evaluation with a mean of 3.6 or higher on a 5 point scale with 5 being the most positive. Students strongly agreed that the WebQuest required them to learn new technology (M = 4.89) while master teachers agreed strongly that the WebQuest created by the students were useful tools for their teaching (M = 4.33).

Some improvements will be made next time the course is offered. First, master teachers will be invited to a class meeting so that students and teachers can meet before they start working together. There were a few communication problems between students and teachers that face-to-face introductions would eliminate. Second, the class Web site was a little crude and changes to its appearance will be made.

Using Web-Based Conferencing to Promote Interactivity and Collaboration in Teacher Preparation

Abstract: The Collaborative Teacher Education Program (CTEP) at Indiana University offers coursework leading to teacher certification in special education through a distance-learning format. CTEP uses the web as a supplement to synchronous video-based instruction and as a stand-alone course delivery approach. The major aims of the web-based activities are to promote interaction and teamwork among teachers, and to build collaborative skills.

Introduction

The Collaborative Teacher Education Program (CTEP) offers distance education coursework to in-service teachers in rural communities in Indiana. The program is comprehensive in that teachers can earn teaching licenses or master’s degrees in special education by completing the twelve courses it offers (Knapczyk, Chapman, Rodes, & Chung, 2001). Our primary mode of course delivery is videoconferencing; however, we integrate web-based activities into the courses to increase instructional opportunities and to promote collegiality and collaboration among the teachers (Rodes & Knapczyk, 1996). Some class sessions meet solely on the web, and one course is primarily web-based.

Collaboration is a key area of emphasis in CTEP. Although the trend toward inclusive educational programs has increased the level of interaction between special education teachers and their colleagues in some schools, many still work in relative isolation. In CTEP, we use a variety of activities and assignments to encourage our students to interact and collaborate with one another and with teachers in their schools. We have found that promoting collaboration in these ways lays a foundation for increased on-the-job professional collaboration, and that the web offers a powerful tool for building these skills.

CTEP uses SiteScape Forum (SSF) as its web conferencing software. SSF is an easy to use web-hosted tool that incorporates two elements for holding discussions: forums and teams. A forum is a collection of related information that allows learners to interact on issues and course concepts. In a forum, our students have class discussions in response to questions or issues posed by an instructor or classmate. A team is a shared environment in which small groups work on tasks and problem solving activities. The forum and team interactions we structure are usually asynchronous but we use synchronous ‘chatting’ occasionally.

Building Expectations and Skills for Collaboration

In order to use the web for instruction, we must consider our students’ skill and comfort level in using technology (Rodes, Knapczyk, Chapman, & Chung, 2000). Some learners are fearful of losing personal contact...
with their instructor. One time we had a teacher who decided not to take one of our distance-learning courses even though the nearest campus-based class was over an hour away. “Oh, no,” she said. “I don't think I would like that. I want to see my teacher.” The absence of a live, face-to-face instructor, the strangeness of the presentation format, and the different roles demanded of learners are factors that can create anxiety and discomfort in those who are more used to traditional classroom instruction. In addition, students may need to learn new computer skills as well.

In-service teachers bring a variety of expectations and backgrounds with them into professional development activities. Usually, these expectations are set by the patterns of traditional classroom instruction: an active, present instructor; teacher-directed activities and discussions; a passive or merely responsive role for learners. Web-based instruction tends to reverse these dynamics, making the instructor less present and increasing the interactive and self-directive roles of learners. We try to shift our students' expectations about their roles and experiences by increasing the amount of team work and problem solving they do with classmates and reducing their reliance on more conventional instructor-centered approaches. We design web conferencing activities to shift student expectations in three areas: participation, assignments, and student interaction.

**Participation: From Passive to Active Learners**

Collaboration requires students to be active learners. Students must learn to rely on themselves and on each other, both to learn to use the technology and to make up for the range of subtle directions, cues and information they normally receive from a live instructor. Since students taking their first distance-leaning classes are generally used to a more passive model of instruction, we begin the semester with a traditional, teacher-centered approach. We quickly move to a more learner-centered model as students become familiar and comfortable with the distance learning format and technology. For example, at the start of a course, we use e-mail rather than the web to communicate with students because most of them are already comfortable with this form of interaction. As the semester progresses, we require students to participate more actively and assign many team-based activities in SiteScape Forum so web-based communication and learner directed activities become integral parts of the class.

**Assignments: From Directed Tasks to Self-Driven Tasks**

In the past, we started a course out by encouraging students to use SSF without structure or direction for how to interact. We hoped that a free form type of dialogue would help students become familiar with SSF and develop more independence. However, the typical responses were short, sporadic and aimless, and students saw web interaction as an extra chore rather than as a space for meaningful work. To remedy this pattern, we develop weekly web activities that focus on specific teaching points and their applications. An early-semester activity might be to have each teacher list ten behaviors they observe in their schools that illustrate a particular concept from the text. An activity like this is simple and clearly contained, but it gives experience posting to the web and accessing discussion pages. As students increase their familiarity and expertise in using web conferencing, we assign activities where they choose the issues they will address and where they work collaboratively on projects and problem solving activities.

**Interaction: From Non-Evaluative Sharing Toward True Collaboration**

Perhaps the most important aim in using web-based instruction with teachers is to build collegiality and collaboration. Through careful nurturing of teams and teamwork, we are able to increase student ownership and support for learning and transfer many of the roles they normally expect of instructors to the group. We encourage students to use SSF to give each other advice and feedback both on course assignments and on everyday teaching situations. Teachers have a wealth of experience and expertise to share that goes beyond what instructors can provide. Unfortunately, in many web-based formats, students are reluctant to give genuine critical assessments of their peers' work and their interactions are frequently cursory or off-topic. To build toward collaboration, our first SSF assignments usually involve sharing work samples, describing teaching situations, and exchanging basic information. As students become more familiar with one another, we have
them provide suggestions and feedback to their teammates. Early in the semester we may ask them to suggest assessment procedures or devices their teammates could use before thinking about the methods they will use themselves. In this way, they can give and receive meaningful suggestions to incorporate into their own activities. By the end of a course, they are comfortable enough with each other and the web format to give critiques of each others' ideas.

Considerations for Using Web-based Conferencing

A major advantage of web conferencing is that it allows students to work in teams, a format particularly useful for building collaboration. We use teams of four-five students because this size seems to give students sufficient opportunities to view a variety of examples and suggestions from their teammates. It also insures that they do not have too many reading and replying tasks to do between classes. We vary the way we organize groups based on the course goals we want to achieve. We usually structure groups according to the following characteristics: members from the same or from varied schools, members from the same or from varied age/grade levels, members with varied skill/experience levels, or student self-selection of members.

Activities on the web are usually more demanding than conventional assignments, often because the instructor is not there to explain activities and assignments. We give clear and detailed directions on both the tasks and the type of interaction we expect. We provide students with a model of what we want them to do in the form of a case study, a sample worksheet, a task breakdown or other exemplar. We also give schedules and deadlines with each assignment. The first part of an assignment typically requires students to do a task posted by the instructor, and the second part might have them respond and give feedback to their teammates' postings. We stress the importance of making postings on time so teammates are not inconvenienced or prevented from completing their work.

We also give students feedback about the tasks they do on the web. SSF allows us to see everyone's postings and the times they are made. We often add postings to the class, a single team or an individual student. We can assess both student and team performance and offer suggestions or evaluative comments when needed. Additionally, we may give remedial information to a particular team, suggest ways that members can interact more effectively, give guidelines for response etiquette, encourage individual participation, or acknowledge good work. In these ways, we are able to build a more effective environment for students to interact with one another and support their professional development.

Conclusion

Web-based conferencing is a valuable tool for in-service teachers because it allows them to share experiences and concerns, engage in problem solving, and develop and test out new ideas. To use web conferencing effectively, instructors must consider the gap between the students' expectations about the learning process and the capabilities and characteristics of web-based instruction. Careful, gradual introduction of web-based technologies can guide and enhance the transition from a traditional model of instruction in which student roles are passive, to a model in which they take a full, active role in directing and achieving their own learning. Encouraging and building collaborative skills are key elements in this process.

Case Studies of Primary School Teachers' Portfolios on Information Technology Competency Training Program – A Reflection on Information Technology Education for Teachers in Hong Kong

Kung, Eton
Instructor
Center for Enhanced Learning and Teaching
The Hong Kong University of Science and Technology

[Keywords]
Assessment; Competency; Curriculum; Evaluation; Information technology; Multimedia; Portfolio; Reflection, Teachers’ education

[Abstract]

The application of Information Technology in education has been strongly encouraged by the Hong Kong Special Administrative Region government since the outset of “Information technology for quality education: Five-year strategy 1998/99 to 2002/03” (Education and Manpower Bureau, 1998). Its primary aim was to promote information technology in education through teacher enablement, development of curriculum and software, hardware provision, and provide network infrastructure. According to the five-year strategy objectives, the promotion of IT in education is expected “to arouse and maintain our students' motivation to learn”, “to broaden our students horizons, so as to enrich their learning experience and facilitate the development of a creative mind”, and “to encourage independent lifelong learning and instil team spirit” (1998, p.1).

As school teachers are standing at the frontier of this change, there have been extensive training courses induced by the Education Department for “enabling” teachers’ competency in using information technology in teaching and learning activities at three levels: “basic”, “intermediate” and “upper intermediate”. However, this policy has brought in controversial issues whereas many teachers training programs are ongoing. The issues include the effectiveness of ways of implementation of the training programs as well as lacking an objective and effective assessment system for assessing teachers’ information technology competency. Under the policy, assessment of teachers’ competency is only done in a school-based format, that is, every teacher has to submit a portfolio of work to the school principal illustrating their ability in using and applying information technology in their
teaching practice. However, there have been queries on the effectiveness of the training program formats as well as whether the quality of their portfolios is reflecting the teachers’ competency for meeting the so-called benchmark.

This paper thus focuses on discussing the content and quality of primary school teachers’ portfolios as a result of a particular “Basic IT” level training course ran by the Center for Enhanced Learning and Teaching, the Hong Kong University of Science and Technology. Case study approach was adopted for the sake of a close examination and exploration of the 15 chosen teachers’ portfolios on their details. Since each portfolio consists of teaching schemes, lesson plans, multimedia teaching packages, etc., all these were analyzed with consent in terms of their subject matter, pedagogy adopted, presentation format and styles, relevancy and appropriateness to the expected teaching and learning situations, etc. Reflection report by each teacher, being part of the portfolio was also analyzed qualitatively for generating implications. Data derived from interviews with teachers also provided essential information for evaluating the training program and gaining a more thorough understanding of teachers’ learning processes during the program as well as the processes of accomplishing their portfolios.

Results of analyzing the above data helped drawing implications on: the effectiveness of the format of information technology education for teachers; the effectiveness and formats of assessment system on teachers’ information technology competency levels; the development of pedagogical strategies in relation to the application of information technology in teaching and learning activities; as well as the echoes to the general policy on information technology education for teachers in Hong Kong.

Unobtrusive Digital Video Capture of Live Classroom Instruction

Chris LaMont, Arizona State University, US

Educational videographers face the challenge of recording actual classroom footage without getting in the way of the teaching. Conventional thinking takes one or more video cameras into a classroom setting, with a wireless microphone for the teacher and a boom microphone for student interaction, and records the lesson in real time. This method is very obtrusive. The team at Arizona State University's Technology Based Learning and Research has developed an unobtrusive video capture method. This innovative approach has met with great success and is changing classroom video practices.

Rather than seeing classroom footage as a single or dual camera video, where the two cameras are edited together to form some sort of cohesive lesson, the TBLR video team looked at videotaping a classroom more like a sports event. To achieve an event capture scenario, the first step was to employ multiple cameras. One or two cameras are fine if you are grabbing bits and pieces with extensive editing. The goal here was to walk out of a classroom with an hour of finished program that could be understood by anyone watching it. Capturing the feel and spirit of the instructional lesson was an important detail that should not be stifled with heavy equipment. The intent is to let the lesson and content stand on its own. This presentation will show a video demonstrating an unobtrusive method of digital video capture.
What Did We Learn in the Six Hybrid Courses?

Amy S. C. Leh, Ph. D.
Department of Science, Mathematics, and Technology Education
California State University San Bernardino
United States of America
aleh@csusb.edu

Abstract: The paper reports lessons learned in six hybrid courses during 1999 to 2001. The goal of the research was to investigate students' opinions toward such courses and to examine the impact of using different strategies on online communities. Data collection relied on online discussion messages, observations, interviews, and surveys. Both quantitative and qualitative methods were utilized in this study. The results revealed that students and the instructor were in favor of hybrid courses and that the use of moderating strategies greatly influenced online communities.

Introduction

Technology advancement is changing our society and shifting our educational paradigm. In the last few years, the number of online courses has increased dramatically, and offering online courses is currently a trend in education. "Online courses," "completely online courses," "web-based courses," "web supplement courses," "hybrid courses," and some other terminology are used by professionals. Some educators consider courses containing online features, such as synchronous or asynchronous communication, to be online courses. According to this definition, courses in which instructors use these features but still meet students on a regular basis would be considered to be online courses. Other educators, however, disagree and only view courses in which instructors meet students half or less than half of the regular scheduled meeting time during a semester/quarter to be online courses. Further, even other professionals only recognize courses in which instructors and students do not meet at all to be online courses. To avoid confusion, the author uses the expression "hybrid courses" in this article to refer to the courses in which an instructor and students meet for half or less than half of the regular scheduled meeting time. Such courses are the courses involved in this research.

In this article, the author first describes her hybrid courses offered during 1999-2001 and strategies used in these courses in order to help readers understand the structures of the courses. After that, she reports the action research including data collection, data analysis, and results. Discussions and recommendations are also provided in this article.

The Six Hybrid Courses

Grabowski (2001) has stated that instructional design is closely connected to the beliefs of the course designer. For instructors who view independent study as a primary goal, they might choose to structure an online course as all independent study. Students would receive credits as long as they complete course assignments during the semester, and no interaction with others would be a required part of the course. On the other hand, some educators consider interaction and communication to be essential aspects of a course. These educators might choose to design an online course in such a way that students have to participate in ample interactive activities with others, including their classmates.

The author supported the latter. She believed that social interaction plays an important role in learning (Vygotsky, 1978) and valued active learning and meaningful learning (Grabe & Grabe, 2001; Brown, 1992; Knapp & Glenn, 1996; Means et al., 1993). Agreeing with Palloff and Pratt (1999), she regarded an online community as crucial in a hybrid course and designed her courses in a way that her students had to interact with other students to enhance learning. In a manner similar to Oliva (2000) and Santema and Genang (2000), she encouraged students' active learning and invited students to construct
course materials together with her. She met her students four times throughout the quarter—twice at the beginning, in the middle, and at the end. All assignment submissions and discussions were conducted online via WebCT. She constructed a variety of forums (discussion boards) for students to communicate with each other and to share resources. Examples included forums for making announcements, asking questions and receiving help concerning technical issues, submitting assignments, and providing feedback and critiques to their classmates. In all her courses, students had to post their assignments to the forums, review assignments of their classmates, and critique each other's assignments. These activities provided students with basic channels for communication.

In addition to using assignments to enhance interaction, the instructor also employed different strategies to facilitate students' communication. While she used moderating strategies during the second year (2000-2001), she did not use them during the first year (1999-2000). During the fall quarter of 1999, all students conducted synchronous communication every week and discussed topics that were posted by the instructor. During the winter quarter of 1999, students used forums to conduct threaded discussion about topics generated by their classmates. During both quarters, students obtained participation points based on frequency and quality of their posted messages. They were aware that they had to post at least two messages every week to receive participation credits. Such participation requirements were not expected during the spring quarter of 1999.

During the second year, the instructor used moderating strategies in the three hybrid courses in which students took turns to moderate their online community for a week. It was understood that the instructor would not interrupt to answer questions unless it was necessary and that the students would receive credits based on how well they moderated the community. For example, if a question or a problem on a discussion board remained unanswered or not acted upon, the moderators of the week would be marked down. Moderators did not have to answer all questions or solve all problems but they needed to facilitate discussions about the issues within the community.

Based on responsibilities and tasks the students conducted, the moderating strategies varied. The instructor categorized them into three types of moderating: medium-duty, heavy-duty, and light-duty. During the fall quarter while the medium-duty moderating was conducted, moderators posted discussion topics, hosted online discussions, and answered questions posted by their classmates. During the winter quarter while the heavy-duty moderating was conducted, moderators not only took on the same responsibilities as in the previous quarter but also assigned readings, generated rubrics, and further evaluated their classmates' online performance. During the spring quarter while the light-duty moderating was conducted, moderators only needed to host online discussion and answer questions posted by their classmates.

The Research Study

The goals of the research were to investigate students' opinions toward hybrid courses and to examine the impact of using different strategies on online communities.

Subjects

The participants of the study were the students in the twelve hybrid classes (three courses offered at two campuses during two years). They were in-service teachers who were pursuing their Master's degree in Instructional Technology at a state university in the western United States and had little experience with hybrid courses.

Methodology

At the beginning of each course, the instructor explained to the students the course and their responsibilities, especially their duties related to the different strategies used in an online community. During the courses, the instructor posted questions for discussion. Examples of questions are: (1) What are the benefits and barriers of hybrid courses? (2) What are the advantages and disadvantages of conducting synchronous and asynchronous communication in hybrid courses? (3) Do you like the moderating
strategies used in this course? During the last meeting of each course, students filled in a survey that contained 10 Likert scale (1-4) questions and open-ended questions. The Likert scale questions were guided to examine the following points: (1) Compared to a traditional class, did students feel that they learned as much as, or even more, in the hybrid course? (2) Compared to a traditional class, did students feel that they spent as much as, or even more, time preparing for the class? (3) Compared to a traditional class, did students feel that they were motivated as much as, or even more, to learn in this course? (4) While taking the course, did students have sufficient access to the instructor? (5) While taking the course, did students have sufficient interaction with other students in this course? (6) Given the choice between traditional courses and hybrid courses, did students prefer a hybrid course if the course content were suitable for a hybrid course? (7) Did students wish that more hybrid courses were offered in the Masters program at the university? (8) Would students enjoy taking another hybrid course? (9) Were students concerned about the quality of hybrid courses? (10) Did students like the delivery format? (11) How many sessions in which the teacher and the students meet would be appropriate for a hybrid course? Open-ended questions of the first year focused on benefits and barriers of hybrid courses while those of the second year emphasized the impact of moderating on online communities.

In addition to online messages and surveys, data was also collected from observations and interviews. The author observed students and activities online as well as during class meetings. Interviews were informal and occurred when there was a need for clarifying students' comments.

The author tabulated the survey data. She also downloaded students' messages related to the research, color-coded messages, and categorized them into appropriate folders based on the topics, for example, benefits of web-based courses and barrier of web-based courses.

Results and Discussions

The results indicated that students were in favor of a hybrid course. The students felt that they learned as much as or more in such course than in traditional courses and that they were more motivated. They wished that more hybrid courses were offered in their academic program, and they preferred hybrid courses to traditional courses.

Most of the means of the survey results went up when time progressed. The instructor felt that this change was partially due to the experiences she and her students gained from the hybrid courses. She also felt that certain characteristics, such as self-disciplines, were necessary for people to succeed in such courses. Since the students and the instructor did not meet every week, students had to be self-disciplined and able to complete tasks without much supervision. More than half of the students revealed in their surveys and interviews that online learners should be self-disciplined and complete tasks on time. Four students who received incomplete grades during the first quarter pointed out a need of such characteristics. One said, "I have difficulty in the online [hybrid] course because I'm not so disciplined and often postpone my work. In a traditional course, I would be reminded every week when I go to class. But this is not the case for taking an online [hybrid] course."

Although people who tend to delay their work might have difficulty surviving in hybrid or online courses, the instructor believed that preparing students' mindset before they took such courses could be helpful. During the first meeting of her courses, therefore she asked students who had taken her hybrid course(s) before to share with other students tips of being online learners. "Don’t postpone your work" was mentioned repeatedly by the students.

As mentioned earlier, students conducted synchronous communication in the first course and asynchronous communication in the second course. In both courses, students received participation credits. In the third class, asynchronous communication was utilized but no participation credit was issued. The different strategies used in these three classes had an impact on the online communities. The research results indicated that synchronous communication strengthened students' sense of belonging. A student stated, "Although we do not see each other every week, the real-time communication makes me feel we belong to the same class." Such a sense of belonging was less common when asynchronous communication was used during the second quarter. During that quarter, a few students addressed that they missed real-time communication and requested the instructor to sometimes conduct such communication while they were enjoying the flexibility that asynchronous communication provided. Observing the three courses, the instructor found that the online community of the third course seemed to be loose and thought that issuing no participation credits might have contributed to the loose community. The instructor
suggests online instructors employ asynchronous communication and synchronous communication alternatively and use participation credits to motivate students participating in online communities.

Students listed several benefits of a hybrid course: flexible schedule, being able to work at any time and at any place, and being able to choose the best conditions for learning. They also mentioned that hybrid courses saved them gas and time on commuting and allowed them more access to instructor and to their fellow classmates.

Barriers also existed in a hybrid course. The participants missed face-to-face communication and personal contact. Students with low technology skills felt pressured and anxious. Such pressure and anxiety might create a negative impact on learning. Despite these barriers, students expressed that they would still choose a hybrid course over a traditional one, if they had an option.

Like the students, the instructor enjoyed the flexibility hybrid courses provided and missed face-to-face contact with her students. Unlike the students, she experienced tremendous pressure of responding to students' messages and of their expectations of receiving responses instantly. Meeting students once a week in a traditional course became meeting students 24 hours a day, seven days a week online. In addition, it was time consuming and stressful to communicate with a couple of students who often got confused and repeatedly asked the same questions no matter how clear information was, for example, on when an assignment was due and when the next meeting would be. Such stress was eased during the second year when moderating was used in her courses.

During 2000-2001, the instructor utilized medium-duty moderating in the first (fall) quarter, heavy-duty moderating in the second (winter), and light-duty moderating in the third (spring) quarter. As mentioned earlier, the differences among the three types of moderating were based on responsibilities and tasks students conducted in the hybrid courses. Data collected from survey open-ended questions, online discussions, observations, and interviews indicated that both the students and the instructor favored the use of moderating in the courses. The students felt a sense of ownership of their online communities and learned from their peers by observing how their peers hosted the communities. They received answers much faster than before because every member of the communities tried to help answer questions. The instructor also favored the moderating. She noticed that she was less stressed responding to students compared to the first year and that the students received responses faster and became very active in the online communities. The communities became very dynamic, and she felt the courses sometimes could smoothly move forward like a car with a "cruise control."

Among the three different moderating strategies, the students favored the medium-duty moderating the most and the heavy-duty moderating the least. During the winter (heavy-duty) quarter, the responsibilities of the students and their activities appeared too complicated. Moderators of every week tried to do a good job by assigning readings, setting objectives for the week, and facilitating discussion; often their readings and objectives were too many to be accomplished within a week. Students conducted many different activities when time moved on. At the end, they were distracted by the objectives of different moderators and forgot the objectives of the course. In addition, moderators often had to participate in activities of a week while they were still evaluating their peers' online performance of the week when they were the moderators. This was indeed a hectic quarter, and the instructor learned a big lesson from the experience. Appropriate amount of online communication could enhance learning while too much communication might cause learners to withdraw from the community (Palloff & Pratt, 1999). Students' dislike of such moderating is clearly revealed in the survey results. A number of the means during the winter quarter dropped and consistently appeared to be the lowest among the three courses. Students spent a lot of time (mean=3.93) on the course but did not necessarily learn more (mean=3.15). They liked the course the least (mean=3.27) compared to the other two courses of the year.

Although the winter quarter was hectic, students still favored hybrid courses. Issues addressed during the first year, such as benefits of such courses and their wish to have more hybrid courses in the academic program, repeatedly appeared in the second year. Students also liked the fact that they had to post their assignments and review their peers' work. By doing so, they learned much from their peers. They liked meeting three to four times per quarter and did not seem to favor an online course without a face-to-face meeting.

A hybrid course did provide flexibility and convenience to learners, especially to learners at remote areas. While hybrid courses are blooming in many places, the author thinks that hybrid courses should not (1) be independent studies in which no interaction among students are necessary, (2) be only task-oriented in which social learning is neglected, and (3) lower the quality of education. Instead, the courses should be structured to raise the quality of education because learners have options to choose their
best learning conditions and opportunities to enhance their learning using resources beyond boundaries of
time and space.

Conclusion

The paper reports action research on online courses conducted from 1999 to 2001. Data were
collected from three courses (12 course sections) at two campuses during the two years. Data collection
replied on online discussions, observations, interviews and surveys. Both qualitative and quantitative
research methods were used in this study.

The results indicated that students and the instructor were in favor of hybrid courses and that the
use of different strategies had an impact on online communities. Using synchronous communication and
asynchronous communication alternatively could enrich online communities, and moderating strategies
with careful design and organization worked well in hybrid courses.

Instructors who employ a variety of strategies to build up and nurture an online community may
achieve the most success with hybrid courses. This new delivery method provides students with options of
choosing their best learning conditions and with opportunities to enhance their learning using resources
beyond boundaries of time and space. One can see the potential of this method for positive impacts on our
education and society.

TNT: Ignite Learning Exploding Barriers and Obstacles to Language Learning

Dr. Donna Lenaghan - Educational Computing and Technology
Barry University, USA dlenaghan@mail.barry.edu

Abstract: In the statement, “All students can learn and be All Star learners” there is no qualifier -- “as long as English is their first language”. The challenge is to identify: how to ignite learning in all learners especially learners with limited English language proficiency and the nuances of learning for all learners? This paper provides: 1) a topical review of Teaching English to Speakers of Other Languages (TESOL), 2) a synopsis of brain-based teaching and learning concepts, 3) a discussion of an instructional design model for infusion of technology resources to augment the teaching and learning process for students with limited English, and 4) a sampling of technology resources for infusing appropriate technology into the teaching and learning process for students with limited English.

The TNT Combination for Learning

TNT (an abbreviation of trinitrotoluene) is a commonly known explosive created by combining three nitro groups into one module (Websters, p.2401 & 2446). Under most conditions, TNT is stable, yet when the three elements are combined in a certain way it becomes a powerful charge to blow away obstacles and barriers to progress. TNT for learning means--Technology Nourishes TESOL learners. It removes barriers and obstacles to learning.

The three parts of the educational TNT are: TESOL/ESL, brain-based learning, and instructional design for infusing technology into the teaching and learning process. TESOL is the field of Teaching English to Speakers of Other Languages and ESL is English as a Second Language. Brain based learning means that strategies and techniques consistent with brain operations are integral parts of the teaching and learning process. Educational Technology is the application of science (in this case computer-based technologies) to learning. A quick review of the literature in each area provides a foundation for understanding this powerful combination to remove obstacles for learning.

TESOL/ESL

Numerous web sites for TESOL/ESL learners and the history of Computer Assisted Language Learners (CALL), demonstrate that technology is not a new concept in the TESOL/ESL arena. When and how technology can be infused to remove barriers for learning is an area for continual and rigorous discussion and investigation by educators and researchers. A selective (not exhaustive but representative) sampling of literature found the following common elements within articles discussing TESOL/ESL and technology: 1) numerous suggestions for types of technology activities to use by or with second language learners, 2) suggestions for the appropriate incorporation of technology into curricula and pedagogy and 3) recommended components of TESOL/ESL learning activities. Suggestions for TESOL/ESL learning activities with technology are found later in this paper.

Shared components of TESOL/ESL activities found in the literature included: language development/acquisition, pedagogy to support social communications competencies and academic achievement, contextualization, and cultural influences in second language acquisition (Bowman, Butler-Pascoe, Chapelle, Egbert & Hanson-Smith, & Warschauer). Incorporating technology as a part of the curricula and integrated into pedagogical goals was a common thread found across the literature review. For example, Vazquez-Montilla’s & Zhu’s (2000, p.17) research comparing the use of web based conferences and e-mail communications for ESL students found that “technology remains an enabler and facilitator or instruction” when it is infused as a part of the pedagogy. Technology should be used to enhance the language learning process. It is a means to the outcome of language learning not an outcome itself. Similar opinions were found in the web-based bulletin board discussion of Computer Technology and TESOL (Healey 2001). Of the pro-technology postings, individuals advocated or documented technology as a part of the teaching and learning process not something to be learned by itself. Douglas, in review of Computer Assisted Language Learning (CALL) resources, postulated that the effective use of technology in language learning requires “putting pedagogy before technology” (Douglas, 2000). Based on her research on using Internet with second language learners, Lynda Terrill (2000) identified benefits and disbenefits of adults learning English with technology. One benefit was that learners enjoy working on the computer. The disbenefits included the language level on the Internet being too difficult for second language learners, limited or no Internet access (also
cited by others in the literature), and lower socioeconomic groups unfamiliarity with or limited access to computers.

Warschauer (1998) posed the most provocative perspective about using technology in second language instruction. He advocated for a holistic re-examination of what literacy means in a multimedia communication culture and how this literacy intersects with class, race, gender and cultural identities. He raised the question of examining how the sociocultural context of a particular educational institution or community effects electronic illiteracies. He advocated that the perspective shouldn’t be “old language learning plus computers” (Warschauer, 2000, p.2) but what does language-learning literacy in a technological communications period mean.

**Brain Based Learning Variables**

Brain based learning is a term for strategies that complement how the brain naturally functions (Caine, 1994; Lenaghan, 1999; Sylwester 1999). The brain based learning strategies to be addressed in this paper are: intellectual potential (multiple intelligences) and brain operations.

**Intelectual Potential = Multiple Intelligences**

Howard Gardner revolutionized educators’ understanding of the brain’s potential through his Multiple Intelligences theory and definitions of intelligences. He redefined intelligence as "the ability to solve problems or to make something that is valued in one or more cultures" (Checkley, 1977, p.9). This definition has grand potential for multilingual and multicultural learners. It is inclusive and not restrictive to one culture's dominant language. According to Gardner, students are smart in a combination of at least eight different areas. Multiple Intelligences theory is not to be used to classify people, but to understand, plan, and evaluate the teaching and learning process. Each person has two or three dominant intelligences that he or she uses to complete daily tasks, solve problems and respond in stressful situations. Teachers should provide multiple opportunities for students to learn, demonstrate and reinforce their learning through all these intelligences. A sampling of Internet activities and sites related to individual intelligences and TESOL are listed in Table 1.

**Brain Operations**

Multiple Intelligences describes the brain’s capacities and brain operations describe the natural functioning or neural pathways of learning. Through brain mapping (observing and analyzing the neuron firings in human brains) the biological paths and processes for learning are identified. Emerging from this research, are five key insights for education (Table 2) and strengths of technology related to these brain-based learning techniques (Table 3).
The emotional brain is the preliminary processor of information thus the gateway to learning. Neural pathways of previous learning are established through repetition. Short-term memory storage capacity is limited. Information must be manipulated or applied for transfer from short-term to long-term memory. New information and experiences shape neural pathways established by prior learning. Problem based learning requires active neural connections across and between numerous memory & activity centers. Brains operate on a ninety-minute energy cycle then needs a break.

**Instructional Design**

Instructional design is defined as the systematic planning of ways to accomplish objectives, outcomes and/or learning. It is driven by the instructor’s (and hopefully learners) philosophy of learning and theories and technologies to accomplish this. The pedagogy mentioned in the TESOL/ESL literature infers an instructional design process. With infusion of technology into teaching and learning activities, the manner in which the technology (instructor and/or student driven) is used and the design of the actual software (concept presentation/programs were written with an inherent pedagogy) must complement and expand the teachers’ and learners’ philosophy and learning opportunities.

Infusing technology into the learning environment changes the learning environment. Like Warschauer’s question of the meaning of literacy in a multimedia communication culture, the educational technology field is asking itself the meaning or process of literacy in a multimedia culture. The question of meaning is still being debated, but the methods consistently reflect the trend of learning becoming more student directed, oriented to problem or solution seeking, cooperative learning, discovery-focused, and individualized. Teachers and students are cooperatively learning, producing knowledge and solving problems together.

Technologically based learning and instruction are initially attractive (once fear of the dreaded computer monster is tamed) because it appeals to one or more of the dominant senses and intelligences. The learner actively seeks information and solves problems in virtually realistic environments and the teacher coaches. This is a shift from "sage on the stage" to "guide on the side", facilitated by appropriate technology. A powerful paradigm shift is occurring with technology-based learning. Teachers are no longer the absolute source of knowledge, but a designer of learning experiences in which the learners actively seek, use and synthesize knowledge. This shift is exploding some barriers and obstacles to learning.

There are many wonderful frameworks for instructional design. Readers and practitioners should adopt or adapt one consistent with their educational values and preferred teaching methodologies. Many teachers and professors have found Multigogy effective with multicultural and multilingual learners. The acronym M.U.L.T.I. (Many Unique Learning Tendencies Impact) is its prefix (precursor for understanding) to which the Greek root "gogy" (which means teaching) is added. Multigogy is a framework for designing instruction that is learner centered and brain-based. It accommodates a variety of instructional techniques supporting Directed Instruction, Cognitive Constructivists and Social Learning Constructivists theories of learning (Lenaghan, 1999).

Two Multigogy principles--FAST SCORE--are consistent with successful learning strategies found in the
TESOL/ESL literature. FAST is an acronym prescribing the learning environment conditions to be: Friendly, Active, Solution-oriented and Technologically assisted. SCORE is an acronym summarizing brain based learning principles. To SCORE a learning module, the teacher and/or learner: 1) Sees the information in addition to hearing it; 2) Chunks or categories the information into small units to easy the retrieval and retention; 3) Operates the information in some manner in order to reinforce neural networks and facilitate transfer from short term to long term memory; 4) Repeats or reviews concepts and skills to enhance retention; and 5) Emotionalizes (positively) the learning content and context. Remembering FAST SCORE to enhance the instructional design and lesson planning process and combined with Multiple Intelligences orientation will set-up learners to be All-Star learners.

Infusion of Technology

Infusion of technology into the instructional design for learning has a range of instructional methods options. Most people agree that its purpose is to accomplish standards of competencies and benchmarks prescribing enhanced thinking and concept mastery. And they accept a variety of different approaches for incorporating technology into instruction. TIP MIC, an acronym within Multigogy, is offered as a summary of the variety of ways technology is infused into the teaching and learning process (Table 4). A sampling of tips and ways to infuse technology into TESOL/ESL activities are listed in Table 5.

Table 4: TIP MIC for Infusion

Specific TESOL/ESL websites recommended by practicing teachers (organized into categories of Teacher/Instructional, General ESL/TESOL and Student Activities sites) are found at http://socrates.barry.edu/ADS0E-dlenaghan/tesol/webresources.htm. Readers are encouraged to complete focus groups to validate and expand this list for your specific multi-lingual and multi-cultural contexts and share their findings with others.

Conclusion

The three elements in our TNT for learning are: TESOL/TNT teaching and learning strategies, brain based learning concepts and instructional design. When combined with technology as a tool wisely infused in the teaching and learning process, the mixture becomes a powerful catalyst to blow away barriers and obstacles to learning. This dynamic mixture is more than knowing the independent compounds; it is in the creative and careful blend of the three elements into one module that creates the positively dynamic potential. With the potential to explode barriers and obstacles, the field is now clear to engage all learning capacities with the infusion of technology into TESOL for the success of students and teachers.

Using Moral Development Theory to Teach K-12 Cyber Ethics

Judith Lewandowski, Purdue University, US

Introduction

Children today face a very different world than that of their parents. A recent television commercial exemplifies this point by illustrating a young teen who, after disobeying her parents, is grounded from the use of the telephone. The commercial depicts the girl joking with her friend, through the use of an Internet-based phone, about the "punishment" she has received. Much to the chagrin of the teen, her mother enters the room and overhears the conversation. Without hesitation, the mother extends the punishment to include banishment from the computer.

Technology, it seems, has permeated into virtually all aspects of our life. Its incorporation has influenced the way in which we communicate, travel, work, learn, and raise our children. Consider the life span of young teenagers born in 1988. For these kids, it is common practice to chat with friends from around the world, watch news events as they happen, interact with experts via the Internet, capture photos digitally, and manipulate historical recordings of events. The environment in which these children will grow is quite different than that of their parents. All of these differences resonate the fact that the skill set that will be required of these children as they mature into adults is dramatically diverse than the skills that were needed by previous generations.

New Societal Skill Set

The role of information technology in our society is increasing at a dramatic rate. According to several governmental reports, there is currently a "critical" need for individuals skilled in the field of information technology. These reports also indicate that this need will grow substantially over the next five years (Critical Infrastructure Assurance Office, 2000). According to a recent National Science Foundation report, by the year 2010, the United States will need more than 700,000 additional scientists and engineers proficient in both content and technical skills (Kopp, 1996). The skills of the past will no longer provide an individual with a secure future. As the needs of our society change, so must our educational system.

Effective and consistent technology use is a critical factor in increasing the information literacy levels of our future workforce. Currently, the amount of knowledge in our world doubles every two years (Withrow, 1993). Consequently, it would be impossible for a worker in the 21st century to memorize all relevant information. Due to this vast amount of knowledge, information literacy skills will need to become a key component of our schools' curriculum. The ability to find, locate, and apply the needed information will require information literacy skills as well as basic technical proficiencies (Withrow, 1993).

According to John Brown (2000), the Internet has the potential to assist in the acquisition of the "new" skills. The use of technology in an educational setting can provide a dynamic framework to enhance and promote the acquisition of the types of skills that our students will need in order to be productive in the future. Technology, in a variety of forms, can help to teach students the process of information gathering, inquiry, collaboration, and simulation (Rice & Wilson, 1999).

Educators, politicians, and parents agree with the idea that technology integration will help to spur the advancement of technological skills in children. This belief has been transformed into school budgets that embrace the integration of technology into the classrooms. The National Center for Education Statistics reports that 66% of public school teachers use computers or the Internet for instruction during class time (2000). According to a 1999 survey, 16 million children (or 14% of U.S. citizens under the age of 18) regularly use the Internet. Of those users, 6 million are children under the age of 6 (Curriculum Review, 1999).

Acquisition of Ethical Guidelines in the Workplace

Familiarity with and utilization of new technical advances are critical components of an educated 21st Century workforce. However, the development of a new skill set goes far beyond simple technical know-how. The Information Technology (IT) workforce must also understand the ethical implications of the programs they write, the actions they take, and the criticality of protecting intellectual property in the online environment. Individuals who learn only the technical side of technology are missing an integral part of the new skill set.
Unethical behavior can be a costly mistake for industries to counteract on several levels. Fines, public embarrassment, negative publicity, professional reputation damage, low employee morale, and difficulty in employee recruitment are all examples of common costs associated with unethical business practices (Nash, 1993). Lands' End, a prominent clothing manufacturer, offers a dramatic example of a commitment to include ethical training as part of the new skill set required of its employees. Members of the Lands' End Information Technology team are routinely placed under security audits which include technical attacks on its information security practices as well as individual ethical tests of the team members (Wilder & Soat, 2001). By utilizing this type of spontaneous performance check, Lands' End is actively working to develop and maintain a workforce that is both secure and ethical in its daily practice. Additionally, a recent Information Week survey indicated that 62% of the reporting corporations monitor their employees use of the WWW, and 54% monitor the email of their employees (Wilder & Soat, 2001). These monitoring practices are deemed both ethical and common by most IT professionals, yet it is not clear as to where the employees are to acquire these skills for discerning appropriate use of the technology.

The nature of the IT world changes the use of ethical behavior for some. In the invisible online world where you can interact almost anonymously, some individuals experience difficulty in translating their real-world ethical guidelines into the online environment. When individuals interact in a direct face-to-face manner, they can see the impact their dialogue is creating. In the online environment, individuals can send dramatic, painful, and derogatory responses without having to witness the pain the receiver endures (DeMaio, 1991).

Acquisition of Ethical Guidelines in Schools

It is imperative that students understand the deep implications that their online behavior may have upon others. If they are unable to draw the connection between real-world ethics and the online environment, the students will need to be guided in this transition by role models, parents, and teachers. Ethical training can benefit students by “increasing their awareness and sensitivity to important issues surrounding ethical problem solving” (Windsor & Cappel, 1999). To this end, it is critical that cyber ethics be addressed as part of the regular curriculum of our K-12 schools. As we teach students the skills to use technology, we must also teach them the proper guidelines for appropriate use.

Ethics and Cyber Ethics Defined

According to the American Heritage Dictionary, “ethics” refers to the set of principles of right conduct (2001). It is “concern with what we consider to be ‘right’ or ‘just’ behavior (Gibney, 1999, p.19). Ethics refers to the guiding principles or ideals of good vs. evil. Ethics are not based in law, religion, or standardized beliefs; rather, ethics refer to a general conception of right and wrong which transcend both religion and law (Webster’s Dictionary, 2001). “Cyber ethics” refers to the application of ethics into the online or virtual environment (Ethics Connection, 2000).

Justification of Cyber Ethics at the K-12 Level

Ethics intervention demands attention at a young age. The majority of children begin developing significant use of their ethical principles between the ages of 10 and 12 (Geide, et al 2000). To hesitate in teaching ethical principles until adulthood is not only ineffective but also risky. There are countless examples of the horror stories of students who once empowered with technical skills feel the need to practice them in inappropriate ways. Distribution of pornography, sexual harassment, credit card theft, destruction of governmental websites, modification of grades, counterfeiting rings, and software piracy are just a few of the technically-based illegal activities with which students in our schools have been involved (Marsh, 2000).

In addition, common classroom distractions have even been impacted by technology, often with a more vicious twist. One prominent example involves the illegal use of others’ email accounts to send inappropriate, threatening, or mean email to fellow classmates. This practice has become so commonplace in schools, that many middle school teachers trivialize it by making it analogous to passing hand written notes about the “un-cool kids” in class (Marsh, 2000).

Not only are students not hearing about the need for appropriate use of technology, it seems that they are bombarded by a constant stream of media clips in which the image of the hacker is portrayed as a romanticized rebel. MTV recently aired a broadcast entitled, “Hackers” which provided the viewer with a day-in-the-life view of a computer hacker. Additionally, several major motion pictures such as “Hackers,” “War Games,” and “Real Genius” have depicted hackers as the new adventure seekers. The actual hackers
do not dissuade these stereotypes; rather, they embrace the notoriety and acclaim the stereotype brings (Governor, 1997).

As technology integration has progressed throughout society over the last several years, it is also interesting to note that the frequency of computer crimes and misuse has also dramatically risen. Specifically, the 2000 Computer Security Institute/FBI Computer Crime and Security Survey indicates that computer crime and other information security breaches are on the rise with 90 percent of the responding 585 participants reporting computer security violations within the previous 12-month period (Smith, 2000). Many experts agree that this trend in increasing rates of computer crime will escalate even further. The consensus from a recent Department of Justice conference on computer-related crime was that due to the increased integration of computers into the K-12 learning environment, the number of potential perpetrators of this type of crime will rise dramatically (Smith, 2000). According to this group, the basic adventurous nature of technology can lead undirected users to misuse the equipment (Sivin & Bialo, 1992).

Other research echoes this sentiment on a more youthful level. In April of 2000, Scholastic, Inc. conducted a survey asking 47,235 elementary and middle school students if hacking should be considered a crime. Alarmingly, 48 percent of the surveyed students reported that it was not criminal (Geide, et al, 2000). Additionally, in a study of 729 high school students conducted by Vincent & Meche (2001), 19 percent of the students indicated that they felt that personal use of company e-mail (designated for company use only) was ethical and 49 percent said that they would use it.

It appears that schools are providing students with the opportunity to develop and learn the skills to use technology; yet, this same curriculum is failing to teach the students the principles surrounding the acceptable use of technology. It is the lack of instruction on these soft skills in the curriculum that has many experts worried about the propagating culture of young Internet users (Geide, et al, 2000).

Society is a dynamic system. It must, by nature, evolve in order to survive. As we develop the new definitions of appropriate behavior in the online environment it is imperative that many members of society be engaged in this ongoing dialogue. An informed community and active discussion of ethical issues will enable society to determine civil and just manners to deal with the nuances of technological advancement (Rezmierski, 1992). By opening this dialogue within the K-12 environment, teachers will be able to prepare students to understand the proper use of technology and explore the issues that will continue to unfold. Unfortunately, many educators are not equipped with the skills to effectively integrate ethics into their classrooms. In order to successfully blend ethical instruction into the K-12 curriculum, educators must develop an understanding of moral development principles, recognize age-appropriate moral dissonance, and learn to advocate for the moral growth of the students' perspectives (Clare, et al, 1996).

The remaining portions of this paper provides a general overview of prominent moral development theories. Its purpose is to provide a general understanding of moral development theories as well as the justification for the selection of Kohlbergian theories as the foundational approach to the integration of cyber ethics into the K-12 curriculum.
Learning Environments in Adult Teacher Education - a Chydenius Implementation

Jukka Mäki
Project Manager
Network University
Chydenius Institute
University of Jyväskylä
Finland
jukka.maki@chydenius.fi

Abstract: Chydenius Institute is a research and education centre of the University of Jyväskylä. It's the only educational department in Finland that selects only adult students for graduate teacher education. This paper raises the problems of adult-students in the use of information technology in studies. It describes especially the use of web-based learning environments as part of their studies.

1. Chydenius Institute, a Network University for Adults

Chydenius Institute is a research and education centre of the University of Jyväskylä. Located in Kokkola, in the western coast of Finland, it gives a regional sample of the University. The Chydenius Institute offers teacher training and in-service training for professional development, makes research in the fields of economics, social and pedagogical sciences, offers open university education and services for businesses and other organizations. It offers also Master's degrees of Information Technology (with University of Jyväskylä) and Electronic Engineering (with University of Oulu). Its newest implementation is European Union funded project of Network University, which is part of the Finnish Virtual University.

Chydenius Institute has a reputation as a Network University for adults. The history begins from mid 80's, when the Institute was founded firstly to give further education for teachers in the region. The name Chydenius comes from Anders Chydenius who was a famous Finnish politician and economist in 1700's supporting liberal economic policy and freedom.

In the late 1980's there was a lack of elementary school teachers in Finland and that's why the Ministry of Education gave an emergency law for some universities to start a two-year-program of teacher training. The entrance to study was given for those teachers who had long teaching experience, university studies, but who hadn't finished a Master's degree of Education. The Chydenius Institute was one of those training units.

Shortly, the lack of teachers was covered, but it became evident that Finland needs this kind of adult teacher education. The Ministry gave the permission for the Chydenius Institute, as a part of Jyväskylä University, to offer permanently instruction using this model of teacher training. And so today, the Chydenius Institute is the only unit that gives "adult teacher training" in Finland. In 2001 every fourth candidate was taken to study, i.e. 50 students started in the fall 2002.

2. The students of teacher training

The "typical" student of Chydenius Teacher Education is married woman with two children, owner of another degree (usually kindergarten teacher) and five to seven years of experience in elementary school teaching. Most often she has a home not more faraway than 200 kilometers from Chydenius Institute. She dedicates her time for studies every week and the husband takes care of the family. Usually she stays the weekends at home. This kind of organizing the life totally differently, although temporarily, means a big understanding from the side of the family but also a maturity and motivation of the student.
3. The studies of teacher training at Chydenius Institute

The teacher training at Chydenius Institute consists of full-time studies from 1.5 to 2.5 years. Because the most of the students are holders of another university degree or at least they have 60 credits (of 160 cr.) of university studies. A student completes the studies by having language and communication studies (7 cr), Science of Education as major (75 cr), minor studies (65-70 cr) and optional studies (13 cr). Everybody makes a scientific research of 22 credits (counted in major studies).

All the students are adults with teaching experience. The studies support life-long learning and they are student-centered and flexible. Everyone has an individual curriculum for Master's degree. All the courses give possibilities for team working, personal counseling, projects, workshops and seminars. Often the assignments are implemented individually, pairs or in small groups. Pedagogical theory and practice are in close interaction and the students are able to develop their teaching abilities during their studies.

4. The use of ICT

Because of high level of Finnish educational system and big use of information technology, all university studies consist of computers, internet, electronic communication and videoconferencing. The Chydenius students have very different background in ICT. This might be a problem, but actually it isn't because of big emphasis that is given to ICT as a part of studies. During the first weeks of the two-year-program the students start their computer training. This is seen as a basic for the further studies. They learn to use the computer, word-processing, graphics, presentations, email and internet. They learn to take digital pictures, scanning and image-processing. During every course the students use open or closed web-based learning environments to perform their assignments but also to communicate and inform one another, both students and professors. Table 1 shows the special courses of ICT during the studies.

Table 1. The special courses of ICT in Chydenius teacher education studies.

The course “ICT-knowledge of a teacher” is a basic course for using computer, network, word-processing, email, internet and graphics. The students learn also to process digital photos. All students come familiar with pedagogical use of videoconferencing and www-page design.

The course “Media education” helps the students to understand media reality of today and phenomena of mass media. They get experiences of communication and media culture. They analyze the views and opportunities of media education. They learn to edit digital photos and videos and evaluate illustrated learning material in www and traditional forms.

The course “Pedagogy of teaching with networks” emphasizes the meaning of human, knowledge and learning as a basis for pedagogical use of ICT. The students think the role of a teacher as a tutor in problem-based learning. They learn to create web-based courses and to build communities in a web-course.

Throughout all the studies internet is utilized as a source of information for every course. Because all Finnish schools are connected to internet it's very important to learn how to use the internet in education. In the region where Chydenius-Institute is influencing and the practice of teacher training is
organizes, all the schools have ATM-network and videoconferencing facilities. The infrastructure supports students, teachers and pupils to enjoy the highways of information society.

5. Learning environments

Chydenius Institute aims to be ahead of developing the education in teacher training in Finland. An essential part of the studies are web-based learning environments. Most common has been WebCT, but others, e.g. Blackboard and TopClass have been tested. Nowadays there are also many learning platforms created in Finland, e.g. Optima, LCProfiler, R5Vision, Humap, Efodi, FLE.

From 1997 there has been developed the platform Discendum Optima, earlier called Telsi. It has been found as a successful web-based learning environment. Because it is module-based, it gives freedom for administrative person to customize the environment the way that serves the purpose in the best way. A teacher can easily implement the pedagogical model of the learning that he has in his mind. It is pedagogically flexible environment offering diverse possibilities for team working and communication. The main tools of Optima are the usual ones: tools for administration, production and updating, documentation, calendar, teaching material, assignments, statistics, asynchronous conversation and online chatting. The power of Optima is that an administrator is able to customize the desktop very easily. Also it’s very user-friendly and simple.

The Discendum Optima-environment is used all through the two-year-program. The Chydenius professors have made own implementations of Optima, according to every course. Here are some screen shots of one course.
6. Training of teacher training instructors in schools

One problem of teacher training is how to organize the instruction for teachers who take care of teacher trainees in their practical training in schools. The Chydenius two-year-program consists of four periods in elementary schools: the first one is four weeks in a local school in Kokkola, the second one is four weeks in a school that is selected as a training school, the third one is a two-week-period in mixed classes in country-size (preferably in home places of students) or abroad, the fourth one is a practice of special education (two weeks) and the fifth one is again in the training school having a period of five weeks.

The teachers, called training instructors, are given training to support students in their practical periods. Except of these instruction periods the Chydenius professors have organized an environment in Discendum Optima, where they can give instruction and information, but also to communicate with each other during these training periods at schools. In this way the training instructors have the possibility to change their ideas and share their problems.

This model for supportive instruction of teacher training is now in the moment created and implemented in Finnish teacher training. ICT and web-based learning environments give the possibility to develop the teacher training more diversified and flexible. The quality of instruction increases with ICT.

An Examination of the Effectiveness of Types of Learner Interactivity in an Online Professional Development Course

Donna Morrow
Christchurch College of Education

Abstract
A professional development course, designed to examine the connection between learning theory and ICT (information and communication technologies) and taught by three methodologies was examined for learner interactivity. The course was delivered in three ways: a face-to-face class that used the online materials as a resource; an online class that received instruction and materials via the Internet; and a hybrid course comprised of a group of students at a remote location which met weekly for a phone-in conference with the instructor but received materials via the online environment. Four types of learner interactivity were examined: learner-learner, learner-instructor, learner-content and learner-interface. Conclusions drawn from this research indicate that students in the online, on-campus and hybrid classes considered e-mail or face-to-face contact with the lecturer as very important aspect of the class. Interaction with other learners online was rated highly but only if the situation in which this took place was organised and structured. Interaction with the course content varied among the different classes, but similarities among all students in the three classes were hands-on activities and lectures or explanatory content. The learner interface interactivity, although reported as somewhat problematic by all students, appeared not to be an issue, with most students solving problems with computers and Internet access either on their own or with the help from the instructor.

Introduction
Given the dramatic increase in online teaching and learning it is not surprising that online professional development courses for practicing teachers should show a corresponding increase in availability. These courses, offered both by tertiary institutions as well as commercial providers, provide a wide range of topics for the teacher in the classroom (Schrum, 2001), and range from self-paced tutorials with little or no interaction among participants to graduate-level courses with web-based discussion facilitated by discussion boards, chat rooms and e-mail (Branzburg & Kennedy, 2001). Within this new structure of professional development delivered online however, the need clearly exists to define the pedagogical issues, understand how the learners interact with this environment and discover the benefits and possible disadvantages of using this methodology.

Information Technology in the Teaching and Learning Process is a core course in a seven course Diploma of Information and Communication Technology at the Christchurch College of Education in Christchurch, New Zealand. The diploma attracts practicing teachers who want to upgrade qualifications and gain skills in using information and communication technologies. This course is designed to examine the connection between learning theory and technology used to enhance learning in the classroom, and is taught as a face-to-face course with provision for the occasional distance student made available through teleconferencing. At the beginning of 2001, an increased demand from students around the country wishing to enrol in the course as distance learners led to the decision to develop the course for online delivery. Due to the configuration of students requesting enrolment in the course, three different methodologies were identified: a traditional face-to-face class that would meet bi-weekly with the instructor on campus and use the online materials as a resource; an online class that would receive all instruction via the Internet; and a hybrid class involving a group of teachers in a remote location who would use the online resources in addition to an initial two-day, face-to-face start to the class and a weekly phone conference between the instructor and the assembled group. The existence of the three classes
presented a unique opportunity to explore how each of the groups interacted with the course materials, the instructor, other class members and with the technological interface used to deliver the course.

**Methodology**

To examine the learner interactivity, Moore’s (2000) model of learner interaction was used. Moore describes this interaction in three forms. The first is learner-content, which is the process by which the learner intellectually experiences the content. Inherent in this type of interaction is the "internal didactic conversation" in which learners reflect on and “talk to themselves” about the content. Intrapersonal interaction, the processing of content within the learner’s own head, is necessary if the learner is to construct meaning from the content (Berge, 1998). Moore’s second type of learner interactivity is learner-tutor. When this interactivity is high then learners are able to draw on the experiences of the instructor and receive more individualised instruction and feedback. When this interactivity is low, more of the responsibility falls on the learner to interact with the content, remain motivated, diagnose learning difficulties and set an appropriate pace.

The third type of learner interaction is learner-learner, which occurs “between one learner and another learner, alone or in group settings, with or without the real-time presence of an instructor” (p. 22). Learner-tutor and learner-learner categories of interactivity correspond to “interpersonal interaction” as described by Berge (1998) who sees this form of interaction as important because students need the opportunity to interact and communicate with other students and with the instructor. This type of interactivity builds a shared meaning and helps to make sense of what is being learned.

In addition to the three types of interactivity described by Moore, a fourth type of interactivity has been described as learner-interface which takes place when the learner must use the technologies to access the content and communicate with the instructor and other learner (Hillman, Willis, & Gunawardena, 1994). Seeing this as crucial to success of online learners, these authors state:

> “Successful interaction in the mediated educational transactions is highly dependent upon how comfortable the learner feels in working with the delivery medium. Learners need to possess the necessary skills to operate the mechanisms of the delivery system before they can successfully interact with the content, instructor or other learners. The challenge to practitioners of distance education is to create new instructional methods that empower learners to work successfully with the technology.” (p. 32)

To discover the perceptions held by the students of the media, activities and interactions used within the course structure, students were asked to rate the contribution of each of the elements to their success in the class. The range of these media, activities and interactions included printed articles that were given or mailed to students prior to the beginning of the class, lectures given face-to-face or the same explanatory content online, PowerPoint slide shows presented face-to-face or online, links to websites, hands-on activities, video tape, discussions in class or discussions online, research article summaries by peers, e-mail contact with peers, e-mail contact with the lecturer, phone contact with the lecturer and face-to-face contact with the lecturer. Archival records of the online discussions and e-mail exchanged by the students and the lecturer were used to triangulate the end-of-course survey results.

To understand the impact of the learner-interface interactivity, students were also asked to comment on how the technological interface affected their success in the course. Students were asked at the beginning of the course to rate their technological skills and comment on previous experience with the use of online materials or participation in an online course. The end of
course survey results were then compared with this initial data and both were compared with students' reported satisfaction with the course.

Results and Conclusions

The results of the end-of-course survey showed that some of the elements of the course were considered important by students in all three of the classes while other elements were specific to certain classes. Shown below are the results of the end-of-course survey showing the distribution of answers across the classes.

Table 1 Importance of Design Elements

- **Face-to-face with lecturer**
- **Phone with lecturer**
- **Email with lecturer**
- **Face-to-face with peers**
- **Email with peers**
- **Peer Research Summaries**
- **Discussion in class**
- **Discussion Board online**
- **Video tape**
- **Hands-on activities**
- **Links to Websites**
- **Powerpoints**
- **Lectures/Explanatory**
- **Text, Chapter 3**
- **Classroom Example Midas**
- **Research Articles**

**Learner-content interactivity**

Interaction with the course content varied among the different classes, but the majority of students in the three classes valued hands-on activities and lectures/explanatory content. Links to websites were considered important by the hybrid and online classes who accessed these more in the course of their study than did the on-campus group. The Powerpoint slide shows and the videos were marked as important by less than half the students, while the research articles and text were considered only slightly more important by students in the course.

**Learner-instructor interactivity**

Conclusions drawn from this research indicate that students in the online, on-campus and hybrid classes considered contact with the lecturer as very important aspect of the class. Only two groups had face-to-face contact with the lecturer and both considered it an important aspect of the class, while the online group, who interacted with the lecturer only online or by phone, did not consider this contact important to their success. All groups considered e-mail contact with the lecturer to be important. Phone contact with the lecturer was available to all and the online group and hybrid group considered this an important method of contact, while the on-campus group, who used it the least, considered it has having the least importance. The level of e-mail contact with the lecturer was high during the course. Table 2 shows the number of e-mails sent and received during the semester long course.

Learner-learner interactivity
Interaction with other learners online was rated highly but only if the situation in which this took place was structured and participation was expected. Statistics from the discussion board showed that postings by all groups were high when this was a requirement of a particular part of the course. The majority of the responses in the discussion board were to initial threads with no continuation of discussion. Second, third or fourth level postings, where students were responding to the postings of others, tended not to occur unless this was also a requirement. The hybrid group, which met each week specifically to participate in a phone conference with the instructor, valued the discussion in class highly, with 100% of participants marking this element of the class either ‘important’ or ‘very important.’ Sixty seven percent of the on-campus group also considered this element important. Research summaries written by peers and posted to the discussion board or presented face-to-face were considered equally important by all groups. E-mail between students was not considered important by over half the students.

Learner-interface interactivity
The learner interface interactivity, although reported as somewhat problematic by all students, appeared not to be an issue, with most students solving problems with computers and Internet access either on their own or with the help from the instructor. Over 75% of students reported their Internet access as reliable. Since the course attracts students who are already somewhat technologically literate, this result is not surprising. While students in all three classes felt that the Blackboard courseware made access to course materials easy, students in the online group were more positive in their assessment. Sixty seven percent of online students marked strongly agree to the question, “I found the structure and organisation of the Blackboard site made access to course materials easy.” This result, probably an outcome of the frequency of access found in the online group, was reflected in the Blackboard statistics. The online class accessed the course most often with a total of 609 times and a mean of 76 times per online student. The hybrid class access the online site 438 times with a mean of 36.5 times per hybrid student. The on-campus class accessed the site 104 times with a mean of 20.6 times per on-campus student. Good learner-interface interactivity is also reflected in Table 1. E-mail with the lecturer, discussion board online and links to websites – all design aspects of the course that required technical skills – were reported as important to the participants success in the course.

Overall, all three groups were positive about the class. The differences were very subtle and would need further research to tease out the distinctions between the methodologies. A limitation of this research study was the size of the sample in each group and the conclusions would need to be validated with other research.

Examining the technology and media shows that for this study students were positive about the technology used to access and complete the course. The use of the Blackboard courseware was seen as an easy and approachable medium in which to work although students were at times frustrated by their lack of timely access. Most students were also positive about the range of media used to deliver the content of the course as well as the
forms of communication embedded within the structure of the course. Overall the students in
the three groups showed that they valued hands-on activities, content delivered in a variety of
formats and being able to have ready access to the lecturer.

Learner-content interactivity appeared to be robust and students reported that they felt that
the course had increased their understanding of the connection between ICT and learning
theory. Learner-interface interactivity, although all students reported technical problems,
appeared not to be an issue, with most students solving problems with computers and Internet
access either on their own or with help from the instructor. Learner-instructor interactivity
appeared strong with all students reporting positively on responsiveness and effectiveness of
the instructor-student relationship. Learner-learner interactivity appeared to be an area that
could be strengthened. E-mail between students did not appear to be rated highly and use of
the discussion board was limited for most students to posting their weekly assignments.

The online environment appears to be a viable methodology for the delivery of professional
development to practicing teachers, although more research is needed to understand how this
new medium can be utilised to reach maximum efficiency and effectiveness.

A Formative and Summative Examination of a Goals 2000 Faculty Development Project*

Rosemary Mullick
SUNY Institute of Technology
United States
rosemary@sunyit.edu

Ronald Sarner
SUNY Institute of Technology
United States
ron@sunyit.edu

Abstract: The Goals 2000 project was designed to facilitate the achievement of the National Educational goals and the integration of instructional technology in the classroom. Eighteen teachers in grades 2-6 and five librarians, from nine different schools, participated. The project consisted of five modules on technological training. Both formative and summative evaluations were made to determine the effectiveness of the project. Formative information was obtained by administering Pre and Post evaluations for each of five modules and a post test for the sixth. Summative information was obtained by having participants respond to a General Pre-test to determine baseline measures for each of the general aspects of the project and a General Post-test upon completion. Results indicated that the project was successful in helping participants acquire knowledge and skills to facilitate the incorporation of technology into the classroom.

Introduction

The purpose of the Goals 2000 Grant is to promote the achievement of the National Educational Goals by providing state and school districts funds to support faculty development to achieve the Learning Standards developed in their state. The major aim of the Goals 2000 Faculty Development Project of the local school district was to provide opportunities for faculty to develop the knowledge necessary to fully integrate technology and to facilitate the use of library resources in instruction.

Method

A total of twenty-three people participated in the Goals 2000 Staff Development Project. Of the twenty-three, eighteen were teachers and five were librarians. All but one participant was female. The participants came from 9 different schools representing grades 2 through 6. The minimum number of years of teaching was 1 and the maximum was 30 with an mean number of years of 10.52. Approximately 56% of the teachers had five or more years of teaching experience. Therefore the teachers who participated in the project were relatively experienced teachers.

Each participant was involved with 14 separate modules throughout the duration of the project. Six of the modules dealt with technological issues and are the major focus of this investigation. The remaining 8 modules dealt with the development of thematic units and materials for achieving the New York State Learning Standards, learning techniques for integration of materials into courses and the development of interpersonal and consensus building skills.

The six technically oriented modules consisted of: PC Boot Camp to familiarize participants with the basic terminology, concepts and skills necessary to use PCs in instruction; Micro-Soft Word as a text-processing software to facilitate written communication; Micro-Soft Power Point for developing presentation materials; and Web Page Design and Web Page Graphics for making instructional materials available to students and for enabling teachers and students to create their own Web Pages. The final technologically oriented module was an extended training workshop for teachers, students and parents for using online library resources.

Formative Results

Formative information regarding five of the technically oriented modules was obtained using a pre-post research paradigm. Each post-questionnaire also provided the participants with an opportunity to make comments about the perceived strengths and weaknesses of the learning experience. The extended training workshop was assessed only by obtaining post session reactions.

937
Page 876
Table 1 shows a summary of the paired sample t-tests performed on five of the technologically oriented modules. As can be seen from the table, all of the paired sample t-tests achieved statistical significance. These results indicate that participants believed that each of the technologically oriented modules was effective in teaching new concepts and skills to the participants.

Table 1: Summary of paired t-tests of changes for each technologically oriented modules.

Summary Results

To obtain summative information regarding the overall effectiveness of the entire project, a similar paradigm as the one reported in Bauder, Carr, Mullick, & Sarner (1997) and Mullick & Sarner (2001) was employed. All participants responded to a general pre-test that tapped their current level of expertise and experience with computing hardware, software and relevant peripherals. Upon completion of the project, all participants completed a general post-test to determine whether changes had occurred as a result of their participation in faculty development project.

Access to and Experience with Hardware

When asked the number of computers available in the classroom the largest number reported was 12. Only one teacher reported a classroom with the maximum reported number computers. Of the respondents, 17% said they had six or more computers in their classrooms, but all but one teacher indicated that they had at least one computer available in their classroom. In addition, 78% of the participants indicated that computers are connected to the Internet. In general the participants had experience with some hardware. Virtually all reported experience with computers, CD-ROMs, and printers. Most had little experience with microphones, interactive video, video cameras, scanners or LCD panels. Participants reported that they felt comfortable with the hardware they had used in the past. These results are particularly interesting since participants indicated that all of the hardware listed is important in helping to achieve the New York State Learning Standards.

Access to and Experience with Software

Participants also reported experience with a limited number of types of software packages. Most had experience with word processing (Mean = 6.86 on a nine point scale). Some had experience with simulation programs, desktop publishing software, drill and practice, email, and web browsers. Virtually none of the teachers had experience with presentation graphics, hypermedia, student management applications or Web Development software. The participants did, however, feel that these software applications were important for achieving the State Learning Standards. The mean ratings of importance for achieving State Learning Standards ranged from 8.73 to 4.36 with Hypermedia being the only exception. The mean perceived importance for achieving the State Learning Standards for hypermedia/hypertext software was 3.50. Teachers therefore believe that integrating these types of software into the curriculum would facilitate the achievement of the State Learning Standards.

Results

Pre-Post Changes to Determine the Effectiveness of the Faculty Development Modules

A series t-tests for dependent (paired) samples were performed using the Total Frequency of Use of Hardware, Total Frequency of Use of Software, Total Comfort in Using Hardware and Total Comfort in Using Software as the dependent variables to determine if significant changes in participants' responses occurred as a result of their participation in the project. The findings from the analyses of the t-tests are displayed in Table 2.
An examination of the last column in Table 2 shows that all of the analyses indicated significant changes from pre to post testing. Rows 1 and 3 indicate that participants rated their frequency of use and comfort of use of hardware higher at the end of the project than they had previously with $t = 2.57$ and $2.67$, respectively. Rows 2 and 4 show similar results for frequency and comfort of use of software with $t = 5.33$ and $7.32$, respectively. These findings indicate that both frequency and comfort ratings for using both hardware and software, were higher at the completion of the project than at its onset.

**Overall Evaluation of the Project**

On the post-test, all participants rated each of the technologically oriented modules on three aspects: overall favorability, extent to which they believe that information encountered in each module will help to achieve the state learning standards, and the extent to which they expect to incorporate the knowledge into their future classes. A summary of the mean ratings for each is displayed in Table 3.

The mean overall ratings ranged from 5.35 to 7.70 on a 9-point scale with a score of 1 indicating low favorability. Therefore if a rating of 5 is the neutral point, all modules were rated in the favorable direction. The module that received the most favorable overall rating was Microsoft Power Point (Mean = 7.70). The module that received the least favorable rating was the PC Boot Camp (Mean = 5.35). In examining the average ratings of the extent to which participants' believed that each of the modules would help to achieve the State Learning Standards, once again, participants indicated that the module that would be most beneficial was Microsoft Power-Point (Mean = 7.61) and the module judged to be least beneficial was PC Boot Camp (Mean = 5.91). The final column summarizes the extent to which participants expect to apply information from each module in their future classes. The pattern of results is similar with Microsoft Power Point rated highest (Mean = 7.48) and PC Boot Camp rated lowest (Mean = 5.61). It may be that participants felt that they were sophisticated enough that they knew the material presented in the PC Boot Camp.

Table 3: Average overall rating, extent each module will help to achieve the state learning standards and extent to which participants expect to apply learning to future classes.

Analysis of Variance for repeated measures using participants' overall ratings, extent to which participants believed the modules would help achieve the state learning standards and the extent to which participants expected to apply knowledge from the six technologically oriented modules was performed. In all three analyses, the within-subjects variable failed to achieve statistical significance indicating that participants' overall ratings on all three measures were not significantly different from one another.
In summary, the three repeated measures analysis of variance show that participant perceived all of the modules highly favorably. Participants felt the knowledge they gained from each module would facilitate the achievement of the State Learning Standards. Finally, the results clearly indicate that participants intend to apply the knowledge they gained from the Goals 2000 Staff Development Project in their future classes. The highly favorable ratings also show that participants felt that the information they received in each module would be beneficial in integrating technology into the classroom.

Changes in Library usage

The Pre and Post-test questionnaires also examined the extent to which participants used library services available to them. The results of these analyses are displayed in Table 4. The last column of Table 4 shows that significant increases in library activities occurred as a result of participating in the project. Participants reported that they used local library resources significantly more, were significantly more likely to access the Mid York Library Web Page and to work collaboratively with librarians. Therefore, the project was successful in facilitating participants to increase their library activities.

Table 4: T-tests of changes in extent to which library activities were engaged in by participants

Overall Evaluation of the Entire Project

Three items of the general post-test attempted to assess the respondent’s overall evaluation of the entire project. On the item that asked participants to indicate the overall evaluation of their experiences in the entire Goals 2000 Staff Development Project, the mean rating was 7.70 out of a possible 9.0. When asked if the participant would recommend this project to their colleagues, the average rating was 7.70. The final question to determine the overall evaluation asked participants to indicate the extent to which they agreed or disagreed with the statement “If given the opportunity, I would participate in a project like this again”. The mean rating for this response was 6.74, indicating a high degree of agreement. Taken together, these results clearly indicate that the participants had very favorable experiences in the project and believe that the knowledge and information they gained will be helpful to them in integrating technology into the classroom. The results also indicate that participants would be willing to participate in similar projects in the future.

Open-ended Responses

Open-ended questions were included in all post-tests. Participants were asked to indicate the single most valuable feature of the module/project and the weakest feature of the module/project. A review of these statements indicate that participants liked the interaction with other participants, hands-on activities, learning strategies for integrating technology into the classroom and the ability to create materials that could be used in subsequent classes. The most common responses regarding the weakest feature tended to focus on lack time; lack of equipment; and the feeling that there was too much material covered in too short of a time period.
Conclusions

The results of the formative examination of each of the separate modules indicated that significant positive changes occurred as a result of participating in the technologically related modules. Participants indicated that they: learned the relevant material; felt they could incorporate the material into future instruction; and rated each module as highly favorable upon completion. The responses to the open-ended questions also provided information about how to improve the various learning modules if they are to be presented in the future.

The findings from both the Formative and Summative analyses indicated that participants’ experiences were highly positive and that the participation in the project had a significant impact on their ratings. After each of the separate modules, results showed that participants intended to incorporate the knowledge they gained into their instruction. Upon completion of the project, results showed that participants were using technology more frequently in their classrooms than they had prior to the project. Secondly, participants suggested that the modules of the Faculty Development Project helped them to learn ways of integrating technology into their instruction and assisted in gaining confidence in using technology and in guiding their students in the use of technology. The results also indicated that although participants believed they were using library resources prior to the project, participation in the project allowed them to find new resources and new activities to be incorporated into future instruction.

Abstract: The efficacy of combining face-to-face and online instruction remains unclear in the literature. Nevertheless, for the mature learner, some combination of delivery models might offer a desirable learning option. Thus, in the Fall Semester, 2001, twenty students enrolled in a graduate level course focusing on learning and technology. Students were dispersed over a broad geographical area. A course was designed for these students that combined three patterns of instruction or learning structures: 1.) online discussion boards, 2.) face-to-face classes, and 3.) on-site small group, student run meetings. Students' ratings concerning their learning experience and the quality of their interactions with the instructor and peers in each of the three learning structures are presented and compared. In addition, students' rankings of the three learning structures related to learning and quality of interactions were collected at the end of the course and are presented.

Introduction

Much enthusiasm exists in the higher education community about the potentials of online delivery systems for coursework. Professional development programs and courses are being offered in a variety of ways, utilizing technology to differing degrees. Some simply use technology to improve the presentations, while others use technology to offer courses entirely online. The U.S. Department of Education’s National Center for Educational Statistics (NCES), reported that the number of distance education programs increased by 72 percent from 1994-95 to 1997-98 (Quality On the Line: Benchmarks for Success in Internet-Based Distance Education, 2000). “However since the quality of these new programs can vary widely, education experts are telling teachers to shop around and ask questions first. Not all online programs offer teachers the right mix of collaboration and feedback (Weiner, 2001).

The efficacy of online versus face-to-face instruction or combining face-to-face and online instruction remains unclear in the literature. For instance, Hall, Watkins, & Ercal (2000) state that web-based instruction can be as effective as face-to-face instruction and that factors that lead to improved performance in face-to-face classes can also increase performance and positive attitude in web-based courses. Conversely, Thornam & Phillips (2001) suggest that those taking an online section perceive less interactivity than those taking a face-to-face section. Additionally, Johnson, et. al. (1999) found slightly more positive perceptions about the instructor and overall course quality in a face-to-face version of a course, although there was no difference between the two course (face-to-face and online) formats in learning outcomes. Cereijo, Young, and Wilhelm (2001) examined students’ comments while taking a CD/Web-based course. Their research revealed that students reported the advantages of CD/Web-based learning to be its convenience, flexibility, and opportunity for
Thus, in the Fall Semester, 2001, twenty students requested an online course. Many learners today some combination of delivery models offers a desirable and “doable” learning option. Despite concerns about web-based learning, for the mature learner hampered by geographical and time considerations, online learning remains a demanded and potentially viable learning option. It is likely that for many learners today some combination of delivery models offers a desirable and “doable” learning option. Thus, in the Fall Semester, 2001, twenty students requested an online course. These students were geographically distributed throughout northwestern Virginia. Because all students were practicing classroom teachers with full day responsibilities, it was not feasible for them to commute to campus for evening classes. Additionally, because of distance considerations, it was not feasible for faculty to commute to weekly classes in students’ varied communities. We asked ourselves if it might be possible to use some combination of online and face-to-face patterns of delivery while continuing to maximize student interactions and learning. A course was designed that combined three learning structures or patterns of instruction: 1.) online discussion, 2.) face-to-face classes held off campus, and 3.) on-site, student-run, small group meetings. Given existing concerns about online learning and the experimental nature of this combination, we asked four questions: (1) How will students rate their learning experiences and the quality of their interactions in each of the three learning structures? (2) Will there be a difference between students’ ratings concerning their learning experiences and the quality of their interactions depending on type of learning structure? (3) Which learning structure will students find most useful and least useful for their learning? and (4) Which learning structure will students report as affording the highest and lowest quality of interactions with their instructor and their peers?

Methodology

Twenty practicing educators enrolled in the course. All of these educators were candidates in a Master’s of Education program emphasizing the integration of technology with classroom practice. All had previously complete 18 graduate credit hours. Four of the educators were elementary technology resource teachers. One was a middle school administrator; another was a district level technology coordinator. The remaining fourteen students were classroom teachers, spanning the K-12 curriculum.

The fifteen-week course focused student attention on learning and technology, placing attention on constructivist learning theory, the role of symbolic competence in learning, and the connection between theories of learning and the selection and use of a range of technologies to support teaching and learning. The course was conceptually divided into three four-week segments with a remaining three-week period for production of collaborative student projects. In each of the three four-week segments, students participated in each of the three learning structures selected to facilitate the course activities. Thus, students attended one face-to-face, instructor led class meeting during each four-week cycle. The face-to-face classes met in a middle school media center with internet-linked computers. During these sessions students shared the results of their on-site activities, discussed readings, and participated in instructor led activities. In addition, students posted weekly to a Blackboard discussion board. Discussions were prompted by the instructor as well as monitored and shaped by the instructor. Finally, during each four-week period, students met in small groups of three to five (organized around geographical proximity). These on-site groups engaged in activities assigned and described by the instructor using Blackboard’s class delivery system. Care was taken to insure that these activities were well designed, comprehensively described, and concluded with the production of a concrete product. In addition, guidance was provided concerning processes the groups might use to successfully complete the assignment. On-site small group activities engaged students in completely a product designed to encourage students to discuss, interpret, and apply insights and understandings from the readings. Products that resulted from the on-site group activities were either shared electronically or brought to face-to-face sessions to be shared. Email was used throughout the course to clarify, remind, and facilitate the work of the course.

At the culmination of each four-week period, students were emailed the link to an electronic survey. The researchers used the Zoomerang (http://www.zoomerang.com) survey service. Students were asked to respond to six questions. Students were asked to rate the usefulness (3 - Useful (U), 2 - Somewhat Useful (S), and 1 - Not Useful (N)) of each learning structure as a learning experience. Students were then asked to rate the quality of their interactions during the four-week period with the instructor, with their on-site peers, and with fellow discussion board participants. Students rated the quality of their interactions as positive (P), neutral (N), or unhelpful (U). Survey results were tabulated anonymously and summarized by Zoomerang. At the conclusion of the course, a final Zoomerang survey was emailed to students asking them to rank the three learning structures and their combination for their importance in students' overall learning experience. In
addition, students were asked to rank the three learning structures and their combination for the quality of their overall course interactions with the instructor and peers. Students were asked to assign 1 to the most important or highest quality through 4 as the least important or lowest quality. Using the Zoomerang survey software facilitated the collection of data. It also insured students' anonymity. However, because of the anonymity of responses, it was not possible to pair student responses across surveys, and thus, statistical analysis of data became problematic. As a result, data analysis was limited to descriptive and summative analysis strategies.

Results

The first question posed was: How will students rate their learning experiences and the quality of their interactions in each of the three learning structures? In order to answer this question, student responses to each of the three surveys were tallied and percents computed. Results of the analysis are presented in Table 1. Examination of the data suggests that more than half of the students viewed all three learning activities as useful. The data also suggest a slight decline for all three learning structures over time. The same basic patterns occur related to quality of interactions. That is, 60% or more of students rated the quality of their interactions to be positive regardless of learning structure as well as revealing a slight decline in ratings over time. Finally, in all instances, the online discussion board structure is rated slightly lower than the face-to-face whole group class and the on-site small group activity.

Table 1. Summary of Ratings of Learning Experience Using Three Different Learning Structures

The second question posed was: Will there be a difference between students' ratings concerning their learning experiences and the quality of their interactions depending on type of learning structure? In order to answer this question, means for student ratings were computed for each survey period and for the research period as a whole. Results of the analysis are presented in Table 2. Examination of the means for student ratings of their learning experience related to the three learning experiences further support the conclusion that students found the face-to-face whole group learning structure to be the most useful followed by the on-site small group structure with the online discussion board being the least useful. Students' rating of the quality of their interactions with the instructor cannot be compared with the on-site and online structures since the instructor played a role during all three learning structures. It is possible, however, to note that students rated the quality of their interactions during on-site activities more positive than the quality of their interactions during online discussions.

Table 2. Overall Mean Ratings for Learning Experience and Quality of Interactions

The third question of the study asked: Which learning structure will students find most useful and least useful for their learning? In order to answer this question, students were asked to rank the learning structures, using 1 for the most useful structure through 4 for the least useful structures. Percentages for rankings were computed and reported in Table 3. Examination of the data suggests that the majority of students (nearly half) ranked on-site group work as the most useful learning structure with face-to-face whole group receiving the next highest or useful ranking. Discussion board activities received the highest percent of “least useful” rankings, suggesting that this learning structure was not highly regarded as a valuable learning experience.

Table 3. Overall Ranking of Learning Structures as a Learning Experience (Most Useful to Least Useful)

The fourth question of the study asked: Which learning structure will students report as affording the highest and lowest quality of interactions with their instructor and their peers? In order to answer this question, students were asked to rank the learning structures for the quality of interactions with peers and the instructor – 1 for highest quality through 4 for lowest quality. Results for the two questions are presented in Table 4. Examination of the data shows that the highest ranked learning structure related to quality of interactions with the instructor was the face-to-face whole group structure while the on-site group structure was ranked lowest. This is not surprising since the instructor’s role in the on-site group structure was minimal while the instructor had a substantial role in the face-to-face whole group structure. Conversely, nearly half of the students ranked the quality of their interactions with peers highest in the on-site group structure. The face-to-face whole group learning structure was ranked second highest for quality of interactions with peers.

Table 4. Overall Ranking of Learning Structures for Quality of Interactions with Instructor and Peers
Discussion

While all learning structures were rated as useful learning experiences and interactions were generally rated positively, the discussion board activities were consistently rated lowest. It seems clear that students found the face-to-face and on-site learning activities more important for their learning. Given that much of online learning centers around individual readings and research and group postings on discussion boards, these results are important. It is possible that the more common learning structure of postings to a discussion may not be the most effective manner in which to organize and conduct online learning. Perhaps Sonwalkar (2001) captures the limitations of discussion boards as extensions of the classroom discussion method of teaching when he writes: “In attempting to harness the capabilities of digital interfaces, the mistake is often made of recreating a classroom-teaching model within an online learning environment. Online technology designed to mimic the classroom becomes a restriction and a barrier to the teacher’s ability to impart knowledge. (p. 2).”

Not only do the results suggest stepping away from conventional classroom-teaching models in online learning, the results of this study suggest a manner in which online learning might progress—small groups of students studying with the guidance of a virtual instructor. In all instances, students in this study rated their learning experiences and the quality of their interactions with peers to be highest when using the on-site learning structure. It might have been possible that on-site activities resulted merely in social gatherings or trivial commentary. Instead, students reported that these activities were the most useful for their learning. This not only reinforces the social constructivist perspective of learning—that understanding is achieved through dynamic, negotiated group construction of knowledge—but it also suggests that the most important role of the instructor in an online learning environment may be as designer. When the instruction in this course was carefully designed around a problem and a product—a performance of understanding, students were able to meet, interact with ideas, concepts specified in readings, and each other to build bridges between knowledge and understanding. Once students had solved a problem and constructed a product, they were able to share, elaborate, critique, and expand upon their understanding through both online and classroom presentation. It seems it is possible to have a virtual instructor—one who designs robust learning experiences and coaches and provokes from a distance. On the other hand, it seems that having virtual classmates—posting comments in response to instructor prompts or peer comments—does not facilitate learning in the same way as face-to-face peer encounters and collaboration.

DEALING WITH DISRUPTIVE PUPILS:
A Professional Development CDRom

Jim O'Brien, Faculty Of Education, The University Of Edinburgh, United Kingdom

Tony Van Der Kuyl, Faculty Of Education, The University Of Edinburgh, United Kingdom

David Thomson, Faculty Of Education, The University Of Edinburgh, United Kingdom

Abstract: The Scottish Executive funded the development of a CDRom to be used for teacher professional development. Following field research a range of stimulus materials in video, audio and text with associated activities were developed and piloted. Teachers are encouraged to review and develop their own skills and school policy and are provided with exemplars and additional references for consideration. The CDRom has now been published and is being disseminated throughout Scotland.

Introduction

The United Kingdom has several legally and politically devolved and autonomous education systems (Greaves & O'Brien 1996). The re-establishment of the Scottish Parliament in 1998 has resulted in even more distinctive Scottish education initiatives emerging despite similar problems and challenges across the UK. For over a decade, Scotland has promoted initiatives in school-based professional development and funded several ICT based support materials (van der Kuyl et al. 1994). The promotion of social competence and social inclusion through meeting pupils' needs in schools and classrooms and building on alternatives to school exclusion is a major UK policy.

Increasing concerns about disruptive behaviour by pupils in schools led the Scottish Executive to fund the "Dealing with Disruption" Project to research and produce a professional development CD-ROM (O'Brien et al., 2001). The identified range of potential audiences included classroom teachers, student teachers, senior management of schools, staff development coordinators in schools. The project (O'Brien and van der Kuyl, 2001) involved reviewing the literature and building on prior research (Lloyd and Munn, 1997; Munn, 1999). The literature search revealed publications with illustrations of work with individual children/young people with social and emotional behavioural difficulties. In addition to trawling recent advice and publications key individuals and organisations with direct knowledge of school and classroom practice were engaged. Existing materials and resources, including video, dealing with the management of disruptive behaviour were identified and reviewed. The most useful material is cited in the resource that also built on good practice and experiences from other initiatives which promote positive discipline and the development of social competence. Case studies based on such practices were prioritised and agreement reached with practitioners to video classroom practices. The CDRom is written in browser format to allow subsequent transfer to the WWW. At the moment, Scottish schools have insufficient bandwidth availability to allow useful video transference and for some time yet CDRoms will be a useful ICT medium for professional development purposes.

The "Dealing with Disruption" CDRom

The CDRom exemplifies for primary, secondary and special school teachers, effective methods for managing behaviour and dealing with classroom disruption and other forms of aggressive behaviour. The exemplars highlight a full range of scenarios but focus primarily on managing mild but persistent disruptive behaviour or low-level interruptions in everyday classroom situations. The CD-ROM includes a menu of situations including sequences of classroom incidents and good practice in managing the interruptions.

The resource developed has a core of exemplification materials in text, audio and video to provide advice and strategies relating to:
whole school approaches
positive ethos and reward systems
departmental and individual responsibilities
classroom approaches.

Drawing on good practice, the disk illustrates
identified common principles in dealing with disruption
comprehensive management strategies for dealing with disruption
a range of teacher skills and behaviours derived from current knowledge about dealing with disruption and identified good practice
and provides suggestions about sources of support which will help individuals and schools deal with presenting issues.

Post in-school research, a concept development phase determined the scope and nature of the resource, chose appropriate issues and associated content and involved the design of the interface between the materials and the users. Production of the CD-ROM including all programming, engineering, de-bugging and beta-mastering was completed by 31 December 2000. Evaluation in 80 schools began in February 2001, this was designed to test the robustness of the curriculum and the product in the field and provide a final check of curriculum and technical standards before production and dissemination.

The evaluation led to significant changes in the interface and the improvement of a number of activities. One of the underlying principles was that the design allowed the user open access to all the assets and activities on the CD-Rom. While this remains, a number of portals into the assets have been constructed to allow users such as school managers or probationer teachers to initially familiarise themselves with the approach. Additionally a section for professional development coordinators (O’Brien and MacBeath, 1999) has been added. This has been an increasing focus of the dissemination phase of the Project.

The dissemination phase commenced in October 2001 and involved distribution of the completed CD-ROM to all Scottish schools in association with 25 national conferences. The Conferences involve an overview of the project and a ‘hands on’ introduction to the CD-Rom. Feedback and responses to date have been most positive. Each Conference includes a workshop where participants working in groups use assets on the CD-Rom plus the Professional Coordinator Portal to develop an additional professional development activity. On average 4 such activities are produced per Conference and these are being data-based and categorised with a view to developing a supporting and complimentary website. An important side effect of such conferences has been to encourage teachers to develop or customise CPD activities using ICT resources. The “Dealing with Disruption” CD-Rom may prove instrumental not only in enhancing teacher skills and knowledge about approaches to discipline issues but also in encouraging the wider use of ICT in learning and teaching beyond professional development.

Program Director: ACT Now!
Educational Technology Department
Sweetwater Union High School District
United States
rusty.meike@suhsd.k12.ca.us

Abstract: The Advanced Curriculum through Technology (ACT Now!) program began as a five-year old partnership between the Sweetwater Union High School District, institutions of higher education, public libraries, hardware manufacturers, software designers, telecommunications firms and local community organizations. With the aid of a federal Technology Innovation Challenge Grant (TICG), ACT Now! has initiated a campaign for systemic educational reform through the effective use of technological resources and learned many lessons along the way about what works, and what doesn’t, when dealing with technology integration and professional development on a district-wide level.

Introduction

The position of the National Council for Accreditation of Teacher Education (NCATE) is clear: “Teacher quality—knowledge and effectiveness—is the number one school based factor in student achievement. ….Student achievement increases when students have teachers who are trained in developing higher order thinking skills, who are skilled at implementing hands-on experiences in the classroom, and who are trained to work with special populations” (2001). While much effort and money has been allocated to systematically prepare tomorrow’s teachers to use technology well, few ongoing efforts to reach working teachers have been as thoughtfully planned. In 1996 the Sweetwater Union High School District applied for, and was awarded, a five-year Technology Innovation Challenge Grant called Advanced Curriculum through Technology Now! (ACT Now!). (#R303A60457) From inception, ACT Now! was different than most other infrastructure build-out and professional development grants in that the vision of reform was district wide. All teachers were afforded the opportunity to participate in the program and 72% did in fact do so.

ACT Now!

ACT Now! focused on integrating technology into the existing standards-based curriculum to increase teacher effectiveness through concentration on higher-level thinking skills and innovative use of Internet resources. (See movie at: http://www.suhsd.k12.ca.us/actnow/review/movie.htm). All teachers who participated agreed to voluntarily attend 40 hours of professional development training in return for the use of a high-end multimedia computer with Internet connectivity in their classroom. Particularly unique was the program structure. Wrapped around 16 hours of application specific classes were 24 hours of Advanced Curriculum through Technology (ACT) classes focused specifically on technology integration.
The program participants choose from two courses of study, the Web Quest Series and the Web Experience Series, and used online tools developed by ACT Now! to create and publish their own online lessons. All lessons created through the ACT Now! program are available through the ACT Now! Curriculum Library and are indexed by subject and grade. The ACT Online lessons are also indexed by special program and by SAT 9 content cluster (http://www.suhsd.k12.ca.us/actnow/curricLIB/curric.htm).

The Teacher Training Quality Assurance Team (TTQAT), comprised of hand-picked district teachers with a combination of technological savvy and excellent teaching skills, provided professional development for ACT Now! participants. TTQAT members attended a summer train-the-trainer academy to polish their skills and familiarize themselves with changes in the program and its curriculum.

The training philosophy was that:

- Teachers are most comfortable learning from other teachers.
- Learning about technology works best in small doses over a long period of time.
- Teacher created curriculum should align with district approved standards, engage students in collaboration and higher-level thinking, and use the web effectively.
- Training should be hands-on and project based.
- Trainers kept their hands off the mouse.

**Lessons Learned**

Now that federal funds are exhausted, the team has worked to ensure that core elements of the original program – and the original vision – are now woven into the District professional development platform. The need to reposition has allowed the team to reflect on their successes and failures, and its those lessons learned this presentation highlights. Briefly:

1. A viable infrastructure must be in place.
2. Buy-in among all key stakeholders is critical.
   - Teacher’s Union
   - Site Leadership
   - Participants
3. Developers and facilitators must take care to neither overestimate or underestimate learners.
   - Self-reported surveys are self-reported surveys.
   - Some teachers are not “experts” in their fields.
   - The product must be scaled to match trainee competence, confidence and motivation level.
   - The team must provide multiple opportunities in scheduling and in credit options.
   - The team must plan for additional assistance (Tech Prep)
4. It’s critical that training objectives align with other initiatives when possible.
   - Highly successful with Digital High School (DHS).
   - Missed opportunity with Specially Designed Academic Instruction in English (SDAIE).
5. Program staff must constantly think about documentation and dissemination; these are not merely “final-year” tasks.
   - Attendance tracking
   - Course registration
   - Tracking of equipment
   - Scheduling of instructors
   - Documenting of participant products
6. Performance (and motivation) improve when learners are required to produce an end-product and present it.
   - Motivates the learner
   - Share successes and validate the learners
   - Documentation is much easier
7. Staff must be prepared to update the curriculum and program on a yearly basis as technology and audience change.

Establishing Graduate Cohorts for In-service Teachers in Rural Regions

Rudy Pauley, rpauley@marshall.edu
Assistant Professor, Elementary and Secondary Education
Marshall University Graduate College

Lisa A. Heaton, heaton@marshall.edu
Assistant Professor, Elementary and Secondary Education
Marshall University Graduate College

Abstract: The rural, in-service teacher is often confronted with many barriers when trying to obtain an advanced degree or additional certification. Geography, time, professional obligations and familial responsibilities are often barriers that hinder the continuing education of teachers today. Marshall University's Graduate School of Education and Professional Development has developed a cohort delivery model that takes degree programs to the teachers. This paper describes the model for delivery that has been developed over the past four years.

Introduction

Participating in Continuing Education courses can be a tremendous challenge for educators who live and work beyond the immediate service area of colleges and universities. Teachers living in isolated regions who want to work toward a Master's Degree, or to simply take courses for professional development, face a real challenge trying to work full time and travel to and from classes. Traditional university formats often fail to provide classes at suitable times for working adults, and in some cases, weekly evening courses are still beyond reach.

Multiple initiatives between the elementary and secondary education program at the Graduate School of Education and Professional Development and public school districts have been established to develop cohort programs in several regions of the state. Through these cooperative initiatives, web-based delivery is used to bring graduate education to working professionals.

Getting Started

The model for developing new cohort programs includes:

- opening lines of communication between elementary and secondary education faculty and school district personnel,
- developing a curriculum for the degree in cooperation with school district personnel,
- developing a working budget for the project,
- advertising within the school district or expanded region,
- conducting an information meeting with interested personnel and university faculty,
- activating student computer accounts, and
- meeting admission/registration requirements.

Program Structure

A program of study and course rotation is established that will allow cohort participants to complete a thirty-nine hour program within two years. Participants typically complete two classes each semester, with three courses being offered during one of the summer terms. Courses are offered in a mixed format, utilizing a combination of online and face-to-face interactions. Each course typically includes three to four face-to-face meetings, or one meeting per month. The remaining coursework and communication takes place via the Web.

The cooperatively designed programs of study can carry a variety of areas of emphasis within the elementary and secondary education program. Recent programs include: science education for elementary teachers, elementary
education with an emphasis in reading and computer applications, general elementary education programs, Spanish education for the middle grades, and middle childhood education.

The first course offered in each program is an introductory computer applications course that includes added emphasis on preparing students to use the online course delivery tool (WebCT). For students to be successful throughout the program it is imperative that they are able to function with the technology—navigating through course content and assignments, corresponding with instructors and classmates using mail and discussion features, submitting attachments, completing online quizzes and surveys, accessing online library resources, etc. Once students have mastered these tools they can focus on learning the designated content of their courses without getting bogged down in the technical setup of the course.

All face-to-face meetings are offered onsite within the designated school district. Class meetings are scheduled at the most convenient time possible, which may include a combination of evening meetings, a Friday/Saturday format, or summer weeklong workshops. The cooperating school district provides appropriate meeting facilities.

Students who may never come to the home campus are provided services in a variety of formats. Textbooks can be ordered by phone and delivered by mail. Library services can be accessed online and books and articles can be delivered through regular mail or in an electronic format. Advising is conducted through mail, over the phone, or on class meeting days.

Conclusions

During the past three years the elementary and secondary education program has worked cooperatively with school districts in establishing seven cohort programs within the state. Four of these programs have been completed with a 91% graduation rate (89 out of 98 participants), three programs are ongoing (86 participants), and two additional cohort agreements are being negotiated. The graduation rate and the level of interest in establishing new cohort groups around the state offer strong support for continuing this type of program.
Passive presentation programs and authoring language programs for classroom teachers - which is best for the K-12 teacher? Depends on your ultimate lesson and instruction strategy!

Marvin Peyton, Middle Tennessee State University, US
James Huffman, Middle Tennessee State University, US
Aubrey Moseley, Middle Tennessee State University, US

Over a decade of teaching passive presentation programs (PowerPoint) and authoring language programs starting with PILOT and SuperPILOT (Programmed Instruction Learning or Teaching) to the current - Hyper*. * programs, has convinced me that the specific use of each tool for instruction has become clear. Initially a teacher must define the lesson and then decide which program will meet needs for that lesson and then plan an instructional strategy. Instructional strategy will determine whether to use a passive style program such as PowerPoint or to use an authoring language program. Each program has instructional strengths.

For several years I have taught the Hyper*. * programs using the supposition that teachers were creating their own programs and presenting these programs 'lessons' to their classes. The basic authoring skills combined with teaching and learning theory are taught to undergraduates teacher in training and to the graduate students taking teacher education classes. The purpose of teaching passive presentation programs was to give these teachers some tools to create and present 'new' lessons for their classes. The purpose of teaching hyper style lesson construction was to provide the teacher with a means for creating interactive, not passive, lessons for their classes.

Teachers are using these two different programs to create very different instructional scenarios. The passive presentation programs are ubiquitous in most schools where technology is available. The instructional technique used for passive presentation programs is straightforward - mostly passive teacher led instruction with a mix of clip art, pictures, some sound and in some instances internet connectivity. Animation and movies when available are making these tools very popular. Instruction using hyper programs is not in the creation of total lessons and presentations of individual lessons but in the presenting the properties of the authoring language and then letting the student use their own creative ability to present information, lessons, projects, etc.

Preservice and inservice teachers have received training for years in the preparation of lessons using passive presentation programs. The current programs are extremely easy and convenient for new and experienced teachers to use for a multitude of lessons and lesson presentations. PowerPoint has become the presentation tool for teachers. The use of authoring programs is very popular for many teachers but not as a presentation tool but as a tool for the students to use in their classes. Teachers teach the basics of Hyper*. * programs and the students take the program and create their own lessons, presentations, etc.

Teachers who use hyper programs as software options for their classes are easily distinguishing passive presentation tools from active programming tools. Even those teachers who take the classes offering training in the use of both tools and then never teach using the specific hyper programs have indicated the value of learning new instructional approaches and methods for their traditional class lessons. In particular, the authoring program, HyperStudio, has served well the new and experienced teachers as they learn new instructional methods for their classes.
Project MITTS: 
Developing Master Instructional Technology Teachers

Susan M. Powers, Marylin T. Leinenbach, Susan J. Kiger
School of Education
Indiana State University, USA
Email: powers@indstate.edu

Abstract: In an effort to not only advanced the technology and curriculum integration skills of area teachers, but also to ensure that preservice teachers have technology-rich field experiences, a state grant was pursued and received to support a special project. The project is representative of new-generation of professional development that encompasses teaching performance standards, best practices for professional development, peer mentoring and preservice teaching mentoring, and utilizes the technology within training. The core of participant teachers have grown in their own integration of technology and are in turn exciting their students and the teacher education students about the uses of technology.

Project Background

As technology advances, it also advances on the educational community. This advancement can often feel like an army marching forward and over all those in its path. Indiana is not immune to impact of the ever-changing technology face on education and teachers. In fact, there are five, specific, yet closely related, needs in education in Indiana in which technology can or does play a significant role. These needs are not specific to Indiana alone, but are currently impacting many states.

One identified need is that the State of Indiana is moving toward a performance-based system for new teacher licensure and also for in-service teacher re-licensure. Many of the state adopted performance standards reflect the expectation that teachers effectively integrate technology into curriculum, and into instruction and assessment strategies; the desired outcome being individualization of instruction and increased academic achievement for the diversity of students and needs represented in any particular classroom. As part of this licensure/re-licensure system, a portfolio is projected to be the primary means of documentation of professional proficiencies along these standards (IPSB).

A second need is that while area schools and school corporations are increasing their technology focus through technology purchases and in-service training, most of the professional development has focused on technology competency rather than emphasizing the infusion of technology for enhanced student learning. Third, a new generation of professional development is needed that incorporates technology as part of the vehicle of the training (i.e. while the teacher is learning how to use the technology, technology is itself enhancing the professional development experience through such modalities as web-based instruction, video conferencing, and online tutorials) (McKenzie 1999; NCREL 2000). A new generation of professional development is differentiated according to participant needs; is contextual according to teaching and work assignments; integrates the technology for teaching and learning; and is grounded in the standards and professional development guidelines that affect teachers, staff, and administrators in Indiana (i.e. K-12 curriculum standards, IPSB teaching standards).

Going beyond a new type of professional development, a fourth need is that to promote substantive change and on-going growth, professional development for teachers needs to be readily accessible and needs to provide exemplars of practice. For example, Teacher X is more likely to learn from Teacher Y down the hall that is innovative in integrating technology into techniques for teaching, learning and assessment than from a university course or professional development seminar.

Finally, the National for Accreditation of Teacher Education (NCATE) 2000 standards (see http://www.ncate.org/standard/m_stds.html) requires that teacher education students participate in field experiences that substantively and effectively incorporate instructional applications of technology. Indiana State University, currently accredited by NCATE although not yet accredited under these new guidelines, strives to acculturate students in technology application-rich environments in on campus coursework, but recognizes the need for our students to be mentored in such application on-site in their field experiences.
The MITTS Project

In order to address these needs, a group of university faculty and area teachers banded together to seek a modest grant to support the necessary work. The group was successful in winning the Eisenhower Grant from the state and university support. The project was labeled Project MITTS – Developing Master Instructional Technology TeacherS. The project began in January of 2001 and continues for an 18-month period.

To address the statewide needs outlined above, MITTS has four goals. First, the project addresses state performance standards by not only directly addressing the educational need concerning effective infusion of technology, but also by providing specific evidence of professional development for participants. Teachers plan their own professional development throughout the grant period by participating in self-assessment and then the creation of a professional development plan of action. Second, the project also supports the incorporation of technology as a training vehicle, especially as it increases the accessibility of idea and information sharing. Much of the training is done through online workshops that have been located for the teachers, the project website, and support, announcements and discussion all evolve through electronic discussion forums instead of traditional workshops. Third, the target of this grant is multi-fold, by first developing the skills of participant teachers, who will foster technology integration with teacher education students, and then mentor colleagues in their buildings. Finally, the long-term focus and outcome of this project goes beyond the 15 participant teachers. The focus is also on the creation of technology application-rich sites and teachers to mentor preservice teachers.

Project's Successes and Concerns

The grant project has not yet reached its conclusion, but some elements are already apparent. First, the participants are noticeably more proficient with technology and display an increased confidence and comfort level in using and attempting different technology applications. This higher comfort level has translated into an increase in the number of ideas for technology integration as reflected in the professional growth plans of participants. Many of the growth plans initially submitted by teachers during Spring of 2001 were extremely conservative in their integration plans. Following a number of interactions with consultants, over half of the participants asked to modify their professional growth plans to make technology more inclusive and more integrated throughout their academic and classroom plan. This change is less a result of any interaction of grant participants, as much as the direct result of peer mentoring. The consultants that were brought in to work with teachers in small groups and one-on-one sessions are practicing classroom teacher who have been successful with technology integration and come from schools that have comparable technology levels. By observing peers who have found creative ways to meet learning goals with technology, and that it may have been done with little help, equipment, or experience, participants discovered a great capacity within themselves to use technology for teaching and learning. Participants have continued to seek out the expertise of these consultants as they continue to plan and create their own learning environments.

The project has not been without its problems. Originally, 27 teachers committed to the grant concept and participation. When the grant was awarded, 8 of these teachers elected to withdraw. The grant team quickly assembled 8 more teachers to replace them. Then, during the course of the semester, twelve more teachers dropped out for a variety of reasons. Although the limited participation from what was originally intended is disappointing, the remaining core of fifteen have been very dedicated to the work and enthusiastic participants. And although the seeming mass exodus of almost half the participants has been extremely unsatisfactory, the remaining teachers have been a joy to work with and the grant resources have been extended further for these participants.

Abstract: As society becomes increasingly entrenched in its commitment to integrating technology into educational settings (Boyer, 1983) teachers are expected to model technology use for students, teach technology skills to students, and integrate technology seamlessly into students learning. However, teachers and administrators who have recently enrolled in graduate level education programs at a regional university in the south have been found to lack the ability to use technology for their own learning, lack the vocabulary to use proper terminology when referring to computer-related technologies, and lack the confidence necessary to construct technology integrated lesson plans. The proposed article will draw on qualitative data collected in four traditional face-to-face graduate education classes to promote the idea that periodic online class sessions help introduce educators to technology integrated learning in a way that is new to them and more importantly, valuable.

Introduction

As society becomes increasingly entrenched in its commitment to integrating technology into educational settings (Boyer, 1983; Achieve, 1999), teachers maintain their pivotal role in society by holding the position of those responsible for carrying out the tasks required to fulfill the commitment. Teachers are expected to model technology use for students, teach technology skills to students, and integrate technology seamlessly into instruction. As Murray (1999) points out, however, “As schools and districts jump on the technological bandwagon, committing significant portions of their budgets to the purchase of hardware, software, and Internet access, they too frequently neglect to provide for the professional development that will ensure the integration of the technology into the curriculum” (p. 33). Teachers often report that they have had few experiences that prepared them to adequately complete the varied phases of the task (Ravitz, Wong, & Becker, 1999; National Center for Education Statistics, 1998). Administrators, and educational leaders too, must be more aware of the new learning environments created by technology innovation so that they can better supervise instruction, as well as design and support professional development.

Across the country teacher training institutions are being required to integrate technology training into pre-service certification curriculum in order to more appropriately prepare new teachers to face the challenge (NCATE, 2001). There are, however, millions more teachers in the field who were trained prior to the infusion of a technology component into formal education and who are not equipped to model, teach, and integrate technology into learning environments. Even with staff development workshops, state mandates on technology skills for recertification (Ga. PSC, 2001), and numerous grant funded nation wide projects (U.S. Department of Education, 2001), experienced teachers and administrators who have recently enrolled in graduate level education programs at a regional university in the south have been found to lack the ability to use technology
for their own learning, lack the vocabulary to use proper terminology when referring to computer-related technologies, and lack the confidence and skills necessary to construct technology integrated lesson plans.

In this essay we draw on qualitative data collected in four traditional face-to-face graduate education classes to promote the idea that periodic online class sessions help introduce educators to technology integrated learning in a way that is new to them. Reduced seat time and increased time in an online learning environment can expand their professional development opportunities, challenge their desire to learn, help them identify learning styles, increase sensitivity to student needs, and allow them to experience technology integration in a manner that can translate to changed teaching practices. Although it is generally accepted in the academy that lifelong learning and continued professional development is important, using the Internet as a conduit for personal training and learning has not yet been incorporated into the education system in a way that inspires teachers to want to use it with their students.

The Study

The study on which this article was based was an action research descriptive case study (Yin, 1993) conducted in four graduate education courses at a regional university in the south. Two professors (also the two researchers) teaching face-to-face classes used online class meetings as a substitute for some of the traditional face-to-face classes. The four classes included; 1 technology course, 1 curriculum course, and 2 research courses. According to Stake, (1994) “Case study is not a methodological choice, but a choice of object to be studied” (p. 236). The object, or in this case subjects, who were studied in this research were students who were in a traditional face-to-face masters program and who had little to no exposure to online learning environments. The combination of the 4 classes makes a “unique case” (Yin, 1998, p. 238) that has multiple cases embedded within. Each graduate education course included in the study had characteristics that were specific to it, and therefore, each course was considered an embedded case (Yin, 1998) within the larger unique case. All embedded cases shared a similar physical setting, which was the traditional classroom. The embedded cases functioned as units of analysis in this action research based case study (Yin, 1998). However, the data reported in this essay was common to all embedded cases and is referenced henceforth as coming from the larger “unique case.” Online discussions, course websites, email responses to research questions, and student comments made face-to-face were shared between researchers and used as data.

The Data

Several quotes form students are included in this section. The quotes are representative of the types of comments students made throughout the study.

“I spent about 4.5 hours on this assignment. It was definitely a learning experience for me. As you know, I am not a very experienced computer (on-line) person, but this assignment taught me so much. I posted a web site that didn’t have anything to do with statistics, but I thought it would be so useful to teachers so I wanted to share it with the class. I’m not sure I would want all my classes to be online, but I am glad I had the experience. The statistics are hard to understand, but I’m sure I’ll get a better understanding after class tomorrow night.”

“The web class assignment was a new and challenging experience for me. I kept getting the same results over and over before I finally understood how to get to where I was supposed to be to post my information. I am still wondering how I could find the discussion board, and couldn’t find the board to post my website. [...] I don’t know if this is better for me, I think hearing you lecture gives it more meaning because you give examples with explanations and we actively participate.”

“This was my first attempt at an online class. [...] It’s been very informative and I think I’ve learned a lot. The websites were the most interesting. I hope I’ve completed the assignments correctly.”

Findings
With all the state requirements, technology mandates, and increase in the number of homes with access to the Internet, it was disturbing to realize the discomfort that our students, most of whom were teachers in P-12 classrooms, expressed with learning in web-based environments. Prior to any web assignments, each class met face-to-face for several weeks, which gave the students the opportunity to get to know each other, the instructor, and the type of expectations that were inherent in the course. A few times throughout the semester students were introduced in the face-to-face class to the website that had been designed to guide them through the next week’s course requirements. Demonstrations were given to enable the students to use the discussion boards and students were given the opportunity to ask questions regarding the online course. Students had 7 days to complete the assignments on the web and could access the site anytime during those 7 days. The freedoms associated with asynchronous learning were explained to them. However, it was also emphasized that discussions depended upon participation in an ongoing manner and therefore they should check the discussion boards repeatedly throughout the week.

After each online session students communicated a sense of uncertainty or lack of confidence in their performance of the activities that were assigned as web activities. They routinely admitted the online experience was a new one that they benefited from but that they preferred face-to-face learning environments. Students commented on the value of learning from websites and occasionally transferred the concepts to their own teaching. Self reported time on task varied for students from one and a half hours to fifteen hours on the same assignments. It was evident that different types of tasks and different content made a difference in student attitudes about the online session.

When students were given the opportunity to find tutorials (some tutorials related to statistics others to learning technology skills), learn the material, evaluate the website, and share high quality resources with peers, reactions were quite positive. Students were able to choose tutorials that catered to their particular learning style, practice Internet searching skills, explore components that help make websites useful, and participate in collaborative learning. When students were asked to read, review, and discuss information they expressed a preference for having the professor tell them the information in class and some students considered lecture instruction to be more interactive than similar activities translated to the web.

Lessons Learned

Instructor’s, whether teaching in higher education or P-12 classrooms, face new responsibilities in the age of the Internet. It has often been said that integrating technology into teacher education face-face classes allows the professor to model best practices that teachers can use in their own classrooms. However, rarely are professors encouraged to cut down seat time in face-to-face classes and model ways that online learning can be effective. By incorporating the online class as an instructional tool in our traditional classes, students were forced to improve their skills with the Internet, and in turn increased their level of confidence with it. Students were exposed first hand to the enormous range of resources available on the Internet and challenged to apply those resources to course specific tasks. Students, although it was not easy and they did not necessarily enjoy it at first, they developed a level of comfort with using web-based communication to participate in collaborative learning activities. This comfort moved the students to the necessary starting point for using web-based activities with their own classes - they succeeded at it themselves.

Suspicions Confirmed

Technologically mediated interactions between learners, instructors, and content in web-based environments are quite different than communicating in face-to-face environments. All of the traditional signals are removed from the communication process and students sensed awkwardness when they tried to decipher messages that were text only (Clevenger-Schmertzing, 2000). By transitioning students to online learning environments at the same time that they are taking face-to-face classes the students can begin to adjust to the different culture of the learning environment and still have access to the traditional culture as a safe space to discuss the new online experience. In this way the online class sessions not only provide new learning opportunities, but they also add to the learning that occurs in the traditional classroom. Framing discussions of
the online learning experiences as problem-based challenges sharpened students’ critical thinking skills and helped them discover benefits to online learning. When we took the opportunity to familiarize our students with learning via computer interactions while at the same time offered the support of the familiar, traditional learning environment, our suspicion was confirmed that they had not considered the Internet a key to lifelong learning and professional development.

Conclusions

According to Mann & Shafer, (1997) “When school districts and teachers make a commitment to instructional technology, student performance improves. Or at least that’s what everyone hopes” (p. 22). At this point in history there are still arguments about the connection between technology and achievement (Phipps & Merisotis, 1999; Russell, 1993). There may always be these arguments, but what is clear to us is that unless instructors, instructional designers, and researchers systematically investigate new technologically based learning environments in deep and meaningful ways, the arguments will not move toward resolution. Evidence, such as that presented in our study, not only moves those arguments along, it challenges us to find new connections between technology integration and learner performance. It is our belief that one area that deserves more attention is the use of the Internet as an opportunity for individualized learning within traditional, face-to-face classes. Modeling such activities in graduate teacher education programs may not only improve those programs but also may trickle down and have an impact on P-16 learning environments as well.

Computer Camp for Teachers

Merryellen Towey Schulz, College of Saint Mary, US

ABSTRACT
Summer camp is not just for children. At College of Saint Mary we conduct a summer Computer Camp for Teachers. Student teachers are excited to enter the classroom and use the skills they have learned during their pre-service education -- including technology skills. They have learned to use technology and write lesson plans integrating technology with learning. Unfortunately, they often encounter cooperating teachers who make little use of technology in the classroom and have limited skills in the area. Many in-service teachers received their training prior to the integration of technology into teacher education programs and were left out of the loop for meaningful training. With Computer Camp for Teachers we are building a cadre of technology-using teachers to serve as cooperating teachers who support pre-service teachers in integrating technology in their student teaching experiences. It is a win-win situation for the college, the students and the practicing teachers.

Introduction
The purpose of this presentation is to inform educators and administrators of a model for teacher educators and in-service teachers to cooperatively learn and implement technology in the K-12 classroom. Just two years ago, much was written about the need to integrate technology training into teacher education. Like many institutions of teacher education, College of Saint Mary acquired additional equipment and software and taught pre-service teachers to use various forms of technology and write lesson plans integrating technology into student learning activities. However, it has been difficult or impossible to require student teachers to use their technology skills in student teaching experiences, because it was found that only a limited number of cooperating teachers used technology at the level the students had learned. To overcome this barrier, the college offered a Computer Camp for Teachers to train cooperating teachers to use the same technologies that student teachers were prepared to implement in their classrooms.

Three objectives of the PT3-funded Nebraska Catalyst Project were combined to create a cadre of K-12 teachers with expertise in educational technology who will serve as cooperating teachers and provide technology experiences for student teachers from College of Saint Mary. Objectives of the camp were: to design and conduct a graduate level summer workshop course to train a cadre of K-12 teachers in educational technology and assign student teachers to cadre teachers during the 2001-2002 school year. Ten K-12 teachers were identified and invited to participate in Computer Camp, for which each received three hours of graduate credit, Inspiration software, and a text.

The camp was conducted in a computer lab and education classroom at College of Saint Mary from 8:00 A.M. to 5:00 P.M. everyday for one week in June, 2001. Working lunches were used to discuss technology projects and demonstrate multimedia classroom equipment to participants. The structure of the camp was based on Jamie McKenzie's book, How Teachers Learn Technology Best. A teacher-friendly comfortable environment was created; lights in the lab were lowered to avoid the harsh environment created by fluorescent lighting, teacher friendly posters were displayed on the lab walls, music was played and plants were placed in the room. Two students served as lab assistants, providing participants with a 3:3 to 1 ratio for instruction and assistance.

Making the Classroom Computer Connection, by Tammy Worcester was the text for the course. Instruction in creating authentic projects to be used in their classrooms was given and teachers created web sites on which projects were submitted. Projects, including student goals for the course, were to meet ISTE standards for Teachers and Students and Nebraska Technology Competencies for Teachers.

Projects created were: graphic organizers with Inspiration® and Kidspiration® Software; digital camera photos; newsletters; WebQuests and Treasure Hunts, using Filamentality; Power Point Presentations; lesson plans integrating technology and strategies to manage classrooms with one or more computers. Assessment strategies were included in all projects.

As a pioneer in the use of technology in elementary and middle school classrooms and as a professor of education courses, it has been natural for me to take this step to bring the process full-circle by including classroom teachers. Since becoming a college instructor, I have integrated the use of technology into all courses I have taught and trained other faculty to do the same.

The presentation will consist of Power Point slides and the camp web site, http://drmts.com/camp/index.htm followed by a question and answer session if there is time.
project is significant and relevant to teacher education in that its purpose is to assure student teachers of placement with cooperating teachers who possess skills and motivation to integrate technology into K-12 classrooms. A symbiotic relationship develops between the teachers and the pre-service teachers as they work together to implement technology projects they have been taught to use. During the 2001-2002 school year teachers will be surveyed to determine their use of technology in the classroom.

Using a Resource-Based Learning Environment to Foster Self-Directed Learning in In-Service Teachers

Mary Shoffner, Georgia State University, US

Presentation Plans:
Self-direction is a necessary characteristic in lifelong learners. Teachers, in order to make best use of the new tools and changes in approaches to teaching, must be life-long learners. As technology is ever changing, simply providing the in-service teacher with basic technology skills will not be enough. They must be able to self-direct and self-regulate their learning for the duration of their careers if they are to effectively practice their profession. A resource-based, WWW-based learning environment was developed for a course in teaching methods, lesson planning, technology skills, and technology integration strategies for students in a graduate teacher education program. This presentation will briefly present the philosophy behind the course design and development, including self-directed learning and resource-based learning environments. A brief review of prior research examining self-directed learner readiness and pre-service education will be given. Pre- and post-test versions of a technology skills inventory that matched the NETS-T profile and the Self-Directed Learning Readiness Scale (Guglielmino, 1977) were administered to as part of the course. Data is currently being collected during the Fall 2001 semester.

This exploratory study examines an alternative approach to technology education for in-service educators. In-service educators were introduced to a resource rich environment, and then given opportunities to use, and thus learn from, this environment. By interacting with this environment, it is hoped that in-service educators will learn not only technology and integration skills, but will at the same time develop or increase self-directed learning skills which in turn might prepare them for successful life-long learning.

Methods

A resource-based learning environment was developed in Fall, 1997 to serve as the basis of a course for in-service educators as elective service course in instructional technology for the College of Education graduate students. Pre- and post-test versions of a technology skills inventory and the Self-Directed Learning Readiness Scale (form A) (Guglielmino, 1977) were administered to as part of the course.

The technology skills inventory is a locally developed self-report instrument containing thirteen demographic items and 25 technology skill items based on the NETS-T performance profile for First-Year Teachers. Technology skill items include open-ended, multiple choice responses, as well as Likert-type indicators of skill level descriptions, and address skills and attitudes toward technology use.

The Self-Directed Learning Readiness Scale (form A) is a 58-item questionnaire with Likert type responses design to indicate a person's readiness to engage in self-directed learning activities. The SDLRS is the most widely used instrument of this type and was therefore chosen for the study.

The basic factors said to underlie the construct of the SDLRS are as follows:

1. An openness to learning opportunities.
2. Self-concept as an effective learner.
5. The love of learning.
6. Creativity; risk taking, skill in designing atypical solutions, and ability to conceive of multiple approaches to topics.
7. Future orientation; self-perception as a lifelong learner.
All of the above skills are necessary for teacher success in the technology infused classroom.

In addition, students were asked to reflect on the following questions at the beginning, middle, and end of the course:

1. What do you hope(expect to learn while you are in this course? Have your expectations for what you hoped to learn in the course changed since you wrote your last Reflection Paper?
2. How much do you feel you have learned/grown in this course thus far?
3. Do you feel you have gained a better understanding of how to tackle challenges?
4. What are you doing differently with technology than before you took the course?

Final reflection questions include:
1. How prepared do you feel to enter the classroom and use technology in a lesson?
2. What might help you to put what you've learned in this class to use in the classroom?
3. What impact will the level of technology resources in your school or future school of employment have on your teaching?
4. In your opinion, can technology help teaching and learning?
5. How do you plan to keep up with changes in technology as you move through your teaching career?

Responses in the reflection papers will be examined to gain further, richer insight into how students are using the learning environment to address teaching and technology concerns.

Students completed the skills inventory and SDLRS as part of the course. Students were given an explanation of the study, and students indicated their willingness for their data to be included in this exploratory study by affixing their signature to an "informed consent" form. To date, data has been collected from 40 students in the Fall 1998 semester and 40 students in the Spring 1999 semester.
Evolving Uses of Technology in Case-Based Teacher Education

Janet C. Smith
National Center on Adult Literacy
University of Pennsylvania/Graduate School of Education

Abstract: This presentation discusses the evolution of technology-facilitated, case study-based professional development for adult education professionals by examining three projects involving the National Center on Adult Literacy (NCAL) and the International Literacy Institute (ILI) at the University of Pennsylvania/Graduate School of Education. The projects in order of development are the International Literacy Explorer: A Teacher Training Tool for Basic Education, Captured Wisdom: Stories of Integrating Technology Into Adult Literacy Instruction, and the Professional Development Kit (PDK): Multimedia Resources for Instructional Decision Making. These projects are in various stages of completion and represent an evolving variety of solutions to the challenges of effective, technology-facilitated teacher education. We briefly discuss some of the conceptual background for using the case study method for teacher education and some of the limitations of using written case studies. We then discuss how technology can facilitate the use of case studies in professional development. Finally, we look specifically at the three projects, which were developed over a period of several years, how each responded to the issues raised in earlier projects, and how they provide crucial background information for a new initiative, TECH.21: A National Technology Laboratory for the Improvement of Adult Education.

Introduction

In 1986, the Carnegie Task Force on Teaching as a Profession published their report entitled “A Nation Prepared: Teachers in the 21st Century,” which recommended using case studies as a major focus of teacher instruction (Carnegie, 1986). Lee Shulman advocated the use of case studies for teacher education, feeling that they were a good means of connecting theory with practice and of showing that teaching itself was a complex activity that demanded high level decision-making skills (Shulman, 1992, p. 28).

Case studies can be teaching and/or learning tools and the key element is that they are situated in real world contexts. Merseth (1994) saw cases as serving as exemplars, opportunities to practice analysis, and stimulants to personal reflection. Case studies were understood, as they had long been in law and medicine, as ways to hone analysis and decision-making skills with authentic situations. More recently, when Putnam and Borko (2000, p. 8) discussed the renewed interest in situated cognition, they pointed out that cases provide vicarious encounters with real classroom environments because they are situated by their very nature. Some of the benefits they mention include opportunities for reflection and critical analysis that are not possible when acting in a real classroom setting, exploration of the richness and complexity of authentic pedagogical problems, and shared experiences for groups of teachers to explore together.

The limitations of text-based case studies for teacher education can be summed up by saying that they fail to capture and communicate the reality of the nuances and immediacy of actual classroom settings, just as they fail to capture the drama of a courtroom for aspiring law school students. The tone of voice, facial expressions, and gestures of the teacher as well as the learners give color to the starkness of black and white text detailing case studies. Video provides all of this and more to preservice and in-service teachers.
The Use of Video in Case Studies for Teacher Education

The introduction of video into case-based teacher education was a great step towards more accurately portraying the complex, real life situations that characterize the reality of teaching. Video is able to capture the complexities and realities of the classroom (including facial expressions and gestures) while providing the time for analysis and reflection that is impossible when actually sitting in a classroom observing. Analysis and reflection are essential for transforming a simple videotaped lesson into a true learning experience for preservice and in-service teachers. Not only can the video be stopped to allow for guided discussion and reflection at various points, but it can also be reviewed several times in order to search for nuances in the teacher's decision process and to examine the action from various different perspectives (learner, teacher, administrator). Unfortunately, linear video without discussion and guidance to help teachers actually change their practice over time is not very effective (Lauro, 1995, p. 65). CD-ROMs, DVDs, videodiscs, and multimedia Internet websites can all help overcome the limitations of linear video viewing and increase teachers' interaction with the case. In this way, teaching is seen more realistically – as a multifaceted problem-solving process.

Each of the media mentioned above has its own characteristic benefits. Linear videotape is important for conveying a sense of the overall lesson and the flow of the classroom. Videodisc technology has the benefit of allowing teachers to quickly focus on specific, shorter segments of the whole and therefore interact more immediately with the material (Atkins, 1998). The Internet and its innumerable websites add (a) the dimension of anytime/anywhere learning; (b) the capacity to utilize listservs, chats, bulletin boards, and so forth for communication; and (c) access to the most current materials through relatively easy and inexpensive updating. The following section will discuss how the various media were utilized in the three technology-facilitated NCAL/ILI professional development projects for adult education teachers.

The Evolution of Three Multimedia Professional Development Projects

Quality professional development that actually changes current practice (and its outcomes – adult learning) is one of the keys to effective adult instruction just as it is to effective K-12 instruction. The National Center on Adult Literacy and the International Literacy Institute at the University of Pennsylvania have been working on solutions to this challenge for well over a decade. The following three projects were designed and implemented by many of the same team members and therefore benefited greatly from the experiences and lessons learned in all of other projects.

International Literacy Explorer: A Teacher Training Tool for Basic Education

The International Literacy Explorer (ILE) is a multimedia teacher training tool for basic education designed to give an overview of literacy and basic education issues and practices in an international context. The Explorer offers ideas, discussions, and activities to teachers/practitioners, policymakers, and researchers in order to enrich literacy thinking. In the context of the worldwide effort to more fully and effectively increase the literacy skills of all people, the Explorer focuses on several innovative, useful, and/or effective literacy projects and programs across the globe. Also included are supplementary sections on general literacy concepts and statistics to help the user to better understand the consequences of widespread illiteracy, the need for and importance of literacy education, and the achievements of the specific literacy projects. The Explorer has four main sections: “Literacy Overview,” “Literacy Projects” (case studies), “Statistics,” and “Resources.” The product is available free in its most up-to-date state on the Internet (www.literacy.org/explorer/index.html) and also in the original CD-ROM version.

The “Literacy Projects” section contains 12 case studies grouped under the following headings: Language and Culture, Gender and Development, Teaching and Learning, Quality and Innovation, and Technology for Learning. Each individual case study contains the following elements: (a) Background (the issue in brief and in
that country’s context), (b) Overview of the Project, (c) Activities (teacher/practitioner focused), (d) Outcomes and Implications (researcher and policymaker focused), (e) Resources, and (f) Questions. The case studies are quite text heavy and represent an almost textbook model of case study methodology. Short segments (10 to 20 seconds) of video are in the Activities sections and there is the potential for some interactivity on the Questions pages, where users can email the creators of the site with inquiries.

The benefits of using technology for this project were multiple and at several levels. Although it was originally planned solely as a CD-ROM (so as to be available in locations where Internet access was minimal), the developers, who were located in several different countries, found it most efficient to design on the web for ease and rapidity of communication. The website was then simply transferred to CD-ROM and involved only the challenge of making the database functional. While it was useful to have the information on the web in terms of a wider audience, the time length of the videos was severely restricted by connection speed over what might have been possible on CD-ROM. The benefit of that decision, however, was that the videos were very targeted and to the point, so viewers actually watched them in their entirety as opposed to what often happens when users move on without completing the videos or just read the transcripts. Because of the hyperlinking potential of the web, multiple perspectives could be delineated for those users with limited time to browse. Thus teachers/practitioners could jump directly to the Activities sections of all 12 case studies and researchers/policymakers could likewise jump directly to the Outcomes and Implications sections without destroying the integrity and flow of the site as a whole. The “Help” (FAQs) section of the website not only walks the user through the organization and navigation, but provides specific suggestions to the various user groups on how to use the site as a professional development tool.

Our retrospective view of the website is that it (a) is probably too text heavy for a website, (b) would benefit from an effective mechanism for information sharing (such as a database interface for new case studies, resources, etc. and a discussion board), and (c) needs an efficient means of updating. The Questions page could have been expanded with some discussion and reflection questions to enrich the user’s learning experience. We do see the site as most effective as a stimulus for group discussion and reflection during guided professional development activities. We know that it has been used that way as well as a resource for college classes and for individuals in various countries throughout the world.

Captured Wisdom on Adult Literacy: Integrating Technology Into Adult Literacy Instruction

Captured Wisdom (www.literacy.org/capturedwisdom.html) is an interactive resource that is designed to help inform educators of successful practices of integrating technology into adult education instruction. Innovative, replicable activities are shown, described, and discussed by front-line classroom educators and learners so that other teachers feel that they have had an opportunity to actually visit and chat directly with the learners and teacher about their work together. The two CD-ROM set contains 7 different 20 minute videos of authentic adult education classrooms. To develop each of the Captured Wisdom stories, teachers and learners were filmed describing and demonstrating how they use technology in classroom-based projects. Each edited, videotaped segment was then viewed by focus groups of adult educators. These educators wrote down questions that they wanted to ask the teacher. The focus group teachers felt the answers to these questions would prepare them to use activities in their own classrooms. The questions were divided into the following categories: Learners, Instructional Activities, Project Management, Technology Issues, and Products and Assessments and directed to the presenting teacher. Responses were tape-recorded and included as companion segments on the CD-ROM. This development process assured that the implementation needs and concerns of real teachers in real adult education programs were addressed. Also included with the set is a short instruction booklet that explains how to use the Captured Wisdom CD-ROMs effectively in professional development. The video vignettes (case studies) are also available on two videocassettes with an accompanying booklet for professional developers with suggested activities on how to use the vignettes in group professional development on topics as varied as alternative assessment, multidisciplinary teaching, and project-based learning. The model for Captured Wisdom was developed by the North Central Regional Education Laboratory (NCREL) for K-12 teachers and was extended to address the needs of adult literacy instruction by NCAL.

The Captured Wisdom CD-ROMs enrich the experience of linear video for adult education professional development with the questions and answers (in text and audio) posed by real life teachers about the
implementation of the technology integration in their classrooms. Although there is no specific mechanism for information sharing and easy updating with Captured Wisdom, the focus group questions and answers provide additional insightful comments about the classroom experience viewed on the video. These can lead to further discussion and reflection on the part of individual teachers or groups of teachers. The print booklets that accompany both CD-ROM sets and videocassette sets contain suggestions and activities that can be used directly by professional developers or groups of interested teachers seeking to improve their practice.

The portability of the self-contained CD-ROMs is a distinct advantage over web-based, video-enhanced professional development that necessitates a fast Internet connection. The CD-ROM medium can contain substantial video segments and is extremely inexpensive to produce. However, without a projection system, the CD-ROM provides a relatively private experience of the product on a single computer screen. There has been discussion of adapting this product for the web, but the length of the videos is problematic. Considerable adaptation would have to take place to customize the videos for typically impatient web "consumption." The videocassettes of the vignettes are more easily shown on large size TV screens to groups, whether they are preservice/in-service teachers, administrators, or board members.

There has been considerable feedback on this product, which has been available for about a year. Professional developers have used it with much enthusiasm as have literacy program directors who have shown it to their funding boards as a vision building exercise for how technology can motivate learners and contribute to their learning.

**Professional Development Kit (PDK): Multimedia Resources for Adult Educators**

The Professional Development Kit (PDK; www.literacy.org/pdk.html) is a multimedia resource for adult educators that utilizes print, video, CD-ROM, and the depth, flexibility, and complexity of the web. It consists of a reflective framework that supports participants' efforts to generate questions and brainstorm solutions to challenging professional situations. PDK aims to support community-building and collaboration among adult educators by providing opportunities and tools for communication. PDK consists of a variety of resources, including:

- 10 hours of video investigations containing interviews with learners, teachers, researchers, and administrators; examples of classroom practice; and in-depth exploration of specific topic areas such as ESL, ABE, GED, math, writing, assessment, integrating technology, and much more;
- a website that contains online tools such as discussion boards; teacher portfolios with self-assessment activities, data collection suggestions, action plan infrastructures, and reporting frameworks; and
- five knowledge databases to search related resources, and a participant's guide that describes the system and identifies possible applications in various contexts.

The three main sections of PDK are the "PDK Community," "Investigating Practice," and the "Knowledge Databases." The "Investigating Practice" section contains 5 video case studies called Classroom Investigations. Each of these includes (a) a 15 to 20 minute narrative with teacher reflection and student reaction, (b) a highlights video section of 5 minutes about the specific lesson, and (c) topic area videos of about 2 to 3 minutes that address techniques or skills that the teachers use to deal with the issues of learner anxiety, motivation, diversity, and disabilities, just to name a few. The taping and editing of the 10 hours of video took place over a 3-year period of time. The role of the video was not to create a model of perfect teaching, but rather to capture what was happening in an actual classroom as well as teacher and students' reflections about those interactions.

Although PDK videos are available on conventional videotapes for viewing in group or classroom settings, the full power of the program can only be experienced through the interaction of all the components on the web and on CD-ROM. The CD-ROM contains the Quicktime™ video that is accessed from within the computer's CD-ROM drive as one navigates through the different organizational elements of the PDK website. In this way, the user is not hampered by Internet connection speed for the delivery of significant amounts of video. This carefully edited video is surrounded with the resource and communication structures of a comprehensive website.
The "PDK Community" is composed of a My Portfolio section (self-assessment activities, data collection, action plans, reporting frameworks with all information saved to an individual's personal online portfolio) and Discussion Boards (for national as well as small group listservs with tools for creation and management). The My Portfolio areas contain information and learning activities that help users articulate questions about their practice, brainstorm creative solutions, implement plans, and write up the results of this process. Not only can users keep track of their own development, but they can participate in larger learning communities via the discussion boards. This leverages technology's capacity to connect people and ideas in information-sharing activities.

The online, searchable "Knowledge Databases" is divided into 5 parts that complement the PDK learning activities. The 5 parts are (a) PDK practitioner reports (contributed by participants in the program), (b) PDK TIPS (short papers providing information on integrating research and theory into teaching contexts), (c) online articles complementing the video case studies, (d) professional development resources (annotated list of online resources with links to conference information and other learning opportunities), and (e) lesson plans. This database will continue to grow with contributions from users of the PDK system and it leverages technology's capacity to store and then locate large amounts of information.

Although this project is not yet complete, prototypes have been tested and used in professional development groups with positive feedback. The community section currently hosts many small groups of practitioners from various areas of adult education and the databases contain materials selected for their appropriateness to the issues presented. The product will be most effective in facilitated group professional development with the extra benefit that the group can be virtually present (via the Internet) if not physically present in one room.

**Brief Analysis of the Projects**

The ILE began with the goal of providing a readily accessible teacher education tool for adult basic education by utilizing video case studies and information and communication technologies for delivery. The limitations of web-based video delivery resulted in very short videos and a quasi-textbook model. The Captured Wisdom CD-ROMs and videotapes captured classroom practice and complexity more realistically and allowed for more substantial video and actual teacher questions and answers. However, the presentation on CD-ROM was relatively static and unable to respond to user's questions and personal professional development. PDK, which encompasses print, extensive video on CD-ROM, and a comprehensive web-based structure, truly uses the available technology in a seamless, unobtrusive fashion. All the technology tools work together to support the growth of teachers.

Abstract: This paper discusses the importance of conducting formative evaluations. The Master’s of Education in Educational Technology at Northern Arizona University is a young online program in its second year of implementation. Because online degree programs are new to the educational arena, little is known about the best pedagogy, workload for both faculty and students, and effectiveness of the program. This formative evaluation will collect information from stakeholders to the program. Data sources are online surveys, synchronous and asynchronous interviews, and anecdotal data. Preliminary results are discussed.

Introduction

Even when teaching is usually one of the last professions to adopt the changes that happen in society at large, it has moved from being a mainly solo endeavor to become a collegial experience (Wise & Leibbrand, 1996). Colleges of education are now offering degrees that take advantage of technologies that promote exchange of ideas and the building of communities of learners through online settings. In fact, many institutions fear that they will be extinct if they do not offer web-based distance education courses (Roblyer, 1999). Because degree programs delivered through online environments are so new to the education arena, it is necessary to evaluate the program as a whole to understand the dynamics that happen in the virtual classroom. Manning (cited by Osborne & House, 1995) discussed that one of main reasons for conducting an evaluation is to determine what has been accomplished and how it might be accomplished better. Although there are several approaches to conducting program evaluation, a valid and accepted approach is for the institution to set its own evaluators to identify its own strengths and weaknesses (Warren & Curley, 1998). It is believed that when the institution takes the first stakes at an evaluation process, faculty are more likely to make the necessary changes to improve the program (Osborne & House, 1995). Program evaluation provides valuable feedback that allows administrators and faculty to examine the effectiveness of the program to then correct, change, improve, add, or delete components of the same. A successful program is one in which the systemic evaluation of the program philosophy, goals, design and outcomes become an integral part of the same and not a reaction to external demands for accountability (Warren & Curley, 1998). Comprehensive evaluations must include all stakeholders: administrators, faculty, students, graduates, and employers.
The Master's of Education in Educational Technology (MED in Ed Tech) at Northern Arizona University has a strong PK-12 emphasis. This 36 credit-hr. degree program is delivered totally online using several interfaces, such as WebCT, Blackboard, and in-house designed Web Tools. Because of the convenience of taking courses without having to travel to far away campuses, this program attracts not only statewide students in Arizona, but students in other states of the country as well as students in different countries. In order to design and implement a comprehensive and effective formative evaluation, two phases are planned. The first phase will collect the perceptions of the closest stakeholders (students enrolled in the program, faculty teaching for the program, and administrators directly involved with the program), while phase two will collect and integrate the perceptions of the farthest stakeholders (university administrators, graduates' employers). This paper discusses the planning, processes, data sources, data collection, and data analysis to evaluate formatively the first phase of the MED in Ed Tech program.

Goals and Objectives

1. Understand the type of students who enroll in the program and their needs. Since this program was conceived as a program serving PK-12 teachers, it is important to know if it is attracting the target population.
2. Look at the processes for program admission and whether they are user friendly and user oriented. Students in this program usually do not meet in person with a faculty for the application process or advisement because the program serves mostly students who are not physically close to the university campus facilities. It is important to measure the clarity and easiness of the application process and whether it is client oriented.
3. Measure the change in self-reported classroom practices and technology adoption that the students experience as a consequence of taking courses in the master's program. The goal of the master's program is to provide teachers with tools and skills to integrate technology into teaching, so it is important to measure this change in daily classroom applications.
4. Gain an understanding of the student as an online learner. It is important to identify the cognitive and metacognitive strategies that students use when interacting with the class material. Also, because most of what happens in an online course is text based, we need to know the student perspective on online course expectations for time, rigor, workload, and accommodations that facilitate or hinder learning in this environment.
5. Investigate the perceptions of efficacy and workload of faculty who teach online courses. Online faculty have many questions regarding what it constitutes a rigorous but time-wise reasonable course. This objective will help identify strategies that faculty use to make an efficient use of time and resources in an online course and whether online courses constitute a burden to faculty's duties.
6. Look at the administrators perceptions of the program in such aspects as revenue, allocation of resources, prestige for the department, and any other administrative issues related to the master's program. Administrators that work closely with faculty in this program will be able to provide perspectives that will inform the scholarship and issues related to budget of the master's program.

Methodology and Plan of Research

Lapan (in press) discusses that the best evaluation studies incorporate data collected through both qualitative and quantitative methods. Data to evaluate the MED in Ed Tech will come from both quantitative and qualitative sources. The quantitative sources include interactive online surveys that are described below.

Personal Information Database. This survey provides information on the background of the students and the current positions they hold in the school setting.

Hardware inventory. This survey gives faculty information about the hardware and software the students have at their disposal to complete the MED in Ed Tech program.

Online Technologies Self-Efficacy Survey (OTSES) (Miltiadou, 1999). The OTSES is a self-report of student beliefs of self-efficacy with specific Internet applications and basic computer skills.

Stages of Concern About Technology. This survey, originally designed and validated by Hall, George, and Rutherford (1977) measures the seven hypothesized stages that an individual moves through when adopting a process of product innovation, i.e., technology.

Motivated Strategies for Learning Questionnaire (MSLQ) (Pintrich & De Groot, 1990). The MSLQ is a self-report of motivational factors, cognitive and metacognitive strategies that students monitor and regulate when studying or working on course assignments.

Qualitative data will include letters of application to the program, messages to a Virtual Conference Center (a bulletin board), student asynchronous exit interviews, and faculty and administrator synchronous interviews. Data collected through quantitative instruments will be analyzed using parametric and non-parametric statistics, while data collected through qualitative methods will be analyzed using content analysis and analysis of emerging themes.
Preliminary Findings

Currently data have been collected on fifty students and preliminary results indicate some interesting findings. Initially students have reported relatively high average ratings of self-efficacy for technology skills. However, a little over 10% of the students had individual total SES ratings that ranged between 2.7 and 3.0 (2=“Not Very Confident” 3=“Somewhat Confident”), indicating they may have difficulty accessing course materials or interacting with their peers in their courses. These students may indeed benefit from advisement on specific technology skills at the beginning of their program. However, the most interesting finding has been in regard to the motivational scales (7 being highest) within MSLQ. Overall students averaged 6.57 (7 being highest) on Intrinsic Goal Orientation items while only a 4.14 on Extrinsic Goal Orientation items was reported. Not surprisingly, students averaged 6.84 on Task Value items (which were worded as computer tasks) and 1.98 on Task Anxiety items suggesting that they valued the tasks, but were not necessarily intimidated by them. Also of interest in the MSLQ, was the overall students’ average of the Peer Collaboration items within the strategies section. Here students reported a 4.87, the lowest average of all of the cognitive or metacognitive strategies.

Conclusions

It is expected that through this project, administrators and faculty will be able to identify the strengths and weaknesses of the MED in Ed Tech program. Early identification of weak points in the program will help build and grow an online master’s program that has the potential of becoming nationally recognized for its quality and student-centered approach. Analyzed data will be disseminated to the stakeholders in the form of a written report and/or a web site.

PalmOS Handheld Computers And Standards, Assessment, And Accountability

Penelope Walters Swenson, Advanced Education, California State University Bakersfield, United States of America, pswenson@csub.edu

Abstract: Teachers and administrators are expected to be increasingly accountable. Standards, normed referenced testing, and other forms of accountability are part of the daily routine. How can teachers keep up with the increased demands and little time? Handheld computers can assist the teacher in meeting these requirements and they can lighten other parts of the teaching load too.

Assessment and accountability is one of the prevailing movements in schools across the US, Canada, and many other areas of the world. In the US and Canada, teachers have scant time to perform the standard functions of teaching and record keeping. Now they are being required to maintain testing records, perform additional assessments, provide extra help for students below standard, and develop strategies for meeting standards that they seldom had a voice in establishing. Teachers and principals are changing the way they conduct their business to accommodate the increased demands of the standards and assessment movement. Some are turning to handheld computer technology.

A typical middle school teacher's schedule in a California school is full. Kate Johnson routinely arrives a half-hour to an hour early. She then embarks on her marathon day. Five classes, four preps. Scheduled potty break. Half-hour lunch. Meetings after school twice or three times a week. One to five parent conferences a week. Afternoons, evenings, and even weekends are filled with meetings, school activities, preparation, grading, and school improvement work. What once might have been called dedication is now considered routine by this teacher.

Where does she find the additional time to chart each student's progress toward standards, work with individual needs, and prepare students for the high stakes testing upon which the reputation of her school and her reputation as an excellent teacher depend? The new reality in education is that teachers have great diversity of backgrounds and abilities in their classrooms. They are teaching in a time of an information explosion, so their traditional role has changed. Schools are not the source of community pride they once were and funding is not at the levels of four of five decades ago. With less money, there are increasing demands. Many of those demands are related to standards, assessment, and accountability.

Having critical teacher and leadership functions in the "palm of the hand" is helpful. Handheld computing enables teachers and administrators to plan and organize, carry reference information, gather and analyze data, exchange information with other handheld computers, and even collaborate more effectively.

State standards and benchmarks, local standards, and even site benchmarks can be loaded into the handheld computer. Rubrics also can be kept in teacher's personal "data bubble". Individual student tracking, including grades, progress toward meeting standards, and other indicators of progress, can be done using the handheld. Scoring of assignments can be done "on the fly" while students are presenting projects or working in groups as the teacher moves about the room. Progress reports can be beamed to a student's handheld, a printer with an infrared port, or sent as a batch for e-mailing or snail-mailing to parents. Additionally, the teacher or administrator can even use the handheld to create memos, take inventory, or make a list for a lesson plan. All of these can be sent directly to the printer or downloaded.

While handheld computing cannot solve all of the problems of teachers and administrators, there are many functions, assisted by software, that can support and make the data-collection and maintaining tasks easier. Available information and the ability to track standards, assessments, and student progress is critical to school improvement and, more importantly, increased student learning. Handheld computers are part of a solution.
Several universities are involved in research projects using handheld computers. One focuses on pre-service teachers, another on enabling teachers to engage students in handheld computing projects, and another on using handheld computers in supporting teachers and administrators in a data-driven environment.

As a Learning Circle attached to the Project TNT PT3 grant at California State University Bakersfield, we are exploring the uses of handheld computers for teachers and administrators within the high stakes, standards and accountability environment of K-12 public education (Swenson, 2001). Currently, the focus is at the middle school level. Teachers and administrators have been supplied with PalmOS handheld computers and software. They are using these handhelds in their work and reporting on their successes and challenges. The Tools 4 Schools Learning Circle is preparing ways to better equip teachers with data needed to help students achieve greater success.

At the University of Michigan, Elliot Soloway and his team of researchers and teacher participants are developing and field testing software tools for student use. Soloway believes every child should have a handheld computer. He suggests these computers are necessary tools, just like paper and pencils (Soloway, 2001). To this end, Soloway and his team have developed PicoMap concept mapping software, a simulation called Cooties, and PalmSheets worksheets for student use. Designed to inspire teachers and students, these programs are available without cost for school use.

East Carolina University embarked on a project that places PalmOS handheld computers and selected software tools in the hands of students preparing to be teachers. The emphasis is on wireless technologies to support anywhere, anytime learning. Through innovative tutorials, targeted support, and courses where the technologies are incorporated, ECU is changing the way professors teach and students learn (Educause, 2001).

Handheld computing is inexpensive and easily learned. Software applications are being developed rapidly. From personal organization to keeping track of student assessment data and even writing and rewriting papers or articles, the handheld computer is beginning to have an impact in K-12 education.

Incorporating Cognitive Learning Theory and Instructional Design Models in Graduate-Level Multimedia Development Courses

David Tarcy
Educational Communication and Technology program
New York University
United States
pdt205@nyu.edu

Abstract: This paper is a description of two, graduate-level, multimedia development courses taught at New York University during the fall term of 2001. One course emphasized an instructional design model to guide the development of student projects, the other focused on cognitive learning theory associated with media types, both shared some learning theory content. A qualitative analysis of the projects and experiences of the students accompanies instructor reflection on the varied approaches. The practice of teacher education may be informed by the discussion of course development incorporating the 'living systems' instructional design process and cognitive learning theory. Theory topics included: cognitive load theory, information processing and models of memory, cognitive flexibility theory, dual-coding theory and its descendents.

Introduction

This paper describes two, graduate-level, multimedia development courses taught at New York University during the fall term of 2001. Instructional Design for the WWW (ID for the WWW) emphasized the Living Systems instructional design model (Plass & Salisbury, 2001) to guide development of student web-based projects. Communicating with Computer-Based Interactive Telecommunications (CBIT) appropriated a three-pronged approach to the study of media types adapted from a similar course taught in the computer science program at George Washington University. Four media types (text, graphics, sound, motion) were evaluated from three distinct perspectives; cognitive learning theory informing the use of the media type, the science or art of the media type, and the technology producing the media type. Students created an instructional project in Flash 5.0 for delivery over the web. Some learning theory content was shared in common by both courses, particularly discussions concerning information-processing models (Mayer, 1997, 1999; Mayer & Anderson, 1991; Paivio, 1971, 1986), limitations of human processing capacities (Miller, 1956), cognitive load (Sweller, 1994; Sweller, Merrienboer, & Paas, 1998), and the influence of multimedia on learning. The courses diverged in their respective emphases. ID for the WWW focused on the process of instructional design, CBIT more critically analyzed the use of media types and only cursorily discussed the instructional design process. Students in both courses exhibited an eagerness to learn the technology and its practical application in educational settings. This paper explores qualitative differences in their final projects and in their experiences.

The Study

The forty graduate students in the two courses varied widely in their level of prior computer experience and expertise, educational background, program of study, and familiarity with educational and cognitive learning theory. All students produced instructional projects to be delivered over the internet, regardless of prior experience. Students in one course developed projects in Dreamweaver 4, incorporating hand-coding of HTML, JavaScript, and the inclusion of a Flash 5.0 file. Students in the other course developed their instructional projects entirely in Flash 5.0, incorporating the media types discussed during the course. Projects will be vetted for conformity to the stated instructional goal/objectives of the developer, coherence of navigation system, appropriateness and use of media types employed, and self-reported explanations of authoring considerations. Feedback from students concerning their experiences in the courses will be elicited.

Findings
Based on initial reviews of works in progress and on the differing emphases of the courses, students in the ID for the WWW course are expected to have more internally coherent navigation schemes within their projects, and will describe the development process with greater clarity than students in the CBIT course. The Living Systems ID model guides developers through design steps commonly found in many other models, though it encourages an evaluation of any step at any time in a somewhat recursive manner. The course emphasized the information architecture of the project, the interaction design (defined by instructional methods and navigation options embedded in the project), and use of the media types within the page design.

Students in the CBIT course are expected to describe individual instructional design features of their projects with greater detail and theoretical support than their counterparts. The possibility exists that students in the CBIT course will intuitively follow the instructional design process (only briefly mentioned in the course) due to the course emphasis on critically analyzing the use of media types. Some transfer of this analysis may occur at the instructional design process level. Evaluation of course topics and sequencing of content will accompany this paper to aid those who are currently developing or instructing multimedia development courses for educators.

Conclusions

Conclusions will be forthcoming as the semester, final projects, and informal interviews are completed.

Evaluation of an Integrated Constructionist Model for Meaningful Online Learning

Gary R. Tucker, PhD
Northern Arizona University, USA
Flagstaff, AZ  Gary.Tucker@nau.edu

Michael Blocher, PhD
Northern Arizona University, USA
Flagstaff, AZ  Michael.Blocher@nau.edu

Shadow Armfield
Northern Arizona University, USA
Flagstaff, AZ  Shadow.Armfield@nau.edu

Abstract: To facilitate this meaningful learning in an online course the course was designed around a model based on the Constructionist Learning Theory. The Integrated Constructionist Model that was implemented was initially developed in a face-to-face (F2F) environment. In the F2F setting, the model was exceptionally successful. However, online environments are often characterized by what Shaw termed as, “social relations that are fractured and social interactions and communications that are strained.” This paper reports on a study that indicates the Social Cultural Environment aspect of the model may reduce its effectiveness in an online environment.

In the Spring of 1999, The Center for Excellence in Education at Northern Arizona University began an online Masters Degree in Educational Technology. One of the required courses for this degree is ETC 567: Education, Technology and Society. As with all online courses, meaningful learning was a primary goal when the course was designed for online delivery. To facilitate this meaningful learning, one aspect of the course was designed around a model based on the Constructionist Learning Theory (Papert, 1990; Kafai and Resnick, 1996). Constructionist theory is based upon the concepts of constructivism but goes beyond in it’s emphasis on artifacts, asserting that meaningful learning happens particularly well when learners are engaged in building external sharable artifacts. In designing this online course a model based upon the constructionist theory was implemented.

The artifact is the goal, but it is the engagement in the building that provides the context for learning. The sides of the pyramid are paradigms that provide the learner the techniques of engagement for ascending to the artifact. The model is based upon the work of Gargarian (1996), Akerman (1996) and Shaw (1996). Gargarian’s (1996) boundary idea, “Freedom in Restrictions,” is the counter-intuitive notion that restrictions provide a learner freedom rather than restraint. Without restrictions, a learner is unable to choose from numerous possible actions and becomes over whelmed and paralyzed. So well defined broad restrictions provide the learner with parameters that result in a sense of freedom to choose a course of action. Akerman (1996) points out that we know from Piaget, Kegan and others (Winnicott, 1971) that the ability to reach deeper understanding also requires moments of separation. People need to get immersed in a creative process, but there also comes times when learners must “step out” and detach themselves from this process. The purpose is for them to become their own observers, narrators, and critics. Then they can “dive back” into the creative process with a new understanding. Both “dive in” and “stepping back” are equally needed to reach deeper understanding. Shaw (1996) points out that social settings are not neutral grounds in which creative activities take place. He emphasizes that the Social Cultural Environment is intimately involved with the process and should not be underestimated. The individual and the social planes are intrinsically linked and when social relations are fractured and social interactions and communications are strained, the social setting is affected and the meaningful learning can be disrupted.

The Integrated Constructionist Model that was implemented into the ETC 567 was developed in a face-to-face (F2F) environment. In the F2F setting, the model was exceptionally successful. However, online environments are often characterized by what Shaw termed as, “social relations that are fractured
and social interactions and communications that are strained.” Does the Social Cultural Environment aspect of the model reduce its effectiveness in an online environment? For example, most students engaged in online learning environments do so alone at their computer where they engage socially with their peers. However, these interactions are mediated through the electronic communication systems utilized within the learning environment. Furthermore, are online courses or programs more attractive to specific types of students based upon the delivery system? For example, do students taking their first online course perhaps thinking they will be studying alone, prefer less social interaction? If so, what do students think about collaborating in the Social Cultural Environment aspect of the model? Although students applying to the M.Ed. online program have suggested that they utilize peer help seeking and peer collaboration as cognitive learning strategies that they employ, do they prefer them?

When asked to rank their feeling of success with this model, 32% of the students reported a positive experience while 32% reported a negative experience, and the remaining 36% were neutral. The ranking was based on a 1 to 5 Likert scale where 1 was extremely negative and 5 extremely positive. Out of an N of 22, four responded 1. When asked to give specific difficulties with the model 75% of these students directly mentioned difficulties in social interactions. Three of the students responded with a 2, and 66% of these directly mentioned difficulties in social interaction. Seven of the twenty-two students responded with a 3, of these 57% directly mentioned difficulties in social interaction. Six of the students responded with a 4 and only 40% of these students directly mentioned difficulties in social interaction. The one student who gave the course a five did not mention any social interaction difficulties. From this preliminary data there is an indication that the social cultural aspect of the model does reduce its effectiveness in an online environment when the social interactions of the students do not develop properly. This would indicate for this type of model to be successful online careful attention must be given to the Social Cultural Environment.

Special Cases: Writing Scenarios for Learning to Teach with Technology

Raven Wallace, Michigan State University, US
Shane Cavanaugh, Michigan State University, US

Teacher education and professional development for teaching with technology have presented many problems for the education community. Teachers need to learn to use technology, but they also need to learn to teach with technology. They need principled knowledge about teaching with technology, but they also need to be able to use the specific technology that is available to them in their schools. Programs have taught general computing skills like word processing or creating Web pages. Others have taught specific software like Hyperstudio or Inspiration. But for a teacher in a specific school with specific software and hardware available, and a curriculum to attend to, the offerings of such programs miss the mark. Being able to create a Web page or use Inspiration may be useful skills in some respects, but they may be entirely inapplicable to our specific teacher's needs.

This study proposes a different approach to professional development for teaching with technology, one that lets teachers use the specific contexts of their own teaching as the content of their professional development. This is done through scenario writing, in which teachers imagine their own teaching with a new technology, and write it up as a narrative, paying special attention to the affordances of technology. They use general principles of technology use to develop and describe plans for their own teaching. These scenarios are then used in the Master's class as the basis for discussion and analysis - they provide a text for the class itself.

The question of this research is this: Can writing cases which imagine and anticipate future teaching episodes help teachers learn to use new tools in their teaching?

It is proposed that scenario writing gives teachers strategies for planning for technology use, as well as for interacting with students as they use computers. It is intended to help teachers develop a frame of mind that allows them to approach teaching with computers in a different way, focusing on the substantive issues of subject matter and interactions with students.

The scenario assignment consists of the following parts: a lesson plan describing the purpose of the lesson, the activities planned, a rationale for using technology in the lesson, and expected outcomes; a narrative describing the lesson as imagined; and reflections on the lesson after the narrative has been written. The narrative is expected to focus on subject matter learning with attention to discipline or classroom management only as it relates to particular issues of using technology. It includes evidence of the following: What the teacher sees on the screen; how she interprets it; how she thinks students will interpret it; what questions students are likely to ask; and how she will respond to those questions.

One rationale for the scenario assignment is that, without some method of stepping back from the moment of practice and considering how best to teach with a particular technology, teachers find themselves in the flow of the classroom doing the things they know how to do best. Their responses in the moment may not be what they would have done if they had time to consider, but these initial responses can establish dispositions that are hard to change, even if they are less than optimal. Thus, teachers may find themselves using routines and strategies suited to working with printed materials, small group discussions, or physical manipulatives, but perhaps not as well suited to the virtual world of the computer. The scenario assignment attempts to give teachers a way to "pre-experience" the chaos of the computer-filled classroom; to anticipate management, subject matter, and pedagogical issues that arise; and to consider how best to handle them.

Teachers in the study (n=19) were students in two sections of a Master's level class focused on teaching with technology in the subject areas. Four academic subjects were included in the class - mathematics, science, language arts, and social studies. Teachers were from elementary and middle school classrooms. Most of the teachers were teaching full-time; others were former teachers pursuing a degree full time. Each teacher developed two (fall semester) or three (spring semester) scenarios during the course. Scenarios were analyzed to identify patterns across teachers, and development in individual teachers over time. The teachers were interviewed after completion of the
class to probe their response to the scenario assignments and their ideas about how the course affected their knowledge of teaching with technology.

**Preliminary Conclusions**
The scenario assignment is very different from retrospective case writing and it had a different impact on these teachers. Several teachers reported using what they had learned from their own scenarios and from the work of other teachers in the class to be more involved with students as they worked on computers and to keep the focus on subject matter. They approached this teaching with new found enthusiasm and confidence even though most of what they had the opportunity to learn in the class came from reapplying their own knowledge and expertise, not from being introduced to new technologies.

The scenarios revealed that practicing teachers may look like novices when technology is introduced: they pay less attention to subject matter and more to management and tools; they focus on their knowledge of techniques (software and hardware); and they downplay their own role in facilitating student learning.
ChalkTalk OnLine

Hilary Wilder, Education Department, College of Saint Elizabeth, USA, hwilder_cdm85@post.harvard.edu
Pat Schall, Education Department, College of Saint Elizabeth, USA, pschall@liza.st-elizabeth.edu
Joel Reiser, Education Department, College of Saint Elizabeth, USA, jdrwcaldnj@aol.com

Abstract: ChalkTalk OnLine is the technology component of the Alliance to Support the Preservice and Inservice Retention of Educators (ASPIRE) program at the College of Saint Elizabeth in Morristown, New Jersey. We are using ChalkTalk OnLine to provide mentoring and support for preservice and novice teachers via web-based message boards and other posted support material and references. Experienced teachers as well as experts in school administration and school law have been selected to be mentors to help teachers with the various challenges that may face them during their first few years. In this presentation we will discuss our experience in setting up this program and findings to date.

Background

The Alliance to Support the Preservice and Inservice Retention of Educators (ASPIRE) is a new program at the College of Saint Elizabeth, currently funded under a Teacher Preparation Quality and Capacity Grant from the New Jersey Department of Higher Education. The ASPIRE program aims to increase preservice and novice teacher retention by providing a series of "embodied" workshops, called Chalk Talks and ChalkTalk OnLine, a mentored on-line support web site for preservice and novice teachers with less than three years of classroom teaching experience.

It has been found that mentoring can help these teachers deal with the many challenges that face them, improving their effectiveness in the classroom as well as their commitment to stay in teaching (Breeding & Whitworth, 1999). It is important to note that ChalkTalk OnLine is not meant as a replacement for any face-to-face mentoring or other supportive measures that the teacher is part of, but rather, to be used in conjunction with these arrangements. While many teacher mentoring programs are more structured and systematically instituted (Newcombe, 1988; Feiman-Nemser, 1996), ChalkTalk OnLine provides an informal arena for any teacher to get opinions and engage in discourse with others outside of his or her school setting. By providing online mentoring that is accessible from any connected web browser, teachers can get support when face-to-face meetings are not feasible (Johanson et. al., 1999; Kerka, 1998).

The ChalkTalk OnLine Web Site

ChalkTalk OnLine is the technology component of the ChalkTalk project and is available free of charge to any teacher who registers. The ChalkTalk OnLine web site uses the Blackboard® learning management system platform. Once a teacher has registered and received a user id and password, they can access the site, which has a Discussion Board section that lets them post questions to the ChalkTalk OnLine mentors. The (paid) mentors we have hired are local teachers and school administrators who are experts in areas such as special education, school law, school management, urban and suburban school needs and conflict resolution in addition to the core curriculum areas of math, science, history and English. We have also selected a few novice teachers as mentors with the expectation that they will offer a unique and similar perspective for new teachers. The mentors receive training in the usage of the web site as well as general mentoring guidelines.
Each mentor manages an assigned discussion forum and responds to questions posted by the teachers. Discussion questions are threaded and open for further response from any registered teacher. A search capability allows teachers to look through all posted discussions for specific topics. In addition, the site has an Announcements section which has news of upcoming events and other relevant news; an Information section about ChalkTalk OnLine and ChalkTalk Workshops; a Documents section of germane resource files; and a Web Sites section with links to relevant government, organization and commercial Internet sites. A Staff Information section contains information about the ChalkTalk staff at Saint Elizabeth and the online mentors. In conjunction with site monitoring, there is also an ongoing "Give us your feedback" survey so we can modify and improve the site as needed.

Current Status

As of this time, the ChalkTalk OnLine web site has been set up and we will be registering teachers. The initial target population will draw from participants of the ChalkTalk workshops and students from the undergraduate and graduate education program at the College of Saint Elizabeth.

Future Plans

We anticipate that word of mouth and mailings to local schools will increase the community as the program continues. We will also be exploring the expansion of this program to include preservice and inservice teachers in Namibia, where one of the authors has worked, in an effort to foster cross-cultural best teaching practices.

Learning to Teach for Understanding in a Technology-Mediated Professional Development Environment

Rodney Williams
Educational Studies Program
University of Michigan
United States
rodw@umich.edu

Abstract: This paper describes a design experiment where I examined whether and how three first-year teachers' ideas about teaching complex subject matter changed as they learned about a new approach to teaching during a six-week technology-mediated professional development program. Findings suggest that although teachers developed new insights into their teaching, their ideas did not change in substantive ways. Teachers' responses to the program according to their entering ideas about teaching, subject matter, and student learning. Demands made on them as first-year teachers, and the design and duration of the program also influenced their responses. A subsidiary question investigated how teachers responded to the technology-mediated learning environment. A report of these findings is the focus of this paper. Despite problems encountered as they used technology, teachers suggested that, with modification, a technology-mediated environment held promise as a tool for professional development. Implications for future professional development programs are discussed.

Introduction

Along with other subject areas in K-12 education, social studies and history are the focus of various reform initiatives. Among these initiatives, new standards designed to facilitate improvement in teaching and learning social studies and history figure prominently. The standards call for new approaches to teaching that result in significant learning outcomes for students. However, until recently, little research has focused on how teachers can learn to teach in ways that standards documents and other reform initiatives claim they should (Putnam & Borko, 2000), with almost no research focused on how experienced teachers can learn to teach social studies in new ways (Newmann, 1990).

In an effort to understand this process, the study described here examined teachers' ideas as they learned about using one theme addressed in standards about civic education in their teaching. The theme, core democratic values, or ideals of democracy, is addressed in various social studies standards documents (Michigan Curriculum Framework, 1996; National Board for Professional Teaching Standards, 1998; National Council for the Social Studies, 1997). A professional development program situated both in teachers' classrooms and in an online technology-mediated environment served as the site for this study. This program was a design experiment (Brown, 1992) where an innovation, a new framework for planning and teaching, was introduced into teachers' practice. It was expected that this innovation might facilitate the development of teachers' insights and shared understandings about new approaches to teaching social studies and history, particularly in the context of civic education and ideals of democracy.

The program integrated several approaches to teachers' professional development that research suggests holds promise for helping teachers learn to teach for understanding. One approach, Teaching for Understanding, a reform-based conceptual framework for teaching and learning (Wiske, 1998) incorporates several elements that are critical for new standards-based approaches to teaching. A second approach, based on research on learning in general, and on teachers' learning in particular, suggests that learning to teach ought to be situated in teachers' practice (Brown, Collins, & Duguid, 1989; Lave & Wenger, 1991; Putnam & Borko, 2000; Wilson & Berne, 1999). Two approaches to professional development that create occasions and environments in which to situate learning to teach are classroom research about one's own practice, and case-based learning. Case learning based on Cognitive Flexibility Theory (Spiro, Coulson, Feltovich, & Anderson, 1988) is especially promising. Other models of professional development suggest
the importance of collaboration among teachers, usually characterized as a community (Wilson & Berne, 1999; Putnam & Borko, 2000; Little, 1993; Lave & Wenger, 1991). Using this integrated model of professional development, teachers collaboratively planned and studied a new approach to teaching and learning social studies.

New communications technologies designed to facilitate teachers’ professional development, and technologies that teachers used to study classroom practice, were interwoven in a technology-mediated environment for this study. The program web site contained a variety of information and links, including links to programs mentioned here, as well as social studies resources. Technologies used for communication included Tapped In (Teachers Professional Development Institute), an online chat environment for teachers which was used for meetings, email, which was used for a variety of purposes, and the telephone, which was used on occasion. ENT (Education with New Technologies), a web site at Harvard, was used to help teachers learn about the Teaching for Understanding framework and to plan their units using an online planning tool, CCDT (Collaborative Curriculum Design Tool). As part of an effort to understand their entering beliefs about teaching about core democratic values, teachers were asked to examine and respond to two examples about such teaching found on the Web; one a hypermedia case study, the other a detailed lesson plan. They examined and responded to both examples at the end of the program as well. To document their research about students’ learning, teachers collected artifacts, including digitally recorded videotape, transcripts, images, and text that we re assembled as hypermedia case studies on CD-ROMs. Although they were not required to do so, each teacher also had students use technology to help accomplish unit goals. This environment offered advantages over conventional approaches to professional development that included the ability to record instances of practice for later analysis and sharing, the use of electronic communication and collaboration to accommodate teachers’ busy schedules, and mediation of distance constraints and problems of scalability usually involved in school-university collaborations.

The Study

This study was conducted in urban and suburban areas of a large Midwestern state. Three first-year secondary social studies teachers interested in advancing their understanding about how to teach about core democratic values participated on a voluntary basis. Lisa Stuart taught 10th grade Civics and Economics at a high school located in an affluent suburb of a large metropolitan area. Kathy Miller taught 9th grade Global Studies West at a high school located in another affluent suburb of the same metropolitan area. Brad Nelson taught 8th grade American History in a middle school located in a working class community in a mediumsized city. All were recent graduates of the large Midwestern research university where I was then a doctoral student and teacher educator. I designed and facilitated the program and participated as a co-researcher. It was hoped that the program would demonstrate that teachers who are separated from each other and from university programs across distances can, with the aid of new communications and collaboration technologies, learn about a new approach to teaching and collaboratively study their classroom practice.

Research focused on teachers’ ideas about how to teach about core democratic values, and their students’ learning. Data was gathered during the six-week professional development program. Teachers constructed, implemented, and reflected on units about core democratic values, as outlined in the state standards (Michigan Curriculum Framework, 1996). For several reasons, including limiting the scope of this study and teachers’ units, and to provide for clarity in the analysis of these activities, teachers focused their teaching on four ideals of democracy - liberty, justice, equality, and the common good. They used principles of Teaching for Understanding (Wiske, 1998) as a conceptual framework for designing, implementing, and assessing the units.

The process was documented with electronically recorded interviews, classroom observations, online discussions, reflective field notes, and hypermedia case studies. Along with discussions about planning and implementing units, teachers also reflected on classroom-based hypermedia case studies constructed with artifacts of their teaching that focused on understanding students’ learning. The hypermedia case studies, which feature videotape of teachers’ teaching, teachers’ interviews with students, and other artifacts of teaching and learning were recorded on CD-ROMs and distributed to program participants. Teachers’ research focused on the study of the cases. Some discussion and activities took place in person-to-person meetings, but most occurred in online synchronous and asynchronous settings.
designed for collaboration and communication. Exceptions were the initial and final interviews with teachers, and most classroom observations conducted by me.

Data analysis involved the description of emergent themes and patterns from observations, interviews, discussions, and communications, and comparative and contrastive analysis of teachers’ ideas about teaching, including analysis of teachers’ ideas about their case studies.

Findings

In this section, I first offer a brief overview of the study findings. Then, in more detail, I report findings about how teachers reacted to and evaluated the technology-mediated environment in which the program was situated.

The data suggest that a lack of in-depth understanding about subject matter and how to teach about it was an important reason teachers responded as they did. Both of these factors were related to teachers’ lack of an informed focus about student learning, and this resulted in problematic outcomes for their own research. In short, the data suggest that teachers’ own entering frameworks for teaching rather than the Teaching for Understanding framework informed their responses. The framework, as it was presented and as teachers interacted with it, did not help teachers develop more in-depth understanding of subject matter, how to teach about it, or to develop an informed focus on students’ learning. Another reason to emerge from the data that explains teachers’ responses was the program itself. As it was designed and enacted, the program did not adequately anticipate or accommodate teachers’ novice status, their busy lives in and out of school, or their status as learners who apparently did not know much about either core democratic values or how to teach about them. Despite flaws in the design of the program, however, teachers may have fared better had they had a deeper understanding of the subject matter, the tools used by historians to investigate history, and strategies to help students make sense of the content.

Both specific technologies and ways in which they were used proved to be problematic during the program. All three teachers had experience using technology before the program began. During the year previous to the program, Kathy and Lisa had been students in a course I taught at the university where they were required to make extensive use of technology, including Tapped In. Brad had been a monitor in a computer lab at the university and appeared to be a proficient user of technology. All three had passed state certification technology requirements for pre-service teachers. They also understood that the program would be situated in a technology-mediated environment. Despite all of this, technology related problems were ubiquitous throughout the program. Some problems were the result of conditions beyond participants’ control such as network and server problems or hardware failures. Other problems, however, resulted from a lack of user proficiency (teachers’ and my own) with software programs used in the program, particularly Tapped In.

Plans for online meetings changed quickly after it became clear that time constraints, and teachers’ busy and somewhat unpredictable schedules prevented them from meeting regularly. After a few problematic initial meetings, teachers suggested that meetings be held one-on-one as needed, a suggestion I heeded. Besides time constraints, there were difficulties associated with the online virtual conferencing environment where we met, Tapped In. Two of the teachers had used Tapped In previously but still had difficulties because of software and connectivity issues, as well as usability issues. At times the conversations on Tapped In were so disorganized that it was hard to figure out who was saying what or when they said it. This seems to be the nature of chat environments though. Without firm structures in place that allow users to communicate more effectively, it seems as though participants in discussions are talking at random instead of to each other. Although I attempted to impose a sort of discussion protocol in one meeting, teachers ignored it.

Lisa encountered problems with technology throughout the program. Our second interview was to be conducted online, but Lisa was not able to logon to Tapped In. After attempting to resolve the problem, we decided to try to have our conversation using email. This worked for a brief time, but a server problem that delayed the delivery of our messages frustrated this attempt as well. Lisa was unable to attend other online meetings because she had not figured out how to access Tapped In through her service provider, AOL™, at home. Lisa also had problems with technology at school. I tried to show her how to access Tapped In on her computer at school but the computer was not functional and had not been for several days. When Lisa asked for my help after looking over the program plan and finding it “bit overwhelming,”
I responded by locating and sending her several online resources to help her think about how to integrate core democratic values with economics. She never mentioned these resources, perhaps because she had not been able to access them online either at home or at school. Only at the end of the program was she able to resolve some of her technology problems. In the final interview, referring to the program, she told me, "... if I would've never had any of those technology problems, you know, it would've been much more of a breeze to me." To what degree these problems actually interfered with Lisa's ability to understand the program and meet its goals is not clear, but it is clear that technology was a formidable problem with which she had to contend.

Kathy experienced technology problems of a different sort. She had an older computer at home that lacked sufficient memory to open multiple windows. This proved problematic when we met for an online orientation session where I intended to introduce her to the Teaching for Understanding and the associated planning tool. Tapped In software allows users to open a web page so that all conference participants can see and discuss the page. Because of computer memory problems, Kathy told me she was afraid to open too many windows at one time, frustrating this part of my plan. In addition to memory problems on her computer, Kathy also found the online planning tool to be confusing and at one point exclaimed that the session was "frustrating." During the final online meeting with all three teachers, Kathy was disconnected momentarily. This caused her to miss Lisa's response to a question, and when she reconnected she continued responding as if Lisa had said nothing. This was not only disconcerting; it also threw the conversation out of synch for a short while.

Brad did not own a personal computer. Since many program activities were scheduled in the evening, it was necessary for me to obtain a computer from the university to loan Brad for the duration of the program. This is obviously not a practical solution to such a problem for programs with many more participants. For an online interview with Brad, I had prepared questions to paste into the text window on Tapped In, hoping to save some time. However, at one point in the interview, because of a glitch of some sort, I pasted in a whole series of questions at once! Brad was overwhelmed and indicated some irritation by asking me to ask one question at a time. He then continued answering a previous question which proved confusing to me since I expected him to answer a different question. Again, this proved to be a frustrating meeting.

It seems that almost every technology problem that could have occurred did occur during this program. A few of these problems included lost network connections, insufficient computer memory, software that didn't work with certain web browsers, server problems that delayed delivery of email, network problems on school computers, computer viruses, software crashes, etc. Teachers were frustrated with these problems, as was I.

Teachers offered valuable suggestions about redesigning the program, including extending the program over a much longer time period (a semester, a year, or two years) so that problems of the sort described here could perhaps be overcome with less frustration. Brad suggested that a much longer program might also promote an environment where teachers could establish a rapport that allowed them to feel more comfortable about talking about their teaching. He also liked the idea of finding someone at a distance to work with since he appeared to feel isolated at his school. Kathy suggested that directions needed to be much more explicit than what had been provided. This was surprising to me since I thought I had provided directions and guidelines that were too detailed. Kathy also suggested that I design planning and assessment tools based on Teaching for Understanding and include them on the program site. She said switching sites was confusing, and that the program should be self-contained. Lisa suggested that programs should be tested for compatibility before using them. Both Brad and Lisa suggested that many teachers are still very leery about using technology and requiring them to use it may be counterproductive.

Despite all of the problems we encountered, and much to my surprise, when I asked teachers at the end of the program whether they thought technology was an effective tool for professional development purposes, they resoundingly supported its use. They all felt that new technologies can provide the means for teacher collaboration and learning about new approaches to teaching.

Conclusions

Despite demonstrating possibilities for teachers' professional development, findings from this study suggest that designing and facilitating technology-mediated environments for such purposes is more
problematic than much of the rhetoric on this subject suggests. For instance, I had assumed that these teachers were proficient users and could use program technologies with little difficulty. I based this assumption on my personal experiences with teachers knowing that they had used at least one of the technologies (Tapped In) previously. I also assumed they had adequate technology resources of their own that would allow them to participate in the program. However, I was wrong on both counts. It cannot, therefore, be assumed that once teachers have used a particular technology a few times that they will remain proficient in its use over time or that they possess adequate resources to participate in such programs. A thorough assessment of teachers' technology skills and resources before the beginning of such programs needs to be undertaken so that teachers have an opportunity to learn technologies they are not familiar with and obtain resources needed to participate. Findings from this study also suggest that the technologies used in the program were far too complicated and that valuable time was expended on solving problems associated with the technology that could have been used more productively. These conclusions are not meant to discourage the idea of using technology-mediated environments for professional development; rather, they are meant to inform future development of those environments.

Content-Based Teacher Education

Marisa Wolfe, New Mexico Tech, US

New Mexico Tech, home to the Very Large Array, Energetic Materials Research and Testing Center, Langmuir Laboratory for Atmospheric Research, and other first class, nationally renowned research centers, offers teachers the opportunity to earn an advanced degree working side by side with the scientists of these institutions. The Master of Science Teaching (MST) Program emphasizes, not pedagogy, but hands-on experiences and content-based courses for teachers of all math and science disciplines.

Began in 1969 to address the needs of New Mexican science teachers, the MST Program has thrived and grown to address the needs of teachers in five states and two countries. Courses are delivered through a variety of methods – intensive two-week on-campus sessions, field experiences, laboratory research, independent projects, and distance delivery. On-line chat rooms for each course and a general science-teaching listserv promote discussion and solidarity among students. Two full time program staff members on campus provide advocacy and administrative support for the students.

The hectic nature of a teacher's life requires practical, useful experiences in their continued education. Through required curriculum development, joint research projects, and special programs, the MST Program strives to offer education teachers can immediately transfer to their classrooms. In essence, the students learn from the program as their teacher learns from the professor.

Through participation in this institutional session, conference-goers can learn more about New Mexico Tech's Master of Science Teaching Program. Selected course material, student work, special projects, and program outlines will be on display.
Faculty Guidelines for the Video Development Process

Ronald J. Abate
Cleveland State University, USA
r.abate@csuohio.edu

Kathleen Benghiat
Cleveland State University
k.benghiat@csuohio.edu

Abstract: Original video materials have been employed in undergraduate and graduate teacher education courses at Cleveland State University (CSU) for the past thirteen years. These videos include K-12 teacher and student use of technological tools as well as traditional methods of instruction. This paper provides a brief rationale for implementing video materials in pre-service and in-service education courses and outlines a process for faculty to follow when they undertake production of video materials.

Introduction

Video can demonstrate how materials, strategies, and lessons can be implemented in the classroom. Historically, video has provided a mechanism for bridging theory and practice in the classroom. (Abate, Atkins, Hannah, Benghiat, & Settlage 1996). In addition, video may furnish focused learning opportunities because edited video affords a quality control mechanism not available in traditional field placements. Video used in conjunction with computers has proven effective in "anchoring" instruction in real problem situations and thus improving student comprehension of content, and problem solving abilities (The Cognition and Technology Group at Vanderbilt, 1990). The increasing connection between video and computers is making it easier for non-professionals to produce and implement video-based materials in the classroom.

Video tape is a relatively mature technology but digital video cameras, non-linear editing, and mass storage devices have only recently become sufficiently inexpensive for non-professional use. The availability of simple-to-use video production and post-production tools is making it possible for faculty to create effective video based instructional materials. However, the availability of sophisticated video editing software, though necessary, is not sufficient for creating high quality video.

Simplified Video Development Process

Thirteen years of video production at CSU have led to an understanding of the key components for the production of video by education faculty, in particular, faculty with little or no experience in video development. Video pre-production, production and post-production include both conceptual and practical/technical steps. These steps compare favorably with the steps of the writing process (pre-writing, creating drafts, and revising and editing) and this similarity provides an understandable context for faculty new to video development.

Pre-production steps analogous to pre-writing include generating ideas, scripting and organizing. The generating ideas step tends to be intuitive to faculty since most enter the development process with a distinct idea of the story they wish to communicate via video. Scripting matches nicely with pre-writing in that it requires the creation of drafts. However, not all scripting is text based. Within the simplified video process model, faculty "script" in broad strokes 1) the events that they anticipate transpiring during video recording, 2) the order of each event, and 3) the purpose or focus of the event. Once these conceptual components are documented, the organizational step focuses on technical issues revolving around the people and equipment required by the script.
To begin organizing, a checklist is suggested to document the practical and technical pre-production issues essential for post-production success. These issues include: 1) recruiting teachers and classroom settings, 2) providing and collecting model clearance forms, and 3) visiting the classroom site. The recruitment of teachers and classrooms is straightforward as faculty members regularly begin the video development process with specific teacher candidates and classrooms identified. CSU has a standard model clearance form, and historically over 90 percent of parents have given permission for their children to participate in classroom video recording. However, arrangements for non-participants must be resolved prior to production. During the site visit, the faculty member documents the physical environment of the room including participant locations, the projected flow of the classroom activities, and the location of power, light and audio sources. From this documentation, the faculty member tests potential camera placement locations. By the conclusion of pre-production, the faculty member has a sensible plan for video production, which may be analogous to an outline or graphic organizer for a written piece.

Whereas a writer has control over temporal constraints and may develop numerous drafts, the videographer has a single opportunity to record events. As such, to provide opportunities for numerous drafts during production, the videographer must record events from multiple perspectives. Thus, a two-camera arrangement is recommended. One camera is placed in a location to capture a wide shot of classroom events. A second camera is placed outside of the line of sight of the wide camera to capture medium and close-up shots of the participants. This simple arrangement makes it possible for a single cameraperson to capture a comprehensive record of classroom activities.

To improve the opportunities for success during K-12 classroom videotaping, CSU faculty members are provided with a list of do's and don'ts. Audio quality is a major focus in this list as it is a frequently overlooked aspect of video production by novices. To compensate for the limitations of consumer quality cameras, a wireless microphone receiver can be connected to one camera. The wireless microphone is usually worn by the teacher since much of classroom audio is conveyed through or to the teacher. An alternative arrangement is to connect a directional microphone to the wireless and vary its location in the classroom according to the focus of the lesson. This method is frequently used for recording interactions of student group work.

Revision is the cornerstone of process writing and it is equally important in video post-production. Viewing footage and logging video segments remain prerequisites to editing despite advances in non-linear editing software. However, the ability to cut and paste video clips has proven to be a tremendous advancement for novice video developers. It is now possible to return to finished works and make substantive revisions. Working on one's desktop has further simplified the revision process by eliminating the need to schedule dedicated facilities. Also, desktop editing places the faculty member in direct control of the finished product. Novice faculty video producers at CSU have benefited greatly from workshops that guide them through the video production process from first idea to final product, much like a process writing workshop.

Conclusion

The technologies of digital video and non-linear editors are making it possible for faculty members with little or no experience to produce instructional video materials. Guidelines for pre-production, production, and post-production simplify the process for novices and increase the likelihood of successful video development. Videos developed via this approach may be ephemeral and not of broadcast quality, but they fill a niche for teacher educators who heretofore have been limited by developmental costs and the limited classroom video market. For guidelines on the video development process visit http://mimic.ed.csuohio.edu/video.html.

Evolution of an Online Graduate Course in Educational Multimedia

Peter Albion
Department of Education, University of Southern Queensland, Australia, albion@usq.edu.au

Abstract: Online education is relatively new and effective course designs are still emerging. A course that was originally offered successfully with small groups has evolved into two courses, which seek to achieve similar goals with greater scalability using divergent designs.

Online courses take different forms. In some cases the term may signify little more than a web site supplementing standard classes. In others all aspects of a course are handled online. As educators seek to develop online formats that work in their particular circumstances, sharing of experience with online courses is an important source of information. This paper describes the evolution of a course in interactive multimedia design offered by the University of Southern Queensland (USQ). In the USQ context, an online course is one where all interactions among teachers, learners and instructional materials occur online.

The course title is Creating Interactive Multimedia but it will be referred to by its code, 81530. The author has been responsible for design, development and teaching of 81530 since December, 1998. From 1997 to 1998 the course was developed and taught by others (Kirkwood & Ross, 1997; Lefoe, 1998). The first few offers of 81530 during 1997 and 1998 were to small groups ranging in number from 6 to 12.

The initial design of the course has been described as an example of a constructivist approach (Lefoe, 1998). It was presented as a simulation in which the teacher, Dr David Ross, acted as CEO of a company in which the students were members of a project team. The team was required to conceptualize, design and prototype a multimedia product for offer on the web, beginning with development of a business plan and culminating in a product launch. The course website was intended as a supplement to a textbook. Its skeleton structure included audio messages from the CEO, a skeleton structure and links to web resources. The core of the course was in the interaction among the group mediated by newsgroups, electronic mail and a weekly IRC meeting with the CEO.

The innovative design of the course attracted strong positive reactions from students and others who were exposed to it during the first couple of offers. However, the activities, which worked well with groups of up to 12 students, were not easily scalable. Moreover, the course was strongly dependent upon the personal style of the CEO. When, in the second semester of 1998, he was unavailable and enrolments rose to 30, the overall experience with an alternate leader proved less satisfactory for some students.

The author became responsible for 81530 in the following semester. Its key strength appeared to be the interaction around a common project, which served as a focus for learning. The principal deficiency appeared to be in the course materials, which were little more than a list of links to support the project work. There were concerns about the dependence of the course upon a particular personal style and its scalability if enrolments continued above 15.

Brief instructional modules were written for each core topic. Because the textbook provided most of the content, the materials were produced as a commentary on the text with links to supplementary resources. The design retained a group activity focus in assessable project work. Of three assignments, only the second, weighted at 20%, was an individual task. The first, also weighted 20%, was a WebQuest (Dodge, 1997) about tools for creation of web-based multimedia, for which students were arbitrarily assigned to groups by the course leader. The third assignment required students, individually or in self-selected groups of up to 5 or 6, to propose, design, develop and evaluate a prototype for a web-based multimedia project and report on the process. This task retained the essential group activity from previous offers but, because the entire class did not collaborate on a single project, it was expected to be more easily scalable. The report requirement provided opportunity for students to demonstrate a grasp of more than the practical skills as was appropriate for a course in a masters program. The course was offered as described, with minor adjustments reflecting accruing experience, during each of five semesters in 1999 and 2000. Enrolments in the various offers were 9, 12, 7, 37 and 13. Over that period the typical composition of the classes changed to include a greater proportion of classroom teachers rather than industry trainers or instructional designers.
An issue that emerged related to group work. All of the students were part-time, most were in full-time work, and most were enrolled through a program which had a policy of permitting individual students to delay submission of work for up to a full semester thereby making it difficult to form effective groups (McLendon & Albion, 2000). In the first minor revision, group work was made optional. Thereafter most students chose to work individually.

A second issue arose from the requirement for students to propose an original project. It seemed that indecision about their project caused some students to delay their proposal and hence completion of the course. Many students selected current work projects, which had the advantage of being realistic and relevant but were prone to restrict students’ opportunity to demonstrate their learning because certain forms of media were not justifiable in terms of the real project. A further consequence was wide disparity in the standards, both in difficulty and performance, of work submitted for assessment. Ensuring comparable assessment under these conditions was very difficult.

Finally, it was apparent that students found difficulty in meeting both the practical requirements of the project and the more theoretical demands of the reflective report. Most concentrated their efforts on the practical elements, which contributed equally to the assessment and were often directly related to their employment. As a consequence it was difficult to maintain the level of theoretical treatment required to justify inclusion in a masters program.

In revising 81530 for the 2001 offer, it was decided split the course. The 81530 course continued with the practical orientation implied in the course title. A new course, 81537 Multimedia Applications in Education, was created to deal with the theoretical aspects of educational multimedia.

Much of the course material from 81530 was retained but the open ended project work was replaced by a series of carefully sequenced required exercises. This approach was adopted to avoid the difficulty experienced by some students in selecting a suitable project and to ensure that, so far as possible, all students would gain a similar range of basic skills in multimedia creation. Activities were structured so as to allow students to reuse content once they had created it and to complete similar activities using different tools. In one example of such a sequence, students write a haiku, set it as text in a font of their choice and convert the text to an image for display in a web page. They subsequently embellish the image, animate it and record their own voice reading the haiku mixed with music or sound effects. The sound and image(s) are then presented first as a QuickTime movie and later using Macromedia Flash. This process affords students opportunity to practice a variety of skills without needing to generate large volumes of content and to compare the capabilities of various multimedia tools. Assessment of these components is by presentation of an online portfolio based on the individual activities.

The 81537 course is distinctly different. Students are provided with a variety of readings and are asked to prepare a proposal for a paper to be delivered in an online conference. The proposals are graded and students are each required to provide anonymous peer reviews of two proposals. The reviews are also graded. Using the grading and reviews for guidance, students complete their papers, which are presented online and used as the basis of discussion over a two week conference period. As a final activity students are required to select 8 to 10 papers from the conference and write an introduction to their collection. The design is intended to ensure that students have opportunity to pursue a topic of individual interest at depth as well as a requirement to gain broad familiarity with the field.

Both 81530 and 81537 have been offered during 2001. Student evaluations reported strong satisfaction with most aspects of both courses. Issues emerging in the earlier version of 81530 appear to have been successfully addressed.

Abstract: The concept of virtual teams is relatively new. However, a virtual team, like any other team, progress through various stages of development and is dependent upon the clarity with which performance outcomes and goals are communicated for achieving success. This presentation focuses on the analysis of the transcripts of on-line meetings of a PT3 virtual team composed of subject area team leaders and project administrators. The lessons learned from this experience helped develop an understanding of the role that clear communication and trust play in building bridges across the digital divide. Lessons from practice will include Internet Field Trips.

The St. Thomas University Plan to Bridge the Digital Divide in South Florida

A consortium of schools with St. Thomas University in Miami, Florida as the lead partner was awarded a PT3 Capacity Building grant during the first year of the PT3 program. The teacher education program at St. Thomas University serves students of many ethnic groups. It is located in an urban area with a large African American population along with immigrants from many Hispanic countries and the Caribbean.

The purpose of the initial grant was to work with area elementary schools, such as Welleby Elementary, to train the pre-service teachers at St. Thomas University and Trinity International University to use computers effectively in classroom instruction and thereby impact the diverse students in Miami-Dade County. The grant sought to train teachers who will not only teach in the inner city schools but stay in the inner city schools. By serving pre-service teachers who represent these underserved populations, the program sought to impact inner city classroom instruction.

What Has This Program Accomplished?

All of the program objectives were met in the first year and a three-year PT3 Implementation Grant was awarded the following year with more partners, including Florida Gulf Coast University and Golden Glades Elementary. The purpose of the Implementation grant changed the focus from the pre-service teachers to a team of professors, pre-service teachers, and K-6 teachers. It became apparent that, in order to effect systemic change, it was essential to train the professors. It was also essential that practicing K-6 teachers become an integral part of the process. Golden Glades Elementary, located several blocks from St. Thomas University, is a school with a student population that is completely either African American or Black American from the Caribbean. Florida Gulf Coast University is the newest Florida State University located on the West Coast of Florida and equipped with the latest technology in each college classroom.

How Did the Virtual Teams Work Together?

Subject area teams of professors, pre-service teachers, and K-6 teachers were formed. The teams focused on Math, Science, Reading/Language Arts, Social Studies, Exceptional Student Education, Curriculum, General Methods, and English as a Second Language. The focus on ESOL is important in Miami-Dade County because all teachers who are hired must also be certified to teach ESOL because of the large number of immigrant children attending school in Miami-Dade County.

During the first year, each team communicated on-line weekly. They met to discuss both successes and failures in their attempts to integrate technology into their classes. They also completed 50 hours of professional development in technology. In
the second year, they worked together as a team to write and field test technology integrated lessons. It was determined that the convergence of learning that takes place in the classroom can be written in detail through lesson planning. The professors and pre-service teachers would begin their attempts to integrate technology into the curriculum with written lesson plans. With assistance from a new partner, BEACON, which hosts an on-line database of lessons, from Bay County, Florida, the professors and pre-service teachers worked together to write lessons that are field tested in the K-6 teacher’s classrooms. In this process of working together, the professors and pre-service teachers learned about the technology available in the partner schools and the classroom conditions such as class size, high stakes testing pressures, and behavior management concerns that they need to consider as they write their lessons.

How Important is Technology Support?

The participants in this program have benefited from expert technology support. The support they have received seeks to decrease reliance on outside sources by empowering the participants to do things for themselves. The effort will be sustained when the federal funding ends as the participants learn enough about technology to be self-sufficient. Instead of the technology support specialist holding the mouse while others stand amazed, the learner maintains control of the mouse. The process is similar to learning how to drive. The technology support specialist is there to assist and direct, but encourages the learner to take charge.

Why is it Important to form a Collaborative?

The fact that this grant is applied for and awarded as a collaborative can serve to strengthen the work effort and bridge the digital divide. In the first year of Implementation, a cost share crisis developed for the collaborative at St. Thomas University. Two of the original partners, Trinity International University and The 21st Century Teacher’s Network, dropped out of the program; their cost share commitment was lost. St. Thomas University also had a problem with resources whereby they were not able to meet the cost share they had committed. Because the PT3 program requires a matching commitment of funds, officials at St. Thomas University temporarily suspended the grant program until documentation of cost share could be established. This was where the title of the grant, “Bridging the Digital Divide in South Florida,” became the reality of what happened. Representatives from Florida Gulf Coast University were able to supply the missing cost share. Other partners responded in the same way and contributed more than they had committed in the grant application. In this way, the digital divide was bridged because those on one side of the digital divide were able to rely on their partners to help them in a time of need.

On-Line Presence

Information about our project may be viewed at: http://garnet.fgcu.edu. To view these discussions, one may register for the PT3 Fall and/or spring courses and create an identity. Once this is done, posting will be enabled for the viewer. Our website also contains information that documents our workshop activities with our partners. Our website is located at: http://coe.fgcu.edu/PT3/home.htm.

Case Study: Internet Field Trips with Dr. Joseph Furner

Internet Field Trips in Mathematics are exciting. There is a need for technology use in mathematics teaching. This is emphasized in the National Council of Teachers of Mathematics Standards. There is a wealth of websites available for teaching math concepts using the Internet. Dr. Joseph Furner from Florida Atlantic University has participated on the Math team. His role as professor and lesson author has enabled him to produce lessons that can be used by his future teachers. He will present some sample lessons he has written with websites that are available on BEACON at www.beaconlc.org.

National Educational Technology Standard-Based Lesson Plans Are Written

The technology enhanced lesson plans for the Fall 2001 Semester are written and can be viewed on the BEACON database. The website for BEACON is www.beaconlc.org. Selected lessons will be shown at this session.
Technology In The Classrooms: New Designs for Learning

Dr. Gerald W. Burgess  
Educational Technology Training Center  
Albany State University  
gburgerss@asurams.edu

Abstract: New learning technology implies a "new" way of learning. Yet, the reality is that much of what is taught using technology is being done in the same "old" way. Conventional classroom instruction may require teachers and training developers to rethink their approach to instruction. New millennium teachers and school leaders must have sufficient technology expertise to integrate technology into meaningful learning paradigms. The impact of technology on teaching, instructional delivery and school reform will require knowledge of technology as a cognitive tool which when used skillfully can bring diverse learners to higher levels of academic achievement and significantly change the way learning communities are developed. This paper revisits the instructional design process as a tool for integrating technology into the classroom.

Introduction

New learning technology implies a "new" way of learning. Yet, the reality is that much of what is taught using computers and multimedia is being done in the same "old" way. Making a paradigm shift regarding learning processes is not easy (Kahn, 1993). Conventional classroom instruction may require teachers and training developers to rethink their approach to instruction. Today's educational reform is based on student-centered teaching and learning in an environment not usually supported by the more traditional uses of computer technology (Morrison & Lowther, 2002). The 21st century information technology explosion and increasing demands for accountability for teaching results, are changing the way 1) schools are responding to learners and 2) preservice teachers and school leaders are being prepared for the classroom. New millennium teachers and school leaders must have sufficient technology expertise to integrate technology into meaningful learning paradigms. The impact of technology on teaching, instructional delivery and school reform will require knowledge of technology as a cognitive tool which when used skillfully can bring diverse learners to higher levels of academic achievement and significantly change the way learning communities are developed. Learning, at all ages, should follow a model that more resembles real life (Kahn, 1993). Morrison and Kowthler (2002) state, "Using computers as tools can help teachers create a student-centered learning environment. Students create an understanding of the world that will lead to the development of knowledge." Using technology to expand both teaching and learning broadens the teacher's view as well as the student's view of the world. History may be taught in the context of events that shape the evening's news.

Learners learn by experiences in a real world, problem-oriented approach and it is on that premise that a design for functional learning for staff, faculty, and students should become reality. Schools using technology, especially those teaching technology, should lead the way in their design and implementation as a model for other schools. The design should have more to do with how students learn, and less with hardware.

What is suggested here is that student-centered learning is favored over teacher-directed learning. This does not mean the teacher is excluded from the learning process. "The primary mode of teaching switches from one of lecturing to one of facilitating student investigation. Teachers work as facilitators and tutors to help students understand the material and to provide
the necessary scaffolding (Morrison & Kowther, 2002). Further, when students are actively engaged in the learning they are more motivated and remain engaged longer than when in a teacher-directed approach. Establishing activities through the use of technology that allow for the learner to be self-directing and problem-centered increases the likelihood of the effectiveness of the learning.

**Issues Confronting Reform Efforts**

*Teachers report little or no use of computers for instruction.* Despite the growing numbers of computers in the classroom and the increase in available training, teachers are still finding it difficult to use the computer as part of their classroom delivery of content. Teachers have found their time to be very valuable and scarce (Mollison, 2001). What time is not spent on lesson planning is spent on grading, and that time not spent grading is other administrative duties. It is small wonder teachers can't find time to develop new or different instructional materials using technology they either don't have access to or don't know.

However, technology as a resource can help teachers cope with a growing paperwork load. Schools, businesses, and organizations have recognized that if they spend less time on record keeping and preparing materials, they can spend more time on productive endeavor (Roblyer, et al. 1996). Teachers can become more productive as they are trained in the use of technology and can gain quick access to information to help them and their students by meeting individual needs. Areas such as, word-processing, spreadsheets, databases, grade books, graphics, desktop publishing, online-communication, and test generation and scoring are just some of the few technology-based outcomes used to increase productivity.

*Using technology can change the way teachers teach.* Students need mentors with whom they can have effective dialogue. Approaches to constructive knowledge are full of alternatives. At any one time an individual may not be aware of all the alternatives. A negotiated discourse can enhance the student's capability to be a divergent thinker and more creative in nature. The teacher can play this role of a mentor and manager of this dialogue. The teacher directs the individualization and metacognitive skills to help the learner through the learning process (Atkins, 1993).

*Increased communications is one of the biggest changes technology offers classroom teachers.* On-line communication between teacher and student, teacher and parent, teacher and teacher, and teacher and information expands the dialog necessary to be effective. Let us not forget that teaching is still a human activity. Technology can offer considerable data, considerable of bits of information, considerable of interesting ideas, but if that information cannot be shared, discussed and used, it is lost. It is through this human interaction that ideas become creative thought and creative thought becomes a new product or service for humanity.

*Helping teachers use technology effectively.* Instructional Technology is a systematic way of designing, carrying out, and evaluating the total process of learning and teaching in terms of specific objectives, based on research in human learning and communication and employing a combination of human and nonhuman resources to bring about more effective instruction. Having said that what contributions has technology made to teaching and learning?

One factor is that *instruction can be more standardized.* One section or one class taught by several teachers can have the same thread of knowledge by using technology.

Because of the various elements of color and motion, learning can be *more interesting.* We can go places with video that would be too costly or too dangerous for our students. Yet, they can have the same vicarious experience as being there.

Though the use of computers *learning becomes interactive.* Students can make choices and respond to those choices.

*Learning time* can be reduced. Much research has been done in this area. Although there still remains some questions as to specifically why time is reduced, student learn faster when using technology...and perhaps as a result the over all *quality of learning improves.* We find, for example, that teachers take care to develop high quality overhead transparencies and other materials for student use that has been fully integrated into the learning process.
Students have positive attitude toward technology. They simply like using technology. There doesn’t seem to be an age restriction on these learners at all levels like using the various types of technology.

Finally, the role of the instructor changes from the possessor of knowledge to the facilitator of the learning environment. Teachers are free to develop instruction and to spend time with students in small groups, helping the ones who need help and enriching the ones who can absorb more.

A Conceptual Plan

According to John Hortin (1988), technology should be seen as a convenient instructional and informational delivery system... Technology is indefatigable, patient and objective; technology allows for individualization; and it is self-directive and interactive (p. 217). A teacher’s time is more efficiently applied through the use of technology. Technology can address the variability of learners and deliver selective, up-to-date, specialized topics. Technology today has made us reconsider instruction and identified the teacher’s new role. One solution toward improving the quality of interactive courseware is to involve teachers in the development process. The solution to the confusion over which strategy to use is to develop courseware that parallels the way teachers teach. Educators need to rethink approaches that have more to do with getting students actively engaged in the learning, like simulations, where the learning grows as the students reason through and solve each step of the puzzle.

Strategies for Planning Lessons

In planning technology-connected lessons, teachers need to keep in mind that technology is a tool that supports instruction. Teachers should view technology as a cognitive tool, which has the potential of reinforcing instructional concepts and encouraging inquiry-based learning. Technology connected lesson planning must take into account the teacher’s teaching style, approach to learning, and goals for instructional outcomes.

The strategies outlined below will help teachers formulate their thinking as they consider developing technology-connected lessons:

1. Teachers should think creatively about the lesson and ways to enhance learning with the use of technology.
2. Teachers should focus on developing the critical thinking skills of students and how technology can stimulate this process.
3. Teachers should encourage students to take ownership and responsibility for their learning and how technology can encourage this independence.
4. Teachers should plan lessons that respond to the variety of ways students learn and use instructional support tools beyond the chalkboard and overhead projector.
5. Teachers should view technology as a rich resource to expand the boundaries of time and place when presenting instruction.
6. Teachers should encourage collaborative and collegial learning and use technology to support out of class interactions among students.
7. Teachers should help students learn how to learn by accessing the vast knowledge base that is accessible through computers.

These new roles require thoughtful reflection on the part of the teacher as to what is taught and how what is taught can be enhanced and supported through technology integration. How many times have you sent your students to the computer to accomplish a task and they end up playing, or becoming involved in the bells and whistles of a computer program instead of focusing on authentic learning?
A good way to overcome this is by planning for technology-connected lessons. This is an overwhelming thought for teachers who have had little experience with technology or who have had little technology training. The place to start is with the curriculum – the teacher’s expertise. Technology-connected activities should be based on ideas and concepts that the teacher is teaching, with the activities being of critical importance to what students need to learn. As plans are developed, technology is used as the tool or the vehicle for acquisition, organization, evaluation and application of knowledge.

The use of technology is not an end state but an integration of instructional planning and learning strategies. Teachers should be able to conceptualize the curriculum and the connecting parts including the activities that make up the daily teaching events. This process is a systematic development process around the learning theory or integration model followed by the individual teacher. However, at the core is the focus on what the student should know and be able to do. As a result of this thinking has come the establishment of technology and teaching standards, which are only part of the story. Reiser and Dempsey (2002) define the instructional development process this way... "The instructional development process encourages teachers to align goals (or objectives), tests, and teaching and to formatively evaluate and revise their test and instructional practices (Reiser & Dempsey, 2002). Teachers are then able to integrate teaching strategies and technology that is a "best fit" for the student.

The Instructional Development Process in Brief

In reviewing an instructional development process, the focus should be on the outcomes from each step. Each outcome provides the teacher with information or a product that directly affects the classroom environment. Teachers are then in a better position to make decision about instructional strategies and the integration of technology.

Analysis - a step to determine what to teach, where to teach, and who is going to be taught. The main purpose is to find out what the learner needs and what skills and knowledges are needed to accomplish that task or assignment. Collection of prior year’s test scores or a pre-test may provide this information causing an acceleration or review of course materials.

Design - the way we’re going teach in groups or individually. A target population description describes the student in terms of mental and physical requirements necessary or prerequisite skills, knowledges, and attitudes. Such information gives the teacher a collective view of this group of students. Objectives are written that capture what the learner will be able to do upon completion of instruction. Test questions are written during design. To ensure that tests adequately measure the objectives they support, the performance required in the test should match the performance required in the objective.

Development - the curriculum plan and materials to carry out instruction. The development phase is as the title suggests, the point where the instructional materials are written and assembled. The first step is to prepare a syllabus. A syllabus serves as the general plan for conducting instruction in a particular course and ensures standardization of the instruction while controlling the quality of the teaching-learning activity. The syllabus will also list for the student the references, tools and equipment, and the sequence of learning. For the teacher, the syllabus helps organize and sequence the material in a single document where lesson plans, computer technology, including the use of the Internet, and instructional materials are itemized.

Implement - to teach what we say were going to teach in an environment conducive to learning. Implementation involves the actual teaching of a unit, a lesson, or a group of lessons. Although important to the evaluation phase, the actual teaching is evaluated with input back to the design or development phase, whichever is appropriate.

Evaluate - looking at what you did, how you did it, and can you improve it. Collectively each step results in producing a syllabus, lesson plans, student materials, testing materials necessary for
instruction. Evaluation is a continuous process that assesses how well course graduates are meeting the established job performance standards. The focus of evaluation is to improve the quality of instruction. It is that opportunity for the teacher to review what he or she did and make improvements for the next session.

Summary

Returning to the original theme, the integration of technology will require instructional development process with clear stated goals and objectives that give the teacher and the student clear direction in the learning. The impact of technology on teaching, instructional delivery and school reform will require knowledge of technology as a cognitive tool which when used skillfully can bring diverse learners to higher levels of academic achievement and significantly change the way learning communities are developed. As teachers apply technology, new ideas will develop and student’s use of the technology grows. As students within both traditional and virtual ‘classrooms’ make greater use of the interactive power of computers (e.g. computer mediated communications and Internet) the boundaries between traditional education and technology-enhanced education are becoming blurred. We can see that technology continues to advance while what we are calling “traditional” instruction has yet to follow. Many classroom presentations are still in the lecture format and have not taken advantage of the available technologies. The gap will be bridged as teachers use the technology to create a student centered learning environment joined by a developmental process that clearly identifies what is to be learned and the outcomes of that learning.

Floating with the Astronauts: Integrating Curricular Elements Through Partnerships with NASA’s Educational Support Systems

Chris Chilelli, NASA, US
Caroline Crawford, UH-Clear Lake, US

Viewing live maps of the Earth from satellites millions of miles above the earth, watching the weather formations move across the United States of America, viewing starscapes and galaxies, talking with astronauts about different missions, looking at different aspects of the planets in our galaxy. So many interesting aspects that can easily be shifted towards opportunities for information within the PreK-12 learning environment. The National Aeronautics and Space Administration (NASA) realized that the data gathering journeys throughout the galaxy offered opportunities for real-world educational endeavors to PreK-12 and higher education learners. Educators could easily integrate NASA’s information into useful objective-driven tools which would not only offer real-world data structures with which the learners can work, but can also enliven theoretically-driven knowledge environments and make the learner’s level of understanding exponentially expand when viewed through the eyes of NASA’s elite researchers and scientists. Numerous subjects within the PreK-12 curricular areas of study could be impacted by NASA’s educational endeavors, such as science, mathematics, English, and is especially useful when curricular advantages pertain to cross-curricular methods of subject-specific instruction. The educational entity at NASA Johnson Space Center offers opportunities for education-related organizations to work with real-world data structures and to view live, as well as digitally videotaped, educationally relevant sources of interest. The curricular elements that educators desire are designed and developed using the desires and lesson objectives specific to the needs of the learners, with the NASA partnership designed to focus upon higher order thinking skills and real-world impact upon the learners. Examples of NASA’s educational support systems and partnerships will be further delineated in the proceedings paper as well as the presentation.
Educational Technology Learning Plans for Student Scaffolding

We all know that lesson plans are introduced to initial teachers as an initial management tool for self-scaffolding organizational learning, but little work has been done to identify what defines the critical thinking process underpinning the instructional design of Educational Technology-assisted scaffolds for individualized student learning. Our research project has investigated and developed a pedagogical protocol for the practical classroom implementation of Learning Plans as a personal task-management scaffold for student-centred learning. The teacher's role in enabling self-organized learning for large groups of students can be achieved through the deployment of Technology-based Learning Plans, which converts teacher-centered curriculum management into student-centered learning tasks suitable for application both inside and outside of the classroom. This paper briefly considers the pedagogical practice behind this innovative curriculum reform initiative in the context of a recently completed research project in Singapore.

Overview of Learning Plans as Critical Thinking Scaffold Templates
Many countries throughout the world are currently investing heavily into implementing Educational Technology policies across the elementary, high school and tertiary sectors. The general belief is that computer learning resources can be a beneficial method toward implementing a more student-centred curriculum (Coombs & Wong, 2000). Many countries in south-east Asia, including Singapore, have national educational policies for implementing both Information Technology (IT) and critical thinking into the high school curriculum. The Singapore Ministry of Education considers that one way of achieving both these targets is through the curriculum adoption of student-centred project work (Ministry of Education, Singapore, 1999). The pedagogic quality and rationale of IT project-based courseware as a learning resource to support and improve the educational National/State curriculum is thus of considerable importance. It is our contention that project work can be delivered through a critical thinking schema that we call Learning Plans (LPs). These Learning Plans can be combined with a Personal Learning Contract (Coombs & Lee Looi Chng, 2001) and used to deliver a student-centred S-o-L curriculum - see figures 1 & 2.

Learning Objectives
By the end of this workshop, you should be able to:
1. List examples of evaporation.
2. Infer that when water evaporates it goes into the air as water vapour.
3. Explain how wind affects the rate of evaporation.

Tasks 1 and 2 are to be completed with your partner. Complete Task 3 individually.

**TASK 1: REVIEW OF CONCEPT**
Collect the resource basket from the teacher's desk and take 20 minutes to complete Task 1.

- Study the photographs:
  - Sample A: Drying of puddles of water
  - Sample B: Drying of vegetables, fruit
  - Sample C: Drying of deserts

Record your answers in the worksheet attached.

- Identify what's common amongst the photographs.
- What process has taken place?
- What has taken place?
- What improvements are needed?

**TASK 2: FACTORS AFFECTING THE RATE OF EVAPORATION**
Task 2 is an activity in which you will determine how wind will affect the rate of evaporation. You have 35 minutes to complete Task 2.

1. In the basket, you will find two handkerchiefs. How are they alike?
2. Wet the two handkerchiefs completely.
3. Hang the two handkerchiefs in the classroom on the line provided by your teacher.
4. Note the time on the clock and record this in the worksheet.
5. Use a fan to blow on one of the handkerchiefs for 10 minutes.
6. At the end of 10 minutes, stop the fan. Record the time in your worksheet.
7. Feel the handkerchiefs and record your observations about the wetness of the two handkerchiefs.
8. Record the time.
9. Continue blowing at the same handkerchief for another 5 minutes.
10. Feel the handkerchiefs after 5 minutes. Record your observations.

**TASK 3 BONUS ACTIVITY: USE OF CD-ROM**
1. Complete the quiz in unit 3 of the CD-ROM.
2. Record the time you took to complete the quiz and your score in the worksheet.

---

---

**Figure 1: Personal Learning Contract**

**Figure 2: Learning Plan**
When LPs are combined with an online learning environment that scaffolds learner thinking, we have what Coombs refers to as a "Knowledge Elicitation System (KES)" (Coombs, 1995, 2000 & 2001) and what Jonassen (1996) describes as a "Mindtool". Critical thinking scaffolds are explained by a pedagogical process called conversational constructivism (Coombs & Smith, 1998) and is derived from a conversational pedagogy called Self-organised Learning (S-o-L) (Harri-Augstein & Thomas, 1985 & 1991). A recent action research study (Lee Looi Chng, 2001) was completed in Singapore, which investigated Learning Plans as critical thinking scaffolds (Coombs, 2000) for delivering project work in Primary Schools and concluded that:

"As a content-free technology, S-o-L conversationalal tools are easy to use and findings from the mathematics and science groups do indicate that the conversational tool of the LP is indeed easy to apply across disciplines and cultures. The easy application of S-o-L tools is based on the process of reflective learning ..., [which has] wide appeal, being easily adaptable to the specific needs of each user" (page 99).

Learning Plans have been designed as a critical thinking scaffold process that can be delivered within Educational Technology supported learning environments. Such Learning Plans are designed as IT-based critical thinking scaffold templates and operate as what Coombs (2000 & 2001) refers to as a reflective learning technology. This paper seeks to explain the process of how Learning Plans operate as critical thinking scaffolds for improved student learning (Lee Looi Chng & Coombs, 2001) and argues that Educational Technology content-free templates assist in that goal. Curriculum examples similar to those exhibited in figures 1 and 2, of both paper-based and online student Learning Plans, will be shared with the conference delegates, along with other conversational tools that operate as a user-friendly reflective technology (Coombs, 2000).

Conclusion

It is from the systems-thinking psychological model of self-organized learning that we can understand how to enable the conversational fluency of learner self-interaction through organized schemas of reflection. These reflective schemas can be designed as technology-assisted critical thinking tools (Coombs & Smith, 1999). The So-L instructional design process provides criteria (Coombs, 1995) for implementing knowledge elicitation tools that operate as a reflective learning technology. In practice, this calls for the design and development of an activities-based project work curriculum that recruits online Learning Plans as Educational Technology scaffolding tools, which empowers students with S-o-L skills that ultimately lead to greater personal retention and transfer of knowledge.

Exploring the Characteristics of Effective ICT Teaching

Tim Denning, Keele University, UK
Tony Fisher, Nottingham University, UK

Abstract

The ICT workshop reported in this paper was funded by the British Educational Communications and Technology Agency (BECTA) and was designed with a particular focus on establishing and disseminating informed guidelines for effective ICT subject teaching. The invited participants were all ICT subject teachers with experience in their field. The event provided an opportunity for subject teachers and researchers to share and explore together successful teaching strategies associated with IT and then to begin the process of identifying the characteristics of good practice.

The workshop incorporated a number of different activities including short presentations, discussion, poster sessions and a plenary. Whilst the general tone was informal, it was hoped that everyone would be able to make an active contribution and benefit from the opportunity to discuss their work with colleagues. Delegates adopted two different roles during the course of the day, acting as either ‘researcher’ or ‘poster presenter’ depending on the schedule given to each group.

As ‘poster presenters’ each delegate was asked to display and answer questions about an activity which they judged to be an example of effective practice in ICT subject teaching. As ‘researchers’ each delegate gathered data from the poster presenters using, as a starting point, a framework of questions provided by the organisers:

<table>
<thead>
<tr>
<th>Activity Title:</th>
<th>Witness Name:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learning outcomes intended</td>
<td>What are the objectives? What knowledge, understanding or skill was developed/extended?</td>
</tr>
<tr>
<td>Audience</td>
<td>Who are the learners? What do they know/understand already? Why would they need to do this work?</td>
</tr>
<tr>
<td>Rationale</td>
<td>Why was this approach or strategy chosen? Was there a particular view of how learning might take place?</td>
</tr>
<tr>
<td>Resources</td>
<td>What materials or resources are used?</td>
</tr>
<tr>
<td>Assessment and Evaluation</td>
<td>How did you or could you evaluate the results or assess the learning that has taken place?</td>
</tr>
<tr>
<td>Key Processes</td>
<td>What are the important characteristics or features of the activity? What has made it effective?</td>
</tr>
</tbody>
</table>

Invitations were sent to some 35 schools in South Cheshire, North Shropshire and Staffordshire in the English Midlands. Twenty-eight colleagues accepted the offer of a workshop place although four of these later presented apologies either immediately before or on the day of the event.

The workshop support team comprised 2 researchers/teacher educators from higher education and 2 school-based members of staff engaged in IT subject teaching and teacher training partnerships.

This paper is organised around the rationale underpinning the design of the workshop model and presents a representative selection of the outcomes. These comprise a tentative list of ‘characteristics’ of good practice, annotated extracts of material presented in the poster sessions and the transcribed workshop evaluations.

The Assessment of Higher-Order Thinking Skills in a Web-Based Distance Learning Project

Pat Donohue
Dakota Science Center
NatureShift! Linking Learning to Life Project

John Hoover
St. Cloud State University
Department of Special Education

Abstract

The NatureShift! (NS) project investigates the impact on learning of its Exploration model, a constructivist, project-based learning model that delivers instruction through its website www.natureshift.org. The website supports educators from formal and informal education to develop higher-order thinking skills (HOTS) in their students. In the NS model, web-based adventures serve as a hook to draw students into engagement with social studies and science concepts. Once students have explored one of the website’s five immersive learning worlds (modules) that form the core curriculum of the site, the educator initiates a related real-world experience, forming a nexus between the virtual and phenomenal world. In the final phase of the model, students produce summative projects in which they construct meaning from what they have learned and present or teach their discoveries to others. Kozma (1991) suggests that multimedia helps many students to construct knowledge based on the characteristics of the medium to incorporate symbol systems and processing capabilities understood by the learner. Initial findings reveal that NatureShift’s web-based instruction appears to engage students in higher-order thinking skills and constructing meaningful learning from their virtual and real-world experiences. A strength cited for the NS modules (Hoover, 2001) was the strength of the links to other websites and the sheer number of visual images made available for educators and students.

Initial Evaluation

In an initial round of evaluation, it was determined that the website’s modules were well designed visually, interactively, and pedagogically. In addition, connections between the NS model and best practices in conceptual development had been established. Finally, NS personnel had redesigned the modules to reflect expert critiques and the project’s goals for perfecting the NS model and its presentation through web-based instruction. The Exploration learning model was also adopted as a method for training educators in the model and in the project’s learning strategies. Early findings from a partner Institute and a national training Institute reveal the model’s effectiveness for teaching others its constructs and theoretical base. Other findings suggest that the instrumentation designed to assess learning was useful, that training activities were successful in developing technology-based skills and pedagogical application of these skills. The latter sets of skill and knowledge components were objectively assessed (Hoover, 2001).

Measuring HOTS

In the presentation, the authors describe efforts to assess higher-order thinking skills featuring (a) objective evaluation of pedagogical skills on the part of adult participants, (b) depth-of pedagogical knowledge components (established via rubrics applied to interview data), and (c) student/end-user outcomes. The innovative feature of end-user evaluation data is that each NatureShift Partner project was assessed individually—yet in a manner that allowed data to be combined, project wide. Outcomes of the assessment data are described, as are challenges in tracking learning at least one stage removed from the project. In addition, use of website use and tracking data is described in detail.

Constructivism and HOTS

A number of theories that try to explain the processes associated with learning and with high order thinking have been developed. The web design and the site development of NatureShift! are based on principles associated
with constructivist learning and with higher order thinking skills (HOTS) more generally. A system for assessing students using the NatureShift! application that is consistent with principles of constructivism and with higher order thinking was developed.

Constructivist theories of learning depict concepts as systems of relations among what a learner has already mastered and new information. The degree of association among the learner's knowledge, the new information, and the learner's beliefs about the concepts vary. At times, the new information is consistent with the learner's knowledge and beliefs; at other times, the new information is markedly different from the learner's knowledge and beliefs. In constructivist theories of learning, higher order thinking is the ability to discuss and to apply concepts in a manner that is consistent with experts in the field. Rather than simply measuring the ability to recall facts and data, constructivist assessments attempt to determine not only what a student has learned but also to determine how that learning has occurred.

It is also assumed that learning is heavily based on the establishment of a context for information—the more this learning context resembles the domains where learned skills are to be expressed, the better the instructional sequence is assumed to be. In the present case, the web site(s) and classroom applications serve as frameworks for learning context.

Constructivist and HOTS assessment

Constructivist assessment requires methods for gathering data on what has been learned and also how the new learning is related to previous learning. Previous reviews of the literature (e.g., Jonassen, Beissner, & Yacci, 1993) have identified several approaches for eliciting this information; the most common approach is rating the association between a pair of words.

Developing Instruments

An alternative method was developed for assessing the student gains from the project. In summary, partners were trained at the summer workshop to develop a system for assessment of student learning tied, as closely as possible, to the information and skills reflected in the specific project developed by that partner. The following specific steps were taught to partners:

1. Develop five factual and questions about the information associated with your web-based project.
2. Develop five questions about technology aspects of the project.
3. Develop essays (one each) that elicit information about (a) higher-order thinking skills, and (b) use of technology in learning.

Initial findings are that the NS model (a) successfully results in "deep" forms of pedagogical knowledge in teachers and others trained in the model. (b) It was found that NS partners could clearly, and with a high level of sophistication, explain the connections between discovery and constructive-based theories of learning and the application of technology (including some misgivings that match extant research literature). (c) Natureshift Projects resulted in statistically significant changes in nearly all students' knowledge-level skills and in some students higher-order thinking skills (though these proved difficult to track). (d) The NS model for combining technology and constructivist approaches to HOTS is a useful one that should be easily replicable.

Essential Instructional Design Competencies for Library Media Specialists

Elizabeth Downs, Georgia Southern University, US
Stephen J. Jenkins, Georgia Southern University, US
Judi Repman, Georgia Southern University, US
Randal Carlson, Georgia Southern University, US

The role of the library media specialist is a dynamic practice that demands versatile skills. The contemporary library media specialist has clearly defined responsibilities as teacher, instructional partner, information specialist, and program administrator (AASL and AECT, 1998). The expectations described for the role of instructional partner include assessing student, identifying content, identifying learning outcomes, designing learning tasks and assessments, and selecting appropriate resources. An analysis of the role of instructional partner and corresponding responsibilities indicates a need for a strong foundation in instructional design.

Although library media specialists describe the role as important, less than 10% indicate that they perform the role to any great extent (Pickard, 1990). Pickard suggests that one explanation for the discrepancy might be the result of differences between the theoretical construct of instructional design and the real-world applications practiced by library media specialists. This difference should influence the approach used for training library media specialists in instructional design. The need to increase meaningful applications of instructional design in the real-world practice of school library media specialists requires feedback from practitioners. The first stage of this project will include surveying regional school library media specialists to assess job-specific applications of various components of the instructional design process. Results of the survey will guide the selection of an instructional design model to match relevant components with the most common or frequently identified applications. Secondly, feedback from the survey will be used to structure the design of course activities. Integrating applications identified by practitioners into the course structure will provide a framework to guide prospective media specialists in the connection between theory and practice. Course activities will draw from feedback provided by practitioners so students will have an opportunity to apply instructional design to a project that reflects meaningful application of systems theory to the role of instructional partner. The school library media specialist must possess skills that form the basis of successful cooperative planning with teachers, often taking the lead in guiding essential decisions in the instructional plan. In order to be successful in the role of instructional partner, prospective school library media specialists must extend beyond mastery of instructional design knowledge.

Competence in this role requires the ability to perform critical assessment of an instructional problem, select appropriate components of instructional design for a given instructional situation, and identify appropriate solutions. The ability to perform these skills might be enhanced if real-world applications drive the selection of an instructional design model and the ensuing course activities.

Bibliography

Abstract: The main goal of this paper is to discuss the main contributions and limitations of constructivism in the design of virtual learning environments. Constructivism is currently a label used for many approaches and it is necessary to improve the definition and delimitation of the different theories and models arising from generic principles on learning. The greatest virtue of the constructivist approach is that it provides a complex approach, which may help to improve the education and training necessary for living in the modern world. Nevertheless, there is a lack of integration of the different proposals within the constructivist approach that enables a systemic vision of the design of learning. Designers must have time to reflect on action. In fact, the current design process should itself be a focus for study.

We will place the main problems of designing constructivist environments in four categories: content of the tasks, sequencing of the tasks, transferral and co-operation.

Introduction

One of the most important problems facing education and training today is probably that most instructive approaches do not correspond to the needs of today's children and young people or the type of society in which they live. The separation of knowledge, the communication of information, the one-directional teacher-student model, and the idea of knowledge as something static are set against a much more dynamic and complex vision of knowledge. As Morin (1999) states, today's teaching must become educational teaching; "it is not a question of communicating pure knowledge, but rather a culture that enables the understanding of our condition and helps us to live. The challenge of the whole is also the challenge of complexity (11)". However, we learn to isolate objects, separate disciplines, solve problems but not to relate to each other and integrate. It is difficult, especially for children, to learn to contextualise knowledge. School behaves in the opposite way to current social development — "it is not a place where knowledge is flexible, but rather the place in which some knowledge is transmitted and classified. The place in which knowledge becomes sedentary, gets older and becomes static" (Simone, 2001, 41). However, knowledge is the organisation and the interrelating and placing in context of information and experiences that we acquire with the passing of time.

Human cognition is complex, and is reflected in the ease with which new problems are recognised and creative solutions found to solve them. There is a great deal of discussion concerning the need to centre learning on abilities and not to worry so much about knowledge. However, it is advisable to distinguish between learning abilities and abilities themselves. Abilities are always related to a particular part of knowledge or with a trade. In fact, they are a mixture of complex cognitive strategies, interpersonal abilities and attitudes which enable someone to show themselves to be in a specific field of knowledge or in a profession.

Contrary to what is frequently suggested, we do not believe that the problem of today's society is that it is more complex than in the past. Instead, we are realising the need to start from systemic models that enable us to have an overall view of the way society works. From this point of view, we feel that the constructivist ideas have a common feature, which is that of focussing design on the creation of complex environments permitting multiple representations and which show the completeness and complexity of learning and the construction of knowledge.

In this contribution we intend to maintain that constructivism is currently a label used for many approaches and it is necessary to improve the definition and delimitation of the different theories and models arising from generic principles on learning. The use of technology from the constructivist perspective leads to highly varied metaphors for the learner: The student as a designer, as a reflexive learner, as a member of a learning community. The greatest virtue of the constructivist approach is that it provides a complex approach, which may help to improve the education and training necessary for living in the modern world.

Constructivism: a label for many approaches.

The label constructivism is being increasingly used but is being applied to many different approaches. Piaget and Vygotsky are the two most important authors who started research into learning using the constructivist approach in the twentieth century. There has been a great deal of discussion regarding the differences between them, with Piager's stance on the importance of individual learning as opposed to social learning subject to a great deal of simplification. Personally, I believe that it is an error to compare the two authors (apart from their analyses of the role of language) because their approaches are not opposing but rather complementary, and concentrate on different aspects of the same situation.
Piaget does not deny the role of the social world in the construction of knowledge, but concentrates on analysing the relationship between a person and his/her environment. For Piaget, learning takes place when the new information interacts with prior knowledge by means of an assimilation-accommodation process, the result of which is the modifying of prior patterns of knowledge or the creation of new patterns. For Piaget, learning must be significant, and only significant learning is able to modify a person's patterns. To obtain significant learning it is necessary to favour the connection between prior experiences and knowledge and new knowledge. To this model of subject-medium interaction, Vygotsky adds features that play a very important role in the learning process – the tools that mediate between interactions and the people who "accompany" the subject during the learning process.

According to Vygotsky, man's superior cognitive processes are possible thanks to constant interactions between tools, environment and symbols. In this respect, "the function of the tool is none other than that of a conductor of human influence on the object of the activity, it is externally directed and must cause changes in objects. It is a medium by means of which external human activity aspires to dominate and triumph over nature. On the other hand, the symbol changes absolutely nothing in the object of a psychological operation. It is therefore a means of internal activity that aspires to dominate itself, the symbol, is therefore internally directed. These activities differ so much from each other and that the nature of the media they use can never be the same in both cases."

The concept of appropriation is a move from a biological metaphor to a socio-historical one. Appropriation is therefore a key concept from the Vygotskian perspective inasmuch as it is used to postulate that through immersion in culturally organised activities, the child appropriates tools, instruments and symbols belonging to each society. The appropriation of socially constituted interpersonal functional systems leads to cognitive representations that the subject includes in his mental structure. The computer, taken to be a tool in the sense used by Vygotsky, introduces another totally new form of interaction with information, knowledge and with other people, different from other media so far used.

The theories of Piaget and Vygotsky have led to different approaches and uses of technology that provide us with significant advances in the field of instructive design, as can be seen in Figure 1.

Many designs have been developed, based on Piaget's point of view, taking the student as a designer as the model's starting point, and emphasising the importance of learning by discovery. Meanwhile, from the Vygotskian perspective, the student is seen as a researcher, with a great deal of importance placed on learning in context and on co-operation within the learning community.

Figure 1: Constructivism approaches.

**Designing learning environments**

In the constructivist framework, the emphasis is not on teaching, but rather on contexts or learning environments. In traditional approaches to teaching, it is the designers that take the decisions regarding what students have to learn, in what contexts they should learn, what strategies they should use to attain this knowledge and how this acquisition should be evaluated. The constructivists substitute these conceptions for a more flexible concept of learning, in which the learning process is not so pre-specified. Design is an iterative problem-solving process that should be modified according to the results obtained.

Constructivist learning environments can be defined as "a place where students can work together, helping each other, using a variety of informative instruments and resources that enable them to search for the learning objectives and activities for..."
solving problems." (Wilson, 1995, 27). The design of multimedia materials and use of the Internet can facilitate student-centred work. Figure 2, based on the ideas of Oliver and Hannafin (2000), presents a taxonomy of constructivist tasks and the requirements of web-based tools that can help in their development.

Figure 2. Taxonomy of constructivist tasks

The design of a learning environment goes far beyond the computer material itself as the entire organisation must adopt this type of approach for it to be really effective. This is clearly shown in Jonassen's conceptual model (1999: 195).

Real life situations which help to put problem solving into practice and their subsequent transferral to other real situations are significant contexts for constructivists. For this reason, they oppose the lineal presentation of information in education, as this stresses memorisation and the acquisition of knowledge and abilities in an isolated manner, which is often out of context. The constructivist alternative to memorisation and activities out of context is to place greater emphasis on learning contexts that enable knowledge to be constructed, organising the contexts with activities that are closer to the real world and which normally involve discussion groups.

Limitations and possibilities of constructivist learning environments

We can place the main problems of designing constructivist environments in four categories: content of the tasks, sequencing of the tasks, transferral and co-operation.

Content of the tasks.

As has been mentioned throughout this article, the constructivist approaches emphasise the idea that knowledge is not something that can be written in a book and transmitted to students, but rather that knowledge is something complex that must be constructed by learners, and learning based on tasks or solving important problems may be a way to reach this type of learning. However, we believe that learning environments defined as environments in which the student works on a relatively complex task provide better opportunities for learning and transferring what has been learnt to other situations. The problem, however, lies in the origin of the learning tasks. What is an authentic task? When is a task motivating? Normally, as van Merrienboer points out very clearly, constructivists substitute tasks based on the world of knowledge for those based on the world of experience or work (in the case of university teaching or in-company training).

This substitution of the contents of knowledge for the contents of experience or work causes some problems. In schools, students' learning can be highly diverse according to the particular circumstances of each group. This aspect is positive but is also dangerous in terms of the lack of overall and integrated vision that is generated. Moreover, authentic tasks in childhood are always mediated by the teacher, meaning that the limits between the children's real interests and what was previously agreed upon by the educators are unclear. From the point of view of the learning medium, it is not easy to anticipate all the tools that the learning environment will have to provide the student with so that he/she can carry out the task or solve the problem. To solve or create problems, it is necessary to have a good command of content. At times, the constructivist perspective seems to underestimate or neglect this aspect.

Sequencing of the tasks.

Another complex aspect is the design of sequences of cases or tasks. As Collins, Brown and Newman point out (1987) "the ability to produce a coherent and appropriate sequence of case studies and problems (i.e., learning tasks) is a key feature in the design of constructivist learning environments". In many cases it seems necessary to go from the simple to the complex, and on the other hand, we can find many examples where there is evidence that the exact opposite is necessary. J. Merrienboer (1999) gives a very good example of this with the case of training students in instructive design. A student cannot start by moving from the simple to the complex without reviewing and evaluating previously produced material, for example.

Transfer.
Il the constructivist theories seems to be convinced that learning in context with authentic tasks improves transferral, makes it possible to apply what has been learned in a school environment outside school, and vice versa. However, this is not an easy statement to prove and in fact we do not think it has been proved in the research into the consequences for learning of the design of multimedia and web materials. This is an extremely important aspect but one which without a doubt needs a systemic research approach that has not been used to date. In our opinion, this is still the greatest challenge of research in this field where the analytical approach is still very much used, although I consider it unsuitable for research into the effects of this type of environment. According to Reeves, research shows that students learn both with and from technologies, but “we know very little about the most effective ways to implement interactive learning. In fact, the need for long-term, intensive research and evaluation studies focused on the mission of improving teaching and learning through interactive learning technology has never been greater” (Reeves, 1999).

Co-operation.

“Collaboration” refers to the fact that a group of people work together on a task. However, much has been written about how best to define “collaborative learning”. A frequent point of departure is to draw a distinction between two terms that are often used interchangeably: “collaborative” and “co-operative” learning. The main difference between these terms concerns the nature of the task being carried out and the role of the group members in achieving the task. In a collaborative learning process, two or more people are required to learn something together; what has to be learned can only be accomplished if the group works in collaboration. Therefore, the group needs to decide how to achieve the task, which procedures they will adopt, how they will go about dividing up the roles, etc. Communication and negotiation are fundamental in a collaborative learning process. In contrast, co-operative learning requires a division of tasks among group members. For instance, the teacher proposes a problem that the group needs to solve and indicates who will be responsible for obtaining references from the library, who will conduct a web search, who will report back on the findings, etc. Dillenbourg’s definition is clear on the matter: “a situation is termed ‘collaborative’ if peers are (i) more or less at the same level and can perform the same action, (ii) have a common goal, and (iii) work together” (Dillenbourg 1999, p.9).

While classical CBL (Computer Based Learning) and most of the current multimedia are designed to support an individual process of learning, in recent years an increasing number of systems that support group learning has been produced: programs that encourage learning in collaboration, videogames to be played in a group (without any element of competition), systems that facilitate communication and negotiation, the production of materials that involve written collaboration, and so on. In a computer mediated collaborative learning situation, the level of interaction is very important. As M. Barker (1999) points out, in order to achieve real learning, grounding and appropriation have to take place.

Grounding is the name given to the interactive processes by which common ground or mutual understanding between individuals are constructed and maintained. Grounding can take place on pragmatic and semantic levels. Interacting participants need to understand each other, learn to collaborate and/or have a common understanding, common domain of the task, meaning, etc. however, reaching this level of relationship is not easy in practice.

To sum up, we feel that although the greatest virtue of the constructivist approaches is that of providing a complex approach that can help to improve the education and training necessary for living in today’s society, a greater degree of integration of the different ideas which enable a systemic vision of learning environment design is preparation for a do-it-yourself theory is necessary.

We give the name of a do-it-yourself theory to the systemisation of the principles of instructive design, which are able to explain the most suitable type of designs based on different educational and training needs. Designers must have time to reflect on action. In fact, the current design process should itself be a focus for study.

ENHANCEMENT OF SELF STUDY OF TEACHING PRACTICE VIA CREATION OF VIDEO ETHNOGRAPHIES

R. Carl Harris
David O. McKay School of Education
Brigham Young University, Provo, Utah
Carl_harris@byu.edu

Abstract: Documentation of benefits of self-study on teacher education practices has gradually emerged during the past decade. Concurrently, the development and exploration of video cases or video ethnographies has also emerged and research on their impact on teaching and learning is likewise underway. However, little attention has been given to the combination of self-study and video ethnography methodology and pedagogy. This symposium will highlight five individuals who share the common attribute of having each created a video ethnography. They will each report self-study data on their respective video ethnography CD-ROMs of how the exploration of their own and someone else’s teaching using video ethnography methodology has drawn attention to and elicited questions about their own professional journey.

Perspective: Documentation of benefits of self-study on teacher education practices has gradually emerged during the past decade (e.g., Connelly & Clandinin, 1999; Whitehead, 2000; Hamilton & Pinnegar, 1998; Cole & Knowles, 1998). Concurrently, the development and exploration of video cases or video ethnographies has also emerged and research on their impact on teaching and learning is likewise underway (e.g., Harris, Pinnegar, & Chan, P. 2000; Pinnegar, Harris, & Chan, 2000; Pinnegar & Harris, 1999; Harris, 1999; Harris, 1998); Harris & Harris, 1998; Harris, 1996; Harris, 1996; Harris, 1995; Harris, 1994). However, little attention has been given to the combination of self-study and video ethnography methodology and pedagogy. This symposium will highlight five individuals who share the common attribute of having each created a video ethnography. They will each report self-study data of how the exploration of someone else’s teaching using video ethnography methodology has drawn attention to and elicited questions about their own professional journey.

Video Ethnographies Defined: Video ethnographies are cases of true and actual practice. The teachers studied are not actors and neither are their students. There is no effort to sanitize the challenges of teaching nor underestimate the effort teaching for active learning requires. The complex performances of teaching and learning can be positioned for deep and insightful analysis. When live teaching is observed there is much that goes unnoticed because so many things are happening at once. However, with video ethnographies pre-service and in-service teachers are invited to make multiple observations and interpretations of single episode.

The platform for each case is a CD-ROM or Internet interface which allows pre-service and in-service teachers to explore and build studies of practice. The "study explorer" provides for inquiry into four studies, 36 video probes and 144 commentaries. The "study builder" enables the pre-service or in-service teacher to create an infinite number of original studies of teaching practice with commentaries from self, professional literature and other teachers. Portions of a case can be studied from the perspective of the teacher, the student, another more advanced teacher, the professional literature, etc. and their own perspective.

Teachers and students who submit to having their teaching and learning documented and analyzed have a strong voice in deciding what will be most helpful to share with other teachers and learners who want to implement active learning.

Using Video Ethnographies: Use of this technology engages users in an inquiry driven experience in studying teaching practice which will lead them to use in inquiry driven approach in their own practice. Pre-service and in-service teachers metaphorically climb inside another teacher's classroom: viewing not only the way the teacher constructs the practice but also the thinking of the teacher, students, and other professionals about practice. Using this technology requires the use of a new pedagogy of
practice, since it demands that pre-service teachers are required from the beginning of their teacher education experience to grapple with their own theories and beliefs about teaching practice through inquiry into the practice of others.

**Creating Video Ethnographies:** Creating a video ethnography includes choosing a master teacher, acquiring media releases, filming in the classroom, negotiating with the teacher and specialists which attributes of the classroom to study in depth, conducting interpretive interviews with the teacher, other teachers, administrators, scholars, students, parents, etc. editing the video capture, identifying relevant quotes from the professional literature, and then assembling video, audio, and text files together so they will run on either the CD-ROM or Internet platforms.

**Self Study During Video Ethnography Creation:** During the process of developing the video ethnographies, numerous opportunities confront the educator/producer of the video ethnography to question and reflect on his or her own professional development. The five educators featured in this symposium have installed their reflections about their own teaching in the perspectives contained in each case as they have gone through the numerous stages of creating video ethnographies of their own teaching.

**Featured Educators:** The five video ethnography self-study teachers and their respective video ethnography products are: 1. A Teacher Educator and Literacy Specialist (The Canda Mortenson Case: A Video Ethnography of Balanced Literacy in the First Grade); 2. A Pre-Service Teacher in an Educational Psychology Class; 3. A Teacher Educator and Physical Education Specialist (The Robyn Bretzing Case: A Video Ethnography of High School Volley Ball); 4. A Doctoral Student in Instructional Psychology and Technology (The Traits of Thinking Case: A Video Ethnography of Mandarin in Senior High School); 5. An Undergraduate Student in Elementary Education (The Mom, Dad, and Me Case: A Video Ethnography of a Pre-Service Teacher’s Study of Her Parents’ Teaching).

Hand-Me-Downs: Reusing Online Courses and Building Courses for Reuse

Susan Hines, Eduprise, Inc., US

Colleges and universities invest heavily in the production of online courses for their virtual universities and online extensions. However, a growing number of institutions may be jeopardizing their up-front investments unwittingly. That is, in the rush to put degree programs online, too many courses are developed in haste—often by inexperienced or over-committed instructors—or developed in such a highly personal or idiosyncratic fashion that courses can be of little use to future instructors who might inherit such courses or teaching assignments.

At the very heart of a flexible and cost-effective online education system is the inheritability and reusability of course content. Yet colleges and universities with online programs have demonstrated little regard for what makes an online course inheritable and reusable. While many statewide systems, schools and universities have turned to course management systems, such as WebCT and Blackboard, in order to establish some semblance of order and consistency, what they have gained is arguably that—some semblance.

This presentation will position the course management system as a means not a method, and will illustrate the kinds of problems and restrictions instructors may face when they inherit online courses. It will also address the undermining potential of such problems and restrictions: the time/labor costs involved in necessary course revisions and the ethical dilemmas of authorship and academic freedom. The proposal fits into a number of SITE topic categories, including PT3, Concepts and Procedures, Distance Education, Faculty Development, Instructional Design, and Special Needs.
Teacher Education from an Instructional Design Perspective

Esther Javetz
Elgin Community College/
National Louis University
United States
Teaching43@aol.com

Abstract: This paper is a report on the findings of the first part of a study conducted in teacher education classes and related activities. Situations and materials were recorded with audio equipment or with notes taken by the researcher. Qualitative techniques were used on the data to determine teaching methods and performance level of preservice teachers. Findings indicate that teachers see themselves mostly as affective leaders or non-specific cognitive leaders. They also do not exhibit all the skills needed to teach. Instructional design theories and procedures are suggested to enhance teacher education.

Introduction
Instructional Design and Teacher Education

The March 1994 issue of Educational Technology was dedicated to the relationship of instructional design and teachers’ planning (Branch 1994, Driscoll et al. 1994, Earle 1994a, Earle 1994b, Garbosky 1994, Kennedy 1994, Martin 1994 and Reiser 1994). The type of instructional design described in these articles was a systematic approach (the ISD concept), but behavioral in nature.

However, the field of instructional design changed in the 1980s to adopt a cognitive learning theory and later a constructivist theory (Driscoll 1994, Ellis et al. 1993, Gagne’ 1985, and Reigeluth 1983). We should investigate to see whether newer learning theories and instructional design procedures are currently taught in teacher education programs, and whether they are applied by new teachers in schools. The onset of calendar year 2002 reminds us that we are at the beginning of a new century, which is a natural point in which to pause and evaluate our profession.

The Importance of a Learning Theory and a Notion of Subject Matter Structure

Teacher planning has been traditionally focused around the concept of “activity” or “routine”(Yinger 1979). The use of activities has the advantages of providing tasks for individuals, groups, or a whole class. Behaviors are controlled and motivation and enjoyment are observed. Every lesson requires more activities, but are they tied to the learning level needed (concept learning, problem solving, etc.)? Do teachers have a strong sense of subject matter and curriculum in order to select key concepts and rules? In short, are activities “chained” to make both “learning sense” and “subject matter sense”?

People who envision a new system of education for this century (Reigeluth & Garfinkle 1992) see a different type of teacher, (“more a guide on the side than a sage on the stage” p.17). But the teaching environment is not that different from what we perceive today:

It might be [a] traditional, discipline-oriented area such as biology, a cross-disciplinary, thematic area such as pollution or cities, an intellectual area such as philosophy, or a technical area such as automobile maintenance and repair.

In all cases ...the cluster guide will be responsible for helping the student put together a program of study that represents a good progression of higher-order skills instruction. (Reigeluth & Garfinkle 1992, p. 19)

It is assumed that producing a higher-order skill level requires a preexisting stock of meaningful amounts of structures such as discipline-specific structures or other types of structures.
Becoming Teachers

Typically, certain coursework, professors, and practicing teachers are all involved in developing a person to become a teacher. Specifically, towards the end of their bachelor degree program, students take general education courses and specialized methods courses (dedicated to a subject matter). They are also assigned to schools, where a cooperating teacher provides support, and where they teach their first lessons. Supervising teachers visit these schools to evaluate these first lessons. In addition, groups of teachers-to-be get together in seminars to share these experiences.

Sometimes, throughout these different components, a theory of learning/instruction is being presented and becomes the pillar of the program (Gleason 1991).

The Study

A pilot study is currently under way at a multi-branch university that has provided a teacher education program for many years. The principal investigator is following a group of 14 preservice teachers with an audio recording machine. Four avenues of learning are being recorded and analyzed: 1) lessons given by teacher educators, 2) discussions and sharing by the prospective teachers as they help each other, 3) presentations of final projects (a three lesson unit) and 4) lessons taught by the group members in area elementary schools.

The principal investigator is looking at relevant concepts and theories presented to the teachers-to-be, the type of presentation (verbal information, practiced concepts and rules, or encouragement for transfer), and the application of the theories into their first lessons/presentations. Clearly, this study is focused on the cognitive aspects of learning and teaching, keeping in perspective that there are also other elements needed in an elementary school teacher's "tool box."

Once all the data is collected and analyzed, strengths and weaknesses of the teacher education program will be identified. Later, this pilot model will be expanded to additional branches, and then to other institutions.

Findings

At this stage of the study, the analysis of the Science-Methods course has been completed. The data consists of audio recordings of lessons, the principal investigator's notes, recordings of final presentations, and a recording of a relaxed interview session in a restaurant.

(Table 1) reveals the achievements of the preservice teachers in their final project presentation. It seems that they are still missing important tools, and therefore, their lessons sound like a list of materials and activities where there is no sequence, no strong relationship to the subject matter, and sometimes no notion of developing knowledge in the children's minds.

Table 1: Evaluating Final Projects in a Science Methods Course

(Fig. 1) presents the data analysis from when preservice teachers each answered the question: "what is teaching?" When the answer was categorized as affective, it was typically similar to the following: "I think teaching is to prepare students for the adult life, being a role model for them, teaching them how to make choices, not just academically, but in every area of their life." When the answer was categorized as cognitive non-specific, it was typically similar to the following: "I believe teaching is giving or helping students attain strategies for being lifelong learners, so they can attain anything that they want to do " When the answer was categorized as cognitive-specific it was typically similar to the following: "For me, teaching is the ability to..."
give children the ability to find knowledge on their own. You teach them many facts, you transfer much of your knowledge to them, but what they need after school is the ability to acquire knowledge on their own and being able to continue on."

![Figure 1: Preservice teachers' types of responses to “What is teaching?”](image)

As shown from these responses, most of this group of preservice teachers does not have a theory for specific cognitive intervention.

One way to explain this level of performance by the preservice teachers is to examine the input phase. (Tab. 2) shows that the theoretical portion of the course was cut short. The instructor preferred statements (Activity 6) to well developed theories (Activity 4). The bulk of the learning was achieved via the verbal information type (Gagne', 1985). See Activity 4 and Activity 10. The feedback from the instructor signified acceptance rather than an evaluation of the level of performance (Activity 14).

The instructor’s assumption was that the preservice teachers were afraid of science, so they needed “easy” assignments and direct talk about that fear (Activity 9).

One of the best activities in the Science-Methods class was Activity 12. It provided many examples of topics and supporting materials. However, examples might not be as easy to follow when concepts and principles are not provided.
1) Group experimentation and later sharing w whole class to find independent and dependent variables  
2) Collecting a large sample of botanic items, including definition without any prior instruction  
3) Comparison between science lab in different grade levels  
4) Each group read about another method and presented to the class: Constructivism, expository, free discovery, guided inquiry, conceptual change, equilibrium and disequilibria  
5) Teacher discusses and gives examples about student prior beliefs in science matters  
6) Teacher recommends that “curriculum should be tied together” w many examples  
7) Students were brainstorming about alternatives to the botanical project  
8) Teacher’s statement: it’s the quality of the understanding rather than the quantity of information presented  
9) Many teacher statements like: I want to expel your fears…  
10) Students paraphrasing articles from science teaching magazines  
11) Students work w different assessment examples  
12) Teacher teaches the concept science-technology-society-issue through discussion and Internet browsing  
13) Discussions about the students’ field experiences  
14) Teacher’s feedback: Good job. That’s wonderful. Very good

Table 2: Teaching methods in the Science-Methods class

Conclusions

The principal investigator will continue to follow the group of preservice teachers as they complete the 4th and last year of the teacher preparation program. However, even from the early data (consisting of just the Science-Methods class), it can be seen that this type of learning is not strong enough to foster a full understanding of science, to understand the learning process, to provide the professionals we need in the new century to bring children to a problem solving level, or to foster teaching for transfer (Perkins & Salomon, 1988).

The preservice teachers exhibited difficulty in coming up with an assessment piece for their units. They saw several examples during the course, but could not find one matching their situation. If provided with instructional design knowledge (e.g., concept learning, rule learning, etc.), they could have easily written objectives, come up with a method/treatment, created an assessment, looked at prior achievements and planned further teaching. A theory is required in order to drive the many elements needed for effective teaching.

The program is also theoretically mixed. The preservice teachers were briefly trained to write behavioral objectives, but the examples of assessment were of different, unrelated types. For instance, they were exposed to the method of journaling. What type of objective does this assess?

The two major elements necessary in a program are a learning/teaching theory and a subject matter understanding. These two should have been covered before the Science-Methods class (through prior coursework), as well as during this class. Thus, there should be a ‘whole program’ focus rather than a system of dealing with one course at a time.

Institutions can use studies such as this one not only for program evaluation, but also for quick improvement. I have already begun working with the Science-Methods teacher to improve the subject matter component in the next semester.

Teacher education may improve significantly when seriously incorporating instructional design theories and procedures. We should keep in mind that teachers are expected to perform better in the new century.

1. Introduction

Faced with a fast changing society, the need to develop versatile instructional materials to update the professional skills of experienced practitioners, be they those of teachers or sales assistants, has become a major necessity. Long gone are the days when the creation of such training material happened within the hallowed halls of specialized educational institutions. Instead, a more client-driven approach to professional training has led many educationalists to look at how the reality of the workplace (office, factory floor, classroom) and available resources, notably information technology (IT), can contribute to the learning process. It is in this context that we will outline the framework of how a series of instructional fragments for a Digital Versatile Disc (DVD)-video, Voilà Madame, was created by systematically harnessing the resources of pedagogues, learners and management.

The value of this project for teacher trainers and instructional material-makers lies in the possibility of transferring the operational framework of this project to other contexts where a premium is put on helping professionals in the field (e.g. classroom teachers) to be more aware of their verbal and non-verbal behaviors. This is of particular interest to those working in the fields associated with communication sciences (e.g. face-to-face interaction, verbal & nonverbal communication) and the linguistic field of pragmatics, for example in the teaching of English/French/etc. as a professional language.

First, in Section 2, we describe the framework for analyzing the needs of the training context and its practical implications. This is followed in Section 3, by an explanation of the five-step Scenistic Approach with its diagesis, scenario, scenation, scenic and setting up the situation phases in terms of the overall structure of a training DVD-video, called Voilà Madame, and its role vis-à-vis other teaching tools, like those of IT. Finally, in Section 4, we present a discussion of the pedagogic implications of our approach.

2. Analysis of the instructional needs

In this particular context, the analysis of the instructional needs can be summarized in three basic questions: (1) Who are the immediate stakeholders? (2) What are their expressed needs and wants? and (3) What are the desired outcomes? The answers to these questions provide a basis for establishing the parameters of the instructional context and the ensuing "pedagogic scenario".

2.1 Who were the immediate stakeholders? The principal direct stakeholder was a regional human resources director in charge of supervising and distributing new instructional materials to all the managers of one of France’s major chain stores in the region of Nord/Pas de Calais. Other significant stakeholders were: the managers of each of the...
the different chain stores of this northern region of France on the border of Belgium; the company’s trainers and; the sales assistants as the end-users of the instructional material.

2.2 What were the stakeholders’ expressed needs and wants? The issue to be addressed was the upgrading of sales assistants’ professional skills by regular and varied in-house training sessions. This meant that new instructional material had to be versatile, so that it could be used both in a traditional, face-to-face instruction, as well as for personal self-study. Furthermore, the technology to be used had to be that which already existed in the work place i.e. VHS videotapes, paper-based documents and email. Interactive multimedia resources, like the DVD-ROM, were excluded because it meant buying new equipment (e.g. multimedia computers) that would exceed the training budget.

2.3 What were the desired outcomes? The essential objective was to show sales assistants how to adapt their verbal and non-verbal behavior to the needs of customers. This was to be done by helping the employees to better understand company policy in dealing with customers. In this context, the instructional material had to help learners become more efficient in their sales techniques by focusing on practical problems that customers encounter at the stores.

3. Scenistic Approach

The principle of the Scenistic Approach (Leleu-Merviel 1996) is to provide a framework of scripting a series of “events” in a way that it ensures overall coherence and transparency in the design process. The technique has five major steps: (1) the diagesis, (2) the scenario, (3) the scenation, (4) the scenic, and (5) the setting up of the situation.

3.1 Diagesis: This involves everything that belongs to the imagined/proposed setting of the document as expressed through the (lesson) content. This includes taking stock of, for example, the different educational paradigms and approaches (cf. LABOUR et al. 2001) that could be used to achieve the objectives identified in the analysis of the instructional context.

In this case, it was decided to use a self-monitoring approach to problem-based learning, centered on skills-reinforcing tasks. This meant that learners would be systematically encouraged to first identify possible dysfunctions in the scenes presented to them, followed by choosing the appropriate solution to remedy the situation. In this way, learners, some of whom have up to 25 years experience in their job, would be called upon to use their existing knowledge to critically reflect on familiar professional situations. It was hoped that by using such a constructivist inspired approach (cf. Jonassen et al. 1999) new knowledge would graft itself onto existing knowledge structures.

One of the practical consequences of reflecting on the diagesis, led to one of the pedagogue-designers of the production team to go on a three-day training course with one of the company’s sales teams. This permitted the team to have a more direct understanding of learners’ pedagogic needs.

3.2 Scenario: The scenario represents a deliberately thought-out text that has a storyline (closely associated to a series of meaningful events), details of the author’s intention, a projected target audience, and a message. In so doing, it constructs the narrative and represents the « story » as it unfolds. In this way, the scenario provides a guide to subsequent choices concerning the production of the document.

The 23-page scenario of the project, called “Voilà Madame4”, was based on notes taken during the three-day training course, and from interviews with sales assistants, heads of departments and management of the company. This led to some major modifications in what the client wanted, notably not to limit the training to VHS videotapes but to also use the DVD-video5, which was not too expensive and offered, for example, more “interactivity6” than videotapes. For the sake of economy, we cannot present the original scenario in any detail, except to say that it has 18 specially written scenes with a playing time of 22 minutes. (A more complete picture of the details of such a pluri-media scenario can be found in a recent paper presented by Labour & Benoit 2001).

4 According to Scene 10 of the scenario, the term voilà Madame ("Here you are Madam") said as a farewell phrase to a client is to be avoided. When concluding a conversation with a client, one must say Au revoir, Madame (Goodbye, Madam) and not, as in this scene, voila Madame, a term used to indicate the handing over of a requested object to someone.

5 The DVD-video, made available in the USA in 1997, can store over two hours of video on one layer of the disc. Compared to a VHS videotape, the DVD-video can make seamless skips from one scene to the next in the sequence chosen by the viewer without waiting while the tape goes backwards or forwards. Commentaries, subtitles, alternate endings and additional language tracks can also be added onto a DVD, which offers a high quality picture and sound quality and can scan, pause and chapter access, and as a laser reads the DVD there is no wear and tear, or loss of fidelity over time.

6 Definition: By interactivity is meant the possibility of action-reaction choices that the system gives to users (cf. LABOUR 2001, p33, 37-44).
In broad terms, after learners have viewed an appropriate narrative fiction recorded on the DVD-video, a series of face-to-face skills-based training tasks can be done on a particular point, for example, in weekly workshops. In this context the observation sheet for Scene 1 (Figure 2), translated from French, shows the pedagogic approach provided for by the scenario. After observing the scene on the DVD-video as many times as necessary, the learner is asked to identify recommended behavior ("Positive points") from dysfunctional behaviors ("Negative Points", "Problems related to manners or behavior"). Finally, some "points of reflection and development" are suggested for further discussion on-line (e.g. by e-mail) or off-line, or for self-study.

The DVD-video is thus only one aspect of a pluri-media learning package (Figure 1).

Scene 1: Prologue and answering the telephone
Length: 1 minute 30
Start mark: 1mn20. Stop mark 2mn53
Staff concerned: all

© Positive points
PQ1 The person picks up the telephone after the 4th ring (or after the 3rd ring).
PQ3 The person is not chewing gum.
PQ6 The waiting time is less than 30 seconds.

® Negative points
PQ2 The person does not mention the company's name.
PQ2,7 The person does not mention the name of the store where s/he works.
PQ2,7 The person does not present him/herself with his/her first name.
PQ7 The person does not indicate in which department s/he works.
PQ3 The person replies in a muffled voice without articulating.
PQ4 The person does not reply to the client's question.
PQ4 The person does not connect the person to the correct department.
PQ8 The person replies in a disagreeable way, making it clear to the client that s/he is tedious.
PQ5,9 The person does not say "Goodbye Madam" at the end of conversation.
PQ5,9 The person does not add a friendly word, nor a polite one at the end of the conversation.

♂ Problems related to manners or behavior
- The person interrupts the client while s/he is speaking.
- The person asks the client to call back later.
- The person hangs up on the client.

♀ To go further, points of reflection and development
- The person justifies him/herself by mentioning the problems in the store: "I am alone". How could the person have avoided this situation?
- The person gives a negative image: "I don't know". What should the person have said?
- One should never ask a client to call back. What should one do?
3.3 Scenation: The scenation is the text that organizes the events or states, taken from the scenario, as operationally interacting elements. It can be equated as the routes that learners could take. The scenation is comparable to the text of a play "on paper" but it is not the theatrical performance itself.

To make maximum use of the video document the objective was to provide a set of meaningful units that would facilitate an intuitive navigation of the document for learners and trainers. But, the essentially linear format of the video documents provides a limited amount of interactivity, so users of the DVD-video could only access the scenes via a Menu of themes, or an Index of scenes (figure 3). The Menu of themes contains a series of sub-themes/contexts of everyday situations (e.g. in the parking lot) and is aimed more at learners. Whereas, the Index of scenes is directed more at instructors who wish to present a teaching sequence around certain objects (e.g. household appliances).

3.4 Scenic: The scenic transposes the scenation into concrete, hands on reality. It is at this stage that one makes aesthetic and logistic choices within the limits of the practical and financial constraints, conditions of usage, etc. (see Section 2 above). This includes the choice of the medium for a given fragment taken from the structure of the scenation (e.g. text, sound, or both together) in order to facilitate the acquisition of knowledge.

In this case, the colors of the company were chosen as the guiding color scheme to present the interactive pages of the DVD-video. Blue, pink, yellow, green and orange hues were added to identify the five different themes in order to facilitate user-navigation and to make the document more attractive.

The choice was confirmed to use the DVD-video in order to maximize the use of the pedagogic material, even if ideally a DVD-ROM, with greater potential for interactivity, would have been preferable.

3.5 Setting up the situation: This final phase defines the practical ways that the user can in fact access the (video) fragments of the document via user-functions. On a computer, this could be a button, an icon, a joystick, and/or a mouse-click.

In the case of a DVD-video one of the main user-functions is the remote control box. Unlike, for example, the "mouse" of a DVD-ROM, the remote control box does not provide an on-screen pointer to facilitate non-sequential navigation in the document. The challenge of the DVD-video and its remote control box is then the danger of potentially laborious linear and sequential navigation.

Taking into account the factor of limited navigation possibilities, 15 icons were created to help learners go through the document efficiently. In this way, the relatively few interactive possibilities of the DVD-video format could be put to profitable use.

In order to get maximum use of the specially written scenes, a 25-page booklet was also made for learners, and a separate one for trainers to help them use the material pedagogically. This was linked to more general guidelines concerning the different skill-based learning tasks possible that could be done online and offline with the DVD-video (Figure 1).

4. Discussion

Without taking the details of his observations too literally, Treicher (1967) reminds us in his book, Are you Missing the Boat in Training Aids? Audio-Visual Communications, that most people "learn" (retain) 10% of what they read, 20% of what they hear, 30% of what they see, 50% of what they both see and hear, 70% of what they discuss with people whose opinions they value, 80% of what they personally experience, and 90% of what they teach other people. In short, a training program should go beyond providing teaching aids that learners can both "see and
hear". The pedagogic scenario of instructional materials needs also to focus on the human interactional elements of
learning to include meaningful "discussions", transforming inputs into "personal (pedagogic) experiences", and 
"teaching" other people (e.g. peer learning). In this light, the video/film format offers some specific advantages, as 
highlights the film historian Turner.

... (with) the abandonment of the idea that there was a core of meaning in a film which the audience had to discover. 
Meanings are seen as the products of an audience's reading rather than as an essential property of the film text itself. 
Audiences make films mean: they don't merely recognize the meanings already secreted in them (Turner 1988:121).

A training scenario should then, for example, get learners to discuss how they saw a scene and how this relates to 
their personal experience and its future implications for them. It is in such domains that network-based technology 
like the Internet (with its discussion forums, chats, emails, etc.) can facilitate learning by communicating with 
different people. That said IT, like Internet, is not in itself pedagogic. What makes these tools so, is the 
appropriateness of what is put in them (content) and how this is done, hence the need for operational frameworks 
such as the Scenistic Approach and other related ones (e.g. Laubin 2002) aimed at making optimal use of the content.

5. Conclusion

In this paper we hope to have taken a step towards reconciling the design process with the need for accountability 
and transparency in presenting the Scenistic Approach as a working framework for designing teaching resources. The 
flexibility of this approach makes it transposable to other teaching contexts in schools and universities seeking to 
prepare learners for real-life situations.

The originality of this work and its relevance to IT-based training lays in its attempt to optimize the use of a 
single visual and audio recording in adopting a pluri-media approach to instruction. A lack of space has not permitted 
us to present fully the scenario, save to say that such a scenario can be complex and needs careful and systematic 
planning and team work, hence the need for a transparent operational framework like the Scenistic Approach.

Finally, it is our contention that the Scenistic Approach can allow an economy of scale, and of time and effort in 
optimizing available resources for maximum efficiency. This is a crucial factor, as it is our working hypothesis that 
the more teachers see how their IT-based creations can be optimized, the more they are likely to use IT in their 
everyday practice.

Abstract

One of the challenges of lifelong education is creating instructional materials to encourage adults to renew what they 
feel they already know. This is especially true, in the field of professional training, with experienced practitioners and 
where information technology often plays an important role. Using a Scenistic Approach to plan a series of teacher-led 
and self-access "lessons", specially written video sequences were reused in various ways so as to optimize the time and 
effort of material makers. This included making access to the content matter more attractive and more varied so that 
learners can acquire knowledge in their own way. To do this a series of hybrid pedagogic techniques was used, which 
included traditional lectures, role-plays, a self-study video, a DVD-video and learning via an electronic network.

INFUSING TECHNOLOGY INTO THE CLASSROOM: A CASE STUDY IN INTERDISCIPLINARY COLLABORATION

Philip Lewis, M.S. and John Hildreth, M.A.
Radford University, McConnell Library, MultiMedia Center, USA
October 18, 2001
plewis@radford.edu

Abstract:

Effectively incorporating technology into the classroom is paramount at many K-12 and university institutions. Both administrators and faculty have seen pronounced increased in effective learning through the use of multimedia technology when presenting any subject. However, not all teachers can be expected to learn the complex applications that enable effective instruction to their students. New forms of interdisciplinary collaboration need to be invented and investigated. These new forms should incorporate technology more readily and effectively while having a low impact on the already over-burdened schedules of faculty and teachers. Following are the results from a case study of a unique form of support developed through Radford University library’s MultiMedia Center and Music Department.

Introduction:

The course, entitled Introduction to Film Music (MUSC 373, Computer Music Composition), incorporates an historic survey of film music media including literature, recordings and film as well as composition assignments. In the assignments, students are required to learn the parameters of different eras’ film music and technology (including the limitations) and then create their own soundtracks to “audio blanked” film clips. The assignments were edited on a computer and presented in VHS or CD format to the class. The course’s curriculum is based traditional collegiate education themes combined with technology via a collaborative, co-instruction effort between a university music professor and multimedia technologist.

Technologies and composition practices of each medium and time period are presented chronologically and are studied, discussed and experienced through assignments. From Radio to modern film, each era (compositionally and technologically) is delivered.

Results:

The collaboration of the two professionals is mutually educational. Issues arising regarding the intense areas of traditional music and contemporary technology were discussed and resolved by information from both sets of expertise. The findings from this experimental case study offered profound results:

1. Instructors do not bear the burden of ‘learning it all’ before they incorporate technology into the classroom. In this case study, both professionals concentrated on their expertise and were able to offer students a higher level of scholarship because they were not required to focus on or fumble through unfamiliar subject matter.

2. Instructors are involved in faculty development as they simultaneously impart and absorb expertise in their relationship with the co-teacher. Traditional faculty development in technology requires faculty to attend application-training seminars, often with mixed results. A faculty member may be required to learn an application for up to 100 hours before developing the multimedia materials, which necessitates further time investment. Further, the success rate and information retention is variable at best.
The collaboration offered each instructor an opportunity to learn key features of the other's discipline. Teacher and student alike learned from the classroom presentation of materials offered by each instructor as well as through the preparation of each lecture. This form of faculty development offers a timely and efficient manner of technology training. Further, a higher success rate of information retention was achieved.

3. The student benefits from the interdisciplinary delivery and application of course materials, part of which include the dual perspectives and expertise of the faculty. Moreover, students enjoy a fresh approach and are better informed as a result. By having two professors from different disciplines, the students are able to pose questions to each instructor and draw interdisciplinary parallels between the two professions.

Conclusion:

This course represents an intuitive utilization of resources, and the student reaction makes it an exceptional experience for all persons involved. At its core, this case study evidences a situation of one faculty member actively seeking another for technological and educational insight. Logically, the scholarship of both instructors increases as a result of the collaborative sharing and dissemination of applied knowledge both inside and outside the classroom. The outcome is an interactive, cross-disciplinary study that yields highly successful faculty development while also creating a new and exciting environment for student learning.

As technology is further incorporated into the classroom, it is important that instructors and administrators look for non-traditional ways to create better learning environments through multimedia. Traditional paradigms regarding faculty development-style 'tech training' cannot account for all the learning that is needed in the ever-changing instructional technology field. The case study presented here is simply one way of accomplishing this end.

Film:

A 25-minute documentary film was produced from in-class footage of interviews and discussions, as well as instructor interviews, commentary and samples of student work. This film reveals in detail the efforts made by the instructors, outcomes of the assignments by the students and a candid discussion on issues of teaching collaboratively. The film offers further insight into the results of the experiment and is available from the authors. Contact plewis@radford.edu to order your copy.
University Faculty Needs and Desires: Support Model During Web-Basing and Web-Enhancing Courses

Caroline M. Crawford
University of Houston-Clear Lake
United States of America
crawford@cl.uh.edu

Kat Ley
University of Houston-Clear Lake
United States of America
ley@cl.uh.edu

Abstract: University faculty consistently weigh the expectations associated with teaching, research and service. Through the faculty desires to support the success of the learners, numerous faculty have waded into the murky waters of Web-basing and Web-enhancing their coursework. The experience, knowledge and interest associated with designing superior Web-based and Web-enhanced coursework must be shared with university faculty venturing into this new arena.

Introduction

University faculty have numerous expectations placed upon them throughout their professional career. The teaching, research and service expectations can, at times, exceed the capacity of even the brightest and most focused of professionals. Adding the time and effort that is required to follow the instructional design process for Web-basing and Web-enhancing coursework, the faculty have nearly enough time to complete their duties. Therein lies the crux of the situation; the best and brightest faculty are immersed in the teaching, research and service expectations of their careers, yet they are the ones with the experience, knowledge and interest in designing superior Web-based and Web-enhanced coursework for the learners.

So as to take some of the pressure off of the faculty, it is imperative to design a support model for faculty endeavors that will encourage the brightest, best and busiest faculty to seriously consider Web-basing their coursework. Support models take numerous directions, with all-inclusive support models not necessarily being the most appropriate for the university under consideration. The progression of a smaller university through the Web-basing and Web-enhancing of upper-level undergraduate and graduate coursework has developed and revised support models that have worked well, worked with some successes, as well as barely supported faculty with the desire to Web-base and Web-enhance their specialization area coursework. Such support models that address university faculty needs and desires, pertaining to Web-basing and Web-enhancing coursework, are of utmost importance.

Professional Development Opportunity Model

The initial consideration when planning to develop professional development opportunities for university faculty must be the time allocation asked of the faculty. All-day events are not realistic goals; due not only to the time allocation but also to the amount of information dispersed during the professional development opportunity. Once this understanding has been realized, the next step is to consider the process towards successfully meeting the objectives of the professional development opportunities. An initial, large-group environment is appropriate, but then the university faculty should be offered the opportunity to either re-take the initial subject matter experience in a small-group setting or choose to further their level of experience within that subject matter realm by self-selecting towards the more advanced level small group experience.

After this professional development opportunity has been realized, the opportunity for one-on-one, face-to-face support is a component of importance. Enabling university faculty to work within their familiar surroundings offers a level of comfort and support that is desired whenever a new learning experience occurs. As well, World Wide Web-based support components should be available to support the learning that was achieved within the large group and small group professional development experiences. A just-in-time model of knowledge dispersal is appropriate, as well as specific materials associated with the sessions.

Finally, listservs and bulletin board interactive activities should be available so as to either disperse information to interested members of the university faculty. This telecommunicative level of support offers numerous possibilities for important technical and theoretical support and discussions upon the training activities, as well as modeling and practice for university faculty so that they can integrate these telecommunicative activities into their Web-based and/or Web-enabled coursework after they have obtained a comfort level with the communication tools. Following is a graphic representation of the professional development opportunity model described above.
Topics of Importance to University Faculty

Defining the scope and sequence of the professional development opportunities is an initial element of importance towards the success of the stated objectives. The initial phase was focused upon three distinct professional development opportunity sessions that would emphasize the basic creation of a Web-enabled syllabus for the university faculty who participated. The three sessions are described as follows:

Session One:
Objective: Support faculty in developing a Web support site for one of the courses they are currently teaching during Spring 2001. We will offer faculty an instructional template, show them how to manipulate the HTML using Netscape Composer 4.7, hyperlinks (internal navigation links and external)
Reward to Faculty: 5 megs of server space for each faculty member who attends the session, using UHCL server resource allocation

Session Two:
Objective: Support faculty in making Adobe PDF documents, and using file transfer protocol (FTP) to publish Web site
Reward to Faculty: 5 megs more (total of 10 megs) of server space for each faculty member who attends the session, using UHCL server resource allocation
At the end of the Session Two session, faculty will receive a disposable camera to record graphic images to place on their Web site, a coupon to have the film rendered to a CD-ROM for free

Session Three:
Objective: Support faculty to manipulate, integrate and upload digital graphic images into their Web site as well as FTP to the Web server
Reward to Faculty: 5 megs more (total of 15 megs) of server space for each faculty member who attends the session, using UHCL server resource allocation

Each of the professional development opportunity sessions noted above offer the university faculty a distinct reward, so that the level of motivation is maintained throughout the faculty participation. As well, each session offers distinct objectives that can be met within a three-hour block of time.

Conclusion

The objective of the Web-basing and Web-enhancing professional development opportunities described within this manuscript enable all UHCL faculty, SoE and other college faculty, to supplement or replace f2f lectures and activities with Web resources and activities. By the end of the three professional development opportunity sessions, the goal is for each faculty member will have an instructional Web site for at least one of his or her courses.
Web, Web-Enhanced or 80/20: Choosing the Instructional Model that Makes Sense

Abstract: The focus upon distance education over the previous decade has offered numerous hardware and software shifts that can support distinctly stand-alone Web-based and Web-enhanced learning environments. Now the question asked is how to make the learning environments more effective.

Introduction

Distance education has been a reality since radio and telephone have been viable options for teaching at a distance. Yet many suggest that the World Wide Web, with a stable Internet structure stimulating its rapid growth, has introduced significant new possibilities for learning environments. Perhaps the delineation between Web-based and face-to-face courses have reached the point wherein appropriate models that integrate Web-based and face-to-face learning environments must be considered.

Web-based and Web-enhanced learning environments have become viable options for educational programs. Educators have moved beyond the mere integration of the Web as knowledge-level support systems, towards the introduction of higher order thinking skills integration and a focus upon learning communities within a Web environment. Perhaps the aspects deemed innovative are merely appropriate instructional strategies that are being labeled as ground-breaking due to the novel learning environment labeled the World Wide Web. As the Web ages and experience accumulates there is a growth in the number of models of distance education. Evidence and logic suggests that combining web with f2f may indeed have distinct advantages overcomplete web based learning or all f2f.

Pareto Principle

The 80/20 ratio first proposed by the Italian economist, Pareto, in the early twentieth century (Hafner, 2001) to explain an economic phenomena in a human economic system, such as in Italy in 1906, wherein 20 percent of the people owned 80 percent of the country’s wealth. “Over time and through application in a variety of environments, this analytic has come to be called Pareto's Principle, the 80-20 Rule, and the "Vital Few and Trivial Many Rule." Called by whatever name, this mix of 80%-20% reminds us that the relationship between input and output is not balanced” (Hafner, 2001, paragraph 1). This is an appropriate framework towards considering the economic and educational phenomena that is under creation within the Web-based learning environments available for today's learners.

20% of Students Can Take 80% of Instructor's Attention

As the economic phenomena stated within the Pareto Principle is appropriate, this same consideration towards focusing efforts upon the “vital few” students refocusing 80 percent of the instructor's attention upon themselves is a concern within all learning environments, but especially within a Web-based or Web-enhanced learning environment wherein the instructor's time is spent communicating with the learners who vie for valuable instructor time and attention.
Concerns Based Assessment Model (CBAM)

To address this significant issue, implications towards the learner and faculty practices that support the 80/20 rule must be considered. One model that supports is the Concerns Based Assessment Model (CBAM) that offers the following stages of concern: (1) Awareness; (2) Informational; (3) Personal; (4) Management; (5) Consequence; (6) Collaboration; and, (7) Refocusing (National Academy of Sciences, 2002, paragraph 6). Through the CBAM stages of concern, consideration towards different appropriate and successful practices that would enable all learners to obtain the desired level of interactive activities is possible.

Distance Education

Within distance education, more specifically Web-based distance education, the interactive activities available to the subject matter may not always be sufficient for all learners. Therefore, the faculty member focuses an inordinate amount of time ensuring that the learners receive an appropriate and successful level of information and communication. The learner's personality and level of self regulation has a significant level of interplay within this environment which, in turn, may effect the learning environment and the level of assistance required of the instructor. For these reasons, the Pareto Principle must be considered when focusing upon the learning experiences within distance education.

Pareto Principle Applied to Distance Education Courses

Learners have distinct needs that must be met within a learning environment. Whether this learning environment takes the shape of a face-to-face course, a Web-based course, or a Web-enhanced course, the learner's needs are of utmost importance. The reality of the successful learning environment must be addressed. Further, the institutional, faculty and community needs are concentrated upon within the Pareto Principle realm; introducing the Web-based learning environment for up to 80 percent of the learner's needs and then meeting in an optional face-to-face learning environment at least 20 percent within the course timeframe would offer an 80/20 solution that would: meet student needs; increase institutional effectiveness; meet faculty needs; and, meet community needs.

Developing a situation wherein the learners, the institution, the faculty and the community needs are met is not only appropriate, but must be an expectation of the successful learning environment.

Conclusions

Each subject area that delves into the world of distance education must consider the instructional design of the course delivery mode so as to ensure the successful knowledge acquisition of the learners. Within some subject areas, a Web-based environment may be appropriate; however, there are subject areas that not only suggest but actually demand a level of face-to-face interaction so as to ensure the achievement of the learning objectives. Web-based, Web-enhanced and face-to-face of instruction are each appropriate models towards the delivery of instruction, yet the subject matter should drive the instructional design and delivery mode of the course. Each of these distinctly separate yet appropriate learning environment models have strengths as well as weaknesses, yet the subject matter, learning objectives, assessment modules, learners, instructional opportunities and real-world educational environments must remain the center of the decision-making process in order to design superior instruction and learning environments.

Abstract: This paper suggests that the processes of change are moving web educators toward new ways to consider web education and that the change process is ready to refocus the current implicit assumption of web education: a web course is delivered exclusively by web interface. One way to refocus is to apply the Pareto Principle (PP) to web education. The PP suggests guidelines for combining web with f2f within a single course that is consistent with the evolution of change while lowering the barriers to teacher education on the web.

The focus upon distance education over the previous decade has offered numerous hardware and software shifts that can support distinctly stand-alone web-based instruction. Many teacher education programs have been among the first to embrace web education and benefits such as learner access and convenience to sustain considerable demand. Some teacher education programs have rushed to the web while others have lagged behind with doubts. This paper briefly reviews the processes of change that are moving web educators toward new ways to consider web education and that the change process is refocusing the current implicit assumption of web education: a web course is delivered exclusively by web interface. One way to refocus is to apply the Pareto Principle (PP) to web education. The Pareto Principle (PP) when applied to web instruction provides a rationale for integrating web and face-to-face (f2f) activities. The ratio refocuses the innovation toward integrating web and f2f activities. The PP suggests a way to distribute instructional delivery according to the efficiency of each media. The PP suggests guideline for combining web with f2f within a single course that is both consistent with the evolution of change and removes barriers to teacher education on the web.

A small number of causes is responsible for a large percentage of the effect, in a ratio of about 20:80. Expressed in a management context, 20% of a person's effort generates 80% of the person's results. The corollary to this is that 20% of one's results absorb 80% of one's resources or efforts. For the effective use of resources, the manager's challenge is to distinguish the right 20% from the trivial many (Hafner, 2001).

The Pareto Principle Explains The Advantage of Integrating Web with f2f

This means that the web instructor spends 20% of his or her effort putting 80% of the course content and activities to the web; conversely the remaining 20% will take 80% of the effort. Once the course is offered, the PP indicates that the instructor will spend 80% of his/her effort on 20% of the student interactions. Conversely, the PP indicates that a web learner spends 20% of his or her effort learning 80% of the course content and 80% of his or her effort learning on the remaining 20% of the course. If this is the case, presenting an alternative delivery mode for the effortful 20% delivered by web may benefit both the faculty and students if the effortful outcomes are similar for both.

The PP, a standard, empirically supported effort to results ratio, could guide the ratio of web activities and content to f2f sessions. This is a guideline suggested by the amount of effort required to engage in a web course. The principle suggests using a different delivery medium for the roughly 20% of the results that requires 80% of the effort. The 20% of the effortful but low yield activities would be conducted f2f. The principle may not be useful in all cases. There will always be some courses far better suited to one medium than another. For example, courses with expensive laboratory equipment are suited to f2f delivery for economic and logistic reasons.

On the other hand for many web courses, the 80% that requires the least effort to deliver on the web would complement 20% of the more effortful activities delivered f2f. The remaining 20% that requires 80% of the instructor's and students' effort to conduct on the web would be delivered through f2f sessions. These could include interactions between the faculty and students that arise from questions requesting more information about assignments, the content, course logistics, etc., than is accessed through the web. F2f sessions may be one way to address needs of high demand students for whom immediate interaction assuages their concerns; the instructor benefits as well by answering two or three related questions simultaneously in a f2f session. Other activities such as social interaction to quickly establish personal relationships among class members may also be better suited to f2f sessions. Experience and research will continue to define which activities belong on the web but the fundamental principle is that allowing faculty to offer courses that combine activities from both web and f2f in a ratio from 20/80 to 80/20 should lead to more efficient use of both media and better outcomes for preservice teachers, inservice teachers in graduate programs, and faculty than a single-medium course. The positive outcomes for faculty and inservice teachers are among a few other reasons to consider the Pareto Principle for structuring courses integrating two media. The PP presents an opportunity to address the concerns of web educators who have been active participants in web education for some time.

Early-Adopter Web Educators Following Change Theory

The evolution of faculty adopting web instruction is rapidly approaching a stage when the early adopters are turning their concerns toward improving upon the ways to use the innovation. In the early stages of innovation adoption, faculty who supported, promoted, and participated in web instruction, were early adopters of an innovation (Rogers, 1995). Because they were early adopters who embraced the innovation, they quickly began participating in web instruction well before most their peers did.
Consequently they were part of the driving force that shaped distance education at the advent of the second millennium. They were among the first to create the demand for the commercial interests that shaped the distance education market.

This pioneering group was the first to move through the sequential stages described in the Concerns Based Assessment Model (CBAM; Hord, William, Huling Austin, & Hall, 1987) that was developed for use with teachers to identify their training requirements. The CBAM classification scheme identifies an individual's stage of change by the individual's concerns about the change. Typically, the person adopting the change will first be concerned about personal and management issues related to the change before he or she considers outcome issues such as student learning. The CBAM proposes that an individual adopting an innovation progresses through stages of concerns that correspond to their level of use with the innovation (Hall, George, & Rutherford, 1977). While the stages may vary by individual, most individuals progress through the stages relatively in order from personal concerns to outcomes concerns. Early-adopter web educators would be concerned about how to manage an innovation before they would begin to ask questions about its affect on student learning. In the later stages of change most educators begin to collaborate about the uses of the innovation. Those concerned about ways to improve upon the use of the innovation have concerns expressed in the last stage of change. Those in the final stage of change explore how the innovation can be used even more effectively than originally intended. Most faculty in the United States are past the first stages of awareness and information seeking and many more have personal concerns about how the innovation will affect them.

If the literature about the web is any indication, by the late 1990s early web education adopters had moved to concerns about how to manage distance education. Reflecting the management concern, the literature includes several guidebooks with prescriptions for creating and managing web-based instruction (Ellis, Wagner, & Longmire, 1999; Hall, 1997; Khan, 1997; Palloff & Pratt, 2001). These books are very useful for producing web-based instruction. Just as the publishing surrounding web course innovation offered solutions to managing web instruction so, too, has the commercial sector offered management solutions. Commercial interests in the form of "corporate entities specializing in total solutions ... offering complete course and distance learning program management tools to institutions" are shaping the most dramatic online change in the recent past (Palloff & Pratt, p. xiii). Both the commercial and the educational sectors have often presented web courses as the alternative to f2f courses. The artificial dichotomy inhibits the adoption and integration of web with f2f for course delivery that has the benefits of both. On the other hand, the PP applied to web instruction can facilitate adoption and integration.

Transcending the Web-f2f Dichotomy

The discussion in web education literature often is polarized around web versus face-to-face delivery and the advantage of one extolled over the advantage of the other. On the other hand media comparison studies have long been ill advised. Much of the literature and research about and with web-based courses juxtaposes web with f2f courses (e.g., Gilmore & Fritsch, 2001) although media comparison studies are not recommended. Even while eschewing "simple comparisons of Web-based courses to those employing any other format," one extensive review focused on the salient predictors of web student success (Anderson, 2001, p. 47).

To examine what leads to web student success is to implicitly assume that web courses can and will be restricted to web delivery. This perspective assumes that the web is an alternative to f2f not a complementary media although even researchers have investigated web courses that included f2f activities.

Because researchers do not define web instruction the same, their conclusions about web instruction may not be comparable. One study with teacher education students operationalized web instruction to include f2f encounters although the abstract and conclusions do not refer to the inclusion (Daugherty & Funke, 1998). The researchers concluded that the students' reactions to web course interactions deviated from the literature: they were more positive and enthusiastic about web communications. Could the f2f interactions have accounted for the greater satisfaction with the web course communications? In this study teacher education students indicated that the primary advantage to web instruction was convenience in working a course into busy schedules. This is a benefit which students still valued strongly although they had f2f interactions included in the course. When combined, web and f2f activities and content offer unique advantages of each through a complementary instructional delivery mode.

Another recent article contrasting web to f2f instruction described two different commercial training courses, one delivered by completely web and one by f2f (Johnson & Buchanan, 2001). They concluded that the f2f course had more faculty and student discussions and the web course had more reading and drill and practice. In the f2f, faculty discussions took about 20% of the activity time and about 70% of the activities in the web were reading and drill and practice. The differing use of activities by course in one or the other medium suggests that it may be easier to include these types of activities in the respective medium each dominates. Therefore incorporating f2f with web may be useful for providing different types of activities more efficiently. Furthermore, applying the PP to the distribution of web to f2f activities can also yield positive institutional, environmental, and community welfare outcomes.

Pareto Principle Applied To f2f Courses

In the larger environment of the university, web courses with complementary f2f sessions can have positive outcomes for the community at large. Both quality of life factors such as traffic congestion and air pollution would be relieved by replacing even a few sessions with virtual activities or content at an urban commuter institution. For example, for every 5,000 students who replace three f2f sessions a semester with web activities and content, there would be 15,000 fewer auto trips a semester; that is 60,000 fewer trips over a year to and from the congested urban streets surrounding the university. There would be a commensurate reduction in auto emissions and road congestion two serious urban problems. Replacing or supplementing f2f activities, such as lectures at an urban commuter university, with web-based information or virtual activities should ease environmental impact of the university on the region. Two f2f courses that replaced at least half of the f2f sessions with web activities could be scheduled in the same classroom space over a semester by alternating sessions. Students in web-supplemented courses will have the benefit of increased access to course materials and content and increased convenience created when f2f sessions are replaced with web. Benefits of placing up to 80% of the activities and content of a course most suited to the web on the web should yield benefits of both web and f2f courses.

Conversely incorporating some web into f2f courses should yield the benefits of both although perhaps in different ratios. Faculty and administration may stimulate further adoption among faculty by promoting limited web integration. Late adopters and
those most resistant to change would have a less dramatic and a less effortful change required to offer f2f courses that incorporate some web activities and content than to begin with a total web course. A partial adoption model for combining web and f2f courses will enable faculty who might hesitate to launch a 100% web course should find a web enhanced course much less daunting. They would be able to use f2f sessions, a more familiar mode, for feedback and discussion with students. Encouraging instructors to offer courses combining web and f2f sessions allows for a wider range of adoption possibilities to facilitate faculty adoption. Faculty might choose a predominantly f2f course with the web as a repository and distribution center for course syllabus, assignments and other materials. Some would also use it as a conduit for submitting assignments. Those who want to begin integrating the web can replace one or two sessions with web activities or content can do so. The combination approach is suited to gradual, incremental change that later adopters of an innovation require.

Administrators may realize the advantages of being able to schedule more classes in the same space. By enlisting more faculty to offer web courses and to supplement f2f courses with web activities and content, administrators should be able to schedule two or more courses within the same classroom. For example a web course with three f2f sessions could be in the same space, at the same hour for three of fifteen sessions shared with a f2f course replacing at least three f2f sessions with web activities. Administrators in teacher education programs should be especially interested since those programs often seek to innovate and to model best practice. Students stand to gain the most since they will have the advantages of both media and be able to engage in whichever of the two media are most appropriate for the instructional activity. They will have the convenience of web activities and content combined with the efficiency of real-time, f2f interactions for activities such as clarifying or explaining web content or written feedback.

Conclusions

This paper suggests several reasons to consider integrating web and f2f activities within a course that may be more compelling than the reasons to use one medium over the other. There are potential faculty, student, administrative, community, and quality of life outcomes addressed through integrating web with f2f activities. The PP provides a guideline for one approach to integrating the two. Faculty and students can benefit from planned f2f activities designed improve the efficiency of the most effortful activities conducted in web courses. Administrators who support faculty efforts to replace f2f sessions with web activities encourage change among late adopters and may find new classroom space when f2f faculty replace sessions with enough web activities to schedule two courses in the same fifteen-week semester space. The community and environment may also benefit from reduced traffic congestion and pollution in urban universities that offer f2f courses complemented by web activities to replace the commute to f2f sessions. Finally applying the PP will facilitate the final stage of change among those web educators who are eager to devise new ways to use the innovation. The opportunity awaits those who want to move beyond managing a web course to redefining how the web should be integrated into a course.

The Inquiry Learning Forum: Online Professional Development with a Community Orientation

Julie Moore, Indiana University, US

What is the Inquiry Learning Forum?

The Inquiry Learning Forum (ILF) is a NSF funded research and development project seeking to support an online community of K-12 math and science educators working together to share, improve, reflect, and create learner-centered classrooms. While developed primarily for Indiana math and science teachers, the ILF is open to all teachers, school administrators, university faculty, and pre-service education students interested in inquiry-based teaching and learning, free of charge.

The ILF is designed around a school metaphor. When members enter the ILF they have the option of visiting several "rooms" that are typical of a school building. Within these spaces members can obtain or share lesson plans, view video examples of fellow teachers, engage in online discussions, and work online with groups focused around a particular topic or idea.

The goal is not to present a practice to emulate, but rather to provide a vehicle for discussing teaching practice and advancing community and individual reflection and understanding. Through observation, discussion, and reflection, each participant can find his or her own path to continued professional growth and development.

Classrooms

When we asked teachers what they would like to do for their own professional development, their response often was to see someone else teach. While that's difficult to do during the school day, the Internet makes it possible for teachers to "visit" other teachers' classrooms at a time when it is convenient for them.

In the ILF Classrooms videos of actual lessons act as anchor points for these virtual "visits." Each Classroom also includes teacher reflections on the lesson, discussions, links to various standards, lesson plans, examples of student work, and resources.

Lounge

Not only do ILF members get to virtually visit other teachers' classrooms, they also participate in discussions about practice with other professionals. The Lounge has a series of discussion forums focused on specific topics related to inquiry based teaching in it.

It is through these dialogues that teachers reflect on their own teaching and begin the process of exploring alternative teaching practices that they can apply in their own classrooms.

Inquiry Lab

The professional development activities found here can be utilized in a variety of settings, whether by individuals or groups. They are designed to fit the needs of teachers starting inquiry for the first time, or looking to enrich their teaching with more innovative applications of inquiry-based teaching.
The ILF Professional Development Labs are based on the Concerns-Based Adoption Model, commonly referred to as "CBAM" (Hall, 1979). This model of teacher change suggests that teachers go through various stages of change characterized by different concerns they have regarding the change or innovation. Our Professional Development Labs are organized around these stages and the types of concerns teachers have at each stage.

**Library**

The Library is a collection of lesson ideas and web links suggested by teachers for teachers. While viewing an item in the Library you can read how teachers have used the resource in their own classrooms. The Library has two collections:
- Lessons, Activities and Unit Ideas: materials and lessons developed by teachers for use in their own classrooms for you to download
- Web links and Other Resources: Links to materials, lessons and resources published in print or on the World Wide Web

**Collaboratory - Inquiry Circles**

An Inquiry Circle is a collaborative group space in the ILF Collaboratory. It's a place where groups or teams can share resources, ideas, and experiences! These collaborations can center around:
- Curricular Topics (i.e. water quality, astronomy, etc...)
- Professional Development Opportunities
- College or university courses

Each Inquiry Circle has a facilitator who serves as the central contact person, provides new members with access to the Circle, and answers any questions. For example, a university pre-service instructor may want to create an Inquiry Circle for her students to work with teachers in the field.

**My Desk**

The My Desk space is a personal portal to the ILF. Through My Desk, users can:
- View and update their personal profile
- Leave notes in their personal journal
- Keep track of their ILF activities, classrooms and discussions
- Store bookmarks to both ILF and external resources

**The ILF Office**

The ILF Office is the administrative portion of the site. At the office members can find out more about upcoming ILF events, make a suggestion for improving the ILF, learn how they can be videotaped for future ILF classrooms, and meet other ILF members by viewing their online profiles.
Beyond Times Roman

Gillian Mothersill, Ryerson Polytechnic University, CA

Since the advent of electronic publishing in 1985, typography has ceased to be the exclusive domain of the craft-based typographer or graphic designer. In a short span of time, more type designs have been introduced into the marketplace than in the entire period of printing history prior to 1985. The widespread use of computer systems has placed layout and design decisions into the hands of many who are interested, but largely unqualified to make them.

The overabundance of typefaces, combined with the lack of understanding of the craft of typography, has consistently led to some egregiously awful examples of typographic design in published material, resulting in viewers ignoring or not receiving the intended messages, in part because they cannot read them.

This workshop seeks to look beyond Times Roman, the typeface that is the de facto standard on many current computer systems. Through a series of presentations, hands-on exercises, and typographic “scavenger hunts”, the workshop participant will develop a practical understanding of:

- Typefaces, families and fonts
  - Size, slant, weight and width
  - Typographic measurement systems
  - Monospaced and proportionally spaced fonts
  - Serif and sans serif typefaces
- Readability and legibility
- Type sizes
  - How to select the appropriate size for your audience
  - How to select the appropriate size for your document
- Measure
  - Identifying the optimal column width
- Letter spacing
- Word spacing
- Leading or line spacing
- Alignment and justification
- Type colour, and “colour”
  - When to add colour, and when to avoid it
  - Colour and the effect of contrast with the substrate
- Special Effects
  - Stretching, bending, masking, adding blends and photographic imagery

Throughout the sessions, participants will learn to identify common errors in typeface selection and use, by investigating everyday items such as magazines, packages, and newspapers for problems.

In addition, participants will learn simple tips regarding mixing and matching typefaces in documents that they are designing.

The workshop will pay particular attention to the needs of the participants and their use and questions about typeface use, whether it is on the World Wide Web, or on materials printed on a laser printer.

Participants will gain insight into the basic technical considerations of selecting Truetype and Postscript typefaces for their documents.

Workshop participants will be provided with:
- A workbook for their session
- A list of typeface vendors and foundries
- An annotated list of resources for obtaining additional information about typography
Realization of a Decision-Making Support System within a Whole Class.

Hiroshi Nakayama*, Rouji Shibata*, Hiroyuki Yaguti*, Siniti Shiwa*, Syoji Yamaguti*, Osamu Hosomura*

Tokyo Denki University
Japan
nhiroshi@hucom.tp.titech.ac.jp

Abstract: In this study, we will lighten the instructor's burden of a decision-making and develop a decision-making support system to support making an effective decision. The mechanism of decision in this system totals the data of a real class situation collected with LAN and the predicted data of a class situation that is determined by the instructor in the stage of instructional plan according to their point of view in the system. It also makes a guideline that becomes the interim data. This system applies the interim data to the rule of decision making and shows the advice that is needed for the instructor. This system has three mode. In an explanation mode, the system searches for a point that confuses students and advises them. In a questioning mode, the system analyses achievement situation of a whole class and shows advice.

1. Introduction
This paper describes the development of a decision-making support system within a whole class. This support system can help the instructor make an effective decision quickly and reduce the burden on the instructor, because it presents digestible information to the instructor in response to the information coming from the students in the class. This decision-making support system is based on Matsuda's (see[2]) instructional activity model.

2. Design of the system
2.1. Connection of the instructional activity model and the test support system
Activities that are used for the test support system are underlined.

Before the class, the instructor makes an instructional plan.

\[ \text{When using a question as the communication method, input questions from the screen to make test questions for the test support system.} \]

In class, the instructor explains and gives directions using the Web, a black board, or by oral expression according to the instructional plan.

\[ \text{In addition, presenting the test using the Web.} \]

Students study the lesson contents and answer the test question.

\[ \text{Students send test answers on the Web, ask questions, and are free to express their feelings.} \]

The test support system gathers and summarizes the test scores in real time, and displays the result to the instructor.

The instructor views the students' test results and estimates the degree of their understanding by way of their movements, facial expressions, and questions.
Show the response of ., compare the test results to the predicted results.

Using the results of . and ., carry out feedback.

If there is no significant difference, continue with the instructional plan. If there is a significant difference, modify the lesson contents or the communication method accordingly to the teaching materials and the instructional aim.

### 2.2 Improvements to develop a decision-making support system

Explaining the detailed improvements with figure numbers of Figure 1. A decision of human is based on the gap between the predicted class situation and the real class situation. In order to support this system, the system needs to have information about the instructional plan including the prediction of the class situation. Then, in stage , which is the making of test questions, set up an input interface consisting of the class’s progress and input data of the class’s progress consisting of four elements (the predicted data of the class situation, the data of the instructional aims, the data of the lesson content, and the data of the communication methods). The predicted data of the class situation tries to find the cause of the test’s mistakes and uses it to provide the instructor with advice by gathering the responses from the learners in the presentation. The presented teaching materials from . plus . are constructed and can gather subjective evaluations of the class from the learner. This system needs to compare the predicted data of the class situation at . and the data of the class situation at . simultaneously by way of . In addition, the system of . plus . acknowledges the gap and advises an appropriate response to it.

![Figure 1: Instructional activity of a decision-making support system](image)

### 3. Conclusion

The purpose of this research is to build a decision-making support system that can help the instructor make an effective decision quickly and reduce the burden on the instructor. As a result, of this system being employed and evaluated in the experiment class, we know that a teacher accepts the advices from the system as an index of the judgment for the class progress support and confirm that this research purpose was attained.

Instructional Development for Knowledge Creation in Large-scale Class

NISHINOSONO, Haruo
Bukkyo University
Kyoto, Japan
Nisinohr@bukkyo-u.ac.jp

Large lecture rooms in universities have been designed to accommodate a large number of students to disseminate the most recent academic and/or professional knowledge produced in the higher education. The recent development of information technologies facilitates the knowledge dissemination through TV, Web sites and other technological media. The role of higher education is expected to change from knowledge dissemination to knowledge creation. Seminars and small group discussions are most widely adopted to meet this requirement. In spite of such expectation, large-scale lessons are indispensable in higher education due to financial reasons and social needs. The large-scale lessons in new style other than lectures are needed to develop for universal higher education in large diversities of audiences.

To develop such instruction in large-scale class, following principles and models are developed;

* Five principles for learning
  - ACCRR model (Autonomy, Collaboration, Contribution, Responsibility and Respect)
* Six components for learning plans and material development
  - MACETO model for instructional design (Meaning, Activities, Contents, Environment, Tools and Outcome).

This method was applied for the development of lesson plan in teacher training course at Bukkyo University in Kyoto. It is very difficult for students to start from the description of instructional objectives to develop lesson plans. They start to express their images and models and describe them in form of graphic representation to express their primitive concepts of school education; Students have their experiences as learners in elementary and secondary school already, feel hard to start from reflection on teaching and have their images on school life, teachings and teachers. Starting from this assumption, students work in team and create instructional modules for their lesson.
Building scenario-driven, real-world online courses

CJ O'Connor, Arizona State University, US
Paul Skiera, Arizona State University, US

In this session, the ASU e-Learning team will share their experiences in developing an online Information Technology Fundamentals curriculum. The team will demonstrate how they use "real-world scenarios" to develop the course content. The use of a "Reusable Learning Objects" strategy will be demonstrated. The team will demonstrate how they created "virtual labs" to simulate the use of "real-world" objects, such as computer parts.
Interactive, Multimedia Online Courses: Meeting Administrative, Development, and Dissemination Challenges

CJ O'Connor
Technology Based Learning and Research
Arizona State University
United States
cj@asu.edu

Abstract: This paper describes the challenges encountered during a 4-year grant to develop and disseminate online courses in technology. These challenges are administrative, developmental, and dissemination and includes: staffing, planning, evaluation, partnerships, intellectual property, interactive multimedia, learner involvement, accessibility, portability, and publicity, among others.

Project Description

The United States currently needs 350,000 computer networking professionals and an additional 1.3 million by the year 2005. Many adults, including displaced military personnel, recent GED recipients, and those with disabilities or special needs, want to begin or advance careers in networking. However, most of these adults do not have adequate access to training due to high cost and limited availability. In order to meet this need, Arizona State University (ASU), Cisco Systems, and Pearson are developing online networking and information technology curricula materials that include graphics, video, hands-on virtual labs, and simulations. The Fund for the Improvement of Postsecondary Education (FIPSE) grant has funded a nationwide integrated training program, the e-Learning Network, to provide 100,000 adult learners low cost, anytime, anywhere quality networking instruction and preparing adult learners for two existing industry certification examinations: the Cisco Certified Networking Associate (CCNA) and the Cisco Certified Networking Professional (CCNP). As of October 2001, the online CCNA and CCNP curricula have been completed and disseminated through the Cisco Networking Academies in high schools, community colleges, and other vendors. Cisco Press has published textbooks and lab companions for both of these curricula. Additionally, ASU has completed several lessons in the online Information Technology Fundamentals (ITF) curriculum, which are available through the ASU e-Learning Network web site. The ITF curriculum is intended to prepare learners for the CCNA courses as well as provide computer literacy for a wider population. Formative and summative evaluation of the networking courses is being conducted by outside evaluators in conjunction with 10 pilot sites around the country.

Challenges

Over the course of a 4-year, multi-curricula, multi-partner, and multi-million dollar project, one can expect that there will be challenges. Indeed, there has been more than enough to keep life interesting. That the project has continued on a successful path is a tribute to government support, project leadership, conflict resolution, positive thinking, staff shuffling, crisis management, talent recruitment, sheer will and determination, and an abundance of dedicated teamwork. This paper will briefly address administrative, developmental, and dissemination challenges likely to occur in a project of this nature.

Administrative Challenges

Administrative challenges include partnership issues, staffing, turnover, timelines, and costs.

Partnership issues

Probably the most critical administrative issue in a project like ours is the choice and formation of a partnership at the beginning of the project planning stage. Many government-funded grant programs require at least one partner who will contribute matching funds of at least 100% of the grant award. Initiating partnerships is a relatively easy process; maintaining them over a period of four years, however, can be extremely challenging. It is particularly difficult for partners who have never worked together before. Invariably, while partners may share common global visions and goals, when it gets down to the operational level, they may find themselves very quickly at a fork in the road, forced to go separate ways. Additional troubles can emerge in the form of battles over the rights to
intellectual property. The result is a recipe for a shaky partnership that needs significant and constant attention to keep it together. Better to have resolved these issues prior to beginning the partnership. Further complications arise when one partner "volunteers" the involvement of another partner, who then bails out of the project. Is the first partner responsible for the actions of the second partner? An economic downturn can force a partner to withdraw from financial commitments that were made in better times. For grant awarded projects, a loss of a partner can mean the collapse of the project, especially if matching funds depend on a single partner. In our project, a battle over intellectual property rights threatened to bring the project to a halt. We lost our publications partner (Pearson) after the first year, leaving the project temporarily without essential pilot sites, student scholarships, and funds for site coordinators. Nonetheless, critical partner support has continued, compromises have been struck, and the objectives of the project continue to be met. For long-term projects, partner recruitment never ends and time must be allocated to this important endeavor.

Staffing

Our project required experienced staff with skills in curriculum development, instructional design, technical writing and editing, web technology, multimedia development and tools, programming, graphics design, video production, networking and information technology subject matter, quality control, project management, presentations, research and evaluation techniques, and grants management. To turn a phrase, it took a village to deliver the goods. Hundreds of employees and contract staff worked for Cisco Systems on the development, production, and language translation of the CCNA and CCNP curricula. At ASU, 45 people (part-time and full-time, employees and students) contributed their skills to the development of the ITF curriculum.

Turnover

Attracting and weeding talent is an ongoing, critical challenge. At the end of the first year of the project, the entire technical staff and project manager left ASU to join our primary partner at the time, Cisco Systems. A new project manager was hired to reconstitute a development team. Over the course of the second year, the team was rebuilt, but the loss of networking subject matter experts was never overcome. As a result, a great deal of time that was intended for production had to be diverted to researching content. In addition, the allocation of all staffing resources in the first year to product development meant that many project management tasks never got done until the second year. In the process of shuffling staff and reassigning tasks, we found some of our best talent within the student body at ASU, especially foreign students. Our best supervisors were professionals with practical graphics, video, and courseware production experience.

Timelines

A significant challenge involves keeping the project on target and producing the deliverables at the appointed hour. A significant amount of time was spent planning the curriculum, with input from pilot sites (students, administrators, and instructors) and subject matter experts. Course maps and course objectives were developed and reviewed. Web interfaces were drafted and tested, and usability studies conducted. Accessibility issues were researched and solutions tested. Production supervisors juggled priorities to handle this project along with several other large curriculum production projects. The word "deadline" seemed to appear in the daily dialogue as often as the word "hello." Yet, the project moved along, with Cisco taking over the CCNA and CCNP curricula and ASU focusing on the ITF. Project participants maintained focus, motivation, humor, and teamwork throughout all the challenges. The team was committed to quality, excellence, and innovation.

Costs

Developmental projects come with high price tags, which is why grant-supported projects are important, especially in the field of education. Our FIPSE grant award is for $2 million over a four-year period, matched with matching funds from our partner, Cisco Systems. To meet the challenge of cost containment, we employed a strategy to streamline the developmental process. This strategy involved the creation of "reusable objects" which include media objects (pictures, animations, video) and lessons or portions of lessons that can be used in several parts of a curriculum. Design templates and programming code also provide economies of scale.
Development Challenges

Since this project is a "development" project, you might expect there to be a number of developmental challenges. In developing a learning product, as with any marketable product, it is essential to assess the target audience and tailor the development to meet their needs. Feedback from students using early versions of the CCNA online courses indicated the need for improvements to the web interface and structure of the program, calling for: non-scrolling, limited text per page; more interactive exercises and less reading; printable pages; more consistency in terminology throughout the course; and better navigation to indexes, glossaries, and lessons. We took these into account in developing the ITF web interface and modules and added innovative features to make the learning experience more interactive and robust.

Content

For the Cisco Networking courses, content was developed to reflect the knowledge and skills required for Cisco technicians. With a great deal of experience in the field, it was relatively easy for Cisco developers to define the course objectives and content. They also had a previous version of the CCNA course to build on. When it came to the Information Technology Fundamentals (ITF) curriculum, it was a different story. The ITF was intended to be both preparatory to the CCNA curriculum and to widespread computer literacy programs. The ITF would hopefully be used to encourage adults new to technology to prepare for a career in technology. To meet these goals, several groups were contacted for input and several debates were held to determine the scope and sequence of the content for the ITF curriculum. The development team selected ten modules, developed course maps, and wrote course objectives. Some modules (the Number Systems and the Electricity modules) were difficult to write, especially since subject matter experts were scarce. Other topics (like networking and computer components) were much easier. One particularly challenging task was to solicit input from networking and A+ Certification instructors at the pilot sites. While we did receive input on the types of modules and subject areas that the instructors thought were essential, we pulled most of our material from other sources for subject matter.

Quality vs. Quantity

One of the biggest challenges in developing online courses is balancing the "quantity" of course content with the "quality" of the learning experience. The CCNA and the CCNP emphasize quantity of content, with dozens of chapters of material in each course, mirroring much of what can be found in the Cisco textbooks, but supplemented with animations and lab activities for students to carry out in the classroom. The ITF modules were constructed to incorporate Pareto's Law; i.e., we addressed only the 20% of the content of A+ and Net+ curricula that would account for 80% of the common knowledge and everyday scenarios that a computer user or new technician would encounter. Then we took this concentrated core and "made it come alive" as a media-rich learning experience, using multimedia such as animations, video, simulations, photos, charts, interactive exercises, crossword puzzles, and more.

Web Interface

The web interface for the CCNA and CCNP curricula was designed by Cisco to be delivered in many countries and many languages. As such, it incorporates the "Cisco" look and a consistent navigation throughout. The act of standardizing an interface creates a new challenge: dealing with the inherent limitations in the degree of creativity and variety that can be produced within it. With the ITF curricula, a great deal more flexibility was planned into it, while also maintaining a consistent style and navigation. The use of Macromedia Flash provided us with a large degree of flexibility in terms of creativity, but has also produced challenges in terms of accessibility issues. In the coming months, we will be creating printable and accessible versions of our ITF modules and will have an opportunity to see how our interactive lessons and web interface translate to handle accessibility issues.

Another challenge we faced was how to "personalize" or "customize" the ITF learning experience, which we felt was important as a way to save people time and provide customer service. We set out to answer some customer service questions. Firstly, why should users have to wade through content they already know? Secondly, when a user quits a course and returns to it another day, why should they have to remember what they already reviewed and how well they did on their assessments. Thirdly, wouldn't it be nice if users could take notes while going through a lesson and store them online, to retrieve them another day? In order to provide the tools to address these questions, the technology of personalizing a web site involves databases, tracking scripts, and dynamic delivery methods. All this requires developmental time, logistics, programming, database maintenance, and login procedures. It also requires the commitment of the user to log in and out correctly. The personalized module enhancements we developed are provided only to Pilot Sites. The general public gets the "plain vanilla" version of the ITF curriculum, which is an excellent program, just not personalized.
Interactivity

During the planning process, we took the position that it was critical to incorporate as many real-world scenarios, activities, and simulations that would provide a rich learning experience and ample opportunities to practice skills in a virtual environment. To this end, we hired students with programming skills to develop a number of simulations and tools including the following: partitioning and formatting a hard drive; editing the BIOS settings; setting up a workstation on a network; a Dynamic Notepad for taking notes while working through the modules; and a messaging feature to send feedback to the developers or to send questions and comments to an instructor. One of the challenges we faced involved the duplication of reality. For our simulations, every screen and activity must look as close as possible to what a learner might encounter in real life. To achieve this goal, real life activities had to be videotaped or repeated several times to record all the text, actions, and visuals involved in the process. These were translated into graphics and programming scripts, which were then orchestrated into lessons containing information as well as instructions on how to carry out the steps. As can be imagined, it took months, a great deal of patience, and attention to detail to produce the simulations and integrated lessons. To be cost-effective, we had to be selective in what we would simulate. One important criterion we used was to choose specific processes that learners would most likely need to do as a technician but which would be difficult for them to practice at home or in classrooms.

In addition to simulations, we created other devices to involve the learner, including: knowledge checks, crossword puzzles, animations, drag-and-drop activities, math calculations, “show-me” opportunities, pre-and post-assessments, tours, glossaries, and references. Each of these devices presented challenges in their creation and implementation. The ultimate challenge we face now has to wait for months (until we get sufficient users and feedback) to determine if any of our design strategies is making a difference to learners or instructors. This determination will be the task of our evaluators.

Evaluation

An independent valuation of products is essential in a development project. We need to get feedback from instructors and students to determine if the courses are making a difference in their lives. In order to acquire meaningful information, our external evaluator, Rockman Et. Al. has had to gather baseline data such as demographics, student achievement levels, and student satisfaction from the pilot sites. This was no small task. Another round of data gathering will need to be conducted from the same sources after the ITF modules have been distributed and tested. Hopefully, the challenges will be met and we will be able to gauge the effectiveness of our learning products.

Dissemination Challenges

The third area of project challenges is one that we are just beginning to encounter and have another 18 months to fully experience. As we move to complete the developmental stage and begin to move into the dissemination stage, our challenges include: product delivery, marketing and publicity, and web maintenance.

Product Delivery

With the involvement of Cisco Systems, the dissemination of the CCNA and CCNP curricula (online and in print) has been done through their widely dispersed Cisco Networking Academies, which are administered by Cisco and delivered primarily through high schools and community colleges. The population they serve exceeds 100,000, so there is a large audience for the courses. Through their assessment system, Cisco is able to obtain valuable information on student achievement and needed course improvements. The Cisco Networking Academies also allow networking instructors to contribute lesson materials, which expands and enhances the curricula. The ITF modules are being released (published on our web site) at an average rate of one per month, with two versions available (a public version and an enhanced version for research purposes and available only to participating Pilot Sites). Our strategy involves the release of the public version first, followed by the research version. There are 4-5 lessons in each module, with an average completion time of 2 to 3 hours to complete each module. As the modules are released, emails are sent to the Pilot Sites informing them of new additions. A distribution list of additional potential users is in development and will be used extensively in 2002.

Marketing and Publicity

Getting the word out and encouraging use of the courses is a challenge common to most developers. Cisco’s course distribution system, the Cisco Networking Academies, provides an excellent marketing and publicity venue. It is our hope that, in addition to the CCNA and CCNP curricula, Cisco will also promote the ITF modules to the
Academies. We expect to make the rounds again in person to the Pilot Sites to encourage their participation in the use of the ITF modules. In addition, the forward plan is to develop a certification course to be offered at ASU once all the ITF modules are completed. We have begun to show the learning products at conferences and offer project papers on our web site.

Web Maintenance
Cisco maintains an assessment server for the CCNA and CCNP courses and the participating schools in the Cisco Networking Academies maintain content servers. ASU maintains the web server for the ITF modules. There are many challenges for both avenues: bandwidth issues, maintaining user databases and confidential test scores, updating content and maintaining links, tracking usage and analyzing web logs, and keeping servers running through various outages and maintenance routines. Staffing these activities and sustaining them past the grant award period is a critical challenge. During the early stages, when usage is low and demand is reasonable, project managers can be lulled into thinking all is well. Then, there comes a day when things go wrong or demand explodes, and customer service is compromised. We use the web logs to stay alert and prepare for the future.

Summary
The e-Learning Network, as a FIPSE LAAP grant project, is progressing with online courses to prepare adults for networking careers. In its path, many challenges have loomed and been met; many more remain. Administrative, developmental, and dissemination challenges have been the subject of this paper. More information is available on our web site and listed below.

Teacher as Instructional Designer Approach to Integrating Technology Into Preservice Teacher Training

Glenn Shepherd
Educational Technology
Jim McGlinn and Sandra Byrd
Education Professors
University of North Carolina at Asheville
United States
shepherd@bulldog.unca.edu

Abstract: This poster/demo will provide information on a PITT sponsored project in process at the University of NC at Asheville. This project is part of a PTTT collaboration between UNG-Ashville, Appalachian State University, Western Carolina University, and Warren-Wilson College. The emphasis of this project is to improve the opportunities for preservice teachers to integrate technology into their student teaching field experiences. Preservice teachers, cooperating teachers, and university supervising teachers were brought together last summer in order to design and develop a thematic unit based on the North Carolina state standard course of study and the integration of information and technology skills. The thematic unit during the summer 2001 institute was archeology. Several teams of teachers participated in this project during the summer to develop unit plans that were then implemented during student teaching in the Fall 2001 semester. Teams used instructional systems design methodology in helping them to decide when and why to use technology as resources to match the selected instructional strategies. Teacher creativity in designing interesting and motivational learning environments is the key to this approach. Further projects of getting teams to work together before the student teaching semester are being developed at UNG-Ashville based on the success of this summer project.

Introduction

The University of North Carolina at Asheville (UNCA) is involved in the continuous process of improving the preparation of today’s teachers. The integration of technology and information skills into the regular classroom is a goal of the UNCA teacher education program and the Impact program in North Carolina.

“Media and technology programs should focus on student achievement and involve the entire staff in planning instructional programs that are enriched by high-quality resources and state-of-the-art technology. A learner-centered approach to instruction focuses attention on media and technology programs as vital instructional forces that expand, support, and complement classroom learning.”

http://www.ncwiseowl.org/Impact/Teaching_learning.htm

The information explosion and the technological advances have caused educators to re-examine what and how we teach and how we prepare others to teach. The effort to change the vision of education to include a dynamic, integrated, student-centered approach will take collaboration between everyone involved in the educational system. "Collaboration, like communication, is essential in today’s world. Working with other organizations to promote a common goal has a greater chance of success. Collaboration involves the communication of one’s vision in such a way as to generate support for one’s program." (North Carolina Educational Technology Plan 2001-2005, http://tps.dpi.state.nc.us/techplan2000)

The NC Impact program goes on to further explain that “Collaborating to achieve instructional goals means:

- Ensuring that instruction takes place in a student-centered, project-based environment.
- Planning projects and activities with teachers that are relevant to real-life problems and supporting the development of critical thinking and problem-solving skills in students.
- Creating small group activities with heterogeneous groupings to accomplish curriculum goals and objectives.” Impact, Teaching and Learning. North Carolina Department of Public Instruction.
http://www.ncwiseowl.org/Impact/Teaching_learning.htm
Project

UNC-Asheville, in collaboration with Appalachian State University, Western Carolina University, and Warren Wilson College, received a PTTT grant in 2000-01 for three years. The overall purpose of our grant is to help us improve opportunities for our student teachers to use and integrate technology into their student teaching field experiences.

This presentation will highlight the Teacher As Instructional Designer approach that UNC-Asheville is presently using to help preservice and inservice teachers integrate technology into their classrooms. The main thrust of this approach is to tap in on the creativity of teachers as designers of the instructional environment. Creative teachers can design interesting and motivational learning activities to engage students in real-world, challenging instructional experiences. This approach was used last summer during a collaborative week-long workshop between the four colleges.

The theme of this summer project was archeology. We had 12 teams of cooperating teachers, student teachers, and supervising teachers who participated in this project. The beginning of the project included an overview of archeology and information about an archeological dig taking place at Warren Wilson campus. We then provided an overview of the Teacher As Instructional Designer approach. This approach, which uses the five major steps in the instructional systems design (ISD) method, was used to show teachers how they can select the instructional methods and materials most appropriate for their stated objectives. All teams worked on specific unit plans that could be used the next semester by the student teachers. Teams went down to the local archeological site and dug for archeological evidence. Then they spent the rest of the week on the Internet and created their unit plans and web sites to support their plans.

At UNCA, we are also incorporating the Teacher As Instructional Designer approach into our education classes and into workshops for cooperating teachers. Emphasis is placed on the use of student-centered instructional strategies, particularly strategies involving inquiry-based learning and real-world, problem-based learning. Teachers are asked to develop thematic units that integrate information skills and technology skills as suggested by the Impact program in North Carolina.

One of the methods for integrating technology with a thematic unit is WebQuest. WebQuest web sites provide students with information from which to begin their investigation into the topic of study.

"Information is the basic ingredient in the active, authentic learning required of today's student."

(AASL and AECT 1998, 83). Two examples of integrating technology with thematic units are included in this poster/demo session. The first example is the creation of a WebQuest web site focused on the theme of archeology. The second example is a web site and discussion forum focused on using primary sources to study the impact of specific wars on the development of the United States.

We hope that this presentation will give others ideas on how to use the ISD process to promote the creativity of teachers in designing exciting and innovative learning environments for higher-level thinking skills and human growth and development.

"Wiring the schools and populating them with computers is necessary but insufficient to ensure equal opportunity to share in the digital revolution. Children need . . . motivation to learn. They need a redesigned education system and teachers who have been retrained and reoriented. Innovative technologies cannot make up for educational professionals who lack innovative methods and merely replicate learning models that don't work." (Tapscott 1998, 262)

Using web-based situated learning as a design strategy in teaching elementary economic concepts

Hsin-Yih Cindy Shyu
Department of Educational Technology
Tamkang University, Taiwan
hysyu@mail.tku.edu.tw

Abstract

Background of This Study

While we are now living in the knowledge-based economy era, economic education becomes essentials for all citizens. However, there are obviously lacks of the present teaching materials and instruction in our schools, especially for elementary teachers and students in Taiwan. Based on the above needs, the author would like to develop a web course, entitled ECONLAND, for teaching basic economic concepts for elementary students.

The web is a powerful medium with many unique attributes for learning. The web technology afford opportunities for multimedia presentation, communication, collaboration and knowledge construction. In addition, there are several theoretical foundations to guide instructional design for this web-based learning environment, such as constructivist principles, scenario-based, authentic activities, multiple roles and perspectives, collaborative construction of knowledge. These principles described as situated learning strategy are illustrated in elsewhere in details (Cognition and Technology Group at Vanderbilt, 1993; Oliver & Herrington, 2000). The value of situated learning has also been demonstrated in classroom settings through many empirical studies (CTGV, 1993; Shyu, 1999, 2000).

Purposes

Therefore, the purpose of this study were to analyze and synthesize the economic concepts suitable for 3-4th grade elementary students; design and develop web-based teaching material; design and develop the teachers’ guide for the web course; and to conduct a formative evaluation. The basic economic concepts were taught, such as scarcity, decision-making, opportunity cost, production, money and interdependence. By integrating the instructional strategy of scenario-based situated learning into design, five pieces of story were presented. Students have to solve the challenges presented from the end of each story and thereby acquire the knowledge of those economic concepts. Finally, based on the results of the formative evaluation, suggestions of
revisions and the directions for further investigation were also included in the end of paper.

Significance of this Study

This study was significant because it provides an example of how and what to teach economic concepts on the web for kids, and it also demonstrates an instructional model using situated learning strategy for developing and implementing web-enhanced learning activities for teaching economic concepts.

The web site is located at http://econland.et.tku.edu.tw.

Adult Learning Styles and Distributed Learning: A List of Preferences

Denise M. Smith, Ed.D.,CCC-SLP
Fidel M.Salinas Jr., Ed.D.

This research study examines adult learning styles and preferences in enrollment in distributed learning courses. Initially, a questionnaire (Yes/No and narrative format) was developed which provided definitions about learning styles, such as visual, auditory, kinesthetic, or varied combinations of these styles. The learning styles and definitions were based on the research of Howard Gardner, Judith Warren Little, and University of New South Wales, Faculty of the Built Environment. Quantitative and Qualitative results were obtained and implications for further research were also cited. Fifty post-graduate students in business and/or education participated in this study. All respondents were voluntary and information was received anonymously. Participants also completed a demographic survey identifying age, gender, and ethnic background. The underlying questions of this investigation included:

1) Is there a certain type of adult learner who is more (or least likely) likely to enroll in distributed learning courses?

2) What information regarding online learning course formats (animation, video, audio (text/ voice/music)?

For example: are adults who identified themselves as a combination of visual and kinesthetic more likely to register for online courses than adult learners who identified their learning style as solely auditory or visual?

As more undergraduate and graduate university programs offer courses online, it would appear to be both cost effective and pedagogically appropriate to examine the learning styles of their students and align course design accordingly. The intended audience for this presentation includes university faculty, students (undergraduate and graduate), and administration interested in developing enhancing distributed learning course work across academic disciplines.
Part of the Online Teacher's Curriculum:

Designing for Collaboration and Participation in Distributed Netbased Learning

Elsebeth Korsgaard Sorensen
Dept. of Communication
Aalborg University
Denmark
eks@hum.auc.dk

Abstract: This paper addresses, in particular, the core challenges of stimulating participation and true motivation in learners to engage in interactive collaboration and knowledge building dialogue in netbased learning. The paper reports on an experiment, which suggests a twofold foundation for design: 1) the learning theoretical concept of Etienne Wenger (1998), and 2) an orientation towards student experiences and competencies, in order to design for collaborative knowledge building online.

Introduction

Design of distributed collaborative learning processes online seems a complex challenge (Collis, 1997; Bates, 1999; Harasim, 1999). To design collaborative processes, which truly integrate and draw upon individual competencies and interests of the adult student appears an even more challenging activity (Sorensen, 2000). It calls for an alternative pedagogical thinking, also in the education of teachers, producing new and pedagogically innovative instructional designs. For years, in particular within the area of continuing education, it has been part of the underlying set of pedagogical intentions to design online courses utilizing the individual student perspectives and knowledge and engaging students in interactive collaboration and shared knowledge building. This ambition has not been realized.

The reason for this is ambiguous. On the one hand, it may be rooted in a lack of awareness of the specific asynchronous virtual conditions for the unfolding of human interaction (Sorensen, 1997b). On the other hand, the lack of encouraging results is related to a weak foundation in learning theoretical frameworks. While the problem of designing for quality in netbased knowledge building dialogues is of a general nature the need for stimulating motivation, engagement, and interactive processes seems especially outspoken in the context of continuing education (Sorensen, 2000). In this context, there is a need for pedagogical designs that in innovative ways attempt to match the communicative virtues of the online environment with alternative, theoretically based, pedagogical implementations of student experiences. There is a need for student experiences and competencies to become operationalized in the virtual environment in such ways that they inspire and form collaborative knowledge building (KB) processes in what has been called "online communities of practice" (Wenger, 1998).

This paper addresses such challenge of instructional design as part of an innovative teacher education curriculum. As a background, section 2 gives an account of some of the experienced problems related to establishing online interaction. Section 3 outlines some of the basic concepts in the learning theoretical framework of Etienne Wenger and introduces a model based on his concepts, for designing for participation (Wenger, 1998; Sorensen, 2001). Section 4 describes the research design of the conducted experiment as well as its assumptions, hypothesis, implementation and results. While section 5 contains the concluding comments, section 6 forms the forum of future perspectives.

Distributed Collaborative Knowledge Building Online: State of the Art

Any pedagogical design, including designs of netbased distributed collaborative learning, implies a latent - and sometimes unconscious - theoretical perspective on what learning is and what it ought to be. Such perspectives always form the context for the choice of pedagogical elements characterizing the learning process (Sorensen, 1997a; Fjuk & Sorensen, 1997). Therefore, it seems essential not only to become conscious of these underlying perspectives, but also to base designs on clear and conscious theoretical understandings in order to be able to choose corresponding pedagogical-didactic features that are likely to promote the learning perspective and goals in question.

One of the most prevailing problems encountered in netbased distributed collaborative learning concerns the widespread lack of clarity of pedagogical design and practice in terms of stimulating a qualified interaction and collaborative KB dialogue. This includes the familiar experience of virtual learning spaces marked by silence and lack of "social presence", and it includes the lack of motivation and commitment between learners to collaborate. In particular, the problems of identification and distribution of teacher-learner roles in virtual learning processes seem to form the key factors in this complex of problems.

Quite a few learning designs of netbased distributed collaborative learning mirror a rationalistic and authoritarian perception of learning as something "delivered from above" by experts down to the "empty" students. In such cases it is not surprising that collaborative KB processes are absent. More thought provoking, however, seems the fact that in many cases where collaborative KB has actually been a main part of the design perspective, it very often does not materialize (Stahl, 1999 & 2000; Sorensen 2000). A clear understanding of why student collaboration so often is absent, regardless of these ambitions, remains to be identified. Unfortunately, the technology used often gets the blame for this - perhaps often unjustified (Sorensen, 2000).

The gained experiences with implementation of distributed, netbased processes evidently has had mixed success. From a perspective on learning as a collaborative phenomenon the significant problem of establishing a qualified collaborative leaning
dialogue working for KB seems to be, not only a very serious problem to address and resolve, but also the most complex challenge to deal with.

Collaborative Learning Through Online Communities of Practice

The problem of establishing a motivated, qualified interaction working for collaborative KB in a continuing educational context may be addressed through the theoretical framework presented by Wenger (Wenger, 1998). The two aspects of interaction and motivation are among the central concepts treated in his learning theory, in which learning is viewed as processes taking place in what he calls "communities of practice" (Wenger, 1998).

Participation and Mutual Engagement in Negotiation of Meaning

To establish a collaborative KB dialogue (to ensure a KB process online) corresponds to his notion of creating "participation" in a community of practice. To ensure student initiative to participate in a collaborative KB dialogue points to Wenger's notion of creating "mutual engagement" (Wenger, 1998).

The theory emphasizes the role of experiences and practices of the individual students as means to support the development of group identity. About this complexity in relation to the learning process, Wenger states:

Learning (...) takes place through our engagement in actions and interactions, but it embeds this engagement in culture and history. Through these local actions and interactions, learning reproduces and transforms the social structure in which it takes place (...). Learning is the vehicle for the evolution of practices and the inclusion of newcomers while also (and through the same process) the vehicle for the development and transformation of identities.

(Wenger, 1998, pp. 13)

Wenger's theory incorporates "participation" and "mutual engagement" as central concepts in the learning process. About the concept "participation" Wenger states:

Participation refers to a process of taking part and also to the relations with others that reflects this process. It suggests both action and connection. (...). Participation in this sense is both personal and social. (...). But when we engage in a conversation, we somehow recognize in each other something of ourselves which we address. What we recognize has to do with our mutual ability to negotiate meaning. (...) In this experience of mutuality, participation is a source of identity.

(Wenger, 1998, pp. 55-56)

He characterizes "mutual engagement" as involving not only individual, but also collaborative competencies (Wenger, 1998 p. 76)

Social presence online, the fundamental element for creation of a collaborative KB process through what Wenger calls "negotiation of meaning" (Wenger, 1998), is threatened by lack of both "participation" (interaction) and "engagement" (Gunawardena, 1995; Rourke et al., 1999). Creation of an online presence in netbased distributed collaborative learning processes based on participation and mutual engagement in order to ensure the negotiation of meaning is a complex pedagogical challenge (Cornell, 1997; Sorensen, 1997a).

PANEL: A Design Model

On the basis of some of Wenger's concepts, PANEL (a model for instructional design of collaborative knowledge building processes on the net) was developed (Sorensen, 2002). PANEL denotes a learning process centered on collaborative KB and qualified by participants. The figure below is intended to illustrate the main ideas of PANEL (figure 1).
It shows a student-centered, open process in which knowledge resources enter dynamically from all sides via the participants as well as the teacher(s), in a process driven and motivated by participants. It illustrates the dynamic interchange between teacher and learner roles. It also provides a rough indication of how much of the teacher contribution evolves at a meta-communicative level. In sum, the PANEL model possesses the following characteristics:

- It stimulates "participation" and "engagement"
- It is process oriented
- It denotes an open concept
- It is participant oriented
- It draws on student experiences
- It operationalizes student experiences
- It creates participant "ownership"
- It equals out teacher and learner roles
- It is, in principle, a lifelong model
- It invites to process assessment

Research Design and Implementation

At Aalborg University, Denmark, POPP (Problem-Oriented Project Pedagogy Approach) is the fundamental pedagogical approach used in the design of distributed netbased education (Fjuk & Dirckinck-Holmfeld, 1997). POPP is a student-centred approach to learning and instruction which, in principle, rests on collaborative group work and truly integrates the perspectives of the individual students and allows them to take "ownership" in relation to all aspects of the learning process.

POPP is also the fundamental pedagogical approach in the design of our Danish cross-institutional, educational initiative, the MS in ICT and Learning (MIL). MIL provides continuing education for people engaged in educational planning and integration of ICT in learning processes at schools and all types of educational institutions as well as employees with educational responsibilities in different types of organizations. The administration of MIL takes place at Aalborg University, but the curriculum is developed and offered in joint collaboration between five Danish universities (Aalborg University, Aarhus University, Copenhagen Business School, the Danish Pedagogical University, and Roskilde University). A large part of the 40 MIL students are highly qualified teachers at the high school level with extensive university education and high competence within their individual work areas.

Assumptions and Hypothesis

In this paper I make the basic assumption that online participation and engagement in collaborative knowledge-building activities (as I have defined them) among students produces learning. Based on this assumption I make and test the following hypothesis:

An online learning environment that

1. is built on the learning theoretical concepts of Etienne Wenger (Wenger, 1998) and
2. provides mechanisms for students to fully use their experiences and competencies

will enhance learning.

Method and Model

With the goal of creating online presence, an experiment was conducted in the context of the first course module on MIL. To address the two problems of insufficient interaction and motivation, the course was designed according to the principles of PANEL (Sorensen, 2002).

The course module lasted 5 weeks. It was divided into a period of reading and preparation (two weeks) and a succeeding period of debate (3 weeks). According to the assignment given, the students, in the two-week preparation period, had to read the literature individually. The literature was distributed in three themes within the course content: Design of netbased learning processes. (The themes corresponded to the names of the three discussion fora in the succeeding period of discussion). The students were asked to distribute a set of roles among the members of their online group (on average consisting of 4 students). The roles were supposed to form and support their later discussion. Some were presenters, others were moderators, etc. The description of the roles was clarified in the assignment. Over the three weeks of debate both teacher and students agreed on attending the virtual learning space for a minimum of five times a week. In the debate period the groups each presented a commonly agreed problem, related to the literature, and initiate, conduct and wrap up an online discussion with all the peers. In parallel with the discussions, the students and the teacher engaged into meta-reflections and meta-communication in a specially created meta-forum, to reflect and discuss the experiences and processes of the students, as they evolved. The student were graded on the basis of a mixture of minimum requirements in terms of both quantity and quality that we viewed to be essential to enhance a collaborative KB process (Stahl, 1999; Sorensen & Takle, 2001a & 2001b).
Results
The 3 weeks debate period generated an enormous amount of engaged participation in collaborative KB (532 contributions, some of which were of the size of half a webpage). Assuming that online participation and engagement in collaborative KB activities among students produces learning, it is fair to say that my experiment has proved itself to be relevant. It was quite an exciting and, indeed, a very interesting activity to follow and participate in the KB process of the students. Viewed from a teacher perspective, the discussions turned out to be of very good quality (for a set of criteria, see Sorensen & Takle, 2001b). However, the activity did not exactly reduce the amount of work of the teacher. On the contrary, while it was very interesting to follow the discussions, it was quite a demanding job to read, relate to and comment on so many reflective and often very long comments. The discussions were truly student-centered and student-governed in that they produced an enormous amount of relevant collaboratively developed student initiatives, student perspectives and student experiences. The motivation of the students was very high and demonstrated an engagement in the discussions far beyond the minimum requirements in terms of both quantity and quality. The teacher occupied a role in the discussions equal to the students. Only in the meta-forum the teacher shifted between the role as a participant and the role as “the one who knows better”.

Conclusions
This paper has been dealing with the overall question of how teachers and instructional designers - in particular within the area of continuing education - should approach the challenge of design of distributed, collaborative learning processes online. Assuming that participation and engagement in online collaborative knowledge building activities produces learning, and that online learning designs are enhanced through teachers and designers consciously basing their instructional designs on learning theory (through the use of PANEL), the results from this experiment are overall positive. It provides strong indication that by basing design on the learning theoretical concepts (participation and engagement) of Etienne Wenger (1998) and by operationalizing student experiences and competencies, collaborative knowledge building online (participation) increases measurably - through the stimulation of student ownership, relevance, and motivation (engagement). The two main intentions to create participation (interaction and online presence) and engagement (motivation through the operationalization of the participants’ experiences) seemed to have been more than fulfilled.

Future perspectives
When aiming at enhancing quality in nethased distributed collaborative learning, it is necessary to for learners as well as teachers to navigate within a different pedagogical paradigm than a traditional face-to-face setting. The changes in design, necessary to enhance quality, may be radical. Instead of navigating in a predictable pedagogical virtual universe where teacher roles, teacher guidance, and fixed resources are decided upon in advance, we are moving towards a virtual pedagogical paradigm marked by an instructional need to act, interact, and collaborate on a more equal basis. We are facing a new age of learning on which fixed entities become dynamic and unpredictable, and in which new instructional competencies, like e.g. comfort in relation to communicatively improvising in chaos, are essential. The new paradigm needs a broader pedagogical perspective of the teacher. Even though the core competence is of pedagogical nature, it is necessary for both teacher and designer to obtain and utilize a wider and more holistic set of qualifications on which to base pedagogical considerations, actions and design decisions.

Acknowledgment
A special thanks to the Danish course participants, who started in the fall of year 2000 on the MS in ICT and Learning, for their positive and engaged attitude in terms of providing their “learning process” for the pedagogical–didactic experiment of this paper. I also thank my colleague, Professor Eugene S. Takle, for his insightful comments to the paper.

References

Townsend (1997) confirmed that Intranet and Extranet platforms offer an opportunity to store and provide learning materials and services in an easy and engaging manner. The author of this short paper experimented using the Web platform to organize course materials and to post Web pages. A powerful teaching and learning model could be built on these platforms for communicating, sharing knowledge, and producing interactive learning prototypes in a cost-effective manner for schools and colleges (St-Pierre, 2000).

The goal of this short paper is to describe the reasons why the Web should be used to develop and deliver courses on site and at a distance in an educational setting. The author will examine the characteristics that an effective web-based course should present.

The World Wide Web is a good platform for delivering instruction (Barnard, 1997; Starr and Milhein, 1996). Professors can create maps to guide the learners through their learning paths. The Web class can be well designed so that the learner can construct from the environment. Critical thinking could be introduced in a Web technology-based class when the students are asked to create Web contents or to search the Internet for different points of view on a controversial subject such as the Space program (Thoms & Junaid, 1997).

Faculty and students of the author's college have begun to realize the full potential of the Internet as a teaching and learning tool. Students are beginning to perceive strong learning outcomes from on-line materials and Web-based contents. The instructional designer should use sound system design principles while developing web-based educational systems (St-Pierre, Bettin, Dillinger, and Ferraro, July-Sept. 1999). In his research, the author shows that schools and colleges needed a theoretical and practical framework to develop in an adequate manner an open virtual course on the web (St-Pierre, June 2000).

On-line delivery is a means of fully augmenting or replacing other methods of teaching and learning. Mediated forms of delivery using the Web made it easy to update dynamic, constantly changing information. A well-designed Web-based instruction provides an efficient delivery medium for the instructor and an attractive content for the students in the classroom. Some instructors in various schools and colleges are using a Web package authoring tool to build a Web class format (Bent, 1997).

Web-based instruction could be defined as the application of a repertoire of cognitively oriented instructional strategies implemented with a constructivist and collaborative learning environment using the attributes and resources of the World Wide Web (Perkins, 1991). Research studies in education suggest that a constructivist-learning environment could be used to build virtual classes and provide an opportunity to explore a rich-hypertext content for the learner. This facilitates multiple linkages among content elements.

Several studies point to a paradigm shift that transforms the professor from simply a deliverer of knowledge to a mentor and a guide in the student learning process (Terrell, 1996). The students build Web pages incorporating numerous links to sites containing knowledge repositories. This enables the student to explore multiple avenues through contents of similar or divergent views, thereby reinforcing cognitive construction.

An effective web-based learning environment well designed with the help of educators should present the following characteristics: enhances student-to-student and faculty-to-student communication, students share perspectives, students experience a sense of equality, instructors are more accessible; enables student-centered teaching approaches, accommodates varied learning styles, provides opportunities for exploration and discovery, provides 24/7 accessibility to course materials, continual access to materials, removes reliance on physical attendance, provides just-in-time methods to assess and evaluate student progress, and adds pedagogical benefits (St-Pierre, 1999).

Schools and colleges have to be innovative in introducing technological media in the teaching process. Training and professional development programs should exist to give the opportunity to experiment with web technologies before they use them in their teaching process. Teachers have to take ownership while developing effective web-based course with sound teaching media (St-Pierre, July 1999).
In conclusion, web-based courses are developed on a day-to-day basis without proper instructional design and experimentation with the learners. In some cases, the response time and the learning outcomes are neglected in the development process. Instructional designers, web-based technologists, and teachers have to work in synergy to prepare effective and sound open learning environments that will enhance learning outcomes. Assessment tools should be developed and used to measure learners' outcomes and satisfaction. The author of this paper will describe further pros and cons of developing and teaching with web-based courses at the conference.

The Discipline-Appropriate Use of Computers in the Classroom:
Two Case Studies

Abstract: The authors present two case studies in the use of computers in the classroom, one involving an introductory computer science class, the other an upper division literature class. After describing each case, the differences are discussed, showing that pedagogical models developed for one discipline may not transfer to another, and that the discipline itself, beyond instructor’s preferences or institutional policies, may determine what works and what doesn’t.

Introduction

Our goal in this paper is twofold. First, we’ll indicate that the successful use of information technology in the classroom depends more on the synergy between teacher, student and the learning context than on the technology itself. The use of technology — as the primary vehicle for teaching (distance learning) or as an adjunct to the more traditional classroom — is effective only insofar as it addresses this synergy. Second, we will maintain that one under-appreciated factor influencing teachers, students and learning contexts is the discipline itself, in a way that goes beyond simply paying appropriate attention to learning (or teaching) styles. We offer two case studies, one drawn from an introductory computer science course, the other from an upper division literature course, in support of these claims.

Enthusiasm for online learning is of course high for students who live in areas not easily served by the traditional classroom, and courses accessible anytime and anywhere can provide valuable learning experiences for mature students who work full time and take courses when schedules permit. But the use of online learning tools within traditional campus-based course delivery structures has become popular as well (Wiring the Ivory Tower; Kathleen Morris; Business Week, August 9, 1999). James Duderstadt, President Emeritus and Professor of Science and Engineering at the University of Michigan, suggests that universities must themselves take a leadership role in remodeling the universities of the 21st century, and that new information and communication technology tools will play a key role in that mission, suggesting that universities will continue to have a physical existence, whatever their virtual roles may become (Duderstadt; Chronicle of Higher Education; February 4, 2000). This is not a completely uncontroversial claim; in a November 17, 1999 New York Times article, John Chambers, then Chief Executive Officer for Cisco Systems, asserts that "the next big killer application for the Internet is going to be education. Education over the Internet is going to be so big it is going to make e-mail usage look like a rounding error." (Thomas Friedman, Next: “It’s Education”; November 17, 1999; New York Times)

As the situation as developed, however, and as other researchers have begun to look at what now seem to be inflated claims, online education has emerged as one aspect of a larger picture. Prosser and Trigwell, in “Understanding Learning and Teaching,” argue that both teachers and students benefit from an increased awareness of their own personal experiences, approaches and perceptions of the learning process and that this awareness facilitates positive learning outcomes. (Understanding Learning and Teaching; Prosser, Michael And Trigwell, Keith; 1999) In particular, they emphasize that “good teaching involves an awareness of students’ perceptions of teaching technologies (including information technology) used in teaching” and that these perceptions can significantly impact the learning experience either positively or negatively. (Prosser & Trigwell, page 169) Given their results, the successful use of information
technology in the classroom is clearly more dependent on interactions between teachers, students and learning contexts than on the technology; it may even indicate that there are some things technology cannot appropriately do, a point to which we shall return.

On the other hand, learning opportunities newly available through the use of technology can support desired learning outcomes—provided (our second claim) those outcomes, as defined not simply by the instructor or the institution but by the discipline itself, are congruent with what the technology can provide.

Astin's comprehensive study of student development characteristics in various higher institutional settings points out that active engagement of students in interdisciplinary courses, course with discussions, debates, and class presentations strongly correlates with critical thinking skills (What Matters in College, Four Critical Years Revisited, Astin, A. W., 1993). To the extent that technology can facilitate (or at least create the opportunity to provide) such active learning strategies, the effort will not only increase student involvement in the course, but also increase understanding of course concepts by relating them to independent inquiry and debate.

The question is whether available technology can do that too.

**Case Studies and Examples**

Our first case study involves an introductory computer science class. Pope's goal in implementing web-based tools the course was to increase opportunities for communication and participation. The class was small (approximately 25), but there was a considerable amount of material to cover and the topics that dominate the headlines -- Microsoft Antitrust litigation, Privacy in Cyberspace -- provide fertile ground for discussion. He began using WebCT as a tool both for distributing informational materials and for on-line testing. In doing this, he relied on the students to read on their own time; his discussion/lecture now addresses related but different concepts in supplementing the text. Making the quizzes available online provided more opportunity for group and class discussion.

Students were positive; they could find their grades, course syllabus, assignments and topic notes in one central location.

In designing this kind of structure Pope was of course not alone. The University of Central Florida, for example, adopted a similar approach to improve its course in America National Government. There, the goals of the restructuring were practical as well as mission-oriented. The course enrolled over 2000 students in sections of 80-100 students. Classroom space was in critical short supply; increasing the number of sections was not a viable option. But the course also had a retention problem and surveys indicated that partially web-based sections had somewhat higher retention rates. Building on this, the department designed a web-based asynchronous learning environment based on web-based modules to encourage student participation. Class meeting time was reduced by two thirds. Bruce Wilson reports "students are, by necessity, more actively involved in the learning process. And instructional technology can also enhance students' critical thinking skills. ... The use of the Internet in teaching Political Science gives instructors more opportunities to design activities that involve students' direct participation and to follow clearly set instructional goals." ("Best of Both Worlds? Web-Enhanced or Traditional Instruction in American National Government."); Bruce Wilson, Phillip Pollock, Kerstin Harmann, Political Chronicle, v. 12, no. 2, Fall 2000)

Pope himself also viewed the electronic interface as an opportunity to evaluate his own teaching. In any implementation of electronic technology in the classroom, a major evaluation of course objectives and teaching strategy is required, and he found this to be a welcome necessity. Drawbacks were a lengthy development and the availability of trained support staff.

Thurber, teaching an upper division class in English literature, had a different experience. It was not obvious to him that the standard distance education model was appropriate, given both the mission of the university and his actual task, which was to investigate, in this case, the work of the English poet William Blake. He does not give quizzes as such, although short exercises related to that moment's discussion do take place; there is no "lecture" and therefore no lecture notes. The course itself, in addition, was already as "interactive" as he (and his 24 students) could stand. Instead, the goal was to use the Web to investigate the nature of hypermedia, particularly as the poet in question, Blake, had done an 18th century
version of the same thing. His goals, therefore, were far more specific to the actual material—more contingent, more dependent on the actual poetry than on any idea about how to teach poetry.

He created, therefore, a course website (www.sandiego.edu/~thurber/CyberBlake) and asked the students to create their own hypermedia websites in lieu of the traditional paper—the rationale being, once again, not so much that hypermedia may be worth investigating on its own, which it is, but that, given this poet’s practice, hypermedia are an appropriate, perhaps the most appropriate, response. The student’s response was positive, in each case suggesting that the course be given again. Typical remarks included “It’s about time English Departments did this,” “an English course that is actually practical,” and “I feel like I’m a writer too, doing something a little bit like Blake.”

The course model that evolved, however, has almost nothing in common with Pope’s. There was a course discussion board; very few students used it, feeling that opportunities for interaction were already sufficient; a few found it intimidating, while others viewed it as just another course assignment. (Participation in the discussion board was optional. Thurber wanted to see what would happen if it was not required.) There were electronic office hours; no one ever showed up, as students uniformly felt either that they already had sufficient access to the instructor, or that personal interaction was preferable. The emphasis was on the student’s ownership and exploration of an electronic medium, the Web, rather than on using the Web to enhance communication or provide additional course materials.

Observations and Conclusions

It is about the differences between these two course structures that we would like now to reflect. Crucial to Pope’s model was the use of the Web in the transferal of information from the instructor to the student. Indeed, he viewed, as is common, class sessions as adjuncts or supplements to information provided online.

But this is already not a model that transfers readily to an upper division literature class. Advocates of distance learning have traditionally emphasized that the use of electronic communications present opportunities for teacher-student interaction that effectively shift the educational focus from “teacher-centered” to “student-centered,” away from the traditional lecture format and towards distance learning. But is the “transmission” of information, by itself, what college courses are for? If so, never mind the traditional lecture; colleges have been masquerading as libraries or, now that the technology is available, web sites. As far as the humanities are concerned the “transmission” of information is only one function college courses serve, and in some respects the least important.

While we acknowledge that modern educational philosophy mandates the critical importance of engaging the student in interactions that will impact his or her mastery of the subject matter, it does not then follow that the hallmark of student-centered learning is the use of computers in the classroom. Particularly if, as at our university, classes are small and instructors, on the whole, couldn’t lecture if they wanted to. Is the give and take in small, discussion-centered, quasi-seminar situations comparable to what we can do in online discussion groups, even with real-time audio and video? If it isn’t, what are the differences, and what is the educational impact of those differences? In the absence of hard answers to those questions, we wonder what’s really at stake. What is being transmitted, pre-eminently in literature classes but in the humanities generally, is not the “information” we possess about, for example, Shakespeare, which is trivial, but the nature and kind of conversations we have and have had about his work. Knowledge in the humanities is both a process (not a result) and always contingent, socially constructed and crucially dependent on the context in which it is acquired. (The French Revolution in the eyes of post-1848 Europe was one thing; to Woodrow Wilson it was another; to ourselves it is yet something different.) From this perspective the transmission of information via the web is a non-sequitur. It isn’t the Web that’s the problem; it’s the word “transmission.”

Using computers according to the first model, therefore, at least interferes with and may even negate the goals and methods of the humanities—not because humanities instructors are Luddites (some are), but because the pedagogical model such approaches embody originated in one discipline, or set of disciplines, and don’t readily transfer to another. Using computers according to Pope’s model would deny Thurber and his students the chance to do what they want to do, which is both to learn what a writer actually did and to forge a response, together, to what she actually did. Here is where the under-appreciated difference between disciplines—world views, at some point—comes into play. There is no, and there had better not be, any such thing as socially constructed knowledge in the sciences. (Actually this is a matter of
current debate. What physicists thought about the significance of Maxwell’s equations in 1890 was a different than what Einstein thought fifteen years later.) In the humanities, on the other hand, and particularly in literature, there is no knowledge except what has been socially constructed – beginning with the fact that literature is made of language, the most social of all constructions, and including the fact that no writer, no matter how august, is a writer unless someone, somewhere, chooses to read her. The artist has an intent, to be sure, but that intent is only one of many variables connected to our mutual investigation of what a work actually is. Reader-response theory, as a matter of fact, would have us believe, in general, that readers are actually as responsible for what a work does as the author is – maybe more so, in some constructions. Whether that is true or not, none of us reads or could read Shakespeare as Shakespeare did; but we still read Shakespeare! What’s that, then? Shakespeare is Shakespeare but he’s also us reading Shakespeare, in ways that he could not have foreseen but which are, still, what Shakespeare “is.” For now. Meanings change; there are no “laws” in the sense that there are for the hard sciences.

Thus when Pope says, for example, that it’s a good thing that online discussions can happen any time, that it frees people from the constraints of time and space so that they can say anything from anywhere, Thurber’s response is – why is that good? It would depend on the crucial insight that online discussion is the same as or better than the kinds of discussions his students and he have in real time, with their real bodies and their real minds in a real place, zoned into a writer they want to try to understand. Is virtual discussion discussion? (We know, for example, that people write and talk differently, and that they behave differently on- or off-camera. What are the differences, are they significant, and are virtual discussions better than, the same as, or worse than virtual discussions? And for what ends? There has been surprisingly little research in these areas, particularly as different disciplines are involved.)

Even, Thurber notices, Britain’s Open University, one of the oldest and most successful implementations of computer-based instruction (http://www.open.ac.uk), supplements online material with local study centers (and tutors) at learning centers around the world. On this model, the discussion, always specific, always local, and always the joint product of the persons present on that occasion, is preserved, together with ancillary electronic material and the opportunity, which he welcomes for his classes, for students to write back at the sea of electronic media they are surrounded by, owning the web by helping, in a small way, to create it.

Our conclusion: we assume each of us is still en route to a full understanding of the implications of electronic technologies for higher education. We would emphasize, however, that our different disciplines seem to require different choices, different ways of using those technologies: one size does not fit all!

Introduction

This paper discusses the place of information design in the Instructional Technology (IT) curriculum at the graduate level. The discipline of information architecture has evolved to meet the challenge of organizing and using information to provide meaningful communication. Information architecture may be defined as the process of developing effective written or visual communication. While good information design stresses the importance of communication that clearly communicates an intended meaning, user-centered information design places primary emphasis on addressing the cognitive needs of the intended audience (Victor, 1999). This paper examines the IT curriculum and suggests course offerings to prepare instructional technologists to use the Web to its full potential.

The Instructional Technology Curriculum

A review of the IT literature reveals that little has been published specifically on the subject of the IT curriculum. There is of course a great deal of literature on such facets of IT as learning theories and instructional design and development issues, but it is striking how little of this literature deals with how best to teach these topics or how to combine them in an integrated curriculum. As would be expected, the literature that does exist calls for a mixture of theory and practice (Heinich, 1984; Winn, 1997).

Winn (1997) notes that most university IT programs emphasize practical skills over theory; it is “concerned with the application of knowledge, not just its generation” (Winn, 1997, p. 35, italics in original). This emphasis has led instructional technologists to seek prescriptive models of instructional design. However, such factors as individual differences and the impossibility of accounting for all variables in an instructional setting teach us that a truly prescriptive model of instructional design is not possible. Rather than apply rigid rules to the design of instruction, the designer brings reason and experience to instructional decision-making (Winn, 1997, p. 37). Knowledge of theory is a resource the designer can draw on in designing instructional strategies for varying situations and needs. Instructional technologists should be grounded in theory related to perception, in cognitive theories of learning, and in theories of the influence of culture and environment on action (Winn, 1997, p. 38).

Toward a Web Design and Development Curriculum

Although the Internet has been in existence for over 20 years, the World Wide Web has only recently gained popular acceptance, and Web-based instruction is still in its infancy. What role does Web design and development play in the instructional technology curriculum? An informal assessment of the types of Web design and development courses offered by instructional technology programs (as evidenced by programs with course descriptions on the Web) reveals a limited number of such courses. Courses typically include basic HTML instruction and Web page construction, computer-mediated communication technologies, and distance learning development. Perhaps within the context of a comprehensive curriculum of educational psychology, learning theory, instructional design theory and practice, and software applications, such course offerings might suffice. However, as the Web is increasingly used as a communication and research tool, Internet technologies will become an indispensable part of the instructional technologist’s repertoire. It seems reasonable to expect Web design and development courses to play a greater role in the curriculum.

An Internet Studies Curriculum

Maule (1998) proposes Internet content studies as an academic field of study. He presents a framework that draws on two existing academic disciplines: instructional science and information studies. Instructional science is the study of learning theory, cognition, and interactive learning systems. Information science is the study of information access, retrieval, processing, and distribution (Maule, 1998, p. 177). His proposed Internet Studies curriculum contains foundation courses in both instructional science and information science:
Can we imagine an IT curriculum that addresses the unique needs of preparing instructional technologists to use the Web in curricular and instructional development?

Web Design and the IT Curriculum

As the Web takes on increasing importance, it is reasonable to expect IT programs to increase their offerings in Web-related courses. Skilled designers of any sort draw on a variety of skills that are difficult to describe. Design takes place through what Schön (1983) describes as “reflection-in-action”: the reflective activity that characterizes the special knowledge of the skilled practitioner. Tripp (1994) notes the complex, ill-structured nature of design activities and the consequent difficulty of teaching design. He suggests that instructional design be taught in a manner similar to the way in which art and architecture are taught. Just as students of these disciplines learn by examining and discussing examples of great art and architecture, students of instructional design should study examples of great instructional design. Students could also learn instructional design in studio courses, in which students, professors, and design experts collaboratively design and critique instructional projects. This model could effectively be used to train students in Web design skills. In keeping with the mix of theory and practical skills suggested above, I propose the following areas of study be included in IT program course offerings:

- Web design methodologies
- Web design and presentation technologies
- Project management skills: planning, scheduling, and tracking of resources; communication skills; team building
- Web design theory: information theory and information design, cognition and perception, hypertext/hypermedia theory, the social construction of knowledge
- Critical pedagogy (Shor & Freire, 1987) and the analysis of Web content: Teach students a critical stance toward content. Whose interests are represented on the Web? Whose knowledge is presented in Web-based instruction? How can Web design be a liberatory experience for both learner and teacher?

Note: This paper summarizes a more detailed discussion. For the complete paper, refer to http://www.svictor.com/itcurr.pdf.
In Taiwan, a brand new national curriculum standard entitled “Grades 1-9 Curriculum Guideline Framework” was published in 1998 by the Ministry of Education, which has features of integrated, school-based curriculum, emphasis on information and technology. The framework proposes the educational goals with 10 key competencies and claimed that new education standard has been executed in schools from grade 1 to 9 by 2001. It did stir up the primary and junior high school teachers and publishers as well. The current education reform is somewhat a revolutionary event among science education community because it brought complex and compact changes of curriculum development as well as various teaching and learning styles and strategies.

The author leads a team of elementary inservice science teachers to work on the new standard and to develop standard-based teaching materials that been try-out taught. The purpose of this report is to present an instructional design of "The Moon" and "Stars" for grade school, which developed and based on the goals of ten competencies and the features of new standard. This report is an example of our product of the past working year and sharing for international understanding. These resources will be linked in WWW for inservice teachers to offer professional growth (temporary home page: www.scitec.ntptc.edu.tw).

The Modules of “the Moon”:

Lesson I: Folktales and Celebrations
Objectives: (1) Be able to collect various folktales and the way of their celebrations of the festivals about the moon through web or books in the library. (2) To know Chinese lunar calendar and festivals.
Descriptions: (1) Pre-request the students to use internet (or library) to collect legends about the moon. (2) Ask students to share their stories collected, particularly Chinese folktales. (3) Students look up the lunar calendar and record all the festivals based on the calendar. (4) Invite students to draw a picture of the moon’s surface. (5) Invite students to write a story after viewing the surface of the moon, and share their own stories.

Lesson II: Let’s travel to the Moon.
Objectives: (1) To know the America’s Apollo project. (2) To know physical condition of the moon. (3) To know how spacesuit, spaceship and astronaut works.
(5) To learn the skills of solve problems. (6) To learn social skills.
Descriptions: (1) Ask students to present (a) the Apollo Project. (b) Who is the first astronaut who stepped on the moon? (c) What Armstrong said when he stepped out of the spaceship? (2) Discuss what did astronaut find or not find on the surface of the moon. (3) Lead group work on following items to see how they work: (a) Spacesuit (b) spaceship (c) Rocket (d) astronaut (e) Astronaut’s living in spaceship. (4) Design a colony on the moon, try to solve the following problems: (a) How to keep people alive without air? (b) How to protect them from space rays, extreme cold and hot? (c) How to supply food without agricultural? (e) How to travel and communicate? (5) Draw a picture of community on the moon.

Lesson III: A Hound Bites the Moon?
Objectives: (a) To change misconception about lunar phases or eclipses. (b) To recognize the sequence of lunar phases. (c) To predict the lunar date according to lunar phases.
Descriptions: (1) Telling the Chinese folktale of “a hound bites the moon.” And students judge the possibilities of it. (2) Showing a table of lunar date vs lunar eclipse, allow students to be aware that eclipse occurs when it is full moon. (4) Having 3 students to play roles of the earth circling the sun (light) and the moon evolving the earth. (5) Students will find out that the earth’s shadow will cover the moon. This is the cause of eclipse. (6) Teacher draw pictures of lunar eclipse, and students demonstrate the lunar eclipse using paper model. (7) Having 4 students act as 4 positions of the moon orbiting the earth all facing toward the sun. One additional student plays the role of the earth at the center. The students will
realize the cause of lunar phase. (insert a photo picture of students' role-playing)

**Lesson IV: Lunar Tides**

**Objectives:**
1. To know the cause of the tide.
2. To predict the high or low tide hour at certain coast around Taiwan.
3. To recognize the high and low tide match the lunar phases.

**Descriptions:**
1. Teacher illustrates Newton's finding about gravity.
2. Teacher guides students to be aware that tide is caused by moon's gravity.
3. Teacher illustrates that there are twice flow and ebb tides per day while the earth spins.
4. Teacher illustrates that there are twice highest and lowest tides per lunar month while the moon evolves around the earth.
5. Ask student to collect data through internet or *Taiwan Astronomy Year Book* about high tide hours within one day around Taiwan's coast.
6. Ask student to read the book of *Taiwan Astronomy Year Book*. The students will find that high tide and low tide match lunar calendar, e.g., high tide is on full moon and new moon days as well.

**Modules of “The Star”**

**Lesson I: What Birth Sign of Constellation You Are?**

**Objectives:**
1. To find the pattern of constellations.
2. To know some myth stories of constellations.
3. To create students' own constellations.
4. To write a creative story about a constellation.

**Descriptions:**
1. Teacher shows the birth sign of constellation, and asks students to tell his/her own sign.
2. Ask why and how the birth sign of constellation named. The students shall notice that the picture of imagine of constellation.
3. Divide students into groups according to the birth constellations, and discuss the stars in their own birth constellations.
4. Present the Chinese folktales of “The Lovers of Vega and Altair,” and Greek’s mythical stories about constellations.
5. Distribute fluoresce star stickers; students stick them on a dark room, so that students can see shiny stars, constellations in a black paper.

**Lesson II: How to Find a Star and Name It?**

**Objectives:**
1. To collective data about stars using internet.
2. Be able to use paper “star chart disk.” practicing how to find a star.
3. To know the star “move” counterclockwise when observe it.

**Descriptions:**
1. Pre-request student to collect data about birth constellation from web, includes verbal descriptions and pictures. Students share their findings.
2. Distribute paper “star chart disk” to each student. Teaches student how to find a star from the chart.
3. Go out in night and find the star from correct angle of elevation and direction indicated on the chart.
4. Find a star and name it in the dark sky guided with the chart.

**Lesson III: Let’s Plan a Trip to an Astronomical Observatory or Field in Night**

**Objectives:**
1. To acquire ability of planning, organizing and practicing.
2. To learn cooperatively work with others.

**Descriptions:**
1. Teacher proposes a field trip to an astronomical observatory/field. The students should work as leader, reminder, data collector, expense manager, and discuss how they cooperatively work as a group.

**Lesson IV: Let’s Go Out to Observe the Stars**

**Objectives:**
1. To recognize a star in the dark sky.
2. To compare the brightness of stars.
3. To learn the social skills.

**Descriptions:**
1. Gathering students in a dark field.
2. Teacher assigns the Polaris/Big Dipper and ask student to identify it in the dark sky.
3. The students use the chart to help finding the angle of elevation and direct of Polaris/Big Dipper.

Chris.Durbin@staffordshire.gov.uk

Abstract
SIfT, as an Approved Training Provider to the Government New Opportunities Fund, ‘ICT for
Teachers’ initiative in the UK, has created a highly structured model for designing and
delivering course materials to remote teachers, via a Virtual Learning Environment. Based on
the face to face delivery model and Gagne’s (1985) nine events of instruction, it incorporates
the qualities of the ‘virtual tutor’ in pedagogically sound materials (TTA 2001). With SIfT
training accessed via the Internet, the international aspects of delivering training for teachers
by this medium are continuing. SIfT materials are currently being used by in excess of 1000
teachers, in England, Jersey and Germany and have been trialled in Norway.

Introduction
Staffordshire ICT for Teachers (SIfT), a collaboration between Staffordshire University and Staffordshire Local
Education Authority (LEA), in the U.K, is a Government Approved Training Provider, to the New Opportunities
Fund, ‘ICT for Teachers’ initiative (NOF 2001). This UK Government scheme, which commenced in April
1999, provides a sum of money for every ‘serving’ teacher in the UK to ‘buy’ professional development training
in ICT (Information and Communications Technology), from Government approved trainers. SIfT (1999) was
approved as a national provider, following a competitive tendering process, to deliver ICT training to secondary
teachers (of students aged 11-18), within the subjects of geography and design and technology.

SIfT delivers highly innovative training materials for secondary teachers, directly into their working
environment using a web-based Virtual Learning Environment (VLE), in this instance Lotus Learning Space. A
VLE is defined as “an integrated software system, which combines within a package facilities for the delivery of
learning materials, communication (synchronous or asynchronous), assessment and student feedback”
(LTSN/THES 2001).

The SIfT ‘Virtual Tutor’ Model
SIfT, through action research, has created a highly structured model for designing and delivering course
materials to remote teachers, through a Virtual Learning Environment. The model is based on delivering
‘learning on demand’ training, which is highly subject focused to the user requirements and which is developed
to a structure which teachers are able to conceptualise. The model also provides a template for the development
of clear ‘bite-sized’ pieces of learning, which incorporate qualities of the ‘virtual tutor’, delivered through the
technology (Whitehouse et al. 2002).

In a face to face training environment, the able tutor will incorporate their own personality and style to the
delivery of their materials. They will not only include delivery of the key messages, but will also incorporate
humour and will provide scenarios and examples to contextualse the subject matter. They will reiterate material
to accentuate importance, will judge the understanding of the audience and will re-visit areas of difficulty if not
understood, adopting a different emphasis or slant to aid understanding. They may ask questions of the
audience, even if no response is expected, to encourage each participant to think and individualise their own
response, or answers may be requested, in order to draw the learner into the process and clarify understanding.
The role of the face to face tutor though goes further in developing and supporting the learner, offering references for background reading, providing hand outs, answering questions, supporting requests from the learner in the form of guidance and ideas and ultimately offering formative and summative feedback to assignments.

Gagné (1985) identifies nine events of instruction for any desired learning, (see Table 1). These instructional events provide the external conditions that are necessary for learning to take place; the events usually occur in the order listed. Within the SIfT Coursework materials, qualities of the face to face tutor and Gagné’s nine events of instruction are developed and incorporated within the ‘virtual tutor’ model, through innovative use of the interactive facilities that the technology provides.

| 1. Gaining attention.  |
| 2. Informing the learner of the lesson objective.  |
| 3. Stimulating the recall of prior learning.  |
| 4. Presenting the stimulus material with distinctive features.  |
| 5. Providing learning guidance.  |
| 7. Providing information feedback.  |
| 9. Enhancing retention and learning transfer.  |

Table 1: Gagné’s nine events of instruction

SIfT’s highly subject specific ICT training for teachers, is based on a 12 Unit grid, consisting of four subject strands, each with three levels of ICT capability - beginner, intermediate and advanced. The extensive multimedia material is innovative, lively, interactive and dynamic, with special emphasis being placed on understanding and accommodating the many requirements of teachers’ daily needs. The materials have been created for teachers, by teachers (Whitehouse et al. 2002).

Teachers are given stimulus ideas within the SIfT units and are supported with tutorials in teaching and learning and ICT skills. The teachers then implement their ideas as part of their assignment, in a way that is relevant to them within their school – usually in planning an appropriate piece of teaching and learning. They have access to an on-line mentor. The teachers get advice on how to improve their lesson assignments submitted. The product of their work goes into the on-line library of the VLE course room, to build the resource base for others, with individuals able to download and use other teachers’ endeavours. Discussion facilities and student profile areas are also provided.

Conclusion

The impact of SIfT provision, under the New Opportunities Fund, ‘ICT for Teachers’ initiative, cannot be underestimated. The ‘virtual tutor’ model has enabled teachers to be engaged in mass on-line training, which is highly targeted and meets teachers’ needs for semi-negotiated professional development. The Teacher Training Agency (2001) said of SIfT “The model is actively chosen by schools, mainly because of it’s subject specific nature and networking potential...The material and structure of the training can facilitate the development of significantly advanced pedagogical thinking and extend the use of ICT within the school.” A library of resources has been created and is continually being updated facilitated by SIfT – reinventing networking between ordinary classroom teachers on a national and international, rather than on a local scale.

Designing a Web-based Curriculum for Middle School Students

Timothy Youngman
University of Houston
Houston, Texas, USA

Abstract: This paper addresses the implications for designing instruction for delivery over the Internet. A small education company in the southern United States has developed a unique Web-based middle school program that incorporates multimedia to deliver instruction in the context of a problem-based scenario. Specifically, this paper outlines a theoretical perspective for the development of on-line education, discusses one company’s approach, and outlines some initial qualitative feedback from students.

Introduction

In recent years an increasing number of schools have made large investments to bring computers and Internet access into the classroom. With this technology, there is both opportunity and controversy as educators seek ways to integrate these innovations into classroom instruction. Much of this debate has addressed whether the pedagogical foundation of instruction changes when components of the class can be delivered via the Internet. Curriculum that was originally designed for the traditional setting is afforded different instructional activities and learning opportunities that were not perceived or even possible before Web-based instruction (Dabbagh & Schmitt, 1999).

Theoretical Perspective

Many organizations have moved toward constructivism as the foundation for the development of their instructional program, but there is a great deal of variety in what people mean when they say they are constructivist. Some of this can be accounted for by the differences in the theories on which constructivism is based. In general, most constructivists agree on three broad principles (Dalgarno, 2001):

- People form their own unique representations of knowledge.
- Learning occurs when people uncover an inconsistency between a new experience and their current representation of knowledge.
- Learning occurs within a social context (Vygotsky, 1978).

Although there is agreement on these broad ideals, different organizations emphasize them in different ways. For example, an individual manipulating objects on the computer screen emphasizes the second principle whereas collaborative learning using computer-mediated communication is based on Vygotsky’s theory. Both activities can be considered constructivist (Dalgarno, 2001).

The movement toward a brain-based curriculum has also taken precedence in recent years, focusing on an integration of both constructivist and cognitive learning theories (Bruer, 1999). Brained-based learning is a progressive movement in education that seeks to recognize the strengths each individual brings to the classroom while supporting students as they overcome their weaknesses. Instruction from this perspective emphasizes that as students improve their underlying cognitive skills and memory levels their ability to learn is enhanced. This creates a strong foundation for the development of higher-order thinking skills (Kuyper-Erland, 1999). Effective instruction should help students learn to self-monitor their performance, reflect on their progress, and use forethought in making decisions about future learning experiences. This promotes a sense of self-efficacy and motivates students to become better learners. In addition, when information is presented in a variety of different formats students learn to recognize the similarities and differences between types of information.
A multi-modal approach also provides for individual differences based on variations in students' learning strengths. Traditional education has placed emphasis on some types of cognition over others (Gardner, 1986). This one size fits all approach to education means that some learners may be disadvantaged if their cognitive strengths fall into areas that are not traditionally addressed by educators (Driscoll, 1994).

**Components of the System**

The curriculum under study has been designed to meet the needs of middle school students. Informal research conducted by the company revealed that although there is a great deal of computer based instruction for use in the elementary school, there is little being developed specifically for middle school students. In fact, it has been argued that the middle school years coincide with the most critical period in adolescent development, and yet it is the least understood age group in our society (Hurd, 2000). Consequently, there is a need for a clearer vision of what a middle school curriculum should address.

From the perspective of cognitive psychology, key instructional strategies have been implemented into the learning system (Driscoll, 1994). Students are able to manipulate information in a variety of ways, which enhances understanding and facilitates long-term retention. Each topic is covered using a variety of multimedia that presents information in different modalities. This further facilitates retention and helps students see relationships among important concepts. Students choose their own learning pathway, increasing motivation and the depth of learning. The students have the freedom to explore new ideas and test their assumptions without the fear of failure that often hinders learning.

The company has developed an on-line system for the delivery of the curriculum. Although the content varies according to the course, there are common elements students use including:

- Problem-based scenarios
- Content according to each student's unique learning strengths.
- Software that allows students to build an on-line presentation.
- An on-line quiz and testing feature.

Currently, the system is implemented in 14 schools across the United States in a variety of settings with differences in both physical environment and socio-economic status. Early qualitative reports from students indicate an overall favorable impression of the system, but continued research will help validate its use and effectiveness for middle school students.

**References:**

It has been a privilege over the years to write the introduction to the International section of the SITE Annual. From the early days of STATE, (the Society for Technology and Teacher Education, the former name of SITE), this section has grown and flowered and changed. At first any paper from a country other than the USA was deemed “International” and arrived with exotic stamps. While I miss the stamps I don’t miss converting files to a format acceptable to PageMaker, our old desktop publishing program. As STATE became SITE so the body of the organization itself became International and the criteria for inclusion in this section changed.

Today an International paper should report on IT in teacher education in two or more countries. Whether the report is a comparison or of a collaborative effort between two nations or a comparison of methods, philosophies, governmental support or lack thereof among several, the underlying criteria is “two or more” countries. Not all of the papers published in the section meet this criteria, however, there is always some slippage between a proposal and the final submission. Time allows for few alterations at this point.

More and more collaborations are occurring; many sprouted from seeds sown at previous SITE conferences and/or at the conferences of our sister UK organization, the Association for Information Technology and Teacher Education (ITTE), some watered by funding from UNESCO. It is always a pleasure to see these develop. In the past those of the more ‘electronically developed’ countries came at partnerships with a patronizing attitude [as an American I can say we excelled at this deplorable practice] which meant no real partnership. Today, more and more I see an equal give and take, a recognition that we each have much to share, but even more to learn from each other. This is the spirit of not only this section, but of this organization. As you read the following papers consider links you can forge across national boundaries. What do you have to share? What do you need to learn?

We have presentations and/or papers representing viewpoints from Botswana, Canada, China, the Czech Republic, Denmark, France, Germany, Ghana, Spain, Switzerland, Taiwan, United Arab Emirates, UK, as well as the USA. Several papers stand out. Beal, Clark, Alibrandi, Pope, White, Robertson, and Lambert explore the results of their students work on a website, part of a larger project: Going Global: Cross Cultural Conversations Around the World. Chatterton describes the experiences of two groups of student teachers, one in Germany, the other in the UK. Morin considers an IT challenge used in the UAE but modeled on successful ones from Stockholm and Rome.

Weber address a question that we all ask, “How does one talk of learning communities with such discrepancies of funding and the effects of terrorism in place?” Davis leads several panels with participants from around the world who begin to address the answers.
The Management of Technological Change within Faculties in International American Schools

Martine Audéoud
Komensky Institute of Prague
Prague
Czech Republic
furaha82@yahoo.com

Abstract: The management of technological change within the schools' faculties was the main focus of this study. What are some of the indispensable ingredients for success in this area? The faculty has been considered as being at the core of the Human Resource Management of these educational institutions. The study focused on 'professional development' and 'instructional leadership' primarily in terms of technology and looked for some answers to the following question: How are international school managers going to manage staff development dynamics within their institution in order to comply with a global world more and more driven by technology? The study looked for factors that affect success in the management of technological change within a school faculty. Cultural richness, connection to the community outside and a high degree of exposure to technology seem to be the major keys to the success of the management of technological change in international American schools.

Introduction

In educational organizations, technology has generally been managed and implemented within specific business-oriented frameworks of thought and action directly influenced by the United States. However, in cross-cultural situations like in the TRI-Regional (Association of international schools regrouping 3 sub-regional associations accredited by SACS) schools, little is known as to the scope of growth in technology. The findings of this research show that international American schools succeed to various degrees in furthering technological growth.

Summary of Findings

Given this context, the purpose of the study was to examine the factors that influence the management of technological change in the faculty of international American schools that belong to the TRI Regional Association. The study focused on 'professional development' and 'instructional leadership' primarily in terms of technology.

In undertaking this study, the concern was to help the TRI leadership and the school managerial teams to evaluate the factors that have been influencing the success of staff development practices in the area of technology and to help them frame decisions and recommendations for forward planning. An action-survey research model has been selected. The survey focused on the following areas:
1. The management of school culture.
2. The management of staff development in schools.
3. The management of school technology.

Part 1: Findings Pertaining to the Management of School Culture

In order to research that question, data collected through the teachers' survey were computed according to the three areas previously defined. Respondents were asked to evaluate their school's staff
development programs against the standards established by the National Staff Development Council. Similarly, respondents were asked to assess their own technology proficiency against the national Milken Exchange standards and to describe their school culture against the two sets of culture traits identified by Wilson (1996). Frequencies were computed and averaged by school in order to get a general description of how the school is perceived against set standards. One could note the following:

1. The means assessing sensitivity to business-influenced (B) Culture traits and those assessing technological proficiency are almost identical, showing a close relationship between both areas.
2. The trends of the means assessing culture, staff development and technology proficiency are almost identical, showing that the three areas are closely linked together. In schools where there was a low level of what could be called ‘cultural presence’, from either B Culture or traditional (T) Culture, there was a lower level of staff development program and a lower level of technology proficiency. The richer the culture, the higher the level of technological proficiency and the higher the level of staff development.
3. The difference between the means describing Culture B traits and the means describing Culture T traits was also calculated and graphed. This was an attempt at finding out whether a high level of discrepancy between the prevalence of each type of cultural traits would have an impact on the level of technology proficiency in schools. This did not seem to be the case.

Conclusion to Part 1

It appeared from the data collected and analyzed that teachers who have had the strongest local cultural background (i.e. who were non-certified, and/or tenured and/or locally hired) were those who have benefited the most from their school’s staff development programs. Their goal was to increase their level of technology proficiency. Furthermore, their technological growth came from the fact that they have been deeply affected by exposure to Culture B traits in their school.

In contrast, administrators seemed to be the only category of respondents who have capitalized on Culture T traits to further their proficiency level in technology.

According to data collected, certified teachers might belong to a category of teachers that presented similar characteristics as the non-tenured and/or import hired teachers and showed a high level of technology proficiency. They must have drawn their abilities in technology from other sources than those analyzed in this study.

Part 2: Findings Pertaining to the Management of Staff Development

School administrators’ perception of their staff development programs was 44% above median and 20% more favorable than the perception of certified teachers. Pearson’s correlation coefficients showed a correlation of 0.21 between technology proficiency and staff development programs for administrators, whereas for certified teachers that coefficient was −0.37.

Non-certified teachers, in spite of, and perhaps because of, their low level of technology proficiency and especially of their low level of job security, have had a greater desire for professional growth than certified teachers. Thus they have been much more sensitive to staff development programs. This may have accounted for the higher correlation coefficient of 0.565 between staff development programs and technological proficiency.

Tenured teachers have had a positive perception of their schools’ staff development programs whereas non-tenured teachers have had a negative perception of their schools’ staff development programs. Staff development programs seemed to positively influence tenured teachers in the area of technology growth, but did not seem to have much of an impact on non-tenured teachers. An explanation may have been found in the fact that tenured teachers have worked several years with the school and might view technology growth and professional growth as more needed or desired. Furthermore, non-tenured teachers may have been in the school for a shorter period of time. Generally, the majority of them have come from an international background and thus they may have been less in need of and more critical of staff development programs. They may have had more extensive or formal exposure to technology during their previous professional experiences.
Furthermore, non-certified teachers were the ones that have made most use of and perhaps have valued most their school’s staff development programs. The Pearson correlation factor between staff development programs and teachers’ technology proficiency was the highest (of all categories) for locally hired teachers. On the contrary, it was negative for the import hired teachers. This has confirmed that teachers hired locally were much more prone to appreciate or take advantage of staff development programs than import hired teachers. They were perhaps more eager to promote their personal growth in technology proficiency for various reasons that have not been researched in this study.

Conclusion to Part 2

At the faculty level, there seemed to be a strong case showing that locally hired teachers were those benefiting most from staff development programs to increase their technology proficiency. Furthermore, they were the ones who took the greatest advantage from their sensitivity to the specific cultural traits they were surrounded with in an international American educational setting. On the other hand, at the school level, it seemed that the culturally richer the school climate, the higher the school’s technology proficiency and the stronger the school’s staff development program. Furthermore, research showed that attention should be paid to increasing teachers’ sensitivity to students’ needs and to the community’s needs in the area of technology.

Part 3: Findings Pertaining to the Management of School Technology

Technology coordinators had been asked to fill in a Seven-Dimension Progress Indicator for Technology in American schools developed by Milken Exchange on Education Technology. This framework has been designed to help technology coordinators, policy makers and researchers to assess their school’s level of technology according to seven specific dimensions:

1. Learners
2. Learning Environments
3. Professional Competency
4. System Capacity
5. Community Connections
6. Technology capacity
7. Accountability.

In each of these areas, several assessment questions were asked that related to a sub-area, according to the same above-mentioned framework. Technology coordinators were asked to respond according to a Likert scale. Data were computed with a spreadsheet, and Likert values have been averaged by dimension.

It was comforting to note that the strongest area of competency was that pertaining to the learners, that is students. Schools are primarily for students, thus serving their purpose in the area of technology. All other types of indicators did not indicate a high number of schools being technologically competitive, with the weakest areas being related to community connectivity and accountability.

Attempts have been made to integrate results drawn from the teachers’ survey and to correlate the level of technology proficiency as assessed by faculty members to the various indicators of progress in the survey presently analyzed. The correlation (using Pearson’s correlation coefficient) between schools’ technological proficiency, all background categories included, seemed to be fairly strong as far as system capacity, technology capacity and accountability were concerned. Next, when narrowing down the range of faculty members to certified teachers (as they constituted by far the greatest majority of teachers’ survey respondents), the correlation coefficient between their technology proficiency and the various progress indicators was the highest in the areas of learning environment, professional competency, system capacity, technological capacity and accountability. The weakest areas seemed to be those related to the learners and to community connectivity, which may be worrisome. Finally, because of administrators’ leadership role, the correlation between administrators’ technology proficiency and the 7-progress indicators has been looked at. The correlation coefficient between both ranges of data appeared to be highest in the areas of learners, system capacity, community connectivity, and accountability. Administrators appeared to have stepped in to cover areas where teachers were less involved, especially in the areas concerning learners and
connectivity with the community. However, the correlation coefficient between administrators and learners was still fairly low, that is 0.208.

Conclusions to Part 3

Survey results have shown that school administrators have a more positive outlook concerning technology plans and their success than faculty members. A possible reason may be that the total staff is not committed to the vision, plan and implementation. Instead, the total school community should be participating to the development of the school's technological vision and plan, including staff development plans, financial management and accountability related issues.

Conclusions, Implications and Recommendations

Culture and Technology in International American Schools

1. Teachers who had the strongest local cultural background (i.e. who are non-certified, and/or tenured, and/or locally hired) were the teachers who benefited the most from their school's staff development programs. School administrators should be encouraged to devise staff technology training plans that focus especially on the needs of local teachers.

2. Teachers with a strong local cultural background also seemed to capitalize mostly on their sensitivity to culture B traits (US-influenced business-like cultural values) in order to grow in their level of technology proficiency. School administrators would be wise to ensure that this sensitivity is enhanced in a productive way and not a factor of frustration for local teachers. The latter need to realize that building positively on their sensitivity to Culture B traits will, in the long term, give them a competitive edge in that 'global village' that their school has been increasingly connected to.

3. The richer a school culture, i.e. with both Culture B and Culture T traits (business and traditional cultural values), the richer the staff development programs and the higher the level of the school's technology proficiency. Therefore, school leaders investing in developing the cultural climate will see their school faculty greatly benefit from that cultural richness in areas related to technology training and technology integration into curricula delivery.

4. Another finding worth noticing is that technology proficiency in schools rises and falls according to the level of Culture B traits in the specific schools. Therefore, school leaders would be well advised to ensure that an appropriately high level of Culture B traits be developed and promoted in their school. This would in turn enhance teachers' understanding of the 'cultural requirements' that technological change in educational settings brings with it.

5. School administrators seem to capitalize more efficiently on culture T traits to increase their level of technology proficiency. They have been taking advantaged of the various opportunities for technology growth throughout their career. They have no doubt as to the necessity for them to continue to expand their knowledge and experience in that area.

Leadership, Management of Staff Development and Technology in International American Schools

School leaders should take the following elements into consideration as they lead and manage their schools' human resources.

1. Certified teachers (who seem to belong mostly to the non-tenured and/or import-hired category of teachers) draw their abilities in technology from other sources than those analyzed in this study. They do not appear to need to be the prime focus of schools' staff development programs in the area of technology. However, they may constitute resources and leadership potential in the area of technology that are available to the school.

2. Students are the most technologically proficient members of school communities. However, their teachers need to become more sensitive to ways of integrating technology into their curriculum.
delivery. This would ensure that their curriculum delivery would adequately prepare students to meet the challenges of this new 21st century. Therefore, the school leaders' role should be to ensure that their technology coordinators are being constantly kept abreast of the possible implications on education of the latest technological advancements.

3. Staff development plans should emphasize a higher degree of hands-on exposure to technology in order to promote a higher level of 'technological know-how'. But it also seems more important that teachers' technological staff development plans aim at demonstrating, modeling, making resources available to teachers on the multiple ways and means by which teachers can integrate technology into their curriculum delivery. Teachers should be given opportunities to be able to become knowledgeable as to the specific assets technology may bring to their own areas of study. This may also take place when schools have subscribed to professional magazines that include reviews of technological advances. It also may necessitate for technology coordinators and school leaders to take a pro-active role to discover what technological advances have been made that may be applicable in various educational fields.

4. Schools need to focus on connecting more closely and consistently with the community outside in order to provide their faculty and students with more resources and partnerships that will strengthen the general schools' technology programs. According to the findings of the survey, school leaders step in adequately into two areas where teachers seem to be lacking: focus on learners and community connectivity. Schools would greatly benefit from reconsidering how they manage their external relationships with the community in order to increase the technological resource base on which they can operate.

5. Schools need to develop accountability procedures in regard to technology management in order to be able to measure progress, both in the quality of curriculum delivery and financial management. This would enable school leaders and community to supervise the coherency of the various aspects of technology management.

6. Schools should make it a priority to develop and monitor their technology vision and plans as a tangible way of monitoring technology growth in their institutions. This should take place while involving all the stakeholders of the community in developing these management tools.

This study hopefully contributed to analyze some of the characteristics of the management of technology international American schools in the TRI Association, a further step towards effectively managing technology in international American schools.

Abstract: The Great Ghana Website is part of a larger project, Going Global: Cross Cultural Conversations Around the World. The website project seeks to help graduate and undergraduate students enlarge their global perspective while developing technology skills for the classroom. The site was developed to supplement a video conversation between a University of Kentucky professor and her doctoral student from Ghana. Their conversation examines what they see as the mismatch that may occur when cultures, values and relationships between developing nations and benefactor nations are dissimilar. To better understand the cultural divide, a website was developed to inform students about the culture of Ghana.

Teaching is never the same day to day. Educators must be ready for unexpected opportunities and be willing to take advantage of them when they occur. The Great Ghana Website grew out of two such opportunities. One occurred at the National Council for the Social Studies Convention in November, 2000. We chose to attend a session that paired an American professor at the University of Kentucky with her doctoral student who was from Ghana, but temporarily studying at the University of Kentucky. They enacted a cross cultural conversation they had written that compared and contrasted the cultures of the United States and Ghana. The exchange was as powerful as it was enlightening. We believed that it would be informative for teachers who were preparing to teach about Ghana to their students. We also believed that to see and hear the exchange was much more powerful than just reading it. We flew in the educators from Kentucky/Ghana and spent the day filming their conversation. As we worked, they offered new information and opinions that proved invaluable in preparing the viewing guide for the video.

The second opportunity came in the person of a former Peace Corp worker. She is the wife of one of our Masters students. When she heard of our interest in Ghana, she volunteered to tell us her stories about her Peace Corp years spent in Ghana. At first, we planned to tape them so that they might be used in classrooms around the state. Later, we determined that because of their richness we could include activities that were inspired both by her stories and the digital pictures we took of her artifacts from Ghana.

After both of these treasures had been taped we examined possibilities for dissemination. How could we best get them to teachers and students and what form should they take to ensure they were used to their fullest? It was decided that a website would be built to include information about Ghana as well as the taped conversation and stories. The viewing guide would also be put on the website.

The website development process by graduate and undergraduate teacher education students was highlighted by a formal study of what makes a good website - design, font, format, appropriateness for the audience, reliability and variability of material presented, etc. Students surfed the net and evaluated examples of website design. We discussed issues of copyright, permission, credits, etc. Students also studied the teaching and learning
approaches that best meet the needs of early adolescents. This helped them understand how students learn and enabled them to craft effective and appropriate lessons. Students viewed the videotaped conversation, heard the Peace Corp stories and saw digital pictures of artifacts brought back from Ghana.

The website was planned to include the following five parts:

$ The first part would have information - population, economics, climate, etc. that was accessed through GIS (Global Information Systems). This part also included a tutorial about GIS, what it is and how to use it.

$ The second part included the Peace Corp stories. Each story was written on two different reading levels. Because all members of the target audience (seventh graders) are not always reading on grade level, both seventh and third grade reading levels were included. Preservice teachers selected four stories and wrote each on the two different levels.

$ The third part was completed by graduate education students, many of whom are seventh grade teachers. They wrote activities to accompany digital pictures taken of artifacts brought back from Ghana. The activities were intended to sharpen middle school students' observation and reflection skills.

$ The fourth part was a retelling of folk tales from Ghana. The folktale segment was prepared by preservice teachers who will student teach elements of African history. They chose several well known Ghana tales, illustrated them and rewrote them on two different reading levels.

$ Finally, the fifth segment included the viewing guide which sketched background information about the long standing relationship between Ghana and the United States and suggested ways to best enjoy the video. The video was prepared to include scenes from Ghana. The video will serve as an ancillary to the seventh grade social studies textbook and will be used primarily by teachers as background information to prepare them for their study of Ghana with their students.

This website development approach is based on learning theory and on-going research that suggest that students who are novices in the area of technology, when partnered and in a supportive, risk free learning environment, have a more positive learning experience using technology, become technology empowered, and are thus more likely to incorporate the use of technology in their own lessons and classrooms.

Abstract

Leaders in education in universities, schools and services to education and vocational training, are challenged in their leadership of new technology. This round table aims to raise awareness of the efforts of 3 European and 3 USA graduate programs of technology in education and teacher education, who are prepared to revitalize leadership through sharing of their graduate communities through a project recently funded by the European Commission and the US Department of Education.

The ILET project aims to permit experts in multimedia, cultural studies, and distance education to develop a certificate in Intercultural Educational Technology within Ph.D. programs of the six partner universities. The planned components of the certificate are: comparative study of educational technology systems, policies, and applications; language and cultural learning activities before, during, and following a semester of study abroad; project work and/or internships that require application of theories and technological skills to real life challenges of digital and cultural divides; and an intensive international course at the major professional conference to induct students into the international professional community. An Intensive International Course may bring together students and faculty and incorporate study and reciprocal mentoring in future Society of IT for Teacher Education conferences.

The project will enable our multi-disciplinary consortium to educate a new cadre of leaders with experience in today’s global context, while taking care to include both sides of the digital divide plus commercial partners. Student selection will positively discriminate to redress inequalities of the digital divide. In addition, students will be encouraged and supported to undertake project work on related issues of national and international importance for agencies such as UNESCO. Exchanges of faculty and staff aim to ensure coherence in curriculum, assessment and support services. Preliminary exchanges and research indicate promising flexibility with innovative web-based learning strategies (see for example Davis, 1999; Bronack Kilblane, Herbert & McNerney, 1999; and Davis, Nilakanta & Li, 2001).

The consortium is committed to creation of a prestigious knowledgeable community of alumni who value their continued collaboration with faculty and students in an online
learning environment that Oracle has created for learners across the UK, USA and beyond. The Universal Forum of Cultures in Barcelona 2004 will showcase the global service of this project worldwide. This transatlantic project is potentially the first stage in an ongoing global program with additional partners and students.

The Round Table Agenda

The 3 collaborating universities in the USA (Iowa State University, University of Virginia and University of Florida) and their 3 partner universities in Europe (University of London Institute of Education, Aalborg University in Denmark and University of Barcelona in Spain) already recognize that there will be many challenges in this collaboration. Obvious issues of the Danish and Spanish languages are accompanied by additional less obvious language challenges: English misunderstandings between the UK and USA and the need to value minority languages of Danish and Catalan. The local cultural differences provide a exciting and challenging mix for faculty and graduate students who will travel, and they will also be visible online. Cultural differences in academic structures and organizational behavior have already been raised in pilot activities. Memoranda of Understanding will be developed to clarify the collaborative activities and mutual support. Selected MOU and other guiding documents will be shared with the round table for review and comment.

The development of a learning community across universities has been the focus of graduate work and pilot activities between several partners, particularly Iowa State, London Aalborg and Virginia (Davis et al, 2001; Sorensen & Tackle, 2001). Other partners include the educational community of leaders in information technology in education who have been creating a learning community and mentoring resource for others called MirandaNet, founded and led by Christina Preston, with support from many organizations including Oracle (Preston, 2000). Examples of the artifacts, environments and associated research will be available for review to stimulate discussion.

Thirty students and twelve staff will study abroad and collaborate with many more in the project’s innovative web-based learning environments, supported by professional communities and commercial experts. Significant challenges are expected in recruiting students and faculty to work abroad for a semester and to become comfortable in foreign and international learning environments.

The project aims to broaden the impact of the EC and US cooperation by ‘training the trainers’ of faculty involved in open and distance learning. While many graduate students in the USA do become future faculty, the lack of turnover in Europe provides additional challenges for that continent. Managing extension of collaboration and dissemination of the project may also prove challenging, but the partners are committed to this and the round table will provide a means to listen to our future audience at an early stage, because the three year project commenced in October 2001.

The round table aims to promote discussion of travel, both real and virtual, and collaboration between programs and institutions in a way that promotes international and inter-cultural education.
Teaching and Learning in Information and Communication Technology and Modern Foreign Languages

This paper examines the experiences of two groups of student teachers working together to encourage the use of ICT in language teaching.

Student teachers specialising in Information and Communications Technology (ICT) have worked with a group of Modern Foreign Language (MFL) students, within university-based sessions and on teaching placement, to support the development of ICT-based language learning activities.

This has recently been extended to include working, via a computer-moderated conference, with a group of students in the University of Gießen in Germany.

A rich range of activities is developing, including the use of the conference to exchange school materials, lesson plans and 'native speaker' recordings of school pupils talking about themselves, their interests, school life etc.

Student teachers and the development of ICT-based language learning activities.

Introduction

As we enter the fourth year of this project, we have been encouraged to build on the success of earlier years and to extend the range of ICT-based activities and experiences available to the 'Modern Foreign Language' students as they work with the 'Information and Communication Technology' students.

Previously (Chatterton, J. and Willan C. 1999, 2000, 2001), the two groups of students have jointly developed appropriate ICT-based MFL teaching materials within the university and have then used the materials to teach French, German and Spanish in local secondary schools.

In this phase of the project, a number of ICT and MFL students have been paired for their school placements so that we are able to examine the extent to which the departmental structures and attitudes affect co-operation in teaching. The work is being further developed with the use of a computer-moderated conference, using FirstClass™. This phase involves links with student teachers at the University of Gießen, in Germany, and will involve the exchange of ideas and the development of materials using English school children as 'native speakers' for the development of materials in German. The final paper will include the experiences of the current intake of students with these materials.

Student Teachers and School Placement

All the students taking part in this study are postgraduates, following a one-year professional training programme leading to 'Qualified Teacher Status'. The majority have worked for a number of years before deciding to train as teachers. All such courses are 36 weeks (180
days) long and a total of 120 days must be spent in schools. Details of the placement pattern and the structure of the course can be found on the PGCE Information Technology website (Chatterton, J. 2000).

Typically, the professional year cohort consists of approximately 360 students training to teach any one of a range of subjects at secondary school (High School) level. The students will undertake placements in two of our partner schools - we typically use around 120 schools, so the average is three students per school. Of the 360 students, about 18 will be studying ICT and a similar number in MFL. Both subjects are regarded as "shortage subjects" as it has been difficult to recruit enough trainees in these areas for some years. Schools offer places in the various subjects, we cannot demand them, and this makes 'pairing' students in ICT and MFL problematic: schools have to offer places in both subjects. Each student is placed in two different schools during the year, teaching a 50% timetable on the first placement and a 75% timetable on the second placement. For the students in the ICT and MFL groups, working together to develop materials and lessons is not compulsory, nor is this aspect assessed. However, the students have shown great enthusiasm for the work, both individually and as a group and, where we have been able to pair them on placement, they have made marked efforts to work together and in some cases have effectively introduced the use of ICT in language lessons in schools where staff have been reluctant to take on the work involved. This is now changing as the new National Curriculum requires all subject areas to make use of ICT in teaching and learning.

**ICT and Modern Foreign Languages**

Government regulations (DfEE 1998) for the training of teachers require that all student teachers become competent in the use of ICT to enhance their subject teaching and more recent changes to the National Curriculum (DfEE 2000) have complemented these by insisting that ICT become an explicit part of teaching and learning in every curricular area. The UK government, through the National Lottery, has provided funding of £230 million ($322 million) to train teachers, not in the basic skills of computer use, but in these much more complex areas: using of ICT in teaching and learning, planning and assessment and in the teacher's own continuing professional development. The expectation is that all teachers will at least meet the ICT competences laid down for the training of new teachers in all subject areas and over all phases of education. At the same time, the government is spending some £500 million ($700 million) on the provision of hardware for schools and every school is gaining a 2MBit broadband connection to the internet, with a nationally supported school-web structure — every school has a website address and every teacher and pupil is to have a personal email address.

To be effective, ICT must be used genuinely to support and develop MFL skills and the ICT must not be just to entertain or to fill time. Many examples of poor practice have be seen where, for instance, pupils spend 30 minutes drawing a picture, then use only a few words or a single sentence to describe it. Part of the standards requirement for student teachers is that they learn to judge when it is appropriate to use ICT and to recognise and evaluate subject gains amongst the various motivating elements, which are not necessarily subject related, that using ICT still provides in the classroom. Learning to work effectively with ICT in the classroom is of concern across national boundaries and education systems. The following two quotes from the *French National Educational Resource Centre* (CNDP, 2001) for example, shows that they too are faced with the same range of opportunities and concerns.

"Démarches pédagogiques
Les cédéroms n’ont pas vocation à remplacer l’enseignant, c’est l’enseignant qui a recours à cet outil pour les besoins de sa pédagogie et qui les intègre dans sa progression."

CD ROMs' job is not to replace the teacher, it is the teacher who makes use of this tool for his pedagogical needs and integrates them into its progression.
Through email school or individual communication becomes quicker and more flexible - there’s nothing like it for preparing for real life encounters!

Materials developed as part of this project have proved to be beneficial from a language learning perspective as well as being enthusiastically received by the school pupils. The school staff have also been keen to retain the materials for their use with other classes. At the same time, ICT staff within the schools have recognised the value of the materials in providing much needed cross-curricular support for the use of ICT.

The Shared Sessions

It was clearly important, for both groups of students, that they developed the skills and attitudes which would enable them to match the government’s requirements for the award of Qualified Teacher Status.

The IT students were asked to evaluate the needs of the linguists and to plan and deliver sessions which would enable the MFL students to cope with the ICT demands of their course and to focus on the development of school-classroom materials. For both groups of students, these experiences would enable them to meet many of the required criteria and would, hopefully, encourage co-operation in the school setting. The current group of students will be trying their materials in local high schools in January and February 2002.

Sheffield Hallam University School of Education takes part in an exchange programme with the University of Gießen, in Germany, and Gießen students form part of the MFL group in the first semester of each academic year. In October 2001 we established a joint computer moderated conference, allowing students in each country to discuss experiences of learning to teach and to exchange materials. Because of the way the two courses are organised, much of the initial traffic has been from England to Germany: this should be redressed as the year progresses.

The School Experience

In the second semester (February to June) of the 200-2001 cohort, we were able to pair MFL and ICT students in three schools and in the first semester of the 2001-2002 cohort (September to January) we were able to pair students in five schools. With the first group we were looking for activities that were both useful and practicable given the local circumstances in each school.

Being paired on placement allowed students to try to take their good practice into a real setting. While the students were able to work together, in some schools the extent of the work was markedly affected by pre-existing relationships between the departments, the perceptions about the ICT infrastructure within the school and by the attitude of some school staff to the usefulness and reliability of ICT in general. Nevertheless, the student experience was sufficiently positive to encourage us to develop the model further and to extend the pairing into the new academic year, starting September 2001.

As teachers have become more aware of the reality of the new curricular requirements, MFL students are being actively used as change agents within language departments: teachers are seeing the students as a useful resource to help to update their own (the teachers’) skills. This has happened in many schools, not just those where ICT and MFL students were paired. The links to Gießen have been used by students who are currently on their first placement: personal information and descriptions of school life have been exchanged and, more interestingly, pupils within the schools have been recorded (sound only) and the resulting mpeg files have been sent to the conference to provide native-speaker examples.
for the German students to use. This aspect is currently being studied and results will be available for the final paper presentation.

Gains — skills and attitudes

In the second placement of last year's cohort, which ran until the end of the course in June 2001, it was noticeable that MFL students were making significantly increased use of ICT in their teaching. This was apparent from the students' own teaching files, lesson plans and evaluations and from the comments of their mentors (usually the head of languages in the placement school). Last year both the ICT and the MFL courses were inspected by 'OfSTED', the Office for Standards in Education and in both cases the joint group work was praised (OfSTED 2001 (a), OfSTED 2001 (b)) and the languages inspector praised the MFL students' ability to apply their ICT skills to MFL teaching. Exit evaluations by last year's students showed that they, too, valued the experience: they regarded it as one of the most useful/interesting aspects of the course. It has proved to be a significant motivating factor in student evaluations and both student-teachers and experienced school staff reported that pupils in schools were motivated by the lessons and materials produced by the students and that they (school pupils) made real gains in language experience.

For the current cohort, even at this early stage, there is no doubt that both groups of students value the experience of working with each other. Comments made of the FirstClass™ conferences show the level of interest and the extent of help being offered during the placement. Teaching placements are inevitably stressful and students are under great pressure to perform well in class at the same time as keeping up with academic assignments, yet almost all have made the time to continue the process of developing skills begun in the joint sessions. This, as much as anything, is a clear indication that the students themselves find it significantly helpful.

Using ICT in language lessons has allowed students to explore, with their classes, areas which would otherwise have been difficult or impracticable. In one of the 'paired' schools, the language student got one of her classes to do a survey of the school, enter the results in Excel, create a series of bar charts and add text commenting, in French, on the results. Such a well integrated example of using a range of key skills' within a language lesson would be rare for an experienced teacher. It will be interesting to follow her progress next semester to see if she remains confident enough to manage similar activities without the direct support of an ICT student.

Conclusion

As we write this paper, the individual and paired work still continues in schools for the current cohort of students. Early indications, from both students and mentors, shows that both groups are making good use of the experience. MFL students are making good use of ICT to support their planning, teaching and assessment and ICT students are becoming positively involved with other departments in their schools and are able to offer appropriate support for the development of subject-based ICT. This is a marked shift from the experiences of a few years ago.

Initial comments regarding the links with Gießen are also positive and we hope to have more definitive results by the time of the presentation: in particular the exchange of 'real' conversations between pupils and students seems to be worth pursuing.

Simple, well-targeted ICT material, designed with careful consideration of the curriculum aims and objectives, has clear benefits for pupils in schools. The supported development of such material, by student teachers, and the experience of planning delivering and

1'Key Skills' are defined within the national curriculum (DfES 2001 (a)) and both the DfES (DfES 2001 (b) and (c)) and the Qualifications and Curriculum Authority (QCA 2001)
evaluating the lessons in which it is used has enormous benefits for all those involved. For the ICT specialists, the ability to help colleagues plan and deliver ICT in subject areas is crucial: for the MFL specialist the confidence gained by working with a supportive ICT colleague is vital in encouraging them to use ICT in their lessons. Each year, the skills demanded of the groups have increased and each year the students have responded with enthusiasm and success. Working together in a challenging and supportive environment has produced gains for the students that have not been matched elsewhere and we seem to have a model that is cost-neutral while bringing marked benefits.

Zayed University

George Kontos (george.kontos@zu.ac.ae)
College of Arts and Sciences – Department of Natural & Quantitative Sciences
Zayed University

Background
The United Arab Emirates will be hosting a regional IT competition in 2002. Based on the well known Stockholm IT Challenge (http://www.challenge.stockholm.se/), the UAE Challenge is an initiative of the Higher Colleges of Technology, in collaboration with the Universities and the Ministry of Education. Dubai Internet City is proudly supporting and sponsoring the Challenge. Many other national and international business organisations have also joined in sponsoring this national event. It involves the three main educational sectors, schools, colleges and Universities of the UAE. The Challenge is designed to reward excellence in the use of IT, increase links between the educational sectors, promote team-work, sharing and co-operation, and best practice in the classroom.

One of the institutions participating in this project is Zayed University. Zayed University (ZU) is located in the Arabian Gulf Region in the United Arab Emirates. It is a four year old all female institution providing undergraduate education in an outcome based curriculum.

The university currently has over 2000 students enrolled in six degree programs on two campuses located in Dubai and Abu Dhabi in the UAE.

This paper first describes the types of projects submitted to the competition by Zayed faculty, staff and students. Second, the paper will review the competition criteria. Finally, it concludes with a review of the success of the projects in the competition as well as the impact of the projects at ZU and the potential for future integration into the regular curriculum. (The competition results will be provided during the conference.)

Description of projects.

Each submission by ZU for this competition was supported by the respective college of department and implemented in 2001 either as test or pilot phase. The results of each of the projects in terms of efficacy in the educational technology integration at ZU is still under review. This is a summary of the projects submitted by faculty and staff.

Description
Project 1 - ZU Magazine is a student-created web newsletter that includes articles of interest to the Zayed University community. Submitted by amy.kayser@zu.ac.ae

ZU Magazine is a web-based newsletter about Zayed University that was written by Module 8 students from Readiness Program using a template on www.tripod.com. The website mainly talks about the students, faculty and the activities at Zayed University. Five students participated in this project with their teacher’s help. The newsletter includes many topics that interest those who would like to know something about Zayed University. You can read about many subjects such as faculty biographies, students’ trips, clubs, etc. Teachers, students, and other members of the university community can enjoy this project. In addition, it includes many pictures and links.
Project 2 - This is an online learning opportunity for students to learn about international management and teambuilding through direct participation in academic projects with others in an international interactive environment. Submitted by Warren.Lee@zu.ac.ae

This is an online classroom project that unites two separate college classrooms from different cultures and countries in an online interactive international academic project that uses high technology as the media and means. The objective is to provide an "open window on the real world" that enables students to learn the basics of intercultural management, leadership and teambuilding through direct experience with peers from another culture and country. This is accomplished by forming international teams, and working collaboratively to introduce themselves and exchange intercultural information, and then to work collaboratively on an academic writing and research project using high technology and the Internet as the medium. It is expected that students will learn more about globalization, intercultural communication, the integration of high technology in management/leadership as well as learning more about themselves and the dynamics involved in intercultural leadership. It further provides students an opportunity to communicate with teacher/instructors from different cultures and countries and to gain new perspectives on the course itself. Communication and study are supplemented by digital photos of students, campuses and campus life that further demonstrate our similarities and differences. A detailed academic project description is provided on a separate page, as are student teams with names and email addresses for each student to facilitate group and direct contact and communications. Each course syllabus is also on-line in the website, and students can compare and contrast learning requirements and course expectations across cultures.

Project 3 - A Math web site developed to provide students, faculties and peers of ZU across both campuses with a unique online course structures with reference and worked examples as well as home works assigned. Submitted by Nakhshin_Karim@zu.ac.ae

This project is a web site based on Front page 2000. It covers two courses of Mathematics ( Algebra and Pre-Calculus) being taught by Ms. Karim and other instructors at ZU. The basic Index of the web site includes, for each course: the outline of the course, MS Power Point Presentations for each topic, assessment of the course (Quizzes and Exams), and references and related websites that students and faculties might use. Students can refer to this site and have the opportunity to acquire what they need. Feedback from students are felt to be the good measure of being useful site for them to strengthen their capabilities in the subject Maths courses.

Project 4 - At Zayed University, College of Education students complete an extraordinary integration of their total University experience by creating a digital portfolio of their work. Submitted by frederick.vansant@zu.ac.ae

The cornerstone of the new outcome based Academic Model, is the digital, or electronic portfolio. A portfolio is simply a container for a person's work. In a portfolio an artist might show a selection of her best work, an architect might show photos and plans from houses or buildings. However, an academic portfolio is not quite so simple. By definition, a student's academic experience is not limited to the work that they have done, rather, the true measure of a student's experience is the learning that has taken place. This then, requires a more defined structure, and the requirement that a student exercise considerable critical thinking about what would go into their portfolio. By bringing together evidence of the student's learning in both formal and informal contexts, the students and the faculty can more easily see the relationships all the different types of learning in the student's academic career. All students enrolled in the College of Education are required to complete a professional portfolio. This portfolio is digital, and web based. It may include web pages, documents, PowerPoint presentations, hyperlinks, images, digital audio and/or video.

Project 5 - This project is a collection of WebQuests that are problems-based units of study supported by Internet resources and have been developed by UAE national preservice teachers and aspiring educational technologists to support UAE K-12 curriculum. Submitted by f7517@zu.ac.ae
The Web Quest is a technology-supported unit of instruction that is problems-based and uses the Internet as an educational tool. It is a teaching strategy that emerges from a problem that requires a unique solution based upon available information. It contains the following components: introduction to the problem, tasks for cooperative group members, processes required for successful completion of the challenge, off-line and online resources, and an evaluation rubric for products and solutions. WebQuests are typically written for cooperative groups with each student having a specific responsibility for doing research that will support decision making and an assigned role in product development. The interdisciplinary nature of WebQuests makes use of student interests and current issues related to the subject being studied. Students at Zayed University are trained to implement technology as a tool to facilitate student-centered educational practices in the classroom. The WebQuest, once published to the Internet, is accessible and usable by all teachers and students. The faculty members submitting this project do so as a model innovative approach to helping teachers develop student-centered teaching practices, create authentic teaching materials, and appropriately use technology in the classroom.

Project 6 - A distance English course in which students collaborated to research, write, revise and post articles on a website using videoconferences, email, chat, discussion board, file exchange, phone and face-to-face communication. Submitted by William.Radecki@zu.ac.ae

The Cross-campus Web Newsletter course was the first distance course offered at Zayed University’s two campuses in Abu Dhabi and Dubai. Twenty-two students (11 on each campus) and two teachers participated in the 10-week (50-hour) course.

Project 7 - Students from various schools around the world get together via videoconferencing technologies (PictureTel) to learn from and with each other. Submitted by george.kontos@zu.ac.ae

The project was established to help broaden the horizons of students in a school by connecting them electronically with students in other countries. Using compressed video and audio-videoconferencing as the primary medium, the project is designed to: encourage a greater understanding of different cultures, investigate selected topics in depth, become familiar with new communication technology, and use student-centered techniques to make learning engaging and meaningful.

Project 8 - Easy-to-use authoring of multimedia capable multiple-choice and fill-in tests that randomize the order problems are presented, and also randomize the choices within each problem. Submitted by dale.havill@zu.ac.ae

Features of Hypertester Hypertester is free to use for educational purposes. Two free downloadable applications are required to run Hypertester: (1) HyperStudio Player (submitted with this project), and (2) Quicktime.? Each time a student takes the test, problems are presented in randomized order and choices within each multiple-choice problem are also randomized (A., B., C., etc.) are changed. Problems are created using a simple text file format, and then input automatically into Hypertester to create a test. A set of alternatives can be defined from which only one alternative will be randomly selected and presented to the student each time the test is run. Tests are automatically graded and can be printed or automatically saved in a results file. Multimedia content can be added to problems using HyperStudio 4, a low cost multimedia authoring application (multimedia example is submitted with this project).

Project 8 - Teacherbytes is an email newsletter and web-based resource for English language teachers in the UAE wishing to use the Internet in their instruction. Submitted by brian.oflynn@zu.ac.ae

Teacherbytes converges the two most useful aspects of the Internet, the web and email to create a resource bank of ideas for teachers. Subscribers receive a regular email newsletter containing a reflective commentary, an application review or a set of topic-based links that can be used in the language learning classroom. This opt-in mailing list is supplemented by an archived web site where teachers can browse and search for ideas on using the net in their instruction.

Project 9 -
The Com 309 portal is a central resource for materials and best practices for students in a web design class. Submitted by brian.oflynn@zu.ac.ae.

Com 309 portal was an all-inclusive website for students in a website design and publishing class. As a one-stop shop, students could access their lecture notes and assignments, contribute their ideas, access extra internet resources, take quizzes online with immediate results and also through the site structure itself, get a view of best practices in website usability design.

**Competition Criteria.**

The competition criteria are an important component of this paper because the same criteria can be used to evaluate the projects relative to the applicability of the innovations into the ZU curriculum. Each category as provided and detailed by the UAE Challenge is outlined into four critical areas. Each area asked the participants to provide details, as well as the answers to several key questions.

These are the areas, as provided to each participant as guidelines:

1. **Innovation**
   An innovation must be new, exciting, interactive, exploratory, engaging. It means more than just displaying data. For example, a website produced by students that displays traffic accident data will score less than the same website that attempts to explain the data and draw conclusions from it, possibly using "what if" analysis. We are looking for projects that go beyond the display of data. New and exciting ways could be 3D rotational models, simulations, online games, chat, guest books, all designed to involve the participants in more than just clicking on a link and looking at text. Is this a project that captivates the attention and imagination of participants? Is there interaction and activity that engages the viewer and allows them to contribute? Are there any feedback mechanisms? In judging this section, jurors will look at the questions on the entry form related to innovation, as well as the aims of the project (how it differs from other projects of the same type). Jurors will also give consideration to the project problems, and how these problems were overcome. For projects that involve websites, jurors are expected to visit the web site.

2. **Transferability**
   Projects are marked on how transferable they are to other educational sectors or areas. Jurors are looking for generic ideas that can be transferred. If the ideas behind the project could be used again by others then they will score high. For example, a website dedicated to preserving culture by cataloguing native birds would score high because it can also be used to catalogue other species. In judging this section, jurors will look at the questions on the entry form related to the project’s future (will it be piloted or used in other schools), are the authors willing to assist other educators start similar projects, and the questions related to how many other participants are involved (this gives an indication on transferability, a project being used in more than one location means it is transferable).

3. **Participation**
   This section deals with how the project has involved other people. Projects that involve a lot of people will score higher than those that involve few people. For instance, a school e-newspaper that is produced by teachers and students, and has a readership of 500 has a great deal of participation. If it was read by people outside the school it would score higher. In contrast, a website produced by a teacher that is only used by their students would score lower. If the teacher took the step of sharing their web site so that other classes or schools could use it, then it would score much higher. In judging this section, jurors will look at the questions on the entry form related to the student involvement, How many students are using the project, teacher involvement, other schools/etc involvement, and how they are involved.

4. **User Needs**
   This section deals with how the project fulfills the needs of the end user. Jurors will be looking for evidence that the project has clearly demonstrable goals and that these are achievable or have been achieved. In some instances, this can be verified by user feedback (typically guestbooks on websites that
have user comments). In other cases, it may be by supporting testimonials included in the project documentation. Jurors are also looking for the future of the project and suggestions for improvement. Projects are seen as learning exercises for those involved; as such projects authors should be able to suggest areas for improvement. Projects that meet user needs would score about average, those that are clearly exceptional will score higher. Projects that fall short of the user needs would score less. In judging this section, jurors will look at the questions on the entry form related to Project Outcomes, the lessons learned by students, suggestions for improvement, and the future plans for the project. Jurors will examine these answers with the original aims of the project in mind, to see whether these aims have been realized.

Integration into the Curriculum - Success Factors.

To be presented at the conference.
Internet and Education in the United States and China

John Ronghua Ouyang, Kennesaw State University, US
Robert Zheng, Marian College, US

Internet is growing rapidly and has a great impact on Education. Distance education has become an extremely important area of using instructional technology. The Unite State is one of the largest developed countries and China is one of the biggest developing countries in the world. What is the current status of Internet in these two countries? How does Internet impact on their education? Presenters are going to examine the development trend of Internet, compare the policymaking and use of Internet in education, and provide suggestions for future implementation of advanced Internet technology in the classroom instruction and the learning at distance according to the similarities and differences of the east and the west giants in the world.

In the late 1960s, the U.S. Department of Defense created a network of computers to share military data in case of being of nuclear attack. Getting into the 21st century, the Internet is accessible anytime, anywhere for people with computers that can connect to the network (Anderson, 2001). In 1999, Nielsen Media Research and NetRatings estimated that there were 35 million U.S. householders with Internet access. Now is more than 56 million. It is estimated that by the end of 2003, the number of users on the Internet will be above 300 million (Sharp, 2001).

In the past three years, Chinese Internet users have grown exponentially. According to China Internet Network Information Center (CNNIC), the Internet users in China have jumped from 2.1 million to 26.5 million from January 1999 to July 2001. Moreover, the instructional use of Internet in Chinese education has also grown rapidly. Online instruction and learning have found their ways into Chinese classrooms (He, 1998; Zhang, 2000).

The comparison of the status of Internet use in Education between the United States and China, presenters will collect up-to-date data about the expenses, educational uses, and Internet accessibilities to discuss the future Internet implementation in distance education in both countries. Instructional strategies, online designing as well as online delivering tools will also been examined for making suggestions.

Web-based Learning: An Action Research

Chien-hsing Wang, Graduate School of Education, National Changhua University of Education, TW

Web-based learning has been a hot topic in education. Student-centered instructional methods are highly recommended to implement web-based learning. It is claimed that web-based learning has the potential to facilitate cooperative learning, enhance group thinking, and cultivate group creativity. Therefore, the researcher will apply action research to explore the phenomena of student learning on the web.

The researcher will conduct an action research in the course “Introduction of Education.” The course is designed based on the thematic curriculum theory. The issue chosen is “Network Café.” Project-based learning, cooperative learning, role-play and discussion are instructional methods employed for this study. Students are divided into ten groups with 4-5 in each group. Each group must study one of the following fields: Educational Philosophy, Sociology of Education, Educational Psychology, Educational Technology, Curriculum and Instruction, School Administration, Teacher-Parents Cooperation, Parenting Education, Psychology of Adolescent, Teaching-Discipline-Guidance All-In-One [TDGAIO]. There is a roundtable meeting for are five weeks. Each group member has to be the representative attending the roundtable meeting at least once. In the meeting, each group has its own role related to its study field. They have to discuss the “Network Café.” issue based on the five topics: the purposes and functions of education, technology integration, adolescents and society development, parenting, school administration with [TDGAIO]. After five roundtable meetings, each group has to submit a paper based on their study, video-taping their oral presentation for the web show.

The web-based learning system for this study consists of 5 main sections: Course Content, Course Information, Class Interaction, Personal Tools, and System Tools. There are 5 subsections in Course Content Section: course introduction, course arrangement, table of content, on-line test, and assignment. Course Information Section includes 6 subsections: news, course announcement, FAQ, classmate information, ranking of courses, grade information. Students can check their grade and feedback from teacher for each assignment under the grade-information section. The system also provides the grade range for the whole class to students. Class Interaction Section has 6 sub-sections: course discussion, online discussion, group discussion, topic discussion, mailto teaching assistant, and survey-voting. Topic Discussion Section allows instructors to post topics for discussion and setup a deadline for each topic. Group Discussion is accessible for group-member-only and instructor. On-line discussion is a synchronous
communication channel. Since the on-line discussion does not provide “save” function and file-sharing function, the researcher uses the software of netmeeting for roundtable meetings. Personal Tools Section includes personal information, my courses, calendar, calculating, and two games. System Tools Section: suggestions, ranking of students, school questionnaire, and on-line help.

The subjects are 46 freshmen majoring in Special Education and 3 first-year master students from Special Education program. The data will include on-line student journals, both synchronous and asynchronous discussion contents, e-mails, surveys, teacher journal, and documentation. Data will be analyzed with the following themes: student-teacher interaction, peer cooperation, student perception and attitude toward web-based learning, technology issue, and administrative support, and the function and design of web-based instructional management system.
Coming in the year of 9-11 and Tropical Storm Allison it is perhaps not surprising that the submission process being piloted this year seemed to be ridden with gremlins. But, as the old adage states, "Real boats rock." Growth and improvement bring their own growing pains which are quickly forgotten once the new has become old. We would like to urge SITE members to be patient as the wrinkles are worked out of the new submission processes. Due to some of these constraints readers of the annual will notice that the section introductions this year are abbreviated, but the sections they serve to introduce remain as crucial and important as ever. We would also like to reemphasize that each paper accepted within the mathematics section was carefully peer reviewed - although the introduction might be abbreviated, the bar for acceptance was held high!

We would like to thank all of those who submitted papers to the mathematics section this year. Although space and time does not allow us to provide the annotated introduction of previous years we feel that you will be pleased with the rich and diverse representation of mathematical themes and teaching approaches and the enhancements which technology has enabled. As was the case in last year, the large number of PT3 related presentations have strengthened not only the SITE conference, but the entire field of technology and teacher education. It is wonderful to finally be able to seriously examine technologies impact upon teaching and learning within mathematics across a broad context of methods, situations, and populations. It's quite exciting to think about what the years ahead might bring when we are able to focus upon substantive issues without having to spend huge efforts in maintaining a stable workplace within which to perform our research.

In looking ahead, we would like to restate last year's themes as organizing frameworks within which to consider and evaluate research efforts. The first area concerns itself with the nature of the content to be taught. Mathematics in a technology-enhanced world looks substantially different than it does when the sole tools to think lived are calculator, paper and pencil. Clearly, content issues need to be addressed in a markedly different fashion in teacher preparation. Secondly, the role of teacher and the interaction between teacher, technology and student will need to be carefully addressed. One might expect to see a growing number of papers dealing with these interactions. The third area of potential change lies in that of the student as they use this new technology enhanced environment to explore mathematics. We feel more strongly than ever that these organizing frameworks will go far in helping readers integrate the various research findings in technology enhanced mathematics education, not only from this conference but from other sources as well.

Teachers’ Learning of Mathematics in the Presence of Technology: Participatory Cognitive Apprenticeship

Mara Alagic
Mathematics Education
Department of Curriculum and Instruction
Wichita State University
United States
mara@math.twsu.edu

Abstract. The purpose of this paper is twofold: (a) to present the theoretical background and development of an evolving design of the learning environment for the technology-based mathematics course for K-12 teachers, and (b) to explore the qualitative features of the instructor-teacher and teacher-teacher interactions, while integrating technological and mathematical teaching/learning through the participatory cognitive apprenticeship instructional methods.

Introduction

Shifts in the philosophy and theory of learning as well as emerging technologies support the view that a paradigm shift in teaching and learning mathematics with the use of information and computing technologies (ICT) is taking place. The existence of increasingly efficient ICT tools lends support to the view that the learning environment in school mathematics is changing into a more technological one. Teachers are aware of current changes and are involved in the processes of these changes in their schools.

Many teachers are disillusioned by their experience with technology integration so far. Marcinkiewicz (1991) points out that teachers are often not sure that the skills and experiences they acquire in available technology training will be easily transferable to classroom instruction. High-quality training, sufficient resources and awareness of necessary change are some of the critical factors necessary to regain the trust (Cafolla & Knee, 1995). To build confidence, teachers need successful experiences and ongoing pedagogical and technological support when integrating technology into their curriculum (Byrom, 1997).

Finding ways to apply modern teaching theories integrating technology within the confines of the traditional classroom poses many challenges. Within the field of instructional design there is a growing support for addressing these challenges (Lebow, 1995). One of these is the need to help students develop mastery of their own learning, and provide teachers with the tools they need to facilitate that development. One of the implications, the shared responsibility for student learning co-created by both student and instructor, termed as an apprentice-mastership (Winn, 1995) indicates a possible direction in instructional design. Several studies have used the cognitive apprenticeship model as a means to support and enhance technology training (e.g. Cash et al.1997).

“Technology in the Mathematics Classroom K-12” is a course that pre-service and practicing teachers take to advance their knowledge of technology integration. This paper describes the evolving design of a learning environment model during facilitation of that course. Learners’ interactions (instructor-teachers, teacher-teacher) played a significant role in developing this course. The qualitative features of these interactions will be explored. Other results have been reported elsewhere (Alagic & Langrall, 2002). Data collected is comprised of online interactions, questionnaires, assignments, and interviews of the teachers (students in the course).
Participatory Cognitive Apprenticeship in the Technology-Based Learning Environment

Cognitive apprenticeship model is developed within the situated learning paradigm. Learners participate in a community of practice that is developed through sequenced guided activity and interaction, in ways similar to that in craft apprenticeship, with more emphasis on the development of cognitive skills (Lankard, 1995). A cognitive apprenticeship instructional model merges the components of Schoenfeld's model for teaching mathematical problem solving and Treisman's collaborative workshop model (Johnson & Fischbach, 1992). These models appear to successfully develop not only the cognitive, but also the metacognitive, skills required for true expertise. The cognitive apprenticeship can be viewed as a representation of Vygotskian “zone of proximal development.” Cognitive apprenticeships suggest project or problem-based group-work for students with close scaffolding of the teacher. An expert does modeling of a task. Learner performance and reflections are accomplished with coaching. Students' tasks are more difficult than students can manage independently, but only so that they require the aid of peers and instructors' scaffolding guidance. Knowledge and skill are made meaningful by the context in which they are acquired. Learning from modeling, coaching, fading, articulation, reflection, and exploration of ideas are the most significant phases of this process (Cash et al., 1996).

Since instructional strategies in developing technology-enhanced material are often complex in natural school settings, a cognitive apprenticeship model is a more applicable means of facilitating technology integration than traditional apprenticeship (Cash et al., 1996). Collins (1991) perceives technology to be the resource-intensive mode of education and a supportive environment for cognitive apprenticeship.

The impact of technology on students' achievement is linked with the way the technology is used: Grade appropriate use of computers, for example, has been found to be more important in producing increased learning than the amount of computer use. Yet as research findings regarding the use of technology in classrooms are domain-specific and often reflect a narrow set of conditions, they require careful interpretation. Jonassen (1999) gives five ways in which instructional technologies have been used to support learners’ internal negotiations and meaning making, as:
1. Tools to support representing learners' ideas, understandings, and beliefs,
2. Information vehicles for exploring knowledge,
3. Support for simulating meaningful real-world problems, situations and contexts,
4. Social media to support learning through conversation, and
5. Intellectual partners to support learning-by-reflecting.

Empowering teachers through the use of technology in open-ended problem solving process, interpreting mathematics and developing conceptual understandings is at the heart of mathematics education. Mathematics teachers need high quality and on-going opportunities to experience and do mathematics supported by diverse technologies (Dreyfus & Eisenberg, 1996; Schoenfeld, 1991).

Emerging research and teaching practice increasingly focus on the role and effects of classroom interaction to the learning process. The effects of social interaction on learning have support in Vygotsky's view of cognitive socialization and Piagetian ideas of cognitive conflict. The developmental research inspired by Vygotsky's view has focused on collaborative cognitive activity emphasizing interaction between learners as a source of development. The theoretical concept of interactions has novel characteristics in a technology-based mathematics learning environment. This view characterizes learning as participatory activities, and includes both peer and student-teacher interactions. The thinking processes behind learning are extending beyond individual cognition to include features of both the groups as well as the technological tools employed. Group interactions and communications converge to the joint task to be solved. A simulation of complex mathematical phenomena or reflections on the learner’s thinking processes assists in reaching a joint goal. This common goal helps students in explaining their difficulties, while providing new opportunities for teacher to scaffold. The teacher-students' interaction episodes in this environment may involve qualitatively new formats.

The participatory cognitive apprenticeship in the technology-based learning environment (PCATLE) is a variation of the cognitive apprenticeship learning model developed as a result of two years of teaching “Technology in the mathematics classroom K-12”, author's work with prospective and practicing teachers as well as teaching experiences in mathematics and ICT. It has been evolving in association with the teachers/networking partners involved. This paper describes the main characteristics of the development of this model (up to this point) and some of the qualitative features of class interactions during that process.

The view of learning for understanding is a backbone for the PCATLE model. We recognize understanding through a "flexible performance criterion" (Perkins 1993). Knowledge and skills are important, but if they are not understood the student cannot make a good use of them. Learning for understanding requires thinking in number of ways with what we “know”, practicing and negotiating our thinking until we can make
the right connections flexibly. That also means that the pillar of learning for understanding must be actual engagement in those performances.

"Technology in the Mathematics Classroom K-12"

"Technology in the Mathematics Classroom K12" is a three credit hours summer course which teachers take either as a part of their graduate coursework or to advance their knowledge of technology integration. Assuming that common overarching goal of teaching and learning mathematics with and for understanding, guiding questions for the course are the general ones: How do I reach a necessary understanding of my audience and how do we together reflect about potential audiences that participants in this class will be teaching? Where do we want to be at the end of this course? How are we going to get there? How are we going to know if we are there?

We focus on what teachers (students in this course) bring in and on the negotiated learning goal in the existing context (where they want to be and where we would like to take them) by the end of the course. We take into account the learner’s original ideas, we stage discrepant or confirming experiences to stimulate questions and encourage the generation of a range of responses with the opportunity to apply these in various situations, as suggested by Berryman (1993).

The second cohort, one this paper is focusing on, had 19 teachers (two primary, five elementary, six middle, five high school teachers, and one pre-service teacher). The underlying themes are:

1. Experiencing and doing mathematics as problem solving, reasoning, connecting and communicating through a variety of representations in the technology-based learning environment.
2. Recognizing how conceptual understanding and procedural knowledge are developed together and that their mutual development is enhanced (reinforced) through technology.
3. Reinforcing awareness of changes in the School mathematics brought both by current school reform for standards-based teaching that supports integration of technology and by the development of ICT;
4. Evaluating a variety of computer programs and web resources for learning and doing mathematics; and
5. Organizing class so those teachers take the first steps towards becoming self-reliant, self-regulating, and self-evaluating learners in their technology based design of mathematics activities. The course environment is structured so that it helps students reach these goals. Both the didactical approach of the course as well as the time available for personal interaction between teacher and instructor ask for the embedding of scaffolding into the course site.

Daily assignments included metacognitive reflections via e-mail with the facilitator and either a mathematical task or reporting on teaching strategies in classrooms that integrate technology. Part of class time was spent on critical evaluations of available software and Web resources based on evaluative resources and teachers’ experiences. The computer lab used during the course had state-of-the-art equipment, including wireless technology and most of the mathematics software available on the market. During class time, the facilitator also had technical support. Teachers chose to complete mathematics projects using the following resources: LOGO (n=2); CAS (n=4); Maple (n=2); dynamic geometry (n=5); spread sheets (n=6). Initially, everyone explored all of the above software, as well as concept mappings, graphic organizer software, and Internet resources.

The entire group was motivated to try possibilities and share their experiences with the contributions of emerging technologies to mathematics education. Nurturing, self-reliant, self-regulating and self-evaluating environment requires ongoing class negotiations where instruction-authority is based both on pedagogical content knowledge related to mathematics and technology, and expert-utilization of what the class participants bring in terms of both knowledge/understanding and classroom everiences. Learning and instruction in both cohorts was based on reciprocal understanding between the participants. That was accomplished by establishing shared goals based on common interests in learning about technology-based mathematics phenomena. The following learning environment rules have also being helpful in keeping everybody engaged in their tasks: Try to find answers on your own before asking questions; Ask your partners first, specific area-experts next, ask your instructor the last.

Activities are brought about in three levels: Learner’s level. The first task for learners is to get oriented to the context and determine a reasonable but challenging goal for their studies based on available opportunities that include not only existing mathematical software but also level of available expertise. The learners can study different things depending on their individual objectives related to the field. The final “product” is realized through the portfolio that includes lessons/activities of technological representations of mathematical
phenomena, a (group) project/presentation on the mathematics topic using appropriate technology for developing the concepts, and reflective online journaling. Network level. The lecture materials are available for students on the Web, which offers a possibility for the discussion on these materials. The students' group projects are also available on the network level. Reflective discussions are usually initiated by instructor's reflective question, but often, they take life of their own. On the local level the studies consist of lectures and activities on integrating technology in mathematics teaching usually done by instructor or experts in the field. Teachers are encouraged to share their classroom experiences in integrating technology. Discussions about student's study products are based on the shared idea of collaborative learning for understanding.

During discussions, although very enthusiastic when preparing lessons for the coming fall, teachers talked about day-to-day obstacles such as class management, absence of appropriate ICT-based curriculum materials and "covering material" -- *capturing the struggle* (Alagic & Langrall 2002) between wanting to promote technological innovations and everyday realities. They indicate that integrating technology require both curricular and scheduling adjustments. Some teachers expressed need for more training. On the positive side, including technological representations of mathematical ideas in developing conceptual understanding through scaffolding was well supported by most of the teachers; well planned participatory activities were most often mentioned. An agreement to keep in touch via online discussion was supported by everybody.

These deliberations clarify for us the need to identify research questions and appropriate methods for both development and implementation of PCATLE model and further investigations of learning opportunities provided by participatory activities and reciprocal interactions in ICT-based differentiated mathematics instruction.

**Implications**

The PCATLE model has been experienced by the participating teachers as a well-designed and a fruitful way of organizing the course, as it makes possible, for example, to share expertise and also to develop the model and the curriculum together. The combination of different kind of activities including lectures, collaborative activities in the lab and on the Web, and individual studying are for many teachers a new way of studying. This kind of learning model is challenge for all involved, but also for the organizing network, because it does not necessarily fit very well to the traditional teaching/learning structures.

For me, the researcher, this report reflects (1) a "term introduction" stage of the concept participatory cognitive apprenticeship in technology-based environment, and (2) beginning stages of this concept expansion. The PCATLE as an orienting framework for the teaching practice is an effort to support teachers as they were learning to interpret and interact in the new mathematical culture they were immersed in.

Although a number of change theorists insist that reform efforts start the process with a clear, specific vision of what they want to accomplish, approaches based on postmodern epistemologies as well as chaos theory suggest that the reverse is preferable (Fullan, 2001). Research outcomes suggest that the PCATLE is an inviting direction/framework for supporting teachers as learners. The following stage of the learning cycle, expansion, awaits new challenges. In believing that a computer-supported learning environment creates an optimal environment for participatory cognitive apprenticeship, we are going to continue revising our technology-based learning environment focusing on analyzing learning (mathematics) for understanding and social interaction in that context.

Attention has to be brought to the fact that this kind of learning environment requires far more individualized attention and interaction than a full-time teaching practice allows. The researcher had a particular affinity for teaching this course, a great support from colleagues, and an excellent technical support in the lab. My belief at this point is that a technology-supported learning environment creates an optimal situation for the PCATLE-based learning. Such an environment provides multiple opportunities for students to negotiate meanings concerning different abstract mathematical phenomena. Appropriate and modest scaffold assistance either from me or my lab-assistant seemed to enhance the learning activity and move the projects forward.

How to create optimal conditions for PCATLE and its interaction challenges future studies. Focus from traditional theories on mutual understanding needs to be broadened to study the other possible aspects of the social interaction. Relevant viewpoints in future studies will be students' motivational interpretations in a computer environment and embedded opportunities for differentiating instruction. Reaching every student at an appropriate, yet challenging cognitive level will increase learning for understanding, recognizing understanding through a flexible performance criterion (Perkins, 1993) and providing better conditions for differentiated instruction which ultimately provides better individualized learning for ALL learners (Postlethwaite, 1993).

Fractal geometry is not just another chapter of mathematics, but one that helps every person see the same world differently."

– Benoit Mandelbrot

Abstract

In recent years, the development of fractal geometry and the study of chaotic structures have gained widespread attention. The study of these “new” geometries has influenced recent work in almost all areas of intellectual endeavor (e.g., computer science, mathematics, physics, art, systems analysis, management, meteorology, and biology). The patterns of scaling geometries also have been found in the hair-weaving practices, architecture, and artwork of several African and Southern Indian cultures (Eglash, 1999). In addition, given that students often find the study of mathematics to be an isolated collection of arbitrary rules and abstract objects disconnected from their experiences, the beauty of fractal imagery provides a unique aesthetic element to the study of mathematics that can have a positive effect on student interest and motivation (Bach, 2002). In short, fractal geometry is a field with wide application, relevance and pedagogical promise.

However, with all of its potential for improving mathematics education, there has been insufficient attention given to teaching the basic concepts of fractal geometry to secondary students (see references for notable exceptions), and providing them with tools that assist and encourage hands-on exploration of these geometries within their local experience, within different cultures and societies, and within other areas of study. The web-based mathematics environment, A Fractal is a Pattern in Your Neighborhood, was developed to address this concern.
The tool was designed with several goals in mind: 1) to present fractal geometry in a carefully scaffolded manner, starting with the most basic properties of fractal structures and building to more sophisticated properties of chaotic structures and complex numbers, 2) to implement a method of teaching mathematics that first introduces mathematical concepts as they can be found in familiar environments, 3) to build into each lesson a writing component that encourages students to seek connections between fractal properties and other areas of human inquiry, 4) to provide students with a communication tool that allows them the opportunity to share their ideas with other students, teachers and experts, as well encouraging self-reflection (e.g., e-mail, online discussions, Web searches, online portfolios), and 5) to facilitate student use of various Web technologies (e.g., QuickTime VR, Java Applets, Javascripted functionality, animated GIFs, and PDF files).

A Fractal is a Pattern in Your Neighborhood was implemented during a NASA-funded project directed at preparing high school instructors to teach fractal geometry, use the fractal site in their classes, gain proficiency Web-based technologies, and utilize online NASA resources. In this session, I will demonstrate the online fractal lessons, describe their pedagogical foundations, and discuss some of the challenges that arose during the implementation of the lessons conducted with in-service teachers over the past year.

Redesigning College Algebra Delivery from Direct Instruction to a Computer Environment

Brian Beaudrie, Northern Arizona University, US

Introduction: In the summer of 2001, the Department of Mathematics and Statistics at Northern Arizona University received a grant from the PEW foundation to radically redesign its delivery of College Algebra. The course would change from a traditional lecture course to one that would be web-based in nature. Part of the reason for making the change is to provide a learning atmosphere that is more active in nature, and one that would allow students of differing abilities to progress at their own rate. A web-based format would also allow for flexibility of use on the part of the students; they could work on the course materials whenever it fit into their schedule. The location would be flexible too; they could work on the course in the computer lab in the mathematics department, in other computer laboratories close to their dorm rooms, or even at home. Another reason for making the change is to attempt to stem the tide of students who fail the course. Approximately thirty to forty percent of College Algebra students withdraw from the course or receive failing grades; of these, almost half (47%) will leave the university entirely.

During the fall of 2001, the committee in charge of implementing the transition began to meet and discuss all of the necessary steps that would have to be taken before the project could be implemented for the Spring Semester of 2002. The committee consisted of an Assistant Dean of the College of Arts and Sciences and three members from the Department of Mathematics and Statistics: a tenured professor, a tenure-track assistant professor, and a full-time lecturer. The following report details the some of the work that has been performed by the committee up to this date concerning the transition.

The Redesigned Course

Software: Once the proposal was formally accepted, it was decided that the department should begin testing various software programs that were written specifically for College Algebra. During the summer sessions, different software packages were tried out in the College Algebra courses that were run during that time. Students were asked to spend a minimum amount of time (about one hour per week) trying out the software and evaluating its functionality from their perspective. The use of the software was not made a requirement in the courses; rather it was made available for the students if they wished to use it.

Based on this, during the fall semester two different software packages were selected to be evaluated by the committee: ALEKS, which is published by the ALEKS corporation through McGraw-Hill, and My Math Lab, an Addison-Wesley product. It seemed to the committee that there existed two possible courses of action. One route was to plan out the course, while at the same time testing each software product to see how well it "fit" the planning, and making a decision on software at the end of the process. The second option reversed the process: choose the software package first, and design the course to best fit the software. It was decided to follow the second course of action, and after roughly one month of testing by individual committee members, ALEKS was selected.

Scheduling: As part of the grant, a new computer lab was created dedicated to the College Algebra classes. Three graduate teaching assistants and several undergraduate students serving as computer laboratory assistants would staff the computer lab. These staffers would be responsible for helping support and enhance the students' learning of College Algebra. However due to constraints in both budget and the staff's own class schedules, the lab could only be open approximately 32 hours per week. And it was decided that part of this time would include the regularly scheduled class meeting times.

It was quickly realized that some initial instruction concerning the proper use of ALEKS would have to be provided to maximize efficient student use of the software. Therefore, it was decided that students would meet at their regularly scheduled meeting times (as listed in the class schedule) for the first week of the course. During this time the students would work through a tutorial, take an initial assessment exam.
provided by the software package (used to determine the level each individual student should begin work in College Algebra), and receive additional instruction from the computer laboratory staff.

Since the students would first come to the computer lab during their regularly scheduled class time, it seemed natural that the computer lab should remain open during these times throughout the semester. It guaranteed that the lab would be open for all students at a time when they had no other classes, thus ensuring that all students had access to it. It was also hoped that if the students knew the lab would always be open at the times when their classes were supposed to meet, some would establish the routine of always working on the College Algebra materials at these times.

By keeping the computer lab open during these times (mostly between 9:00 a.m. and 3:00 p.m.), a majority of the allotted hours were used up. The remaining time was designated for Sunday evenings.

Assessment: The committee considered several different ideas on how to best assess the students. After much debate, it was decided that traditional paper-and-pencil testing would be used. While this has the disadvantage of not being aligned with instructional method, the advantage lies in accountability; in other words, it would be known that the person taking the test would indeed be the same person who should be taking the test. The students could take these tests at any time they believed they were properly prepared for them. However, it was decided that a deadline should be set for each test, to ensure that students did not wait until the last week of the semester to begin taking them. There would be five tests during the semester; each would be worth 50 points. The final test would be worth 100 points, for a total of 350 points.

It was also decided that the use of ALEKS should in some way be calculated into their assessment. While discussing many options, it was determined by the committee that students would be given credit for working 6 hours each week on ALEKS, and making adequate progress. They could earn up to 4 points per week (for 12 weeks), and if they met established goals for at least 10 of those weeks, they would receive two bonus points, for a total of 50 points.

Because students could take the tests at any time (up to the deadline), it would be necessary to have several versions of tests available. For this purpose, it was decided to create a large database of College Algebra questions. These questions would be created and stored electronically on a computer; if a student wished to take a test, the lab assistant could use the program to randomly select the appropriate questions for each test from the various databases.

Finding an appropriate software product to handle this proved to be a difficult task. Many software packages investigated could not handle the complicated mathematical symbols and graphs necessary. Others only allowed for a multiple choice/true false/short essay type of question. In the end, a database program (File Maker Pro) was chosen since it had the ability to handle most of the demands that would be placed on it. The committee then hired three other instructors to write questions for these test databanks. Each question will have 15 different versions of it, making it virtually impossible for anyone to be dishonest when studying for the tests.

Assessing Impact: During the Spring Semester of 2002, half of the College Algebra classes will be taught traditionally, and half using the web-based curriculum. The numbers of students in both designs should be roughly the same. For comparison purposes, all students in both designs will be given a pre-test; and throughout the semester students in both classes will have identical (i.e., similar in content) questions in their exams. These matched questions will allow for the comparisons of student performance on specific outcomes, as well as compare student performance on those outcomes in both the traditional and web-based course. The pre-test data will be used to help control for variations across the different sections. Questionnaires will also be used to assess the affective variables concerning how the students feel about using a web-based curriculum in general, of ALEKS in particular, and of the entire redesigned course structure. All of the assessment measures will look at the overall effectiveness of the redesigned course when compared to the more traditional method of teaching College Algebra.
Mathematical Modeling of Motion
Captured with a Calculator-Based Ranger

John E. Bernard, Ph.D. and Olga M. Ramírez, Ph.D.
Department of Mathematics
The University of Texas-Pan American
Edinburg, Texas (USA)
bernardiet@panam.edu and oram@panam.edu

Abstract: The National Council of Teachers of Mathematics (1996) has stipulated that a most exciting potential of technology is its effect on increasing the amount of time that can be devoted to developing conceptual understanding and reasoning processes that lie at the heart of mathematical problem solving. In fact, whether it be with the use of spreadsheets, graphing utilities, or instructional software, technology permits students to explore situations enabling them to visualize relationships readily and to test ideas quickly. In general, the same is true in using a Calculator-Based Ranger (CBR), a motion detecting device. A CBR enables real data from real experiments to be captured in real time. In turn, using a CBR with graphing calculators (e.g., TI-83 Plus graphing calculator) permits rapid production of visual displays, with statistical summaries possible leading to prediction models. For this reason, a CBR should be a standard instructional tool in mathematics classrooms 8th-12th grades. This equipment shows promise in making algebraic and statistical ideas accessible to all students. With CBR-based lessons, simulations and modeling, in particular, make it possible to study mathematical situations in a less abstract way.

One role of mathematics teachers is to help students interpret and analyze situations from mathematical perspectives, as well as to assist them in seeing interrelationships of mathematics (e.g., unifying ideas such as set, relation, function) that tie various concepts together. However, even students who display a high level of mathematical skill often fail to see any relationship in what they may be learning or doing to real-life situations. Furthermore, in recent years greater emphasis has been placed on teaching problem solving in the mathematics curriculum. Nonetheless, research shows that students' problem-solving skills are still considerably weaker than their computational skills. Although most educators agree that much more needs to be done to improve students' abilities to solve problems and to think critically, as well as to ascertain that mathematics not be learned in isolation from its applications, seemingly the level of maturity required to work with data, formulas, graphs, and other such mathematical concepts, generalizations, and procedures can be a hurdle for many students especially when data collection and analyses is cumbersome and time-consuming. Yet, if one feels that problem-solving skills and an understanding of the usefulness of mathematics is important, shouldn't one teach students to transfer the mathematics they have learned or are learning to applied areas despite the toil or challenges? Is it possible that with a little technological help, opportunities that make applications and connections accessible and that help students make discoveries can and will make a difference? We believe such is the case. With a Calculator-Based Ranger (CBR) and a TI-83 Plus graphing calculator, students can collect, view, and analyze motion data without tedious measurements and manual plotting. Motion data is essential in many applied fields of mathematics (e.g., physics, engineering), so rather than having this skill be a stumbling block to students' continued success, studying motion data, even in mathematics classes, can be a real benefit then and later as students encounter awareness of computational skills.

From a curricular perspective, a Calculator-Based Ranger lets students explore mathematical and scientific concepts such as: (1) motion: distance, velocity, acceleration; (2) graphing: coordinate axes, slope, intercepts; (3) functions: linear, quadratic, exponential, sinusoidal; (3) calculus: derivatives, integrals; and (4) statistics and data analysis: data collection methods, statistical analysis. Indeed, the Calculator-Based Ranger sonic motion detector can also be used with TI-82, TI-83, TI-85/CBL, TI-86, and TI-92 and easily brings real-world data collection and analysis into the classroom making it possible for students to also explore relationships between studied concepts. Fortunately, for most people, a Calculator-Based Ranger is easy-to-use, especially with the TI-83 Plus Graphing Calculator which includes the RANGER, MATCH, and BOUNCING BALL programs as standard built-ins. Consequently, getting started with CBR activities does not require extensive calculator or programming experience. To exemplify how to operate a CBR, the activity entitled AExperiments about Motion Captured with a Calculator-Based Ranger shall be demonstrated. This activity acquaints students with basic functions and properties of motion under various settings (e.g., people, cars, and pendulum in motion). The purpose for elaborating on this activity is to demonstrate that a CBR enables real data from real experiments to be captured in real time, helping students to develop the skills to apply mathematics to more realistic settings, as well as to help them see interrelationships between concepts studied. This is demonstrated by using a CBR with a graphing calculator (e.g., TI-83 Plus graphing calculator) which permits rapid production of visual displays, with
statistical summaries possible leading to prediction models. Critical to this demonstration is the belief that when students actively participate in helping to shape their own understanding of an idea, as facilitated with technology, they are learning how to learn. Consequently, their view of mathematics as a tool for answering questions that are meaningful to them can only be strengthened.

As an example, the diagram from a TI-83 Plus graphing calculator display shown below shows the motion detected by the CBR of a person walking away from the motion detector from a distance of about 5 feet. The person is walking rapidly away from the motion detector for about 3 seconds, and data is collected for about 10 seconds altogether. The diagram depicts these continuous actions. The second diagram depicts the motion of three distinct battery-operated “toy” cars. Here, the velocity of the cars are detected by the CBR and diagrammed in a TI-83 Plus graphing calculator environment. By using technological tools, students are able to obtain skills via experiments which show them how to look for applications, and how to see unifying ideas in mathematical context. Indeed, this equipment shows promise in making algebraic and statistical ideas accessible to all students.

Start at about 5 feet from the motion detector and walk rapidly away from the motion detector for 3 seconds. Collect data for 10 seconds.

CBR Ranger Settings
Realtime: No
Time(s): 10
Display: Dist
Begin on: [Enter]
Smoothing: None
Units: Feet

Who's the FASTEST? Data Collection on Three “Toy” Cars

Collect data for 15 seconds. Run each car in turn, with a few seconds in between. Interpret the graphs generated by the motion detector on the TI-83 Plus Graphing Calculator. What do the graphs suggest?

General Logic Actions and Database Oriented Methods of Their Development in Teaching Advanced Calculus

Mikhail M. Bouniaev
Mathematics & Computer Science Department
Southern Utah University
United States
bouniaev@suu.edu

Abstract: This paper discusses how databases can be used in developing general logic actions in teaching Advanced Calculus. The methodology of teaching advanced calculus that we are currently developing has a special importance for training mathematics teachers. Actually teachers of mathematics and those who are going to pursue careers in other related to mathematics fields are going to use knowledge and skills from this class differently. For mathematics teachers the most important thing is to learn how to structure calculus theorems, how to use previously proved theorems in proofs of other theorems, how to use examples and counterexamples to substantiate different issues, etc. The methodology that we have been developing for the last four years is designed specifically for teaching this kind of things.

Introduction. Functional and operational composition of action.

As theoretical and experimental research shows (Bouniaev, 1993) that databases and bases of knowledge (complete with a designed interface) can serve as construct frameworks in organizing interactive computer oriented instruction.

The methodology of teaching advanced calculus that we are currently developing is of particular importance for training mathematics teachers. Actually teachers of mathematics and those who are going to pursue careers in some other related to mathematics fields are going to use knowledge and skills from this class differently. For mathematics teachers the most important thing is to learn how to structure calculus theorems, how to use previously proved theorems in proof of other theorems, how to use examples and counterexamples to substantiate different issues, etc. The methodology that we have been developing for the last four years is designed specifically for teaching this kind of things.

Our analysis of using information technologies is based on the theory of stage-by-stage development of mental actions (SSDMA theory) developed by the Russian school of psychology (Galperin & Talizyna, 1979), (Talizyna, 1975) as applied by the author in teaching advanced mathematics (Bouniaev, 1991 & 1996).

According to Talizyna (Talizyna, 1975) all actions can be referred to two categories: general logic actions and specific actions. General logic actions are inherent in every subject field and are different only in objects at which they are directed. Examples of such type of actions are qualification, break up into classes, comparison, contributing to a concept, action of proof. For example, qualification as a type of action exists in mathematics (qualification of the conics and differential equations) as well as in other disciplines. Specific actions are basically inherent to a given subject field. For example, in mathematics they are arithmetic operations, differentiation, etc.

The SSDMA theory specifies four independent characteristics of any action used to judge the level of development of an action. An action can be in a materialized (material), speech or mental form. Mental form of action is the highest form of action development. The mental form of action also means that its objects are representations, notions, concepts and all operations are performed in the mental form. The ability to perform a whole action in the mental form indicates that it has gone through all the stages of development and interiorization.
As a rule, the performed actions themselves consist of other, more primitive actions and in their turn can be part of other actions. Actions that are part of a given whole, are called operations. That is, operations are also actions, hence the term emphasizes only the hierarchial subordination among actions.

**Databases in studying advanced calculus**

The structure of any database significantly depends on what kind of information this database is used for. Therefore as points of reference for constructing databases we offer students typical questions that will be part of the test (Bouniaev, 2001).

1. Formulate the theorem. 2. What is the theorem’s premise? 3. What is its conclusion? 4. What notions are used in the theorem’s formulation and what is their meaning? 5. What theorems were used in the proof of the given theorem? 6. Give examples of problems, which are based on solving this theorem. 7. What theorems need to be used to do this problem? 8. Is the conclusion true in absence of any of the premises? 9. Are all the premises necessary for the conclusion to be true? 10. If you answered, “yes” in 9, demonstrate it. 11. Give an example of an object that can be attributed to this concept. 12. Give an example of an object that cannot be attributed to this concept. 13. Prove this theorem. 14. Solve a proof problem.

At our first experiment the students themselves determined the structure of databases, fields, records, etc. Theoretical analysis conducted after the experiment led us to the conclusion that teaching was based on the first type of the orientation part of an action (Talizyna, 1975), the learning process was not fast enough and required considerable efforts on the part of a student. Thus taking into account this fact at our next stage we made a decision to base instruction on the fourth type of the orientation part of an action.

We believe that fields in the databases can serve as this generalized system of points of reference in developing the action of theorem proof. Since the structure of proof of any mathematical statement is practically identical, the system of reference points developed by us can be successfully used both in Advanced Calculus and Abstract Algebra as well as in any other course with one of the main goals being to teach proofs. Thus as a generalized system of reference points the students were offered tables “Theorem Statements”, “Concepts and Their Definitions”, “Theorem Proofs”.

In table, “Theorem Statements” the following fields were established: “Name of the theorem” (for example “Intermediate value theorem”); “Object of the Theorem” (for example “A function f”); “Premise 1” (for example “Domain is an interval <a, b>”); “Premise 2” (for example “Continuous on the interval”); “Premise 3” (for example “Domain is a closed set”); “Premise 4” (for example “f(a)<C<f(b)”); “Premise N”; Conclusion 1” (for example “There is a point “c” between “a” and “b” such that f (c)=C); Conclusion N”; “Concept 1 Used in the Theorem Statement” (for example “Continuity on a set”); “Concept N Used in the Theorem Statement”; “Model Problem 1”;...; “Model Problem N”; “Theorem Used for the Proof of...” (For example, Theorem used for the proof of Theorem 5-11, Theorem 7-3, etc.)

It should be noted that filling in fields while developing a particular action takes place at different time periods of study.

The structure of table “Theorem Proofs” is determined by the following fields. “Name of the Theorem”; “Object of the Theorem”; “Definition of Concept 1 Used in the Proof”; “Definition of Concept N Used in the Proof”; “Theorem 1 Used in the Proof”; “Theorem N Used in the Proof”; “Transformation 1 of the Proof” “Transformation N of the Proof”; “Proof Structure”.

Table “Concepts and Their Definitions” contains the following fields (as an example we use the definition of the least upper bound). “Name of the Definition” (in our example “least upper bound”); “Object of the Definition” (number L); “Auxiliary objects (in our example it will be set A, since we analyze the definition of the least upper bound of a set); “Concepts, Used in the Definition” (in our example “upper bound”); “Requirement 1” (L is an upper bound); “Requirement 2” (for any upper bound L’, L’<L’); “Requirement N”; “Example of the Object that Can be Attributed to the Concept” (1 for interval (0,1)); “Examples of the Object that Can Not be Attributed to the Concept” (1 for interval (0,1)); “Definition Used in the Proof of Theorem...” (Theorem 3-4, Theorem 8-2, etc.); “Definition Used in the Statement of...” (Theorem 2-1, Definition 3-4, etc). “Hierarchical Relationship with Other Concepts” (in our example “least upper bound” implies “upper bound”; “maximum” implies “least upper bound”)

As we already noted, any action developed in the process of instruction can be presented as a sequence of general logic and specific actions or operations. In the study of the majority of disciplines development of general logic actions is not the goal of instruction. In this respect advanced math courses
significantly differ from any other disciplines. One of the main goals of instruction of Advanced Calculus is development of the action of theorem proof and the action of using the theorem in solving practical problems. In order to achieve this goal we need to develop certain “elementary” general logic actions. These “elementary” actions include among others such actions as comparison, generalization, concretizing, attribution to the concept and drawing conclusions.

Developing of elementary logic actions

The action of comparison. As a rule, development of the action of comparison is directly connected with the development of concepts. Comparison implies singling out criterions of comparison. Knowledge of the system of possible criterions of comparison and the chronology of their appearance in the process of instruction demonstrates the level of development of basic mathematical concepts.

At the initial stages of instruction criterions of comparison can be presented to students. As observations show, in studying every new concept a student makes a comparison using only the studied criterions. Psychologically it is understandable and logical. However, in the process of instruction it is necessary to make sure that every new criterion does not stay isolated but gets incorporated into the already existing system of criterions. That means that every new criterion first should be added to the set of already existing criterions and, second, that a strong hierarchical connection of the newly added criterion with the previously existing criterions be established in the mind of a student.

Using databases helps to solve this problem in the process of independent construction of databases, during their utilization and updating. Probably, the most important role in incorporating a new criterion into the system of the already existing ones is played by the fields “Object” and «Hierarchical Relationship with other Concepts” in table «Concepts and Their Definitions».

At the initial stages of instruction, students often experience considerable difficulties in understanding what is the object of the definition. Thus the object of the notion “least upper bound” is often described as a set which means that in analyzing the definition the students don't focus on the fact that “least upper bound” is a number. The existence of the field “Object” makes it possible not only to make an explicit note of this very important element of concept but also to make a query about what concepts studied before had the same object, i.e. incorporate a new criterion of comparison into the already existing system. The necessity to fill in the field “Hierarchical Relationship with other Concepts” not only makes it necessary to make such a query but also to analyze the relationship of the new added criterion of comparison with the already existing ones. The logic of presenting a new material as a rule implies that the newly introduced concept involves theorems connecting this concept with the already existing ones. Therefore in most cases the hierarchical relationship of the new and existing criterions will be established when the students compile the table “Theorem Statements”.

Action of generalization. Development of the action of generalization while working with databases is connected first of all with generalization of the earlier applied ways and methods regarding a new class of problems. A significant role in this is played by the field “Transformation” with the table “Theorem Proof” and students actions while working with this field. In the process of filling in this field it is required not only to identify what transformation (inequality, identity, idea, etc.) was used in the theorem proof but also to indicate in the proof of what theorems this or similar transformation was previously used.

As an example let us consider Bernoulli inequality and generalizations related to it. Probably it is used in advanced calculus for the first time while proving that the limit of the sequence \( a^m \) is equal to one. The proof that the sequence \((1 + 1/n)^n\) is monotone in most cases is based on binomial theorem. The proof of Bernoulli inequality can also be based on binomial theorem. That’s how the idea of using binomial theorem in “convergence proofs” can be generalized for a wider class of problems.

The next example is the use of triangle inequality in proofs related to convergent sequences (series), uniformly continuous functions, etc. The triangle inequality is used for the first time in advanced calculus while proving that the limit of the sequence is unique: \(|a - b| = |a - a_n + a_n - b| \leq |a - a_n| + |b - a_n| \leq d/2 + d/2 = d\). Later \(t\) is used in various proofs. In the chain of inequalities that is written above two beautiful ideas are used. The first one is triangle inequality, the second is the idea of adding zero in the form \(a_n - a\) to the algebraic expression. Both these ideas are then generalized for a wide class of problems. At the same time despite the fact that the use of the second method as a rule involves the use of the first one these two are different. If a student cannot distinguish between the two and views them only as one entity (what happens in a traditionally organized instruction) then the development of each of them goes very
slowly. In this respect it is difficult to overestimate the use of the fields “Transformation # N” in the table “Theorem Proof”. First, while filling the fields in “Transformation” a student has to separate these two methods. Second, later on when these methods come up in the study of some new material a student has to analyze the history of using them. This means that a student develops in his/her mind a set of problems that require the use of these approaches together and another set of problems where these approaches are used independently of each other.

**Action of attributing to the concept.** Performing the action of attributing to the concept implies answering the question whether this object belongs to this concept or not. For example, “Is this sequence monotone?” “Is this function differentiable?”, etc. While performing this action it is important to understand what objects in principle can be attributed to this particular concept. As our observations of the traditionally organized process of instruction indicate a student very often simply does not understand the meaning of this question. In this regard the presence of the field “Object of the Definition” and the table “Concepts and their Definitions” “play a very important role. The necessity to frequently answer the question about the object first of all develops a general understanding of the importance of the object and secondly, connects the object with the system of its possible criterions/attributes. The action of attributing to the concept can involve working both with the Table “Concepts and their Definitions” and “Theorem Statements”. In the first case attributing to the concept is based on the definition of this concept while in the second it deals with the use of the theorem. In both cases the student is required to define characteristic criterions of the given concept. A set of characteristic criterions is incorporated into the corresponding record. In the process of work at this record a student is required to single out each of these criterions, so we see the development of the action of attributing to the concept in the step-by-step form. If in proving by definition some of the characteristic criterions present any difficulties then the action of attributing to the concept can be based on using the theorems. In this case a model of proof is developing in the mind of a student with the initial stage being not the analysis of the given but the analysis of the conclusion. For example, it is necessary to decide whether a given sequence has a finite limit or not. To solve this problem it is expedient to analyze the premises of all the theorems with the conclusion “sequence converges”. Maybe one of the possible sets of premises that leads to the required conclusion matches the characteristics of the given sequence? The existence of a database allows us to easily do this. Naturally, we do not assume that every time when there is a need to use a theorem in order to attribute an object to a concept the student goes to the databases. Our goal is quite the opposite, i.e. to develop this action in the mental form. However, as practical experience shows at the initial stage of abstract mathematics study a simple explanation that there is a possibility to start with the conclusions and after that go to the required premises is far from being sufficient. It is necessary for a student to associate this mental action with some external activity. Working with databases can become such external activity.

**Action of drawing conclusions.** As in the case of attributing to the concept action, the structure of the action of drawing conclusions involves singling out a set of characteristic criterions. Another similarity is that systems of characteristic criterions are actually presented to students in the explicit form. In attributing to the concept this is presented as a system of criterions of the single given concept while in the case of drawing conclusions it is given in the form of a set that is a combination of systems of attributes (criterions) of one or several concepts.

The action of drawing conclusions can be broken up into three classes. The action of drawing empirical conclusions belongs to the first class; the second class contains drawing conclusions with the given premises based on the logically substantiated rules of drawing conclusions and previous knowledge. The third class encompasses drawing free (not given) conclusion with the given premises. Development of the third class is closely connected with organizing the instruction process based on the learning search activities. We believe that this kind of instructional process while studying abstract math disciplines at the baccalaureate level does not fit the level of students learning skills developed by that time. Development of the action of drawing conclusions as empirical conclusions is one of the goals of studying Calculus at the intuitive level. Therefore we will focus on the second class of drawing conclusions.

The very activity of building tables “Theorem Statements” and “Theorem Proofs” is a material model of the action of drawing conclusions. While making a record in the table “Theorem Statements” a student learns to make clear distinctions between all the given premises. Learning to analyze the premises of a theorem is essential for learning how to prove a theorem.

In a traditionally organized instruction the process of reading theorem proofs as a rule is not yet performing an action. The situation radically changes with databases oriented instruction. In the process of creating records in the table “Theorem Proofs” structuring of the whole proof in the material form takes
place. All the used theorems, definitions, transformations and the order of their use are presented in the explicit form.

The action of concretizing. One of the most important problems in organizing instruction of advanced calculus is that of developing the skill to use the proven theorems to solve concrete problems. We can not consider a theorem to be learned until a student knows how to apply it. Even if a student knows how to prove it.

In the development of the action of concretizing in database oriented instruction practically all the fields in the table “Theorem Statements” play a very significant role.

The first step in the development of the concretizing action is a search for model problems of the studied theorem. By model problems we mean problems that significantly rely on this theorem for solution. Let us consider the theorem that any monotone bounded sequence converges. When students begin to deal with this theorem their technical skills are not quite developed yet and the number of concrete sequences that are worth discussing without distracting students from the major topic of study is extremely limited.

Formally, the problem to prove that \((1+n)/n\) converges can serve as an illustration (a model problem) for the theorem that monotone bounded sequence converges. At the same time this problem can be easily solved just by using the definition of a limit. Moreover, this problem looks as an ideal model problem for the proof by definition. A «good» model problem for this theorem is the problem that \((1+1/n)^n\) converges.

Taking into account the fact that this kind of situation occurs quite often in the process of instruction we advise students not to use the same (or similar) problem as a model for different theorem. Development of the action of concretizing can be viewed as a sequence of actions of attributing to the concept. In the action of concretizing an object and theorem premises are given. The given set of premises determines a certain set of objects. The problem of concretizing boils down to the attribution of a given object to the concepts defined by each particular premise. The possibilities of using databases in developing the action of attribution to the concept were discussed earlier.

Abstract: Mathematics methods coursework can be an innovative environment through which to emphasize the integration of real-world data structures and opportunities. These opportunities can create instructionally informative opportunities for learners, as well as inform teacher candidates of innovative teaching tools at their fingertips. NASA offers numerous curricular opportunities to the mathematical methods coursework, with work focusing on both PreK-12 learners as well as university learners. Such a wide array of interest levels integrate numerous learning objectives, depending upon the needs and desires of the instructors and learners whom they serve.

Introduction

Teacher candidates with a specialization area focus in mathematics maintain a working knowledge of the learning environment due to their superior university methods faculty; however, the integration of opportunities that will be available within the field are of utmost importance. NASA offers the opportunity to maintain educational excellence through partnerships with PreK-12 instructors. Such partnerships are available through the United States of America as well as around the world. The focus of this presentation, as well as proceedings paper, will focus upon the innovative opportunities that the NASA educational entity offers to the PreK-12 as well as university mathematical methods courses. The integration of NASA's superior real world curricular abilities into math methods coursework, which offers teacher candidates opportunities to work with real-world data structures and environmental elements that would otherwise be unavailable to the majority of teacher candidates in methods courses, present professional development and learning that will then be integrated into curricular scope and sequence for future PreK-12 learners.

National Standards

The “Technology Principle” is one of six principles that the National Council of Teachers of Mathematics (NCTM) designate as imperative for all teacher candidates to master (NCTM, 2000). The “Technology Principle” states that “Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students’ learning” (NCTM, http://www.nctm.org/standards/principles.htm, paragraph 28). However, the key to the success of mathematics teaching is the mathematics teachers, not the technological tools that may support the educational endeavors (Garofalo, Drier, Harper, Timmerman & Shockey, 1990; Kaput, 1992; NCTM 1991, 2000). Through the collaboration that can arise between PreK-12 education environments, higher education environments that support teacher candidates and the National Aeronautics and Space Administration (NASA), the possibilities towards supporting and realizing NCTM's “Technology Principle” are available.

NASA Educational World Wide Web Sites
There are numerous Web sites that are supported by distinct arms of NASA. Each of these Web sites delineate the orientation for each NASA campus, such as the following Web sites:

- **Practical Uses of Math and Science: The On-line Journal of Math and Science Examples for Pre-College Education**
- **InfoUse’s PlaneMath**
- **NASA Spacelink**
  [http://spacelink.nasa.gov/index.html](http://spacelink.nasa.gov/index.html)
- **NASA-JSC Distance Learning Outpost**
  [http://learningoutpost.jsc.nasa.gov/](http://learningoutpost.jsc.nasa.gov/)
- **The Space Place**
- **NASA Human Space Flight Metric Converter**
- **NASA-AMATYC-NSF Mathematics Explorations I and II**
  [http://cctc.commnet.edu/lta/](http://cctc.commnet.edu/lta/)
- **NASA KIDS**
- **LTP Glenn Learning Technologies Project**
- **Space Science Data Operations Office of NASA/Goddard Space Flight Center: Space Science Education**
  [http://ssdoo.gsfc.nasa.gov/education/education_home.html](http://ssdoo.gsfc.nasa.gov/education/education_home.html)

The examples presented in the above Web sites are developed by and in collaboration with scientists, engineers, educators, instructional designers, and other professionals. The sole intent of these endeavors being the support of education pertaining to the emphasis of mathematics and cross-curricular, real-world support in PreK-12 educational environments.

**Conclusions**

As delineated in NCTM’s “Connections” section (NCTM, 2000), “Mathematics is an integrated field of study, even though it is often partitioned into separate topics. Students from prekindergarten through grade 12 should see and experience the rich interplay among mathematical topics, between mathematics and other subjects, and between mathematics and their own interests. Viewing mathematics as a whole also helps students learn that mathematics is not a set of isolated skills and arbitrary rules” (NCTM, [http://www.nctm.org/standards/standards.htm](http://www.nctm.org/standards/), paragraph 30). NASA has made available interactive workshops, real-world data sets and lesson plans focused upon specific levels of mathematical principles to support the educational endeavors of our education profession, and are to be commended.

Virtual Manipulatives in Mathematics: 
Addressing the Conceptual Dilemmas

Abstract: The authors are co-principal investigators for an NSF project to create a web-based National Library of Virtual Manipulatives for learning mathematics in the elementary grades (K-8 emphasis). Our virtual manipulatives are tightly focused, highly interactive Java applets, some based on physical manipulatives commonly in use in the schools (e.g. geoboards, tangrams, pattern blocks, fraction bars, etc.); others are concept manipulatives especially designed to teach or reinforce basic mathematical concepts.

These virtual manipulatives, designed for children's learning, are at least as important for the instruction of teachers. They provide unprecedented opportunities and a relatively non-threatening learning environment for teachers. Teachers, as students, "learn by doing." At the same time they give teachers tools with which they can communicate, we believe, a more correct and mathematically accurate understanding of key concepts.

The fact that these teaching tools are web-based also opens entirely new ways to assess mastery in distance learning environments.

Background and Setting

This paper is in some sense a follow-up of, or at least related to, a paper presented at a previous conference, SITE 2000. At that time we were just beginning our three-year National Science Foundation funded National Library project. We are now nearing the end of the funding period, but as with any project of substance, we see as much more to be done as we may have already accomplished.

Our goal in this project is the creation of a substantial library of interactive Java applets that can be used by teachers and parents anywhere to increase conceptual understanding of mathematics. The entire library will continue to be freely accessible from the web at www.matti.usu.edu. The library must be viewed at present as a work in progress; all the virtual manipulatives (applets) presently available at the MATTI site are functional prototypes, subject to continued refinement. (Software has been said to share an aspect of an oil painting in that it is "never done, just at a point where it can be left.") Many of the manipulatives, even if not in finished form, are also being made commercially available from several sources, and we anticipate additional sponsored versions in the future. Early in our project, we worked with the Electronic Format Group and the writers of the NCTM Principles and Standards of School Mathematics ("Standards 2000"). Many of the E-examples that appear in the web version of the Standards are early versions of our virtual manipulatives.

As we continue to create new applets and work with those on our site, we are actively working with teachers and students. Their explorations and experience make a significant contribution to our evaluation and refinement process.

We have been particularly pleased with the reception of our materials by teachers. We intended from the beginning that our applets should serve both elementary students and their teachers, both as instructional tools and to strengthen the mathematical preparation of pre-service and in-service teachers. It
has been a pleasure to work with several groups of in-service elementary teachers. In both web-based distance instruction (in Utah and in North Carolina) and in on-site classes (in Utah and North Carolina and Ohio), we have used our virtual manipulatives as part of our technology-supported mathematics courses.

It is this work with teachers that supports our claim that virtual manipulatives provide a relatively non-threatening learning environment. By having teachers working individually, or in very small groups at a shared computer, we can encourage them to explore without exposing any perceived areas of ignorance. One of our primary goals in applet design is to maintain a tight focus. We don’t want an applet that “does too much.” Keeping a single goal in mind and giving the user control, we permit each individual to explore the consequences of various choices at a comfortable pace.

Another critical design objective is to help the user, student or teacher, to develop a clear understanding of a single mathematical idea. An animation or demonstration can perhaps encourage memorization of a rule or algorithm, but a rule seldom helps understanding. It is often not easy for beginners to see why a particular mathematical relationship holds or for them to make a connection to more basic principles. Anthony Ralston has articulated this distinction well (Ralston 2001):

...many Americans believe that elementary school mathematics consists of nothing more than a lot of rules to be learned (“the algorithms of arithmetic”) ...there is much more to arithmetic that should be learned by children in elementary school: not just the how but the why, not just individual procedures but the connections between procedures and the concepts underlying them, and the value of viewing problems from multiple perspectives. (Italics added.)

**Why Virtual Manipulatives?**

In addition to the above-listed advantages, research into the value of physical manipulatives for student learning is increasing. They have numerous advantages that apply across the spectrum of student ability and interest, from those disadvantaged by economics or language or minority status, to especially gifted, curious students who can direct their interest into unanticipated explorations. Recent studies are supporting our contention that an electronic format, with student interaction with software on a computer screen, shares many of the same advantages, with some additional capabilities not available with physical manipulatives.

Our concern here, however, is teacher preparation. Although not yet quantified, the advantages of virtual manipulatives are real. It has been a delight to have experienced teachers exclaim over the possibilities they see for the use of our Library materials in their classrooms: “Oh, that’s why that works!” or “This will help them understand why common denominators.”

Math methods courses, and content courses for prospective elementary teachers, often involve physical manipulatives for demonstration or exploratory purposes, to familiarize teachers with important teaching tools. For virtual manipulatives, working with the computer has a respectable cachet. They are freely available at home, on the web and in the classroom. Furthermore, virtual manipulatives often have features that are impossible to duplicate with their physical counterparts. The computer allows real-time dynamic control. The user can change colors, save, and even print, the state of an applet after creating an interesting or illuminating example. Even when the computer activities are child-intended and designed, controlling their use and exploring consequences is somehow more acceptable than just handling physical objects. There is also the acknowledged value of “learning technology” even if it is really mathematical concepts that are being learned.

With the level of engagement necessitated by interaction with our virtual manipulatives, we get away from what Cuoco (2001) has called “watch-and-do pedagogy” that is so pervasive in college and university classes (and which young teachers often try to carry into their elementary classrooms): the teacher works out a problem, the students mimic the procedure on very similar problems, and then practice on a larger set of worksheet or homework problems. This teaching (learning?) style infects too many current mathematics textbook writers and has been called, in even less complimentary terms, “monkey-see, monkey do.” Virtual manipulatives can be used by imaginative instructors to encourage fairly extensive individual explorations, in the best situations using student discoveries to stimulate class and small group discussions.
And because we recognize the importance of drill for learning, the number of variations on simple themes that we can build into our applets encourages repetition without excessive "sameness."

We are learning that virtual manipulatives also have versatility and applicability in the areas of assessment and distance learning. The potential for using our manipulatives in a distance education format is essentially the same for students five feet or five hundred miles away, as long each person is in front of a computer and has real-time access to our manipulatives on the web. We are developing an on-line testing and computer-grading procedure, where the person taking the test also has access to all of the tools that have been used for learning. Thus the computer activities can furnish versatile concept-based test questions. This is important future work, and we will explore these at some length in another paper. Here we more closely examine some specific examples.

Examples from Fractions

Manipulation of fractions is perhaps as frustrating as any single topic in elementary mathematics. The perplexity and apparent difficulty continues into college, interfering with the learning of calculus as the same mistakes are repeated by those who have ostensibly mastered the techniques years earlier.

Liping Ma (Ma, 1999) has raised questions of serious import for mathematics educators. One of her best-known examples deals with the question of dividing by fractions. She worked with a set of 23 American and 72 Chinese teachers, interviewing them, individually and in groups, on several topics in the teaching of elementary mathematics. The question posed was to compute the quotient of two fractions, $\frac{13}{4} + \frac{1}{2}$. The lack of general understanding of the concept of division was reflected by a question that came from the father of one of our elementary students, "How come when Brent divides by $\frac{1}{2}$, he gets a bigger answer? Aren't things supposed to get smaller when you divide?"

Not only were there differences of opinion among Liping Ma's interviewees about how to teach the concept, only 9 of the 23 Americans teachers were able to compute the quotient correctly; all 72 of the Chinese teachers succeeded. And several of those who had an algorithm to accomplish the task (usually some variation of "invert the denominator and multiply"), to get the correct answer, didn't have an adequate explanation to give to students as to why their rule should work. In subsequent chapters, Ma talks of the need for a "Profound Understanding of Fundamental Mathematics," that embodies "an understanding of the terrain of fundamental mathematics that is broad, deep and thorough."

We are under no illusions that we have a magical "fix" for the deficiencies observed by Ma or that the proper use of virtual manipulatives will necessarily create a Profound Understanding of Fundamental Mathematics. What we do assert is that we have a collection of tools that can contribute to a better understanding of some fundamental principles. We focus on a couple of ideas to illustrate.

Figure 1: Equivalent Names for Fractions

Figure 1 is a snapshot of an applet in which the user is presented with a shaded fractional portion of a whole and is asked for an equivalent name. The up and down arrows change the number of divisions ("pieces"), and as is obvious in the figure, 10 divisions don't line up to divide 2/3 evenly. Any multiple of
3 clearly works, and the computer will accept any numerical answer of the form \( \frac{2m}{3m} \), allowing the user to observe the validity of cancellation (or multiplying by 1 in the form of \( \frac{m}{m} \)). The user can provide as many equivalent names for each fraction as desired, with or without changing the number of pieces. It also becomes apparent that the only possible denominators are multiples of 3. Pressing the New Fraction button shows up a new fractional portion of one of several different shapes.

This is the first of several applets in which the user changes the grid or the number of pieces to show a simple idea. The next one we show examines the ideas necessary for the addition of fractions and why a common denominator makes sense of the process. The goal is to add the fractional parts shown. The first step is to rename the fractions with the same denominator, again using the up and down arrows to change the grid so that both copies of the whole are divided and the shaded part is also divided evenly, as shown in Figure 2.

When the Check button is pressed and the computer verifies that the answers are legitimate (without requiring a least common denominator), a new page appears. In Figure 3 we show the result of following the instructions. Initially, the shaded pieces are still located as in Figure 2, but they are now movable and can be dragged to the sum square, where they snap together as in Figure 3. Again, the answer is checked for numerical accuracy, not simply as strings. The pieces cannot be moved until the user has provided common grids that make sense of the idea of putting them together.

![Figure 3 Fractions successfully added](image)

What we hope to accomplish with this applet is the idea that while fractional pieces of a common whole can conceptually be put together to make a larger part of the whole, we cannot reasonably name the sum without proper names (common denominators) for both pieces. There are several observations that may be relevant. First, we only attempt to add fractions of the same whole. This is not explicitly pointed out to the user, but the initial seedings always show the same whole for each part and for the sum. We expect the teacher or parent to observe that kind of distinction, that we are adding numbers. While we use fractions to model parts of physical items, it makes no sense to apply a fraction name to what we get if we add half of an apple to a third of an orange. Secondly, the only sums we illustrate with this applet are less than a whole. We could have allowed other options, but each applet is intended to focus on a single idea. We consider it more important to work repeatedly with the simpler situation, which does, after all, clearly illustrate the utility of a common denominator.

We regret that space limitations do not allow us to more than sample an applet for the division of fractions. It is our hope that a description will encourage interested readers to visit our web site and explore this and many other virtual manipulatives in the NSF Library. We have applets to illustrate multiplication of whole numbers, and of fractions, by showing shaded rectangular regions where the user controls the size of the two factors. Division of whole numbers is similarly illustrated, where dividing 23 by 5 shows 23 squares on a grid, with 4 copies of the set of 5, and 3 left over. Again, the user can change the divisor at will, each time seeing an answer to the question, “How many copies of 5 (or whatever) are there in 23?”
With this kind of experience at hand, Liping Ma's question of dividing $1\frac{3}{4}$ by $\frac{1}{2}$ becomes, "How many copies of $\frac{1}{2}$ are there in $1\frac{3}{4}$?" We have a new fraction division applet that allows the user to produce an arrow (rectangular region) of length $1\frac{3}{4}$ and another, immediately below the first, of length $\frac{1}{2}$. When the user changes the grid size (much as is done in the figures above) to represent a common denominator, the labels on the rectangular regions become, respectively, $\frac{7}{4}$ and $\frac{2}{4}$, and the user sees that the question is equivalent to "How many copies of 2 are there in 7?" To complete the division, the user lines up three more $\frac{1}{2}$-length (yellow) arrows below the longer one. The labels change, but the number of copies of $\frac{1}{2}$ in $1\frac{3}{4}$ is shown visually as 3, plus $\frac{1}{2}$. While these activities are underway, they are accompanied by the following sequence of fractions, providing a robust symbolic algorithm that can be used for any division of fractions.

$$\frac{3}{4} \div \frac{1}{2} = \frac{7}{4} \div \frac{2}{4} = \frac{7}{2} = \frac{3}{2}$$

The power of this manipulative, as with the others in the library, is that the user is engaged, in control, and can repeat the experience with as many fractions as desired, reinforcing both the concept and the symbolic algorithm.

Enhancing Statistical Content in Pre-Service Elementary School Teachers’ Web Constructions

Jack A. Carter
California State University
Hayward, CA USA
jcarter@csuhayward.edu

Beverly J. Ferrucci
Keene State College
Keene, NH USA
bferrucc@keene.edu

Abstract: Research on future teachers’ mathematical Web site constructions shows there is a tendency for these constructions to emphasize design aspects rather than the mathematics content of the sites. In this study, students received more detailed, knowledge-based guidelines for completing Web construction projects. A cognitive analysis of the statistics content in 38 student Web sites constructed before, and 43 Web sites constructed after the more-detailed guidelines were used, showed that the later Web sites contained more items at a procedural applications level of cognition. There was also evidence of small increases in the later Web site items at a conceptual applications cognitive level, but little change was evident in the number of items at the highest of the cognitive levels, problem-solving applications. The findings suggest that further improvements in the cognitive levels of the students’ examples and exercises on their Web pages are feasible.

Introduction

Ivers and Barron (1999) reported that there were nearly 10,000 US schools connected to the Internet in 1998, and half of these were elementary or primary schools. The authors further predicted that virtually all US public schools would be connected to the Web by 2001. With this proliferation of Web access there is a growing trend for schools to use their presence on the Web for interactive communication and for more teacher Web pages. Moreover, access to Web site creation programs makes it increasingly possible for non-programmers to create effective Web pages. However, these rapid advances in Web technology may serve to indicate that the instructional purposes of elementary school Web pages have yet to be well defined. As in the introduction of computers into the classroom, it may take some time for elementary school teachers to utilize the full potential of the Web.

The Study

A prior study of future elementary school teachers’ mathematical Web site constructions (Carter & Ferrucci 2000) showed that there were tendencies for these students to focus more on the design aspects of Web sites rather than on the statistical content. The present study was consequently undertaken to encourage prospective teachers to emphasize the statistical content of their constructions. This encouragement involved the use of more detailed knowledge-based guidelines in the instructions to the students for completing a Web site construction project. After students completed their projects, the statistical content of the completed Web sites was analyzed to determine the cognitive levels of the examples and exercises that the future teachers incorporated into their sites. Particularly, the examples and exercises that the future teachers used in reviewing the statistical concepts of the mean, median, and interquartile range were analyzed with respect to their cognitive levels. To facilitate the analysis, a
cognitive taxonomy was used to classify the examples and exercises from the Web sites. The categories in the taxonomy were essentially the comprehension and applications levels of the well-known Taxonomy of Educational Objectives (Bloom, Englehart, Hill, Furst, and Krathwohl, 1956). The comprehension level of the taxonomy was adapted directly from the Bloom taxonomy, but the applications level in the Bloom taxonomy was refined into three levels to elaborate the complexity of examples and exercises that students used in their Web pages. Hereafter, the designations Mean1, Median1, and IQR1 indicate the comprehension level (Level 1) of cognition about the mean, median, and interquartile range, respectively. Similar notations designate procedural, conceptual, and problem-solving applications cognitive levels (Levels 2, 3, and 4) for each of the three statistics for which students prepared Web pages.

The revised instructions for completing the construction project stipulated that students should include examples and exercises that involved problem solving and higher-level cognitive processes, and samples of these types of examples and exercises were included in the guidelines. Students received a handout of the guidelines in class, and a copy of the guidelines was also included both on the students’ and on the instructor’s Web sites. To complete the Web site project, students replaced given, blank Web pages for the mean, median, and interquartile range with Web pages intended to help their own future students in reviewing these statistics. Web pages about the mode and the range were included in the students’ Web sites as further examples. Students’ Web sites also contained a homepage that was customized, as part of in-class instruction, to show the teacher’s name, school and grade level. Also in the sites was a Web page that showed assignments and other information about the mathematics program in the future classroom, as well as another page that listed Web resources that the future teachers might use in completing their Web site constructions.

To prepare the prospective teachers to complete the Web site projects, separate class sessions dealt with modifying and editing text on Web pages, inserting backgrounds and images into Web pages, and inserting links onto Web pages. In each of the class sessions examples were used that illustrated images, objects, or text that students could use in preparing their own Web sites. For instance, students practiced inserting images of box-and-whisker plots and links to electronic examples (e-examples) within their own Web pages. In all, the instructional component for the Web site project consisted of four 70-minute class periods in a lab where each student worked individually at a computer. Students were also informed that they should expect to spend 10-15 hours to complete the project.

In all, 38 students from two classes completed the Web site project using an original, unmodified set of guidelines (Carter & Ferrucci, 2000), and the students in these classes are referred to as the “earlier classes” in this report. The cognitive levels of the examples and exercises in the earlier classes’ Web sites were compared with the examples and exercises in the Web sites created by two later classes (with a total of 43 students) who completed the Web site project after receiving the revised instructions. The students in these later classes are referred to as the “later classes”, hereafter. Aside from the different guidelines, efforts were made to ensure that other instructional materials and activities about the Web site projects were the same for the four classes.

To analyze the examples and exercises in the Web sites from the earlier and later classes, a panel of two instructors and two graduate students rated the examples and exercises using the taxonomy developed for this study. The panel reviewed the Web sites and categorized the exercises and examples based on the taxonomy, and there were no unresolved differences with respect to the cognitive levels of the examples and exercises.

Figure 1 shows the number of items (exercises and examples) on the mean, median, and interquartile range in the Web pages prepared by the earlier and later classes. Although the number of items on each of the statistics is greater for the later classes, the number of items on the interquartile range is approximately half the number of items on the mean and the median.
Figure 1: Number of Items on the Mean, Median, and Interquartile Range in the Web Pages Prepared by Earlier and Later Classes

Figure 2 shows the earlier and later classes' distributions of Web page items on the mean by cognitive levels. Mean2, Mean3, and Mean4 in figure 2 refer to the levels of cognition concerned with procedural, conceptual, and problem-solving applications. At each of these levels of cognition, the average number of items increased from the earlier to the later classes. Notably, the increases at the levels of the conceptual and problem-solving applications were small (about .25 of an item) compared to the increase at the procedural applications level (about 1 item). Figure 2 also shows that the average number of items at the comprehension level of cognition (Level 1) was essentially zero for both the earlier and later classes. Moreover, there were comparable distributions for the earlier and later classes' Web page items on the median and the interquartile range.

Figure 2: Earlier and Later Classes' Distributions of Web Page Items on the Mean by Cognitive Levels
Figure 3 shows earlier and later classes' average number of Web page items by the entire range of cognitive levels for these items. Particularly, at the procedural applications level, the average number of items increased from about 4 to 5 items for each of the mean and median, while the average number of items increased from about 2.5 to 3.25 items for the interquartile range. At the conceptual applications cognitive level, the average number of mean and median items increased from less than 1 to more than 1 item, while the average number of interquartile range items increased from about 0 to less than .25. For each of the three statistics, the number of items at the problem-solving applications level (Level 4) was virtually negligible for both the earlier and later classes. A possible exception to the later finding may have occurred for items on the mean written by the later classes. The average number of these items at the problem-solving applications level was almost 1/4 of an item.

Figure 3: Earlier and Later Classes' Mean Number of Web Page Items by the Cognitive Levels

Conclusions

The results of the study give evidence that the number of items on the mean, median, and interquartile range increased from the earlier to the later classes. This indicates that the revised guidelines for the students for completing the Web site project may have increased the number of examples and exercises prepared by students in completing their projects. The results also showed that the number of procedural, conceptual, and problem-solving applications involving the mean increased between the earlier and later classes. However, the increase was less pronounced in the case of the conceptual and problem-solving applications. In both the earlier and later classes' Web site constructions, there was no evidence of items on the mean written at the comprehension level of cognition. This level of cognition may be applicable to the mean in only the most trivial instances when merely an observation of data or a graph can identify the mean. With respect to Web page items on the median, there was some evidence that the number of items at the procedural and conceptual applications levels increased from the earlier to the later classes. At the comprehension and problem-solving applications levels of cognition, there was no evident increase between the earlier and later classes. For the earlier and later classes' distributions of Web page items on the interquartile range, there was also some evidence that the average number of these items increased from the earlier to the later classes. Particularly, this increase was more evident at the procedural applications level.
An examination of figure 3 shows that there was little or no difference between earlier and later classes on the average number of Web page items at the conceptual and problem-solving applications level of cognition for all three of the statistics. This indicates that the revised guidelines for the Web site project probably resulted in, at most, an increase in the number of items at the procedural applications level of cognition. Correspondingly, the revised guidelines did not appear to affect much change in higher-level thinking. That is, items at the higher cognitive levels (conceptual and problem-solving applications) increased little compared to items at the procedural applications level. Future work in this area may find it feasible to increase the number of higher-level items that students include in their Web site constructions.

Figure 3 indicated that the average number of items at the procedural applications level increased by about 1 item for each of the mean, median, and interquartile range. Particularly, this increase was from an average of 4 to about 5 items in the case of the mean and median, and from 2.5 to 3.25 items in the case of the interquartile range. Consequently, future work on pre-service teachers’ Web constructions about statistics may endeavor to increase the number of items at the procedural applications level for the interquartile range. Figure 3 also indicated that the average number of items at the conceptual applications level increased from about .8 to about 1.2 items for the mean and median. The comparable figures for the interquartile range showed that the average number of items increased from 0 to less than .2 of an item. As a result, Web site construction projects in the future might also be aimed toward increasing the average number of interquartile range items to at least match those for the mean and median. Finally, Figure 3 further showed that the major increases between the earlier and later classes occurred mainly at the lower as opposed to the higher levels of cognition for all of the statistics. Notably, the average number of items at the problem-solving applications level of cognition for the mean, median, and interquartile range (Mean4, Median4, IQR4) were almost zero. This result further indicates that work remains to be done to increase the number of higher cognitive level items included by prospective teachers in their Web pages.

A major motivation for this study related to prospective teachers’ tendencies to focus more on appearances than on content in Web site constructions. By revising the guidelines for completing the project, there was evidently some increase in the number of items at the procedural applications level of cognition for each of the statistics in the students’ Web pages. Consequently, the revised guidelines apparently provided some impetus for students to move from learning about a technological tool to statistical learning with that tool. Put another way, the findings of this study produced some evidence that the powerful technology of Web sites did less to distract the later classes from the underlying statistics than was the case with the earlier classes. Clearly, ensuring that the content is not compromised is an important consideration whenever technology is used in mathematics education.

The Web certainly offers unlimited possibilities for improving statistical understanding, and there are increasing indications that future teachers will need to use sophisticated Web-based systems to post information and to close communication gaps between teachers, parents, and students. Aiding teachers to become more proficient in their Web skills should lead to the creation of more effective and dynamic displays of mathematical information, and projects such as the Web site construction project outlined in this study are apt to facilitate these proficiencies.

Abstract: The purpose of this study was to determine Algebra I, Algebra II, IPC, and Chemistry teachers' initial perceptions of change prior to their participation in a year-long professional development program that emphasized integration of the math and science utilizing graphing calculators. The results indicate that as a group, the teachers (1) exhibited high information stage concerns, high personal stage concerns, and collaboration stage concerns; and (2) are more aware of the graphing calculator and its potential than previous groups. Algebra I and Algebra II teachers reported higher technological proficiency, but their stage concerns were not statistically different from the IPC and Chemistry teachers.

Mathematics and science educators include the use of technology as a common goal in their most recently developed standards. The National Council of Teachers of Mathematics Principles and Standards for School Mathematics (NCTM, 2000) suggests a framework for the types of technology-based activities and content that should be taught. Similarly, the National Research Council's National Science Education Standards include suggestions for science education reform in technology-based content and professional development (NRC, 1996). Further, both documents point toward significant increase in the integration of math and science. Reading between-the-lines, technology is encouraged as a tool that can facilitate such integration.

Graphing calculators show promise for integrating mathematics and science. There is a growing body of recent research into the use of graphing calculators in the teaching of algebra (Beckman, Senk, & Thompson, 1999; Dunham & Dick, 1994; Embse & Yoder, 1998; Milou, 1999); in both chemistry and physics (Adie, 1998; Roser & McCluskey, 1999; Taylor, 1995); and even the integration mathematics and science (Tharp et al.).

The State of Texas has developed the Texas Knowledge and Skills (TEKS) (http://www.tea.state.tx.us/teks/). The TEKS clearly extend the national reform documents by specifically indicating the use of graphing calculators in algebra:

Students use a variety of representations (concrete, numerical, algorithmic, graphical), tools, and technology, including, but not limited to, powerful and accessible hand-held calculators and computers with graphing capabilities and model mathematical situations to solve meaningful problems (§111.32. Algebra I (One Credit) #5).

Beyond the explicit statement that graphing calculators be used in the teaching and learning of mathematics, the new Texas Assessment of Knowledge and Skills (TAKS) (http://www.tea.state.tx.us/student.assessment/taks/index.html) requires the use of graphing calculators on the state-mandated tests at the ninth, tenth, and eleventh grades for math and at the eleventh grade for science.
Theoretical Framework

The implementation of technology will require change in the classroom. One model that has been utilized to inform the decision-making process when innovations are introduced is the Concerns-Based Adoption Model (CBAM). CBAM states that successful implementation of an innovation is a process not an event (Hall & Hord, 1987; Fullan, 1991; Friel & Gann, 1993), developmental in nature (Hall & Hord, 1987), and a highly personal experience for each teacher (Hall & Hord, 1987). Hall, George & Rutherford (1986) define concerns as the feelings, thoughts, and reactions that individuals have about an innovation or a new program that touches their lives. To measure these concerns, Hall, Wallace & Dossett (1973) developed the Stages of Concern Questionnaire (SoCQ). Initial research on the instrument construction verified the existence of seven stages in the concerns process: awareness, informational, personal, management, collaboration, and refocusing, with internal reliability for individual scales ranging from r=0.64 to r=0.83 (Hall, George & Rutherford, 1986).

Participants

The participants in this study are high school math and science teachers from a single large urban school district in Texas participating in a year-long professional development program that is ultimately aimed at improving math and science achievement. Within the professional development program, the teachers are divided into two sub-groups. The two subgroups are Algebra I (ALG I) with Integrated Physics and Chemistry (IPC) and Algebra II (ALG II) with Chemistry I (CHEM). The teachers are paired because the vast majority of students who are enrolled in ALG I will also be enrolled in IPC and because there is significant overlap in the knowledge and skills that are taught in each course. There is less overlap with students for the ALG II and CHEM group, but curricular overlap is strong enough to warrant the pairing. The teachers are recruited through their building principal and science department chairs and must participate as pairs, one from math and one from science.

The focus of the professional development is on increased communication and collaboration between math and science teachers within the district and specifically in individual schools, with a heavy emphasis on technology. Graphing calculators (TI-83s), Calculator-Based Laboratories (CBLs), and Calculator-Based Rangers (CBRs) with multiple probes were provided to all teachers at the beginning of the program to be used in all subsequent workshops. Each teacher will ultimately receive a minimum of 125 hours of professional development that culminates in a two-week summer institute. Upon the completion of the 125 hours, each teacher will receive a set of ten calculators, CBLs, and CBRs, an overhead panel for display purposes, and up to four additional probes for use in their classrooms.

Methods

Research questions

1. Are there significant differences between the holistic stage concerns profiles for ALG I, ALG II, IPC and CHEM teachers?
2. Are there significant differences between the mean stage score profiles for ALG I, ALG II, IPC and CHEM teachers?
3. Do the demographic profiles differ for ALG I, ALG II, IPC and CHEM teachers?

Data was collected from a total of forty-three secondary mathematics and science teachers during their respective introductory sessions in September 2001. The largest subgroup was the ALG I with IPC and consisted of twenty-five participants. Twelve participants taught ALG I and eleven participants taught IPC, with two participants teaching both courses. Eighteen participants were enrolled in the second subgroup, ALG II and CHEM. Ten participants taught Algebra I. Eight participants taught chemistry.
All participants were administered the Stages of Concern Questionnaire (SoCQ) on the first day of the in-service. The SoCQ is a thirty-five item Likert-scale instrument that contains seven levels of responses. The responses range from 0 = irrelevant to me, 1 = not true to me now, to 7 = very true to me now. A demographic survey also was administered at this time. The survey collected two types of information: background and technology-using history. Background information collected included gender, years teaching, highest degree earned and age. Technology-using information collected included self-rating of the ability to integrate graphing calculators and computers in the classroom, in-service training received, and number of years integrating a graphing calculator and computer in the classroom.

Mean stage scores and total concerns score were calculated for ALG I, ALG II, IPC and CHEM teachers. To determine overall concerns levels, two analyses were performed. First, mean stage scores were converted to percentile ranks based on the norms presented by Hall, George & Rutherford (1986). Second, a peak stage score analysis was calculated for each group. Peak stage scores are defined as the stage at which an individual has his or her highest percentile rank score on the seven concern stages (Hall, George & Rutherford, 1986). Finally, analyses of variance (ANOVA) were performed on mean stage scores and total concerns score to determine subgroup differences. Since there are seven stages of concern, the significant p-level for mean stage score ANOVAs was p=0.007 (p=0.05/7). Total score ANOVAs used a significant p-level of p=0.05.

Results

ALG I teachers had the highest percentile concerns at the information stage and their lowest percentile concerns at the refocusing stage (Awareness=77, Information=84, Personal=70, Management=43, Consequence=43, Collaboration=68, and Refocusing=38). IPC teachers had the highest percentile concerns at the information stage and their lowest percentile concerns at the management stage (Awareness=81, Information=90, Personal=76, Management=47, Consequence=54, Collaboration=84, and Refocusing=52). ALG II teachers had the highest percentile concerns at the awareness stage and their lowest percentile concerns at the consequence stage (Awareness=84, Information=75, Personal=83, Management=56, Consequence=48, Collaboration=68, and Refocusing=52). CHEM teachers had the highest percentile concerns at the information stage and their lowest percentile concerns at the consequence stage (Awareness=86, Information=93, Personal=83, Management=65, Consequence=59, Collaboration=76, and Refocusing=69). Overall, the percentile scores demonstrate that all groups were very aware of graphing calculators and their uses and wanted to learn more about how this technology impacts their classroom. The profile also demonstrates that the participants were users of the technology in the classroom but still needing information on how to best integrate the technology to impact student achievement.

No significant differences (p<0.007) were found between ALG I, ALG II, IPC and CHEM teachers group means. Thus, while percentile scores varied slightly as to highest and lowest percentile concerns, all participants entered the in-service with similar expectations.

Demographic analysis found that (1) teachers in each subgroup were predominantly female (>60% for each subgroup), (2) almost all CHEM teachers had a masters degree or higher while the other groups had more teachers with only a bachelor's degree, (3) years of teaching experience was related to course taught (CHEM vs. IPC; ALG I vs. ALG II), (4) few ALG II teachers had used computers in instruction while almost half of the ALG I teachers had integrated computers, however, most science teachers regardless of level had integrated computers in their instruction, (5) all ALG II teachers and almost all ALG I teachers had integrated graphing calculators in the classroom while few CHEM and IPC teachers had used graphing calculators in instruction, and (6) CHEM and IPC teachers self-rated themselves as novice users of graphing calculator and intermediate (almost experts) at using computers in the classroom while ALG II and ALG I teachers considered themselves novices at integrating computers in the classroom and intermediate (almost experts) at using graphing calculators in the classroom.
Summary

All groups entered this in-service wanting to learn more about the how to successfully integrate technology in the classroom (high information stage concerns). These needs focused primarily in the areas of how will this curricular change impact me and my teaching (high personal stage concerns) and how can I work with others to help bring about this curricular transition (collaboration stage). This early awareness of graphing calculators and interest in the integration process is atypical for those entering previous math, science, and technology professional development programs (Chamblee, 1996; Chamblee & Slough (in press A); Slough 1998). This warrants further investigation.

Demographic data present distinctly different groups. Group differences can be classified according to discipline more than subject taught. This fact agrees with previous research in this area (Chamblee & Slough (in press A)). Of particular note, both groups of math teachers, ALG I and ALG II, rated their technical proficiency high with regard to the graphing calculator and the science teachers, IPC and CHEM, rated themselves as novices. Yet, there was no statistically significant difference between the groups mean stage concerns. At first, this may appear to be problematic with regard to either the self-reporting or the CBAM model. When, in fact, mere technological proficiency does not make one immune to the same concerns. This warrants further investigation.

Similar research questions were utilized to analyze the differences between all math and all science teachers who participated in the professional development program. Due to the limited space, the results are discussed in a separate paper (Chamblee and Slough (in press B)).

References

Abstract: The modern classroom computer has an unparalleled ability to implement both graphical and procedural components of mathematics understanding in a single unified object. This dual encapsulation allows students to see both the form of representation and their actions upon the representation simultaneously. An extension of activity theory, Action on Objects (Connell, 2001), has been developed incorporating this ability which has proven of great worth in instructional planning and effective utilization of technology to enhance mathematics learning.

During the summer of 2001 the author lead a graduate course where we carried out an extensive review of existing websites focusing upon those best fitting this action upon objects model. This paper will provide a brief overview of the model and the rubrics used in the course of this website evaluation together with annotated links to the resources themselves.

Background

A major conceptual framework used in my research and writings has been that of action upon objects (Connell, 2001). This has in turn lead to some foundational questions surrounding the nature of the technology-enhanced objects and the types of actions that one might be expected to perform upon them. I have created a conceptual framework of actions upon objects that has proven to be very powerful in both experimental settings as well as in school classrooms. I feel that it also captures recent thinking on object reification in mathematics (Sfard, 1994).

It is clear, however, that if this approach is to be effective that the objects to think with must be developmentally appropriate for the student. The following model captures my current “best attempt” to put this into an easily presentable format.

![Figure 1. Model illustrating the type of actions as performed upon the objects of thought.](image_url)

Evaluation Rubrics

During the summer of 2001 the author lead a graduate course where we carried out an extensive review of existing websites focusing upon those best fitting this action upon objects model. The following illustrations serve to outline the evaluation template used. The final paper will develop the rationale for these in more detail and provide a copy of the template for inclusion on the SITE CD. It will also include some selected sites and their annotations so that a preview of the database might be achieved.
Figure 2. Summary of Evaluation

Figure 3. Detail of data collection 1.

Figure 4. Detail of data collection 2.

Conclusion

I am planning on including both the template file and the developed database of all reviewed websites (94+) with this submission. The inclusion of the database will allow others to have access to a peer review of excellent materials that support not only the action on objects model, but also the NCTM emphasis upon student-centered learning and problem solving. It is my hope that SITE members will avail themselves of the opportunity to contribute to this developing database using the provided template.

Using Technology Tools to Revitalize Mathematics Teaching: Perspectives from the United States and Namibia

Thea K. Dunn
College of Education
University of Wisconsin – River Falls
thea.k.dunn@uwrf.edu

Abstract: This study reports on a research project whose goal was to provide secondary mathematics teachers in the United States and Namibia with opportunities to utilize technology tools to teach mathematics for understanding. Qualitative and quantitative methods were utilized to examine the responses of the teachers to the introduction of technology tools in the mathematics classroom and the ways in which the teachers utilized the technology tools in their teaching. The teachers were provided with extended opportunities to teach mathematics in an environment supported by diverse technology tools, including dynamic geometry software, graphing calculators, virtual manipulatives, and general-purpose tools such as word processing, paint programs, and spreadsheets. Throughout the study, the researcher provided a mentoring component by offering technology support, instructional ideas, classroom activity samples, and suggestions to enhance instructional ideas developed and implemented by the teachers. Examples of instructional practices illustrate that technology tools encouraged the teachers to pursue more conceptually focused teaching strategies. The analysis suggests that the technology tools facilitated the teachers constructing an image of technology-enhanced mathematics teaching and learning.

Introduction

Technology tools have a powerful role to play in education. As Bransford, Brown, and Cocking (1999) note, “What has not yet been fully understood is that computer-based technologies can be powerful pedagogical tools...extensions of human capabilities and contexts for social interactions supporting learning” (p. 218). The research reported in this paper is part of a project to revitalize mathematics teaching and learning by providing teachers with extended opportunities to do and experience mathematics in an environment supported by technology tools. An overarching goal for the project examined in this study was to promote innovative practices in the use of technology tools to enhance secondary mathematics teaching and learning. A secondary goal was to promote the use of technology tools to facilitate the teachers’ own understandings of mathematics while enhancing their ability to utilize the technologies to teach mathematics in the spirit of educational reforms of both nations. The part of the project relevant to this paper examines the responses secondary mathematics teachers in the United States and Namibia to the introduction of technology tools in the mathematics classroom. It explores the ways in which the teachers utilized the technology tools in their teaching. These tools included dynamic geometry software, graphing calculators, virtual manipulatives, and general-purpose software such as word processing, paint programs, and spreadsheets. The teachers were provided with extended opportunities to experience mathematics as problem solving, communication, reasoning, and building connections (President’s Committee of Advisors on Science and Technology, 1997) and to teach mathematics in an environment supported by diverse technology tools.

Theoretical Framework

While the existent literature does not directly address the issues raised by this study, several works provided a lens through which the data in this study were viewed. Research on the appropriate use of technology reveals that students can enhance their mathematical knowledge and conceptual understandings with technology tools (Groves, 1994; Dunham and Dick, 1994). Because they enable students to visualize and experience mathematics, engage in real-world problem solving, and generate representations of their own learning, technology tools are important resources for teaching and learning mathematics (International Society for Technology in Education, 2000). According to the National Council of Teachers of Mathematics’ Technology Principle: “Mathematics Instructional programs should use technology to help all students understand mathematics and should
prepare them to use mathematics in an increasingly technological world.” (NCTM, 2000, p. 40). This suggests that teachers should be provided with adequate preparation and support to implement technology tools in their classrooms. Teachers should be provided with ongoing mentoring and should have time and support to familiarize themselves with software and content to incorporate technology into their lesson plans (President’s Committee of Advisors on Science and Technology, 1997).

When Namibia became an independent nation in 1990 it mandated reforms based upon the goals of access, equity, quality, and democracy (MEC, 1993). The reformed educational system rejects authoritarian, teacher-centered instruction, emphasizes student-centered learning, and takes into account students’ prior experiences. The redesigned school curriculum is structured upon a constructivist view of knowledge, learning competencies in content areas, and developing a reflective attitude and creative, analytical and critical thinking (NIED, 1998). In the United States, implementation of reforms regarding mathematics curriculum and instructional practice efforts requires that teachers and students engage in problem solving, reasoning, communicating, and making mathematical connections (NCTM, 2000). The technology-rich environment for teaching and learning mathematics in this project supports the implementation of these standards which assert, “Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students’ learning” (NCTM, 2000, p. 24). The research study described in this paper sought to combine the findings of these earlier works by providing mathematics teachers with extended opportunities to experience and do mathematics in environments supported by diverse technologies (Dreyfus and Eisenberg, 1996). The essence of the pedagogical theme underlying this study is to empower teachers through the use of technology tools in mathematics explorations, open-ended problem solving, developing understandings, and communicating about mathematics (Bransford, et al, 1996; Schoenfeld, 1982, 1989, 1992; Silver, 1987).

Methods

Participants and Context

The participants for this study were four secondary mathematics teachers in the United States and six secondary mathematics teachers in Namibia who voluntarily enrolled in one of two professional development workshops taught by the researcher. A fundamental goal of both workshops was to assist teachers in becoming familiar with technology tools available for teaching and learning secondary school mathematics. The teachers met in the workshops for one week, then returned to their respective schools. During the workshops, the researcher modeled the ways in which technology tools can improve teaching and learning (Knapp and Glen, 1996). The teachers engaged in activities that included the integration of technology tools with, or application to content areas in the secondary mathematics curriculum: geometry, including constructions; algebra, including graphs of relations; patterns and functions; estimation and computation; and, data display. The participants spent time engaging in mathematical investigations utilizing Geometer’s Sketchpad, TI-82 calculators, and Excel Spreadsheets and in discussions of those explorations. The activities examined in this paper focused on exploring the capabilities as well as the limitations of the technology tools. The teachers were required to explain and justify their results. Included in the spreadsheet explorations was creating a spreadsheet to find a solution to a system of two linear equations. Another activity involved designing a spreadsheet to show the calculations that occur in computing a square root using the divide-and-average method. One investigation with the dynamic geometry software involved constructing square ABCD, with point E as the midpoint of AD. After constructing segment BE, the teachers were to construct point F on segment BE such the CF would be perpendicular to segment BE. The teachers were to determine how the area of quadrilateral CDEF compared to the area of square ABCD and explain their reasoning. Another exploration required constructing a trapezoid with three sides of 6 cm and then determining what length the fourth side would have to be in order to maximize the area of the trapezoid.

Data Collection

In order to enhance the validity of the findings, multiple data sources were utilized during the research process (Lincoln and Guba, 1985). Data were triangulated via multiple sources of evidence including informants, events, and documents. The methodological underpinning of this study is derived largely from orientations to research that draw attention to the importance of detailed qualitative fieldwork and the observation and analysis of teachers in context. Several interrelated research strategies facilitated the analysis of the teachers’ experiences. These included: (1) participant observations, audio and videotaping, and field notes of the professional development
workshops and the mathematics classrooms; (2) structured and semi-structured, open-ended interviews with each of the teachers; and, (3) collection of teaching artifacts, including the teachers’ technology-based problems, activities, and visual representations. Each participant completed questionnaires designed to probe their mathematics content knowledge and their knowledge of mathematics-specific pedagogy. The questionnaires were completed at the beginning of the workshops, at the conclusion of the workshops, and after returning to their classrooms to teach with technology. In addition to the questions pertaining to pedagogy and content knowledge, the teachers were asked to respond to the following questions, in writing and during their interviews, at the onset and the conclusion of the study: (1) how do technology tools influence decisions about what mathematics should or should not be taught? (2) how do technology tools impact teaching? (3) how do technology tools affect students learning? and, (4) how do classrooms that employ technology tools differ from the classrooms in which you may have learned mathematics?

Data Analysis

In order to gain insights into the ways in which the teachers interpreted and implemented technology tools, the developmental research cycle was utilized to organize, analyze, classify, and consolidate the data (Spradley, 1980). Major themes were developed using taxonomic and thematic analytic strategies (Spradley, 1979). Findings were shared, discussed, and compared by the researcher and the teachers. In order to provide a measure of external validity (Goetz and LeCompte, 1994), the researcher reviewed transcripts and analyses with the participants and allowed them to react to analyses and clarify and elaborate on their responses. This process also enabled the teachers to reflect upon what transpired in their classes when they used technology tools for teaching and learning mathematics.

Findings

This study sought to examine the responses of the teachers to the introduction of technology tools in the mathematics classroom and the ways in which the teachers utilized the technology tools in their teaching. Several themes emerged from the analysis of the data. Four will be summarized here: (1) modeling; (2) problem solving; (3) student-centered learning; (4) collaboration; and (5) education reform.

The researcher utilized technology tools to model for the teachers the ways in which the tools could be utilized to enhance mathematics teaching and learning (Barron and Goldman, 1994) in their own classrooms. Conceptual knowledge and procedural knowledge were emphasized together and technology tools were used to reinforce their mutual development. The data from this study support the notion that effective modeling of the ways in which technology tools can enhance teaching and learning should be an integral component of teacher education programs (Knapp and Glenn, 1996). During the workshops, all of the teachers mastered the use of the technology tools and explored the potential of the tools for doing mathematics. As the teachers engaged in teaching with the tools, they began to design innovative and effective ways in which to integrate the tools into their mathematics teaching. At the conclusion of the study, Z, a teacher from the United States wrote on her final questionnaire, “I understand what you were doing. When you taught us the technology, you showed us the way to teach.”

One of the most widely noted insights by the teachers was the recognition of problem solving as a method of teaching and learning mathematics. Across both sites, the majority of teachers utilized technology tools to create visual representations and began to introduce mathematical concepts within the context of problems. All of the teachers used the technology tools to design pedagogical presentations of mathematical concepts. However, several noted that this process was more difficult than they had anticipated. At the conclusion of the study, Ms. H, a Namibian teacher noted, “One important thing I have learned is that the technology was fairly easy to learn. Teaching with it will take more time. It requires many changes for me.”

The teachers developed their knowledge of how to use the tools to enhance their own as well as students’ mathematical learning. When they returned to their respective classrooms, the teachers engaged their students in technology-enhanced mathematical investigations in which the students were active participants. The technology did indeed influence what and how mathematics was taught and learned (NCTM, 2000). Observations revealed that the teachers moved toward a student-centered approach as they engaged their students in technology-based mathematical explorations. For example, after interacting with and observing their students, several teachers restructured the planned activities to accommodate students’ interests and experiences. This suggests that working with the technology tools challenged the teachers’ pedagogical thinking. During a final interview, a teacher from the United States, Mr. K, stated, “I took an idea from the workshop but when I saw that it was going nowhere with the kids, I had to make some adjustments to make it work for them and keep them involved.”
Mentoring and collaboration facilitated the ability of the teachers to create visual representations to model and explore mathematical concepts. The high ratio of teachers to technology made it necessary for the participants to work cooperatively in groups of three or four as they engaged in open-ended problem solving tasks. It appears that this collaboration, because it encouraged discussions about both the technology and the mathematical concepts, may have facilitated the teachers' construction of mathematical understandings as they developed proficiency with the technological tools. The data from this study suggest that the introduction of technology tools transformed teaching and learning in fundamental ways, including facilitating communication about mathematical ideas. At the conclusion of the workshop, a Namibian teacher, Mr. K., said, “I never imagined learning maths in this way – talking about problems, working together as one.”

Significant differences between the teachers in the United States and the teachers in Namibia did not emerge. The findings from this study suggest that utilizing the technology tools enhanced the teachers’ ability to teach mathematics in the spirit of educational reforms of their respective nations. With regard to the teachers in Namibia, an unexpected observation was that staff room discussions about the technology tools often cited Toward Education for All (MEC 1993) and its implications for teaching mathematics. One Namibian teacher, Mr. T, stated, “As I have done this kind of teaching, the reforms are now understandable.” It appears that participating in the process of teaching and learning mathematics with technology tools enabled the teachers to recognize connections between this seminal policy statement of the independent Namibian government and the way in which the technology tools changed how they taught mathematics. In particular, the discussions centered on a critical element contained within this document, that “teaching methods allow for the active involvement and participation of learners in the learning process” (MEC, 1993, p. 60).

Conclusions

At the core of the project examined in this study is the development of mathematical power—understanding, using, and appreciating mathematics. The results of this study point to the conclusion that technology tools enabled the modeling and exploration of collaborative instructional strategies, diverse and creative problem-solving, and investigations of mathematics content areas. This study generated a large body of data pertaining to the teachers’ responses to and uses of technology tools in the classroom. These data may be presented to teachers as a basis for reconsidering their own uses of technology tools in the mathematics classroom. The present study revealed that mentoring and collaboration within a mutually supportive environment facilitated the teachers’ use of technology tools in mathematics instruction and enhanced their pedagogical practices. This study suggests areas for continued research that will extend our understanding of how teachers construct an image of technology-enhanced mathematics teaching and learning, including examining what conceptualizations of mathematics teaching and learning are useful to teachers as they integrate technology tools into their teaching. The next critical step will be to examine the impact of technology tools on student learning.

Using Animations in the Teaching of Calculus Concepts

Jose H. Giraldo, Texas A&M University-Corpus Christi, US

SUMMARY

During the last decade a lot of emphasis has been placed on the understanding of calculus concepts. To achieve this purpose the use of technology has been introduced as part of the regular instruction. The visualization of mathematical concepts plays an important role in developing intuition about them and insight in their understanding. With the idea in mind that the visualization helps in understanding of some mathematical concepts, I am implementing animations to teach certain key concepts in the Calculus course with the use of Mathematica, as a Computer Algebra System. In this paper I will share my experience in the implementation of these concepts, the reaction from the students, and some qualitative and quantitative results on the learning of those concepts and use of Mathematica as a software package.

BACKGROUND

Through my teaching experience in Mathematics one of the problems I have faced and that has intrigued me throughout the years is the lack of students' insight into mathematical concepts, which leads to confusion and rote memorization of concepts without meaning, with the obvious consequences. Research shows that the proper use of technology, new pedagogical approaches, and a good learning environment are factors, which will favor the learning experience. Even though I have used a variety of techniques to enhance the learning of Calculus such as graphing calculators, projects, group work, computer laboratories, and web support, I noticed that the use of animations brings more attention from the students.

As part of the web material I use to enhance the learning I decided to implement the use of animations for certain concepts to which I will refer later. The main drawback was that in order to accomplish this I had to spend a lot of time learning software itself in order to create the animations. A major disadvantage to this approach was that the students could see the results but without any option to manipulate the information, or explore the concept deeper. However, a year ago as part a project I was involved in, I ran into one the Computer Algebra Systems most broadly used in the teaching of Mathematics, Mathematica. With the use of Mathematica I have been able to create animations that can be modified as needed to explore the concepts. It is likely that I could have done the same things with another software, but in this case I got the motivation to work with Mathematica.

A Computer Algebra System (CAS) is a software package with which one can perform mathematical manipulations, and computations. Their use is becoming more popular in education as well as in private industry. The type of software used by a particular institution depends greatly on the needs.
THE PROJECT

The Calculus I class is one of the two classes offered by the Mathematics program as part of the Core Curriculum at Texas A&M University- Corpus Christi. As a Core course the class emphasizes on verbal, written, critical thinking, and mathematical skills among others. Students from a variety of majors and with different backgrounds take this class, even though the majority of them are from the College of Science and Technology. The class meets three times a week. Two of the meetings are for the regular lecture, one hour and fifteen minutes each, and the other meeting is for the laboratory component, two-hour block. During the laboratory meeting, the student works on projects aimed to reinforce the concepts learned in class or to explore concepts to be covered soon in class. Each lab has a capacity for thirty students where each student has access to a computer.

In this project I am teaching two classes, one uses Mathematica during the lab and the other one uses Derive in the lab. With Mathematica one can create notebooks (pages), in which one can type regular documents (wordprocessing), as well as mathematical expression. The mathematical capability of this software includes among many of them: solving equations, plotting graphs, create and see animations. The class that uses Mathematica in the lab component also has the opportunity to see the software during the class to demonstrate some of the concepts. The other class sees some of the demonstrations but mostly concentrated on the animations, and some times fixed graphs needed for the concepts.

The Mathematica notebooks can be made available on the web for demonstration purposes using the Mathematica Reader. As I said they are available only as demos and cannot changed. However, students who have the software installed in their computers can download them to their machines and manipulate them as desired.

These are some of the concepts covered in the notebooks:

1. Transformation of functions. In this case a familiar function is taken and a parameter is changed in the animation. The student can see the effect on the graph when the parameter changes.
2. Intuition about the existence of the derivative of a function at a point. A function is zoomed in at a point. The linear or not linear behavior of the graph locally will indicate the existence or not existence of the derivative.
3. The meaning of the tangent line at a point and its relationship to the derivative of the function at the point. Animations showing the secant lines to a curve from a fixed point are shown. The slopes of those lines are displayed during the animation, to develop the intuition of the concept of the derivative as a limiting process.
4. The graph of a function and its derivative. One of the focal points of calculus I is to interpret the meaning of the first and second derivatives in terms of the original function. Through this sequence of simultaneous animations, the original functions, its first, and second derivatives the student can visualize in a more vivid manner those relationships.
Abstract: The project leverages students’ fascination with 3D digital entertainment and medieval fantasy stories to teach mathematics to middle school students by situating the mathematics in an appealing virtual environment—an Internet-based Massively Multi-Player Role-Playing Online Game (MMPORPG) called Warrick’s Secrets. The development team consists of individuals from the IT industry and researchers from three universities. Warrick’s Secrets is the result of a Phase I Small Business Innovation Research grant (SBIR) completed for the US Department of Education in April 2001. Second stage development is on-going following the September 2001 award of a Phase II SBIR by the U.S. Department of Education. An MMPORPG is used as the vehicle to deliver National Council of Teachers of Mathematics Standards-based educational content. The system includes advanced 3D computer rendering capabilities and high quality 3D artwork since both have proven crucial to maintaining players’ attention in the gaming community. The results of the pilot study are reported along with the progress of the Phase II program.

Background & Theoretical Framework
What are Massively Multi-Player Role Playing Games?

Warrick’s Secrets is modeled on currently popular MMPORPG’s such as, Ultima Online (UO), Everquest, and Microsoft’s Asheron’s Call. Currently, more than 150,000 customers play Ultima Online—including players from 114 countries. (Walton, 2000). Sony’s EverQuest and Asheron’s Call each have a substantial customer base as well. A MMPORPG is a game with a thousand or more players gaming concurrently in real time. Role-playing indicates that a human player controls an in-game character’s speech and actions. The virtual world in the most successful games is like the historical middle ages, including some degree of fantastic creatures (e.g., dragons) and magic. Due to limited resources and time, the Phase I prototype of Warrick’s Secrets only supports single-player activity. With future funding, we plan to add multiplayer capabilities.

At first glance, some people mistakenly think the educational tool described and the total system planned differs little from existing products which attempt to make learning into a game, e.g. Math Blaster, etc. Most existing products are far more successful with younger students. The approach of simply trying to transform learning into a game is less successful with middle school and high school students. Our approach is to tightly integrate the educational content with a MMPORPG. This seemingly subtle difference (integrating educational content with a particular game genre versus attempting to make learning into a game) has an enormous impact on the way students react to the product. There are numerous other differences in our
approach that significantly increases the student acceptance rate, potential learning success rate, and age range for which the teaching tool can successfully be used. Physitron's educational tool is the only one based on a MMPORPG. Additionally, it is one of the few tools to use standards-based mathematical content (NCTM, 2000) and provide teachers a mapping of each mathematical challenge to the corresponding topic/skill within the standard. Other distinctive advantages of Physitron's educational tool are listed below.

- Educational content imbedded into realistic situational context
- Inherent promotion of cooperative learning
- Ability for students to interact with remote students
- Vehicle for covert and overt learning
- Advanced motivation and reward system

Related Research

Areas of mathematics education research for this project are situated perspectives on learning and constructivist views of representation. Mathematics viewed as socially constructed knowledge has strongly influenced other learning theories. Many researchers (Kieren, 2000; Steffe & Thompson, 2000; Sfard, 1998; and Cobb & Yackel, 1996) describe the theoretical underpinnings of their work in terms of "social constructivism." The learning theory that grounds many of these researchers, including those in the present project, may be traced to von Glasersfeld's (1991) radical constructivism, and Piaget's (1970) genetic epistemology. Lave and Wenger (1991) describe situated learning as developing as a function of the activity, context, and culture in which such learning occurs. One of the primary benefits of integrating educational content with a virtual environment and storyline is that educational content is imbedded into a realistic situational context. These ideas are important here because we consider how such theories apply to the development of educational interactive multimedia. An example of such multimedia research is the work of Herrington and Oliver (1997).

Mathematical representation is considered from a constructivist perspective. Representation describes the form in which a problem is encountered—such as graphical, numerical, verbal, or symbolic representations. It also describes the learner's mental construct of the problem. Another advantage of the virtual environment for problem solving is that students have many opportunities to attempt solutions of mathematical tasks. Furthermore, the virtual environment affords a natural mechanism for providing hints and alternative teaching representations based on a student's previous success with a concept or skill. This may increase the number and quality of the mental representations that the students apply to the problems. The project relied on the research of Cifarelli (1988) and Goodson-Espy (1994, 1998) to use the notion of reflective abstraction to explain how, as students work through multiple attempts to solve a problem, they may develop progressively more abstract mathematical conceptions. It has been observed that if students cope with recurrent mathematical themes, they are more likely to develop higher levels of reflective abstraction, and thus attain more powerful mathematical concepts.

Example Problem Included in the Phase I Prototype

The Phase I prototype included on complete problem pathway. This began with a meeting between the mentor magical character, Adel, and the student character, Palus. The first challenges required him/her to solve a series of problems involving percent. If the student was not successful, he or she was provided with a series of hints and provided with the opportunity to try again. The next series of challenges required Palus to interact with a series of talking flasks in the laboratory. The flasks gradually helped Palus learn to read the measurements on a flask and, in a progressive manner, helped him/her learn how to solve a mixture problem such as the following:

**Flask #4 asks Palus:** “I have 75 milliliters of liquid, which is hoffish soup diluted with the spittle of glowworms. If there is a 30% concentration of glowworm spittle, then how many milliliters of glowworm spittle do we have?”

The prototype including this series of challenges was piloted tested with middle school students, as described below.
**Pilot Study Methods**

**Subjects**

The subjects included seven students from a middle school in the southern US. The subjects included two sixth graders, two seventh graders, two eighth graders, and one ninth grader. The subjects included one African-American, six Caucasians, four males, and three females.

**Data Sources and Analysis Method**

The prototype testing took place at school on April 6, 2001. The individual sessions each lasted between 45-60 minutes. Students attempted all the problem scenarios and completed a questionnaire and participated in a concluding interview. Students were given a pen, paper, and a calculator. The problem set included two problem paths—an initial problem path dealing with percent and a second developing a series of questions about mixture problems. The data sources for the pilot study include: (1) videotapes and transcripts of the prototype testing sessions, (2) student written artifacts, (3) completed questionnaires, (4) observational field notes, and (5) researcher notes from the post-game interviews. Analysis of these data resulted in seven case studies.

**Summary of Results**

The results of the game prototype testing include three parts: (1) a summary of student reactions, (2) the questionnaire results, and (3) seven case studies. Only excerpts of the results will be discussed below.

- All subjects expressed increased interest in working on mathematics problems that were situated in a computer gaming environment.
- All subjects reported some level of self-confidence in solving mathematics problems but expressed less self-confidence in terms of solving word problems in a classic classroom or textbook setting.
- One of the students specifically stated that he liked the graphics quality of the characters and that the quality was much higher than those of characters in computer game he had at home.
- Several of the students indicated that they enjoyed being an active character in the game and that this improved their ability to interact with the mathematics. Students wanted to control the character's gender, skin color, clothing, ethnicity, character name, and skills.
- Numerous students indirectly noted the fact that the mathematical content was imbedded into a realistic situational context increased their ability to understand and thus solve the problems, particularly the mixture problems. All students indicated that they clearly understood what the problems were asking them to do. Students indicated that it was easier to solve the problems because the in-game flasks were displayed with measurement calibrations. Another student made a similar comment about the collection bins used to represent the percentage problems. The students liked the visual representations of the problems. All of the students attempted all of the problem scenarios. Two of the subjects were able to solve all of the problems on the first try. Three of the subjects were able to solve all of the problems on the first attempt.
- All of the subjects were able to attain the levels of reflective abstraction: Recognition and Representation in their problem-solving activities. Three of the subjects were able to attain the level of Structural Abstraction. Three of the students were able to complete the second problem pathway by building on their solution strategies for the previous problems.

**Conclusions and Future Directions**

**Student Enthusiasm for this Genre**

The favorite adjective used by the students to describe the game was, "Cool!" The students explained that the game made learning math easier for them because it placed the mathematics into a meaningful context for them. The students indicated that they were motivated to solve problems because they wanted to find out what would happen next in the game or because they wanted to gain access to the next magical tool that was described in the story.

**Character Creation and Communication**

The students made numerous positive comments about the faces, clothes, and details such as being able to see the characters breathe. The students were intrigued by the ability to assume the role of a character in the
game. They were greatly attracted to the capacity to arbitrarily maneuver their character in the virtual world. Students wanted to be able to choose gender, race, clothing, facial appearance, and other attributes of their character, including the character’s name. This is a standard option in most MMPORPG’s.

**Interactivity In The Game**

The students were universally interested in gaining character mobility in the virtual world. They were fascinated by character head motion, lateral motion, climbing stairs, moving underwater, etc. Most of the students wanted to wander about in the game world before beginning the problem sequence. This activity allowed us to gain valuable data about the ease of character controls. It also reinforced our notion that interactivity with objects in the game environment and exploration of new aspects of the virtual environment are crucial factors in gaining and maintaining student interest and represent mechanisms for in-game rewards.

**Problem Pathways**

The students indicated that they found the collection bin representation for the initial percent problems to be very helpful in solving these problems. The students were very emphatic that the visual representations were extremely useful to them. The students’ interactions with the flasks in the laboratory appear to have influenced their problem-solving success with the mixture-related problems. Based on the researchers’ experiences in teaching very similar problems to college-aged students in traditional college algebra classes, the success rates of the middle school students on these problems were much higher. In the videotapes and post-session interviews, the students indicated that the visual nature of the representations were also useful in reducing their anxieties about this type of question. The students positively evaluated the hints that were provided for each task. Because of the visual representations of the problems and the scaffolded hints that presented themselves upon incorrect student responses, students were more willing to attempt what they considered to be difficult problems. The students problem solving activities and successes indicate that carefully crafted problem pathways can be a successful teaching tool in assisting students with making necessary conceptual connections via reflective abstraction.

**Progress of the Phase II Program**

We seek to explore the on-screen 3D conceptual vehicles that can be used to pose interesting mathematical problems in this interactive computer environment. In Phase II, we plan to answer a number of research questions, including the following:

- Does use of this type of an educational tool raise the performance level of students in a regular mathematics classroom?
- Can the notion of reflective abstraction be used to describe mathematical concept building when educational content is integrated with a MMPORPG setting?
- Will our collection of situation-based and “scaffolded” mathematics pathways encourage students to apply problem-solving skills that encourage the development of higher order thinking?
- If allowed to create their own character, what kind of character will they choose in terms of gender, race, ethnicity, facial appearance, and clothing?
- Given that research has found computer gaming to be more popular with males (except for role-playing games, which are essentially as popular with females), will this educational resource be popular and effective with females?
- Do students display an increased motivation to try to solve problems?
- Can standards-based mathematical content be integrated into an MMPORPG in a manner that allows students to discover, learn, and even teach other students without forcing the student to step out of the role of their online character?
- Can the mathematical content be integrated into the MMPORPG innocuously enough so that it does not destroy the enjoyment factor we are trying to leverage?

The number of research questions is obviously large, but warranted, as this area has very little formal investigation.

Are Teachers “TechReady?”
Evaluating the Technology Competencies of Preservice Teachers

Delwyn L. Harnisch, C&I, University of Nebraska, Lincoln, United States, harnisch@unl.edu
Michael L. Connell, University of Houston, United States, MKahnl@aol.com
Ronald J. Shope, Assessment, Grace University, Omaha, United States, rshope@mail.graceu.edu

Abstract: Technology must be essential part of teacher preparation. Technology training also needs to be evaluated against ISTE standards. This paper is a report on the development and initial findings of an online self-reporting instrument that can be used to evaluate the technology competencies of preservice teachers. Data from the field-test of the instrument reveals that while teachers understand how to use the hardware and software, they need more help in knowing how to integrate technology into their instructional strategy.

Introduction

Today’s world has grown smaller because of technology. Satellite trucks allow us to view images from anywhere in the world. Cellular telephones allow instantaneous communication. Palm top computers give us powerful tools to plan, store, and present data. Satellites, with power imaging technology provide us with high quality images from hundreds of miles in space.

New technology has created two broad changes in our world today. First, there is a changing economy. New technology is making workers more productive. In addition, financial trade, communications, and assets are being acquired globally. An example is “Sony” who has major holdings in the entertainment business in the U.S.

Second, there is a changing workplace. Globally, we have entered into what some have termed, “The information age.” There are many sources of information that are available electronically that can be accessed at the click of a mouse. Therefore, knowledge is quickly becoming a major commodity. I believe that one skill that an educated person must have is the skill necessary to search the vast number of information sources that are available, which address the problems that need to be solved (Report from National Commission on Mathematics and Science Teaching for 21st Century 2000). The skills needed for successful living have altered radically, primarily as a result of the technological revolution and its impact on most jobs and professions. That is to say that technology is changing the way we work and live.

These global changes have two implications for educators. First, we must train our children to use the technology and information tools that are available to them so that they can work effectively in our global society. Schools of education must provide school systems with prospective teachers who can help student’s function in our new society, and that means that the teachers themselves must gain new skills and new knowledge. Second, we must use technology to create a more effective teaching learning system to deliver our lessons. If technology is to be used effectively in teaching, it must be used to create a student-centered learning environment. Teachers entering today’s classrooms must not only be competent in teaching skills, but they must also be able to integrate technology in their teaching. Technology can be used to help supply five key conditions for learning: (1) real-world contexts for learning; (2) connections to outside experts; (3) visualization and analysis tools; (4) scaffolds for problem solving; and (5) opportunities for feedback, reflection and revision. In short, the focus of the technology evaluation should be on learning and the learners and not the technology. The long-term goal is to build schools as learner-centered communities by expanding the notion of collaboration, which will transform current educational systems. Technology has an obvious role in both of these areas, but it is a role that must evolve from the foundation of research-validated principles and practices.

Because of these global changes, technology has become an integral part of instruction in P-12 schools (NCATE, 1997). New demands are being placed on teachers to use technology in their instruction, which has been brought on by the rapid influx of hardware and software (Matthew & Kimball-Lopez, 2000). Both the National Education Association (NEA) and the National Council for Accreditation of Teacher Education (NCATE) consider...
computer technology skills critical for teachers (Gladhart, Carroll, & Ellsworth, 2000). Rosenthal (1999) notes, “Bringing faculty members and America’s teaching force up to speed [technologically] is a massive task...a problem that will be greatly exacerbated if the teachers entering the profession have not been adequately prepared to use information technologies” (p. 22).

Preservice teachers, therefore, must be able to demonstrate technology competencies that are based on the National Education Technology Standards (NETS) set by International Society for Technology in Education (ISTE). The ISTE standards are an appropriate framework for evaluating technology competencies because they are widely recognized and are comprehensive (Ropp & Brown, 2000). The NETS Standards are divided into six categories which are Technology Operations and Concepts, Planning and Designing Learning Environments and Experiences, Teaching, Learning, and Curriculum Assessment and Evaluation, Productivity and Professional Practice, Social, Ethical, Legal, and Human Issues. In each of these categories are suggested skills that should be mastered before an individual enters the Teacher Education Program, following the completion on an Educational Technology course, following the completion of methods courses and student teaching, and following the completion of the first year of teaching.

The challenge is to properly assess the technology competencies at each of these areas. McCombs (2001) notes the following four essential questions that should be the focus of assessment: (1) How is technology perceived by individuals learners and teachers relative to its teaching-learning support?; (2) What changes in learning and performance outcomes can be observed with different technology uses and with different learners?; (3) What changes in teaching processes can be observed that enhance learning outcomes?; and (4) What changes in the learning context can be observed that create new partnerships and climates for learning?

McCombs (2001) also identifies five data sources that can answer these questions. These are student and teacher self-assessments of technology practices and strategies; students and teacher attitudes toward technology and its specific uses; multiple student motivation measures; multiple students achievement measures; and observational information on learning outcomes, teaching and learning context. I would like to add a sixth, which is student products. While this is related to student achievements, I would like to emphasize that student projects give teachers and other administrators the opportunity to observe the student’s ability to apply knowledge to real-world situations.

The Study

To measure the competencies of preservice teachers, a self-reporting web-based form was developed that consisted of Likert type items that were built around each of the six NETS standards for teachers. The six items on the form were as follows: Basic Computer Operations; Basic Communication Tools; Planning Technology-Rich Learning Activities; Plan Multiple Strategies to Facilitate Critical Thinking about Electronic Information; Use Multiple Technologies to Support Learner-Centered Lessons to Meet Diverse Needs of Students; and Use technology to Facilitate Effective Assessment and Evaluation Strategies.

There are two parts to each of the six items on the form. First, respondents were asked to rate their level of professional knowledge proficiency. The “Levels of Knowledge Proficiency” were represented in the following five areas:

1. Converse about the content in general ways
2. Relate the content to broader non-technical issues
3. Give explanations about critical concepts
4. Apply knowledge to challenging practical problems
5. Give expert advice.

Second, on each of the “Levels of Knowledge Proficiency,” respondents were asked to rate the “Extent of Professional Knowledge” they had on a Likert type scale from 1-7 where 1 indicates “Not at all” and 7 indicates “A Great Extent.”

The survey was administered during the spring 2001 semester to a convenience sample of 36 teacher education students from several colleges and universities in the Midwest. The results show that for each of the six items, the “Level of Knowledge Proficiency” was greatest in their ability to “converse in general ways about the topic” and least in “giving expert advice.” This indicates that preservice teachers in the sample have a general knowledge of classroom technology tools, but are not yet comfortable giving expert advice to someone else in any of the six areas. In addition, the “Extent of Knowledge Proficiency” as measured by the Likert scale is highest in “basic communication tools” and least in “planning multiple strategies to facilitate critical thinking about electronic information.” In general, the extent of the knowledge proficiency was greatest regarding technology tools, and least
regarding issues of planning and assessment. The data was analyzed for each of our research questions by using SAS.

The Findings

Figure 1 outlines the mean scores in each of the six ISTE Standard areas. The students rated themselves fairly high in all areas in their ability to converse about the content in general ways. In each of the succeeding competency levels, however, the student's ratings of their level of competency went down. This indicates that they had a broad surface knowledge of the content, but the are still lacking in their ability to explain it, apply it, or give expert advice about it.

Another observation is that the students appear to feel fairly competent regarding basic operations and telecommunications tools, but less competent in the areas of planning learning activities, critical thinking strategies, supporting learner-centered activities, and in the area of assessment. What it appears is that while the students are literate in technology, they do not feel competent in using technology in the classroom.

It might appear, therefore, that the reason for this is that students are not being shown in the methods classes how to use technology as part of an instructional strategy.

The Conclusion

In conclusion, we must begin to rethink the concept of "school" in our technology rich world. We must not think in terms of seat time, and textbooks, and in school libraries. We must add to our thinking learner-centered collaborative activities that give students the tools and the freedom to explore their world and the tools they need to improve their own learning and develop their knowledge base. In addition, we need to better understand the ways in
which technology-supported education represents a melding of the learner and the discipline as framed by inquiry-based learning.

You know, when Sony built the Walkman, they weren't satisfied with being second best. They began to look for ways that they could daily improve their product. Their hard work gave the consumer access to new technology and features. Sony set the standard for portable sound. Just as Sony didn't quit, we as educators should not quit. We should be asking ourselves this question, "What can I do today that will help the students to learn just a little bit better?" It doesn't have to be a big change, but if we do this each day, we will, like Sony, begin to set new standards for education and better prepare our students to live in the 21st century.

Schools in the 21st century must begin to prepare students for a world rooted in information and technology. Such a world calls for students with the kinds of skills and understandings that enable them to function within and contribute to this emerging world. Students must have opportunities to participate in problem-oriented learning activities that are relevant to their interests and worthy of their investment of time and effort. Improving student learning must depend on more than symbol manipulation, generalized learning, pure mentation, and individual cognition. It must lead to competence acquired through authentic activity presented in an environment that encourages collaboration. Students have the right to expect that the knowledge and technology commonplace in their homes and communities are accessible in their schools. They have the right to a learning environment rich with resources both printed and retrievable from the World Wide Web.

Abstract: Today's students are receiving "superficial" knowledge of math and science concepts. According to a report from the National Commission on Mathematics and Science Teaching for the 21st century, in science, students are not mastering the "big concepts," while in mathematics, they are given little information about "how" and "why." To address these concerns, connections need to be made between mathematics and science. Visualization combined with Problem Based Learning (PBL) is one teaching strategy that can be used to address these issues. This paper reviews the findings of a study conducted at two mid-western high schools that used visualization in math/science classrooms. The results revealed that students made meaningful connections between math and science data, connections between math and science language, and connections between math, science and daily life experience.

According to the report from The National Commission on Mathematics and Science Teaching for the 21st Century (2000), entitled Before It's Too late, U.S. students are receiving only a superficial knowledge in today's classrooms. The report states, "In an age now driven by the relentless necessity of scientific and technological advance, the preparation our students receive in mathematics and science is, in a word, unacceptable. Despite our good intentions, their learning is too often superficial. Students' grasp of science as a process of discovery, and of mathematics as the language of scientific reasoning is often formulaic, fragile, or absent altogether" (p. 10). The report notes that the problem with current science education is that students are not required to master "big concepts that make science so powerful and fascinating" (The National Commission on Mathematics and Science Teaching for the 21st Century 2000). In mathematics, the content is limited to questions that answer "What" and get little content that addresses "How" and "Why should I care." These two issues could be addressed by making connections in the classroom between science and mathematics. These two subjects and the daily world are linked. Scientists generate data and use mathematics as a tool for data analysis. Yet, in our education system, students see these two subjects as separate and distinct because we have chosen to teach them separately giving students a dichotomous view of science and mathematics.

One teaching strategy that could be used to make connections between science and mathematics is visualization. Combined with Problem-Based Learning, visualization uses classroom technology to help the learners create a visual picture of concepts and make connections between mathematics and science through discovery learning experiences.
According to the 1999 report, *How People Learn* (Bransford, Brown, & Cocking 1999), from the National Research Council, technology can be used to help supply five key conditions for learning. These conditions are central to the success of visualization. They include real-world contexts for learning; connections to outside experts; visualization and analysis tools; scaffolds for problem solving; and opportunities for feedback, reflection and revision.

First, technology can support real world context for learning by using simulations, which can form the basis for Project Based Learning. Project Based Learning uses in class projects that are used to cover course content and fulfill certain course objectives. Students have the opportunity to work on the project as teams and report their results to the entire class. One way to do this is through the use of simulation. Simulation exposes students to real-world problems to which they must find solutions. They are looking for answers that are “situation specific” rather than the “right answer” from a textbook (Teaching and Learning 2001).

Second, technology can connect students with outside experts. Through the Internet, students can have access to experts in practically any field all over the globe. They can send e-mail to them and even “chat” with them online. In one of my own classes, the students became very excited when they were able to have their questions answered during a “chat” session with a well-known expert in education. Students can also download documents that are not available in the library, and they can keep up with the latest research.

Third, technology can provide visualization and analysis tools (Harnisch 2000). Rather than talking about concepts, teachers can use technology to visualize them. For example, schools that do not have microscopes can use advanced imaging technology to look at the parts of a flower rather than relying on textbook photos or drawings. Also, 3-D imaging allows chemistry students to construct a three-dimensional model of an atom and animate it so they can see it from all sides. In mathematics, graphing calculators can visually show students relationships between variables. Concept mapping using “Inspiration” software can help students visualize processes and relationships.

Fourth, technology can provide scaffolds for problem solving (Harnisch and Sato, 1990). In today’s rapidly changing world students need to learn much more than the knowledge written in a textbook. They need to be able to examine complex situations and define solvable problems within them. They need to work with multiple sources and media, not just the single textbook. They need to become active learners, and to collaborate and understand the perspectives of others. What we are talking about is the ways in which students today need to learn how to learn; that is, they need to learn how to:
- Ask: find problems
- Investigate: multiple sources/media
- Create: engage actively in learning
- Discuss: collaborate; diverse views
- Reflect: learn how to learn

This shift to an inquiry-based mode of teaching and learning is now widely recognized (Bruce & Davidson 1996; Minstrell & Van Zee 2000; Shavelson & Towne 2002; Wells 2001). The National Science Foundation has asked for “research–validated models (i.e., extended inquiry, problems solving).” The Carnegie Foundation's Boyer Commission on Educating Undergraduates in the Research University (1998) has set its number one priority to make research–based learning the standard. The American Association for the Advancement of Science, in its Project 2061, has as its number one goal to have “science literacy for all high school graduates,” by which they mean to develop the broad, critical perspective and habits of mind that develop through scientific inquiry.

Fifth, technology can provide collaboration between students, teachers, and outside experts that help students to solve problems. Through email, discussion boards, and web pages, students have access to educators, and to experts who can help them to think through problems. Also, technology can provide students with problem-solving experiences by developing “Inquiry Units.” This is available to both teachers and students through a web site at the University of Illinois at Urbana-Champaign at http://inquiry.uiuc.edu/. The “Inquiry Page” is more than a web site. It's a dynamic virtual community where inquiry-based education can be discussed, resources and experiences shared, and innovative approaches explored in a collaborative environment. One example is “Web Quests” which will help them to develop problem solving skills. Based on John Dewey’s philosophy that education begins with the curiosity of the learner, we use a spiral path of inquiry: asking questions, investigating solutions, creating new knowledge as we gather information, discussing our discoveries and experiences, and reflecting on our new-found knowledge. We invite you to visit the inquiry page. There are lessons on life that can be downloaded and adapted for use in your classroom. Also, you can place inquiry units on the page and access them from anywhere in the world. Your students can also develop units as part of a lesson and put them on the page to share with others. By doing this, you will become part of a world-video learning community.
The Study

The Visualization teaching/learning strategy was tested in two mathematics and science classrooms in a suburban high school during the 2000-2001 school year. In each school a math/science cohort of 25 learners was formed and a teaching team of math/science teachers. The learners consisted of Honors students taking Algebra II with Trigonometry /Honors Chemistry at one school, and “G” learners having a combination of Algebra II/Physics at the other school. The learners took math and science together as a group rather than changing classes. In addition, the teachers had the opportunity to observe each other’s classes. The Project Based Learning (PBL) Coordinator, who was a teacher that specialized in PBL and was selected for the project, trained each teacher in PBL. In addition, the Associate Superintendent of Schools, and the Assistant Principal of each of the schools was kept informed of the progress of the project. This collaboration helped to form a foundation for a culture of learning in math and science at each school.

During the project, students had access to classroom technology including computers, software, web access, graphing calculators, and science laboratory equipment. The Honors class also had the opportunity to upload projects to a secure website for review.

The data for the project consisted of survey instruments, images of projects, field observations, student and teacher reflections, teacher portfolios, interviews with teachers and school administrators, and student focus group interviews. Some of this data was collected electronically using a secure website.

Findings

The use of visualization and the grouping of students into math/science cohorts and teachers into math/science teaching teams helped students make connections between math and science. Through visualization, which also facilitated collaborative learning, students and teachers built a math/science learning community that was formed through their shared classroom experiences. This is illustrated in Figure 1.

![Figure 1: Math/Science Collaborative Learning Community](image)

Visualization helped students and teachers make connections between math and science. There were three types of connections that were made. First, there was a “data” connection, second, there was a “language” connection,” and finally, there was a “life” connection.

Data Connection

Students had the opportunity to make connections between math and science by using mathematical formulas and concepts to analyze and draw conclusions from data they had generated in a science class. For
example, the students in one cohort spent the day in research teams throwing softballs at different angles and measured the angles and distance of each throw. The students then used vector concepts and formulas to determine which was the best angle to throw the ball to achieve the greatest distance. In their reflections, students remarked about the connections they saw between mathematics and science. A student wrote, “We created connections from Algebra 2 to chemistry in different ways. For example, when we were learning about log in Algebra 2, at the same time we were learning to determine the pH of different substances. We used ‘log’ in the equation.”

**Language Connection**

Second, visualization helped students and teachers begin to form a common math/science language. One of the department heads associated with the project noted, “completely integrating a Math and Science course may not be feasible, but speaking a common language in all Math and Science classes would be very powerful.” The advantage of a common language to the student is that now students began to see a common set of terms for a concept rather than two sets, one in math and one in science. Teachers also see this as a big advantage. One math teacher said that a common terminology would help the students make connections between the two disciplines because, although math and science have common concepts, they use different terms to describe them. One of the administrators also added that a common language would also serve to make the curriculum more cohesive.

**Life Connection**

Finally, the students in the project expressed that the teachers connected concepts in Math and science to daily life. One student remarked, “Well, for instance, sometimes when I had math it tended to be a little abstract and you might have wondered what you would use this for?” As result of this experience, however, students expressed they “experienced” a concept rather than just “reading” about it.

Another example was the “Roller Coaster Project.” This project allowed students to see the “science” behind roller coasters. It culminated in a trip to a local amusement park. Students did research on roller coasters and then, during their visit to the park, they divided up into teams and collected data during their rides. They used this data to answer questions about the rides and what they experienced. A student in the project summarized it this way: “A teacher that uses technology teaches differently because they don’t necessarily teach in the traditional teaching manner. They seem to bring more of the outside world into the school.”

**Conclusion**

In conclusion, visualization is not an easy task. Technology, and access to technology, is an important component for developing visualization. Both students and teachers see visualization as a common link that helps all students have access to the concepts. The group work in the classroom also facilitates learning because it provides a support group and another means to help students learn. Students, who may just “tune out” during a lecture and may be “left behind” as a result, now have the opportunity to be actively engaged in the learning process through visualization and group work.

Technology is also important for teachers as part of their professional development. Teachers need to learn how to use current software packages in their fields and keep up with developments in their field. Technology is one of the factors that is fueling the changes we’re seeing in the world by providing an expanded information base. No longer is information confined to physical libraries. The Internet provides access to libraries and resources worldwide. Students and teachers must learn to how to access and use the information that is available if they are to succeed.

While both teachers and students grew academically and professionally, teachers found that teachers who take on this challenge must be willing to view teaching just a little differently. They must be comfortable with restructuring the curriculum, trying different methods, tolerating just a little more “noise” in their classrooms and working through the frustration when the technology just didn’t work. Students also faced the challenges associated with discovery learning that sometimes there might not be a “right” answer to a problem, and that the teacher may not have all the answers. Through visualization, students and teachers can learn together to develop shared knowledge that encourages students to develop a sound understanding of the “big concepts” in math and science and how math and science is related to their lives.

Visualization and Collaborative Learning in Math/Science Classrooms

Delwyn, L. Harnisch, C&I, University of Nebraska, Lincoln, United States, harnisch@unl.edu
Ronald J. Shope, Assessment and Institutional Research, Grace University, Omaha, United States, rshope@mail.graceu.edu

Abstract: In many of today's math and science classrooms, learning today is highly “teacher directed.” As a result, students often miss the “big concepts” and see little connection between math and science. In a study done at two high schools in the Midwest, math/science student cohorts, and math/science teaching teams, developed a collaborative learning environment that uses visualization and Problem-based learning which formed the foundation for collaboration between math and science teachers and students. Student collaboration took the form of student mentoring. Collaboration among teachers led to faculty mentoring, breaking down some of the walls between science and math, and better classroom help for students.

Introduction

A report from the National Commission on Mathematics and Science Teaching for the 21st Century entitled Before it’s Too Late, underscores the poor performance of U.S. students compared to other nations in math and science. One reason for the decline in scores is the way that math and science are taught. According to the report, there are two major problems with current math and science teaching methods. First, “Seldom are students asked to master the “big concepts that make science so powerful and fascinating.” Second, the methods used to teach mathematics have “remained virtually unchanged in the last half-century.”

In many classrooms, math and science learning is highly teacher directed and focuses on definitions, labels, teacher directed problem solving rather than on discovery learning that is student centered. What is needed is a student-centered learning environment.

A student-centered learning environment is centered on eight key instructional and motivational factors. First, instruction must me made meaningful and relevant from the individual learner’s perspective. When instruction is learner-centered it implies, according to Margaret Riel (2001) that the learner “is actively engaged in the process of knowledge construction.” This means that learning is anything but “boring.” In a learner-centered environment, the learners take part in setting the goals, which are then guided by the teacher.

Second, instruction must provide appropriate learning challenges and standards. Classrooms in our technology rich world can no longer reduce learning to memory exercises. While there are areas that require extensive memorization, students must be taught to think and apply that knowledge. In addition, standards of student performance must be established so that students will know what is expected of them. Riel (2001) calls this being “Assessment Centered.” Teachers must know “what students are learning and what they need to know. This means that the curriculum needs to be matched to the classroom assessments. The assessments should flow out of the curriculum. A major focus should be on criterion referenced, rather than norm-referenced. One problem with norm-referenced testing is the temptation to “teach to the test.” When this is done, the test, rather than the curriculum drives the learning process. In addition to tests, teachers need to find other methods of assessment such as student portfolios to determine the quality of student work.

In addition, the teachers must be what Riel (2001) terms “Knowledge Centered.” Teachers must have the knowledge base to be able to evaluate the essential skills and knowledge that students need in a particular discipline. Third, instruction must accommodate needs and be supported in critical thinking and learning skills. This is also related to being “Assessment Centered” Critical thinking involves skills and dispositions. Dispositions are attitudes regarding higher-level knowledge. Tishman et al. (1995) has identified four ways to help students develop higher order knowledge. These are to use real world examples; make comparisons across disciplines; encourage interaction by engaging students in problem solving activities or inquiry; finally, give positive feedback to students when they demonstrate the appropriate use of higher order knowledge that is relevant to the subject being studied.
Fourth, instruction should attend to the climate and context in which learning occurs. Recent brain research suggests, “The richness of early learning experiences affects the physical development of the brain and may be a major cause of intellectual development. If these new theories linking learning experiences with brain development come to be accepted, the optimal match between characteristics of the learner and the learning environment, rather than parental genetic code, might be seen as responsible for school success” (Riel 2001). This means teachers must be concerned not only about children learning, but how they learn it. Teachers must create an environment that targets a broad range of learning styles.

Fifth, instruction should honor individual needs for choice and control. This is another aspect of being “Learner Centered.” McCombs (2000) notes that teachers must value the unique perspectives of the learner. For example, the student could be involved in classroom assessment of their work. Students could be asked to help design the rubric used in evaluation and then asked to apply it to their own work to determine the strengths and weaknesses of their work. They could then be given the opportunity to do the work again. Just as businesses are constantly looking for ways to continually improve their product, involving students in the assessment process not only gives them a measure of control over their work, but it helps them to know how to improve their work.

Sixth, instruction should support individual interests and creativity. The “learner-centered” teacher attempts to learn what interests the student have and allow them to work on projects or use classroom resources that target those interests. For example, students who are interested in drama may be able to use this interest as part of a project. Or, students who are interested in and have access to computer technology may be able to use this interest to make computer presentations.

Seventh, instruction should provide positive social interactions and personal relationships. This means that student-centered learning maximizes collaboration between students and between students and teachers.

Based on these eight factors, a student-centered learning environment must maximize collaboration and discovery learning. One instructional strategy that does this is Problem-Based Learning (PBL). Barbara Dutch of the University of Delaware, describes Problem Based Learning this way: “Problem-based learning (PBL) is an instructional method that challenges students to ‘learn to learn,’ working cooperatively in groups to seek solutions to real world problems. These problems are used to engage students’ curiosity and initiate learning the subject matter. PBL prepares students to think critically and analytically, and to find and use appropriate learning resources” (Dutch http://www.udel.edu/pbl/).

The PBL approach requires teachers to become “facilitators” rather than the primary means of delivery for instruction. As facilitators, teachers structure the situation, make technology and data resources available to the students to solve the problem, and offer advice. The approach is visual, hands on, and student centered, rather than teacher driven. For example, one teacher I know created a PBL situation by accident. While preparing for a biology class she set beakers with various liquids in them and set them aside without labeling them. When the students arrived for class, she realized that she had forgotten what was in the beakers. Instead of throwing the liquids out and starting over, she turned her mistake into a learning opportunity for the students. After she explained to the students what had happened, she said that they were to design tests to see if they could figure out what was in each of the beakers. She said that the students took this as a personal challenge and were very engaged in their work! After about two days, they discovered what was in the beakers! Not only did they learn a lot about science, but, they had an opportunity to solve the problem themselves.

PBL can be enhanced by using visualization. Visualization uses technology to help students “visualize” math and science concepts rather than relying on lecture as the primary classroom delivery system. Visualization enhances PBL because it provides tools such as computer software, the Internet, calculators, and laboratory to help students solve problems. When students learn through PBL and Visualization, both students and teacher generate shared experience because the process is interactive and mediated by technology.

Another form of collaboration that could be built is collaboration between teachers and students in math and science. Collaborative learning between these disciplines would enable students and teachers to make conceptual and practical connections between the two disciplines. This would help students to get what the Glenn Report describes are the “Big Picture.”

This could be accomplished by forming math science teaching teams and math/science student cohorts. Teaching teams would enable classroom teachers would be able to share ideas and identify the relationships between their two disciplines and then through visualization allow students to see for themselves these relationships. Students could also be teamed. Rather than taking math and science separately, math/science cohorts could be created. Students would then be able to learn in an environment that favors the development of group cohesion. Cohesive groups would facilitate interaction, which should result in students feeling more free to share information with one another. This process is illustrated in Figure 1.
The Study

For the past two years, I've been conducting a research project based on the visualization model using math/science student cohorts and math/science teaching teams. The research was conducted in two high schools to determine the way in which visualization and PBL facilitates collaborative learning in math and science classrooms. The study also explored the problems associated with this approach to learning, the changes in classroom dynamics, and the professional benefits to teachers of this approach.

In each school a science teacher was teamed with a math teacher. One teacher on each team was experienced with at least 10 years of teaching in that field, while the other was a young teacher with less than five years of experience. Each member of the team had teaching credentials in math and science and advanced degrees in their field. In addition to the teams of math science teachers, a teacher was appointed PBL Coordinator for the project. The coordinator helped each of the teachers develop PBL activities for their classrooms.

During the school year, the teachers were given time to visit each other's classrooms and to plan as a team. Periodic visits were made to each school by the primary researcher to observe each class, and hold interviews with the teachers. A website for the project was created to collect survey data, and as a place for students to post projects. Teachers also submitted periodic reflection reports to the website.

Students at each school were selected to participate in the math/science cohorts. The student cohorts took both math and science classes together for the entire school year. Students in the cohorts had a variety of career interests and learning styles. One cohort was composed of Honor Students and the other was "general" learners. At one school the cohort met in different rooms for math and science, while at the other, they met in the same room.

Both quantitative and qualitative data from a variety of sources was gathered for this project. Some of this data was collected and stored at a website that was developed for this project. The data includes faculty and school and district administration interviews, student focus groups, surveys, faculty portfolios, faculty journals, faculty and department chair reflections, images of classroom activities and projects, and direct classroom observations.

Findings

There were two major areas of collaboration. There was collaboration between math and science teachers and collaboration between math and science students.
Collaboration Between Math and Science Teachers

Collaboration between math and science teachers was forged through the team approach to teaching. Both math and science teachers spent time in each other’s classrooms. There are three advantages of collaboration between math and science teachers. First, math and science teachers learn about each other’s discipline. One of the science teachers described his experience with the project as “enlightening” because he had the opportunity to “see how the other side lives.” He observed that while math people may know the answer to a problem, science people may not have a single answer to a problem. Also data in science must be generated and is not supplied like the data in Math problems. This is an important difference between the two disciplines. One solution to this problem proposed by one of the science teachers was to find ways to generate data from science projects that could be used in Math Classes. To maximize the collaborative effort teachers must have the time to work, plan, and reflect on how their two subjects come together and how they can conceptually support each other.

A second advantage of collaboration is that teachers were able to provide better help to students in the classroom. While some were a bit nervous with having two teachers present all the time, nearly all students agreed that having two teachers helped them in the learning process. As one student put it they can “help each other.” If there was a question about an area that one teacher couldn’t answer, the other teacher was there to answer the question.

A third advantage is that collaboration can begin to break down the walls between the two disciplines by providing a platform for teachers to share their experiences with other faculty members in their department and in the district. By sharing these concepts, a team of teachers who are familiar with visualization and PBL can be built. Finally, collaboration also facilitates faculty mentoring. In each team, the young teacher reported that they had learned a great deal from the experienced teacher. One of the young math teachers for example said that he had begun to think more “visually.” In addition, one of the teams said that by working together they had a better idea of what their students were learning.

Collaboration Between Math and Science Students

Collaboration between math and science students took place during the classroom group activities. Heddi Pfister characterized this collaboration between students as a “support group.” Generally, students at both High Schools involved in the project liked being together as a group. Many students said that they felt they could get to know others in their class better because they were together for two periods in a row.

This “student” mentoring was an important part of the experience. The students began to see persons in the class they could call on for help. One student wrote, “Since we had the same kids in both of the classes, it let us know what are the kids’ strong points and weak points.” In addition, some students felt that a peer in the class could explain a concept better than the teacher. A student remarked, “Sometimes you have the teacher explain it and some kids do not understand what they mean by it. So, they ask something else and they explain it in easier terms.”

Conclusion

The results of the collaboration between students and teachers mediated by visualization was the development of maturing minds. For teachers, there was professional growth. Teachers experienced growth in learning new methods, restructuring the curriculum and experimenting with new technology and classroom environments.

Students grew in their level of maturity in their conceptual understanding of math and science. In a reflection about one of the classroom projects, a student wrote, “It required me to think in new ways and to work on my own without a lot of help from a teacher. This made it different from any other project I have ever done. You made your own decision based on your information, data observations, and personal knowledge on the subject; which means there is no “wrong” answer as long as you have information to support your idea. Because you did it mostly on your own, it was satisfying and rewarding to see how much progress you were making and how much knowledge you were acquiring on your own.”

This is what education is all about. It isn’t easy. It will take many teachers and students out of their “comfort levels.” But, through collaborative learning, students will be developing skills that will be even more valuable than the knowledge in a particular subject. They will experience the joy and frustrations of how to think, reason, and work together in partnership to make decisions.

Abstract: The National Council of Teachers of Mathematics in its 1991 publication Professional Standards for Teaching Mathematics (NCTM, 1991) and the current Mathematics Program Standards for the National Council for Accreditation of Teacher Education (NCATE, 1998) stress the importance of the disposition of the classroom teacher towards mathematics. Unfortunately, research has reported that many preservice elementary teachers have negative attitudes toward mathematics, are not confident in their own mathematics ability, and claim to have a high level of anxiety towards mathematics. The Education and Mathematics Departments of King’s College recognize the phobic attitudes towards mathematics displayed by preservice elementary teachers and have collaborated to establish a plan to hopefully reverse this negative disposition. This paper reviews current strategies implemented and future techniques planned to overcome the negativity and promote a more positive disposition.

Introduction

The National Council of Teachers of Mathematics in its 1991 publication Professional Standards for Teaching Mathematics (NCTM, 1991) and the current Mathematics Program Standards for the National Council for Accreditation of Teacher Education (NCATE, 1998) stress the importance of the disposition of the classroom teacher towards mathematics. They maintain that if K-12 students are to develop a disposition to do mathematics, it is essential that the teacher communicate a positive attitude towards mathematics. Additionally, teachers need to establish a supportive classroom learning environment that fosters the confidence of students to learn mathematics. Unfortunately, research has reported that many preservice elementary teachers have negative attitudes toward mathematics, are not confident in their own mathematics ability, and claim to have a high level of anxiety towards mathematics (Harper & Daane, 1998; Tooke & Lindstrom, 1998).

The Education and Mathematics Departments of King’s College recognize the phobic attitudes towards mathematics displayed by preservice elementary teachers and have collaborated to establish a plan to hopefully reverse this negative disposition. This paper will review current strategies implemented and future techniques planned to overcome the negativity and promote a more positive disposition.

Fall, 2001: Initial Implementations

During the fall semester, the mathematics methods course was taught by a mathematician for the first time. This was done with the hope that someone who actively teaches the subject and is confident in her own ability to do mathematics would model a positive attitude towards mathematics. The methods course is taken after our elementary education majors have taken three math courses. In light of the change of instructor for the methods course, we are reviewing the curricula of the math courses to be sure that they are in line with the techniques that are being stressed in the methods course.
In conjunction with the mathematics methods course, our students participate in a pre-professional field experience. This gives our students an opportunity to observe an elementary classroom, as well as present lessons. The more site-based experiences our students have prior to student teaching, the more confident they become in their ability to teach. Included in this experience is an opportunity to discuss with their classmates the lessons presented and strategies for solving problems encountered in the K-6 schools.

Additionally, we have started to collect information from our students to better understand their attitudes and backgrounds in mathematics. The initial assignment in the methods course was for the student to write his/her mathematical autobiography. This gave us a better idea of how their attitudes were shaped and the concerns they have about teaching. At the end of the semester, we issued the MARS-R to assess the mathematics anxiety that our students still have at the end of the pre-professional semester and to provide a baseline to test how future initiatives influence mathematics anxiety.

Spring and Summer, 2002: Planned Implementations:

At the beginning of the semester, we will again use the mathematical autobiography for an informal assessment of their attitudes towards mathematics. We will also use the MARS-R as both a pre-test and post-test to measure their mathematics anxiety.

We will also be constructing a web site available to students participating in the pre-professional semester and student teaching. This site will include lesson plans that our students developed during previous pre-professional semesters and links to other sites that contain lesson plans. We will be including an S.O.S. button to email the mathematics methods instructor for advice or help. The web site will also contain tips for dealing with mathematics anxiety.

During the summer, we will examine various tutorials that are commercially available to help our students review concepts, as needed, while taking the mathematics courses that are required for the major. These tutorials should also be available to students who wish to use them while in a classroom setting.

Conclusions

The Education and Mathematics Departments recognize the critical need to prepare elementary teachers with a positive disposition towards mathematics. Both departments work collaboratively in designing and evaluating the most effective math curricula for our students. We have begun appropriate interventions to ease the mathematics anxiety of our students and will continue to assess the strategies we employ. Hopefully, our efforts will help prepare teachers who can effectively teach their students mathematics in a positive learning environment.

Interactivate Your Math Students

Bethany Hudnutt, Shodor Education Foundation, US

Project Interactivate is mathematics courseware developed by the Shodor Education Foundation in collaboration with classroom teachers, content experts, curriculum designers, and education technologists. Interactivate has been described by the National Council of Teachers of Mathematics (NCTM) as setting "a new standard for on-line support for math teachers" (see reference, below). The project contains more than 80 classroom-tested interactive activities and tools. Suggested lesson plans and discussions based on various concepts contained in the activities help support standards-based approaches to mathematics education. Supplemental materials for the activities and lesson plans exist in the form of help files, worksheets, open-ended explorations, a dictionary, and links from those pages to related NCTM, NCEE, and DoDEA, standards.

Interactivate runs on any computing platform with any browser that supports Java and can be freely accessed on Shodor's website, http://www.shodor.org/interactivate.

The poster session will center on Project Interactivate. After the session, participants will be able to navigate through the site and be inspired to use Project Interactivate in their own classrooms. Participants will also learn about the Shodor Education Foundation as a non-profit organization dedicated to integrating computational science and modeling and visualization tools at all levels of education. Bethany Hudnutt, a former high school math teacher and currently the Project Interactivate manager, will present.

The presentation will suggest multiple ways of utilizing the courseware in the mathematics curriculum at all grade levels. Also, the usefulness of modeling and visualization to enhancing student understanding of math and science concepts will be discussed.

Shodor's philosophy on the role of technology in the classroom will be an integral part of the presentation. Technology should be used when the computing power of a computer will either make a task less time consuming or make a task which was impossible to complete using other means possible. For example, demonstrating the difference between empirical probability and theoretical probability using dice can be time consuming and uninteresting to students. Asking a student to roll a die one hundred times and keep track of results is a dull and time consuming task where no learning can take place until the experiment is complete. Even then, one hundred times may not be enough rolls for the empirical probability to approximate the theoretical. A computer can be programmed to simulate rolling a die thousands of times and keep track of the results in seconds. Interactivate activities are designed with this type of technology in mind.

Interactivate has received wide-spread recognition and numerous awards including:

- Eisenhower National Clearinghouse Digital Dozen award (twice):
  http://www.enc.org/resources/records/full/0.1240.012956.00.shtml
  http://www.enc.org/resources/records/full/0.1240.018591.00.shtml
- National Council on Teachers of Mathematics' Illuminations:
  http://illuminations.nctm.org/webresources/pinteractive.html
- Forbes Magazine's Best of the Web:
  http://www.forbes.com/bow/b2c/category.jhtml?id=142

Interactivate originated with the Presidential Technology Initiative in partnership with the US Department of Defense Education Activity (DoDEA) with the goal of producing high-quality interactive activities to support a variety of middle-school math texts. Since its inception, Interactivate resources have been linked through tables of contents of various standards-based texts, including Math Thematics, Middle Grade Mathematics, Interactive Mathematics, and Mathematics in Action. Interactivate is in DoDEA schools around the world and in many schools and homes in the US, with more than 25,000 documented users per month.
PDA’s: The Swiss Army Knife of Handheld Technology for Mathematics Classrooms

Elliott Ostler
Teacher Education Department
University of Nebraska at Omaha

elliottostler@mail.unomaha.edu

Neal Grandgenett
Teacher Education Department
University of Nebraska at Omaha
United States
ngrandgenett@mail.unomaha.edu

Abstract: This paper provides an overview of software applications and peripheral devices designed for the Personal Digital Assistant (PDA) that can act as powerful tools in a technology enhanced mathematics curriculum. PDA applications are being introduced at a time when mathematics education reform movements are accentuating the need for functional pedagogical technologies. Attention has been focused on including applications that tend to support traditional curriculum in non-traditional ways. Excerpts from field tests have also been included.

Introduction

The willingness to embrace new technologies as tools for learning can only be justified to the extent that teachers are also willing to embrace, alter, or adapt the curriculum that supports efficient learning through these technologies. Mathematics teachers in general have been fairly willing to experiment with technology applications in an enrichment context, but perhaps less so when it comes down to engaging students in traditional textbook-based topics. Teachers of mathematics commonly report that the most productive technology-based learning environments are those in which students are actively engaged in dynamic mathematical problems involving modeling and problem solving, yet difficulties with management and assessment still have appeared to limit the commitment to creating these learning environments. Unfortunately, special efforts to utilize technology in the traditional mathematics curriculum have often resulted in little more than a series of isolated exercises done on desktop computers, and have ultimately failed to justify why technology was even needed. The Internet has certainly provided new opportunities to learn and express mathematical ideas, and perhaps more importantly created a medium for mathematical discourse. Curricular arguments involving technology however, continue to dissolved into a struggle to justify cost, availability, and time versus the proverbial “payoff” in terms of what students have learned, or at least how well they score on standardized tests. For many mathematics teachers, the solution lies somewhere in the promise that reasonable continuity can be established within and between mathematical topics, and that thoughtful productive learning occurs because of requisite technology rather than having technology use appear forced or contrived.

Although the primary factors for effective classroom technology use remain curricular, emerging technologies for education have demonstrated that availability and cost are much less a factor than even three years ago. The Personal Digital Assistant or PDA is a classic illustration of this point. PDA’s, which are still considered by many to be day planners, have captured the attention of educators at all levels, largely because of the recent availability of software and peripheral applications. Because PDA’s are handheld devices smaller than most graphing calculators, and in many cases costing about the same, they provide students an opportunity to view mathematical ideas in a variety of ways just as graphing calculators do. The many applications now available for PDA’s however add a much greater dimension of realism to the mathematics curriculum than is possible with a graphing calculator, and much greater portability than is
possible with a desktop computer. The PDA is in essence a kind of Swiss Army Knife approach to handheld computing where one very small device can act as many different tools. Much of the power of these devices rests in the simplicity with which students can switch back and forth between applications within a single lesson. A lesson might include students collecting data on water samples with probe devices that can feed information directly into the PDA, organizing the data in a database application, calculating and graphing levels of impurities using spreadsheets or graphing calculators, and writing up lab results using a word processing application. The most amazing aspect of this activity would almost certainly have to be that the students could do all of these things while standing ankle deep in the water where they took the sample.

The scenario described above would certainly be possible given the right circumstances, as would many other scenarios, given the right software and hardware applications, and most importantly, an imaginative teacher. The next two sections of this paper provide an overview of a few software applications as well as some interesting peripheral devices that with appropriate curricular considerations can be used in some very powerful ways to support traditional mathematics curriculum.

Software Applications

In addition to the standard tools of the PDA (i.e. calendar, calculator, memo pad, “to do” list, etc.), a mountain of software as emerged virtually overnight that will allow students to seamlessly navigate through activities which require them to use data from one application to complete tasks in another. Most of this software is free and can be easily accessed through various web sites. Other software is available at nominal fees.

Graphing Calculators

Perhaps the most widely used technology to date in the mathematics classroom is the graphing calculator. Most graphing calculator models run between $70-$120 and require a significant amount of classroom time to learn the basic functions and to confidently navigate through the menus. Although these tools have a great deal of potential, students can get lost in a sequence of button pushing that may detract from the innate message of the lesson being taught. Conversely, the graphing calculator applications designed for the PDA run about $30-$50 and have a very short learning curve. Most students can have basic functions mastered in a matter of minutes. Many of these applications include the ability to view standard functions and parametric graphs, as well as allowing the user to simultaneously graph multiple equations. Graphs are managed through various types of equation “managers” and can even utilize a number of built-in functions. Functions can be explored through a series of table values as well as the standard graphing mode. One particularly powerful advantage is the zoom feature that allows the user to use the stylus to drag over an area of interest to better examine graphical properties. This includes being able to calculate values for individual points on the highlighted area of the graph which make exercises such as finding points of intersection easy to do. Most standard graphing calculators require these tasks to be managed through a series of menus. Several of these PDA graphing calculators allow users to create their own custom worksheets using the fully integrated equation solvers. These equation solver applications use a pop-up input screen that allows a user to enter a virtually unlimited number of equations and then solve for any desired value or variable. Common built in functions include those for advanced algebra, trigonometry, computer science, physics, chemistry, statistics, Boolean logic and engineering.

Animation

Free applications such as Sketchy (available at hi-ce.eecs.umich.edu) allow users to create a series of pictures that can be animated in such a way as to demonstrate geometric, algebraic, or recursive processes. Tools include basic geometric figures, lines, shading, and freehand stylus drawing. Pages can be easily duplicated and edited as well. In field tests, this program has been particularly powerful in reinforcing concepts in a tutorial setting when students need extra help but are unable to get help from the teacher. The PDA actually acts as the teacher, allowing students to view a specific procedure and stop the
animation at any point they deem necessary. Methods courses at the University of Nebraska at Omaha have included instruction in Sketchy for the purpose of re-teaching processes in mathematics, and also to help illustrate how science and mathematical topics can be better integrated in meaningful ways. Reactions from pre-service teachers of mathematics and science have been very positive. In one case an elementary teacher used Sketchy to help teach the algorithm for long division. However, instead of having Sketchy demonstrate division problems, the teacher had students build an animation showing how long division is done. The students were so motivated and excited that they finished the division unit and tested ten days earlier and scored better on the unit test than the other three classes in the school at the same grade level.

Simulations

Although simulation software is still a relatively new venture in the mathematics classroom, free programs such as Cooties (available at hi-ce.eecs.umich.edu) allow for the study of probability and mathematical modeling in the context of the spread of infectious diseases. The application uses the PDA's beaming feature to have students “meet” each other. Starting with one or more infected Individuals, the Cooties spread to other PDAs thus providing students with the opportunity to observe and create mathematical models for predicting how long it will take for everyone to be infected, and to pinpoint where the Cooties originated. Other simulation programs support more traditional textbook topics by allowing the students to adjust variables such as gravity coefficients and then examine the resulting effect on falling objects.

Spreadsheets

One of the more common tools used in mathematics classrooms is the spreadsheet. Both free and nominally priced spreadsheet packages are available on-line and tend to vary in power. The more expensive versions run approximately $50 and have nearly as much power as common desktop versions. These applications also have the ability to dump data directly into spreadsheets such as Excel or MS Works. Even some of the free versions of PDA spreadsheets have graphing and logic capabilities, which make them an attractive option for linking textbook topics and problem solving. Curriculum designed for spreadsheet use on desktop computers would require very little modification and could be assigned as homework, allowing for more productive use of class time. Secondary level mathematics methods students were encouraged by the ease of which they were able to learn and use a free version spreadsheet, as well as to develop some simple curriculum related to amortization tables. These students were a bit concerned that free versions of spreadsheets tended to be limited in the number functions currently available. Trigonometric, statistical, and logic functions were routinely omitted by the free versions.

Games

In addition to the common drill and practice games, free game applications such as Code Cracker allow students to have fun in a mathematical modeling and problem-solving environment. Secondary level mathematics methods students at the University of Nebraska at Omaha competed in a contest to see who could develop the most efficient algorithm for cracking a four-digit code. Ensuing discussions among class members yielded some interesting revelations about how an effective mathematics curriculum should look. From a methods standpoint, the code cracker activity had some very productive pedagogical byproducts. Other strategy games such as Backgammon, checkers, and various card games are also extremely abundant, but have yet to show any real curricular potential past enrichment.

Peripheral Utilities

One of the most exciting aspects of the PDA is the availability of peripheral devices, which have so much potential for mathematics and science education. It is becoming more and more clear that the manner in which students collect data in the mathematics classroom can be a very motivating force for
learning. PDA’s now have peripheral devices including Global Positioning System (GPS), digital cameras, digital voice recorders, a whole line of probes for temperature, turbidity, acidity, sound level, etc., and even robots that can be controlled with various program applications. All of these peripheral devices are attached directly to the PDA using the same pin connector as is used in the HotSync cradle. Managing software is included with each device, and in many cases works in unison with other PDA applications. The probes, used primarily for science activities, are still somewhat costly but allow for dynamic field experiences that would otherwise be impossible using traditional desktop computers. These probes are similar to the probes used for graphing calculators but provide greater flexibility in the collection and interpretation of data. The camera and voice recorder devices are relatively small and are primarily used as qualitative data collection instruments. Free software is available at hi-ce.eecs.umich.edu that allows pictures taken with the PDA camera to be annotated. Finally, with robotics being so pervasive in fields such as manufacturing, law enforcement, and medicine, programming robots in the classroom could provide some interesting avenues for students to investigate mathematical topics. Robot kits are currently available for use with the PDA and cost about $260. Once built, different software applications allow students to steer the robot using the stylus or even to examine how a robot learns using sensor technology. The applications for supporting traditional curriculum in the area of robotics are certainly limited, yet innovative teachers may see these as opportunities to motivate students in a more exciting way than ever before in an otherwise dry subject discipline.

Conclusion

With so many possible features yet unexplored, PDA’s can almost certainly be thought of as a kind of 21st century Swiss Army knife for classroom technology. The utility and power of these devices goes far beyond any type of technology that has been used in mathematics classrooms to date. No longer will technology based activities need to be contrived, or forced to fit within the parameters of traditional textbook curriculum, but rather they will be supported and made more efficient by a type of technology that allows for seamless transfer of data from one type of application to another and from one subject discipline to another. One would speculate that with appropriate consideration of curriculum, we have begun to tap a source that will revolutionize mathematics education in America.
Using Online Discussion Forums to Develop Teachers' Understanding of Students' Mathematical Thinking

Jeffrey C. Shih
Department of Curriculum and Instruction
University of Nevada, Las Vegas
United States
jshih@unlv.edu

Abstract: This paper is a report of the findings in a study of the development of online discussion forums to help create learning communities that provide professional development for pre- and inservice elementary school teachers in mathematics. With the support of a PT3 mini-grant, this study was designed to create opportunities for pre- and inservice teachers to build their understanding of number, number sense, computation, problem solving and mathematical communication, as they engaged with their colleagues in both monthly and online workgroup meetings. Three findings from this study are: sufficient time is necessary to establish a learning community, technology issues are a potential constraint in the successful development of a learning community, and specific mathematical tasks are better suited for the online discussion format.

Introduction

As part of the Principles and Standards for School Mathematics (NCTM, 2000), the standard for the responsibilities of colleges and universities includes the need for mathematics education faculty to be a part of school-based mathematics communities. "Teacher educators, mathematicians, and practicing teachers working together can create a rich intellectual environment that will promote veteran teachers' growth and demonstrate to new teachers the value of learning communities." (NCTM, 2000) Until recently, the development of these learning communities was accomplished through face-to-face interaction. This paper will describe the use of online discussion forums to help create learning communities that provide professional development for pre- and inservice elementary school teachers in both content and pedagogy reflected in the Principles and Standards for School Mathematics of the National Council of Teachers of Mathematics. With the support of a PT3 mini-grant, this study was designed to create opportunities for pre- and inservice teachers to build their understanding of number, number sense, computation, problem solving and mathematical communication, as they engaged with their colleagues in both monthly and online workgroup meetings.

The Study

Twenty inservice elementary school teachers from an urban, at-risk school participated in the study. The Hispanic population of the school is forty-two percent, while twenty-seven percent of the students participate in English as a Second Language curriculum. Forty-seven percent of the families are in the low-income bracket. Sixty percent of the students fall in the below average or average group in ability level in mathematics. 35 pre-service teachers enrolled in undergraduate mathematics methods classes also participated in the project.

Each month the participating pre- and in-service teachers were given a problem to pose to their class in preparation for the in-person workgroup meeting. The problem provided mathematical focus, an opportunity to examine trajectories of students' understanding, a challenge to teachers' expectations and a way to talk about details of mathematical thinking. Having a problem to pose to their students also immediately engaged the teachers in thinking about the relationship between their children's mathematical thinking and their classroom
practice. Posing the problem led teachers to see that their classrooms could be a place that they could learn with their students.

Concurrently, the inservice teachers used digital cameras to upload examples of their student work to a private web site. As part of their elementary mathematics methods course, preservice teachers examined the students' solution strategies and related them to the NCTM Standards and research-based frameworks of the development of student understanding (Carpenter, et. al., 1999).

Threaded on-line discussions between preservice teachers, inservice teachers, a mathematics education professor, a mathematics professor and the principal of the school took place on the web site, focusing on both content and pedagogical issues. These experiences, in addition to visits to inservice teachers' classrooms, enhanced the preservice teachers' undergraduate training and focused them on "real" student work and student learning.

All of the participants attended monthly one and a half-hour workgroup meetings. The teachers began the workgroup meeting by filling out a reflection sheet that asked focused questions about their own student work or the examples provided on-line. Discussion of the student work followed for approximately one hour. The discussions were centered on the mathematical strategies evident in the student work. The range of strategies was documented and the discussion focused on how the strategies were mathematically similar or different from one another. The existing research documents the effectiveness of using students' mathematical work to support teacher learning (Franke, Carpenter, Fennema, Ansell & Behrend, 1998; Lehrer & Schauble, 1998; Sherin, 1997). Pedagogical issues were also discussed as they were raised in the workgroups. Each meeting concluded with the teachers summarizing verbally and on paper what they learned during the conversation. As the pre- and inservice teachers developed content knowledge, appropriate pedagogical strategies addressing the process standards of problem solving and mathematical communication within the context of the teachers' classrooms were also modeled.

Findings

There are three main findings that come from the current study of the development of on-line learning communities: sufficient time is necessary to establish a learning community, technology issues are a potential constraint in the successful development of a learning community, and specific mathematical tasks are better suited for the on-line discussion format.

The first finding is common to all professional development projects: sufficient time is necessary to establish a learning community. Even with the best of intentions, instantaneous familiarity between pre-service teachers, in-service teachers, administrators, education professors and mathematics professors is not possible; "sustained, intensive professional development" is very difficult to achieve in one academic year. While things are moving in the right direction at the host school, more time is necessary for change to occur. Fortunately, the current project has been extended for another year.

Though effort was made to facilitate the use of technology in the study, logistical constraints made ongoing threaded discussions difficult. The initial workgroup meetings and technology orientation sessions took place in the computer lab of the host elementary school. While the pre-service teachers were regular contributors to the threaded discussion boards, in-service teacher participation was sporadic. At first, the assumption was made that this was because of familiarity with the technology. However, after examining the computers in the in-service teachers' classrooms, the discovery that the discussion board software required 4.5 browsers provided an explanation for the lack of participation: 4.0 browsers were found on all of the classroom computers. The in-service teachers assumed that their computers were simply slow. For them to effectively participate in the discussion boards, they would have to log on either in the computer lab or in the teachers' lounge. The continuity of the threaded discussions was affected by availability of the technology.

Finally, certain mathematical tasks are better suited for the on-line discussion format. There are a limited amount of tasks that can be shared among pre- and inservice teachers that truly serve both populations. Posing a word problem to use as a context for the discussion of the development of children's mathematical thinking is effective for one continuous group of pre- and in-service teachers. In the ongoing study, a new class of pre-service teachers begins in the spring semester. The new pre-service teachers require a shift in the on-line discussions, since they have neither the experience nor the familiarity with the research frameworks on the development of student thinking. Contrast this to the beginning of the project when the pre-service teachers
were more familiar with the research-based frameworks and offered these perspectives to the in-service teachers.

**Discussion**

On-line discussion forums are promising in the context of professional development and creating on-line learning communities. As with other forms of professional development, there are both logistical and methodological concerns about their success. Time and access to technology are two fundamental concerns in the development of on-line learning communities. Clearly, further study is necessary to better understand the interplay between the use of technology and participation in a learning community.

Technological Dilemmas:  
A Guide to Selecting and Implementing Resources for Secondary Mathematics Instruction

Tobin White  
Stanford University  
twhite@stanford.edu

The NCTM Principles and Standards Vision for School Mathematics (2000) posits classrooms where all students have access to computer and calculator technologies, and where those technologies play an essential role in instruction. Examples of the effective integration of such tools into the teaching and learning of mathematics appear throughout the document. But any well-intending teacher or school inspired by this vision and equipped with a budget for such resources, on turning to the array of software titles and calculator resources on the market, faces a daunting pair of questions: How does one know what to buy? Trickier still, once the purchase orders are signed, the calculators removed from their packaging, or the software installed, how will these new tools be best used?

This paper emerged from an effort to provide preservice mathematics teachers with a framework to guide the selection and implementation of new technologies in the classroom. I propose a framework that actively engages teachers in the process of navigating the contested ideological and pedagogical waters of decision-making about technology. I argue that the complexity for practitioners of identifying the most appropriate technological resources for their students’ needs, and incorporating those resources into instruction, is organized around several fundamental dilemmas for secondary math instruction. Many authors offer compelling sets of general principles and criteria by which to judge new technologies (e.g., NCTM 2000, Rubin 1999, Linn et al 2000, Nickerson 1995), each representing a clear and coherent vision of the best of contemporary insights into the teaching of mathematics. By virtue of their generality, however, they inevitably fall short of firm answers to many complex questions that can at best only be answered within the highly localized, diverse, and shifting contexts of particular classrooms.

Larry Cuban has distinguished between the “tame” and “wicked” problems faced by educational practitioners (Cuban, 2001). Problems classified as tame are generally resolvable when given proper time, research, discussion, or resources. Wicked problems, or “dilemmas”, on the other hand, prove far more intractable. Such dilemmas, rather than ever achieving elegant resolution, demand difficult choices and sacrifices in order to patch together working compromises. More pointedly, while the thorniest dilemmas might be resolved in principle through the application of lofty guidelines, in the reality of school practice they are generally impossible to overcome without giving up at least some principled ground. To address this challenge, I frame the decision-making process for teachers in terms of tensions between competing poles, approaches, and outcomes, each of which potentially represent dilemmas of this sort for selecting and implementing technology. These dilemmas include: developing students’ procedural skills versus teaching for understanding; using technology to promote equity versus widening the technological divide; individualizing instruction versus fostering cooperative learning; and informed use of tools versus dependence on tools.

These four sets of tensions reflect the major concerns behind many of the principles and criteria cited above as they apply to technology in math education. They are also intended to evoke some of the research that has framed and the rhetoric that has polarized debate over secondary math instruction in recent years (Battista, 1999; Becker & Jacob, 2000). The scope of these dilemmas is by no means exhaustive, but they do crucially frame many of the decisions teachers must make as they seek to draw technological resources into their practice. Lampert (1985) has argued that the key for teachers selecting between the alternatives forced by dilemmas lies in not choosing at all; in her framework such problems that emerge from practice can only be resolved in practice, through temporary, ad hoc, and improvisational moves that depend on the context of a particular classroom and the instincts of a particular teacher. Drawing on the insights offered by exploring these dilemmas, I offer a model for generating technology evaluation frameworks that balance the goals of principle against the necessities of practice. Using a common tool from the contemporary classroom, namely an assessment rubric, I locate the software evaluation process within the bounds of teacher assessment practice in order to highlight the ways technological dilemmas might best be resolved in practice.
Dilemmas

Procedure versus Understanding. A recurring theme in the accounts of computer-supported learning reviewed above is that the ideal contributions of instructional technology should be those which lead to deeper student understanding of mathematical concepts. Many authors make the argument even more strongly, stressing as Andee Rubin (2000) does that new technologies which simply replicate old pedagogies, even by making them more efficient or otherwise more effective, are not worth developing, given the importance of finding ways, technological or otherwise, to improve instruction through radical change and the potential of computer technologies to support such changes. As one author puts it, “given our sorry record of teaching mathematics and science, it is clear that changes in kind are needed. Changes in degree, helpful though they may be, simply are not sufficient” (Perkins et al., 1995).

But what does this mean for a teacher who, for example, believes drill-and-practice software program might shore up crucial skill deficiencies and enhance performance on high-stakes standardized tests for some or all of her students? Should she, say, embrace occasional or even regular use of a computer resource that targets procedural skill development through repetitive multiple-choice problems, and provides tutorial support only through textbook-style lessons? Or should she restrict her use of computer-based technologies to those resources (provided she can find and afford them) which emphasize higher-order reasoning, discovery learning or open-ended problem solving? The kind of procedurally oriented programs this teacher might seek emerge from a lineage grounded in behaviorist learning theory and process-product models of educational research. Such software has evolved over four decades from routine and repetitive exercise delivery that characterized the early use of computers in math instruction to contemporary efforts at intelligent computer-assisted instruction, and still thrives in a variety of more and less sophisticated forms today (Scott et al. 1992).

In a comprehensive review of literature on the cultural context of computers in education, Scott, Cole, and Engel (1992) worry that while drill-and-practice programs may be of some value, they are too often used in the absence or at the expense of developing higher-order reasoning and concepts. More recent research and innovation point to a variety of alternative approaches to software-based instruction which promise to engage students in more meaningful learning. Enumerating examples of more effective uses, various authors laud the power of software to facilitate discovery learning for deeper understanding (Nickerson, 1995); to encourage students’ moves from conjecture and hypothesis to abstraction and proof (Schwartz, 1995); to embed mathematical concepts in data, simulations and other real-world contexts (NCTM 2000, Rubin 1999); and to mediate students’ developing understanding of concepts such as functions through multiple representations (Goldenberg, 1995). These and other alternatives to tutorial and drill-and-practice software certainly show revolutionary promise grounded in learning theory and increasingly supported by examples of successful practice (Bransford et al., 2000). But the idealized learning scenarios envisioned by the proponents of these technological innovations don’t necessarily come ready-made for incorporation into the classroom as many teachers know it; they may require corresponding curricular, pedagogical and even institutional revolutions in order to be fully realized in many schools. For many teachers, the massive effort required to bring about such changes may be at cross-purposes with their need to keep up with the daily challenges of a relentless job. And even granted the value of these technological innovations for student learning, they may not erase the challenges for our teacher struggling under district and administrative pressure to raise test scores or solidify basic skills.

Equity: Technological Solutions versus the Technological Divide. While ‘Equity’ and ‘Technology’ are listed separately among the NCTM’s principles (2000), the elaboration of the equity principle articulates a vision through which “technology can help achieve equity in the classroom” by widening the range of learners to whom high-level mathematics can be made accessible and engaging. Of course, technology cannot increase all students’ access to mathematics unless all students have access to technology. Indeed, this claim in the 2000 NCTM standards builds upon a call made by the same organization a decade earlier for calculators and computers to be made available to every student, and for the presence of a computer for demonstration purposes in every classroom (NCTM, 1989). The overlap in NCTM’s principles is hardly surprising; technological issues are often difficult to separate from economic ones. Financial resources are a necessary precursor to access to computer technologies, and technological skills arguably enhance students’ future access to financial resources by qualifying them for high-paying jobs (Office of Technology Assessment, 1988; Stone, 1998). We must endeavor to incorporate technology into instruction in ways that interrupt rather than replicate this closed circuit.

Any truly equitable vision of technological implementation should ideally begin with the assumption that all students have equal access to the technology in question. Such a starting point, sadly, is far removed
from reality. While wealthy or well-funded schools might purchase graphing calculators for every student, and maintain large computer labs, schools in poorer districts may not be so lucky. School resources aside, students from middle and upper class families can more easily afford their own graphing calculators and computers at home, while students from lower income families may only have access to such tools in the classroom, if at all. This disparity means that those students with easier access to calculators and computers will likely feel more at ease and have greater facility working with such tools. Hence, when a socioeconomically diverse group of students encounters instruction with such technologies, those tools may only exacerbate the consequences of unequal access and the resulting disparity in technical skill and comfort among students (Bromley, 1998).

Given this context and the prohibitions imposed by the cost not only of purchasing instructional technologies but also of training teachers in their effective implementation, innovative computer programs risk enhancing the learning only of certain students, namely those students sufficiently privileged to access them. Likewise, even when all students have equal classroom access to software or other tools, socioeconomic or other disparities may mean that some students will benefit more extensively from using those resources than others. Indeed, in an open software market, the more exotic, sophisticated, innovative, and unique the technology, likely the more expensive, and thus quite possibly the more likely it will only land at the fingertips of a select few students.

If computer software and calculators are to help ameliorate rather than accentuate these overlapping technological and mathematical divides, they must be adopted strategically, and often in ways that specifically target the needs of disadvantaged students. The NCTM equity principle emphasizes the power and the potential of technology to remedy equity concerns by making mathematical ideas and representations more accessible, more engaging, and more easily shared by a wide range of learners. Still, such potential never resides in the technology itself, but rather in the form of its implementation, and the most equitable ways to implement technology are no more easily deduced than the most equitable ways to teach mathematics. To return to the problem posed in the previous section, some authors have recently suggested that, by making the codes of the classroom and the rules for successful mathematical performance explicit, instruction which emphasizes repetition of algorithms and procedures may actually be more equitable than pedagogical strategies geared toward more open-ended problem solving and reasoning (Lubienski 2000). Boaler (2001) counters that these arguments, in highlighting the ways students might fail to achieve in classrooms that emphasize open-ended work, overlook the more crucial question of how educators might implement alternatives to procedural instruction more equitably. Seeking support for low SES students in procedurally-oriented software also may lead to a situation in which, as Scott et al (1992) caution on the basis of a 1984 Center for the Social Organization of Schools study, “wealthy and poor schools have equal numbers of computers but poor children spend their time on drill-and-practice exercises while better-off students spend their time in more meaningful activities.”

**Individual versus Collaborative Instruction.** Just as efforts have been made in recent reforms of math curricula to shift focus from procedural or skills-based forms of mathematics instruction to those emphasizing reasoning and open-ended inquiry, those same reforms have likewise noted the value of complementing individual student work with group classroom activities (NCTM 1989). Rather than suggesting that instruction should be organized only around individuals or only around groups, calls for math education reform generally stress the importance of appropriately balancing these different pedagogical strategies (NCTM 1989; NCTM 2000). A recent volume summarizing research in learning points to studies indicating that problem-solving and reasoning strategies may be more effectively developed when students work in groups than individually, but cautions that group work may also inhibit learning in certain contexts as well, especially in early grades. Ultimately, the authors conclude that many questions about the relative benefits of group and individual work in various instructional contexts require further research (Bransford, et al 2000). The 1989 NCTM standards take a similarly balanced view to these instructional approaches as they apply to the use of computer-based resources, simply stressing that “every student should have access to a computer for individual and group work” (p. 8). But some research suggests a stronger stance on this instructional divide. Scott, Cole, and Engel (1992) cite two early studies which indicate that given the potential benefits of pair and small-group work on computers, the optimal student-to-computer ratio may be higher than one, and that the use of individually oriented software such as drill-and-practice programs is likely to be out of synch with the goals of sophisticated and effective teaching practice. On the other hand, computers are designed primarily for single-user interface, and challenges ranging from the tendency of many software programs to target single users to negotiations over who gets to type at the keyboard or handle the mouse make group work on computers potentially difficult to implement in practice. More practically, implementing computers into both
collaborative and individual work will likely require multiple software packages, and will certainly require multiple schemes for integration into instruction. And of course, while one computer per student may be ideal, financial limitations often stop the achievement of that ideal far short of reality. Once again, teachers are faced with the endlessly complex challenges of resolving different, though potentially complementary, instructional practices against practical constraints.

Dependable Tools versus Tool Dependence. One of the most distinctive new features of the secondary math classroom over the last two decades has been the increasingly widespread use of calculators and computers as problem-solving tools. In addition to those software programs which facilitate either drill-and-practice, adaptive tutoring, or more open-ended exploration of concepts, teachers have made extensive instructional use out of software and graphing calculator features which allow for the exploration of functions, data, and equations through graphical utilities, spreadsheets, probe devices, and symbolic manipulators. These technologies not only facilitate new forms of teacher-led multimedia demonstrations and exploratory activities for students, but also place at students’ fingertips the power to easily solve most problems from the pre-calculator and computer high school math curriculum with a few keystrokes. Many advocates of curricular reform see the advent of these technologies as a tremendous opportunity to push classroom activity toward more sophisticated mathematics and deeper student understanding. They argue that working with calculators and computers can foster powerful learning in the context of real data and meaningful models, increase the availability of students’ attention for higher-order thinking by reducing the need for rote procedures, and provide students with essential skills for an increasingly technical world (NCTM 1989, 2000). Other educators and policy makers disagree, however, cautioning that scientific and graphing calculators and computer algebra systems may encourage tool dependence rather than skill mastery or sophisticated thinking (California State Board of Education, 2000).

Solutions

Some of these dilemmas may ring in our ears with more authenticity than others depending on the classroom contexts with which we are best acquainted, and that is precisely my point—the dilemmas themselves are as situational and emergent as their solutions. To that end, the approach I propose to educators for navigating these dilemmas as they attempt to make decisions about technology involves categorizing aspects of mathematics instruction that may be addressed by computer-based resources, and that attend to the concerns raised in the preceding section. In keeping with my theme of locating problems in practice, I borrow an educational practitioner’s tool, the assessment rubric, to provide evaluative descriptors for a range of potential ‘performances’ for a given software package. In the sample rubric shown here (Fig. 1), criteria are provided for evaluating two different axes of performance keyed to the features different computer resources might variously emphasize: collaborative learning and individualized instruction. Other useful categories within which to consider software in a complete rubric might include skills and procedures, real-world connections, multiple representations and learning styles, problem solving, interactivity, assessment features, flexibility, and so on.

<table>
<thead>
<tr>
<th>Unsatisfactory</th>
<th>Satisfactory</th>
<th>Exemplary</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Collaborative Learning</strong></td>
<td>Designed exclusively for use by a single student per computer with no instructionally useful avenues for student-to-student interaction</td>
<td>Includes some lessons or activities which may encourage cooperative investigation or stimulate meaningful discussion among two or more students</td>
</tr>
<tr>
<td><strong>Individualized instruction</strong></td>
<td>Organizes lessons and work into a highly linear or inflexible structure, offers little freedom for navigating, self-pacing</td>
<td>Offers some curricular flexibility, allows students to work at their own pace and repeat or skip lessons as needed</td>
</tr>
</tbody>
</table>

Figure 1: Sample software assessment rubric

The crucial features are that each category should reflect the various and potentially competing priorities that compose the dilemmas of technology selection, and that educators should have the freedom to select and prioritize these categories in accordance with their instructional goals and school or classroom constraints. In this way, rather than constraining teachers or forcing them into dilemmas, a software evaluation rubric designed
in accordance with global principles and research results should free them to select and implement resources in ways that are most appropriate for their students. To take the opposing poles of one of my dilemmas as an example, collaborative learning and individualized instruction are now posed not as competing alternatives in the quest for the ‘best’ uses of technology in instruction, but rather and more simply as distinct axes of software performance. Two different teachers might decide to emphasize one or the other of these uses, respectively, in evaluating software, and thus place higher priority on reviewing one category or the other, while a third teacher interested in both collaborative and individualized uses of software might focus on evaluating a package’s performance in both categories while perhaps placing less weight on the effectiveness of other features.

One of the keys to the reliability of a rubric is that it be tested against a large sample by multiple judges; the sample here is still only in the earliest stages of such development (Wiggins, 1998). But with continued refinement, a rubric of this sort might serve at least two powerful purposes. By making performance standards explicit along a range of instructional categories, this evaluative mechanism should serve not only as a flexible tool for technological decision making for educators, but also as a guide to software designers that might help them to better account for the realities of the classrooms into which they might insert their products. Just as assessment rubrics in the classroom provide students and teachers with a common frame of reference for exemplary performance standards, the same assessment tool might be used in technology evaluation to raise the bar for design and instructional implementation alike.

SECTION EDITOR:
Sara McNeil, University of Houston

Recently, I received an email called “Just a hundred years ago.” In the message, the writer used historical facts and data to recount what life was like 100 years ago. It was informative and often surprising to realize that everyday products such as crossword puzzles, canned beer, and iced tea hadn’t been invented in 1902. In contrast, marijuana, heroin, & morphine were all available over the counter at corner drugstores. The average life expectancy in the United States was 47 years, and only 14% of homes had a bathtub. Only 8% of the homes had a telephone, and a three-minute call from Denver to New York City cost $11.00 at a time when the average wage in the US was 22 cents an hour. In the United States there were 8,000 cars, 144 miles of paved roads, and the maximum speed limit in most cities was 10 mph. The writer ended with the question, “Wonder how much it will change between now & the year 2102?”

That article was the catalyst for this introduction to the papers accepted for the New Media Section of the 2002 SITE Proceedings. I shortened the timeline to a decade since technology changes so rapidly and asked, “What was new media like when the third annual conference for SITE was held in 1992?”

1992: The Beginning of the New Media Explosion

The Internet
Although Tim Berners-Lee wrote the initial prototype for the World Wide Web in 1990, a graphical interface was just a vision in 1992. At the University of Minnesota, a team led by computer programmer Mark MacCahill released “gopher,” the first point-and-click way of navigating the files of the Internet in 1991. MacCahill called it the “first Internet application my mom can use.” Also in 1991 Tim Berners-Lee, working at CERN in Switzerland, posted the first computer code of the World Wide Web in a relatively innocuous newsgroup, “alt.hypertext.” Many computer programmers were excited by the potential to combine words, pictures, and sounds on Web pages, and they saw the potential for publishing information on the Internet in a way that can be as easy as using a word processor. And the rumble begins...

In 1992, the number of host computers on the Internet passed the 1 million mark, and there were about fifty World Wide Web servers. In December 2001, the number of web servers is estimated to be over 36 million. In 1993, students and staff at the University of Illinois’ National Center for Supercomputing Applications created a graphical user interface for Internet navigation called NCSA Mosaic. It’s not until 1994 that Jim Clark and Marc Andreessen found Netscape Communications, and the first Netscape browser becomes available.

Personal Computers
Speed has always been an issue, but in 1992, the Pentium chip was just a dream. The standard was Intel’s i486 and iPSC/860. In late 1991, Apple released its first generation of PowerBooks that were an instant success. The PowerBook 145 had a CPU speed of 25 Mhz and maximum RAM of 8 MB. In contrast, the 2001 PowerBook G4 has a CPU speed of 667 Mhz with a maximum RAM of 1 GB.

Personal Digital Assistants
Although the Sharp Wizard with a small LCD screen and a tiny keyboard was developed in 1988, the term “personal digital assistant” or “PDA” was first coined by Apple CEO John Sculley who drove the development of the Apple Newton. The Newton was the first organizer to include a touchscreen and handwriting recognition software. In April 1996, a small company called Palm Computing took the idea of the Newton, shrunk it, made it more functional, and halved Newton’s price to produce the first modern PDA, the Palm Pilot.

Computer Viruses
The first computer virus, known as the Brain virus, was created in 1986, and many other viruses with strange and exotic names such as Dark Avenger and Frodo followed. In 1992 the Michelangelo virus created mass hysteria; United Press International filed a newswire saying “hundreds of thousands of
computers around the world" might fall victim to Michelangelo on March 6. But contrary to media hype, the virus
did not cause significant damage. In 2002, there are over 57,000 virus definitions listed on the Symantec web site
and topics such as “The Economics of Information Warfare” are posted across the Web. http://
securityresponse.symantec.com/

Programming and Software Development
In 1992 Microsoft introduces Windows 3.1, and more than 1 million copies are sold within the first two months of
its release. Bill Gates is the second richest man in the United States, with a net worth estimated at more than $4
billion. Word 5.0 is released in 1992 and featured a built-in grammar checker; a drawing window for simple
graphics, and search-and-replace formatting.

Adobe Photoshop 1.0 was shipped in February 1990 after 10 months of development by Thomas and John Knoll.
In 1993, Version 2.5.1 and the first release of a Windows version of Photoshop dazzled users. It is not until 1994
that Version 3.0 ships with the “layers” capability.

In 1992, the company, Authorware, created by one of the developers of PLATO, Dr. Michael Allen, merged with
the Macromind company. The merger resulted in the formation of a new company called Macromedia. Because
Macromind was already an established producer of multimedia tools, the merger helped solidify Authorware's
place in the interactive multimedia market.

Video
In 1992 the first audio and video broadcasts took place over a portion of the Internet known as the “MBONE.”
Two years later, in 1994, the Rolling Stones broadcast the Voodoo Lounge tour over the M-Bone. The camcorder
reached its voyeuristic heights on March 3, 1991, when George Holliday caught a trio of Los Angeles policemen
beating a motorist named Rodney King. The resulting furor prompted police departments across the country to
install video cameras in their patrol cars and consumers to start using camcorders to record civil disturbances. As
the quality of the footage produced by camcorders increased, many shoe-string cable organizations started to employ
.camcorders instead of professional video equipment. In 1992, Sharp became the first company to build in a color
LCD screen to replace the conventional viewfinder.

E-Commerce
Until 1991, corporations wishing to use the Internet faced a serious problem: commercial network traffic
was banned from the National Science Foundation's NSFNET, the backbone of the Internet. In 1991 the NSF lifts
the restriction on commercial use, clearing the way for the age of electronic commerce. In 2002, e-commerce is
projected to exceed $1 trillion in the next few years.

The New Media Section of the 2002 SITE Annual
The topics of the papers accepted for the New Media section of the 2002 SITE Annual reflect these changes in the
software and hardware capabilities and features, but overall they reflect the same concerns and search for innovations
that were discussed in the 1992 Annual. Several papers such as the Advapize Profiling Tool for Teacher Education, the
Web-based SMIL Tutorial, and Using Advanced Screen Capture in Support of Educational Technology Instruction grapple with
creating new software applications to enhance learning. Others such as More Than a Movie: Using Animation to Promote
Learning of Complex Subject Matter, MediaMakers Produce CareerCommercials: The Softer Side of Technology, and The Benefits
of Streaming Media in E-Learning wrestle with using new media effectively to promote learning.

Virtual Reality in Education: Exploring QTVR as a Tool for Teaching and Learning

Naglaa Ali, University Of Florida, US
Richard Ferdig, University Of Florida, US
Gail Ring, University Of Florida, US

One of the reasons multimedia has been so successful in education is the dual coding aspect of information processing theory (Bagui, 1998). According to this theory, humans take in information from the environment through their sense organs: the eyes, ears, taste buds and nerves in the skin. This information then goes into short-term memory and is eventually processed into long-term memory, becoming the person’s knowledge base. The more senses involved in the learning process, the better the learning experiences. VR (Virtual Reality), a technology that encompasses numerous media, evokes multiple senses as opposed to more traditional methods of learning that generally involve the use of a single sense, such as sight (Rodriguez, 2001).

Researchers are now beginning to explore various learning opportunities through virtual reality. For instance, "VR in the Schools", a quarterly publication of the Virtual Reality and Educational Lab has recognized the impact and potential of VR and has begun to research new medium for incorporating VR productively into the learning process.

Others have also defined many benefits of using VR in the teaching and learning process. Follows (1999) suggested four such benefits:

- Provides the students with context for the learning process to take place.
- Allow students to control the learning process.
- Makes learning a personal experience for the student.
- Accommodate a wide range of student learning styles.

Technologists have considered the potential of using VR in the classroom, and many projects are currently exploring the educational uses of VR:

- The Virtual Reality Skeleton Project (Rodriguez, 2001) at http://www.lib.uiowa.edu/commons/skullvr/background.html is a computer-based tutorial to help students learn the anatomy of the human skull.
- TerraQuest's Virtual Galapagos at http://www.terraquest.com/galapagos allows a visitor to study the ecology, wildlife, history and geology of the Galapagos Islands.
- Wright State University's Anatomy Department at http://www.anatomy.wright.edu/QTVR/qtvr.html have suggested that advantages of VR include a) allowing students to visual abstract concepts, and b) allowing students to interact with events that distance, time, and/or safety factors make unavailable.

QuickTime Virtual Reality (QTVR) is a technology that allows users to explore virtual reality. QTVR developers can create and display 360-degree views of objects or panoramic scenes that can be manipulated and navigated. With this technology, it is possible for teachers and students to share classroom projects that others can rotate and examine. It is also possible for users to look at various environments (a classroom, a different country, outer space, etc.) without the need to actually be there. QTVR software allows designers to construct three-dimensional representations of objects from two-dimensional photographs. QTVR is a wide reaching educational tool that can be used not only in a large variety of locations, but also in a large variety of situations to attain multiple educational goals.

This workshop will introduce attendees to VR, and specifically QTVR. After completing the workshop attendees will be able to:

- Explain how QTVR works.
- Produce QTVR movies (panorama and objects).
- Determine ways in which they can use QTVR at school.

Tutorial Description:
Phase I – Whole group session

In Phase I we will address the basic principles of Virtual Reality. We will discuss the hardware and software that are required to produce VR, as well as some of the design principles associated with developing virtual realities. Participants will be introduced to a number of current projects in virtual reality. During these initial phases, we will also introduce QTVR, and describe the creation of QTVR objects and panoramic scenes. Participants will be exposed to the complete process of developing QTVR products. For instance, the audience will participate in the process of planning the scene to be shot and the shooting process.

Phase II - the production process (Two participants for one computer)

Participants will have the opportunity to create their own QTVR production. The participants will be given images (to make a QTVR panoramic movie and QTVR object movie as well). The steps they will go through will include: “pre-production and planning”, “production”, and “post production”. In this Phase, participants will:

- Familiarize themselves with the nuances of QTVR development.
- Develop a QTVR panorama.
- Develop a QTVR three-dimensional object movie.

Phase III – Whole group evaluation:

After the groups have completed their individual tasks, they will come back together to discuss the following:

- Identify ways in which VR and QTVR can be utilized in the classroom.
- Utilize applications and web sites that support VR & QTVR.
- Incorporate the many uses of VR & QTVR into their lessons.
- Evaluate the effectiveness of VR & QTVR as a learning tool.
- The participants will have the opportunity to present and share their QTVR movies.

Abstract:

Virtual Reality (VR) is an extremely useful and easy to use tool for classroom settings, because of its ability to show situations that would not otherwise be easy to imagine. This characteristic of VR enables a large variety of topics to be taught to students, who would otherwise struggle to visualize the information being presented. VR is also very useful in settings where student experience with technology is not advanced. QTVR, one example of VR, will be demonstrated. In this workshop we will give the attendees general ideas about VR and QTVR, have them brainstorm ideas about the applications of QTVR in their field. We will then have them take pictures and create QTVR movies (panorama and object). After finishing this workshop will give the attendees a survey about their perceptions of how they will incorporate QTVR movies in the teaching and learning process.

Hardware and Software for QTVR

Digital Images: Pictures for QTVR production may come from digital cameras, scanned pictures, video cameras, or Kodak PhotoCD (camera film processed on CD-ROM discs). In the workshop we will use Digital Cameras to produce the pictures needed for the producing of QTVR.
Computer: A Power Macintosh with enough RAM memory.

Software: Several choices exist currently. Most QTVR creation software is fairly easy to use. We will use VR Worx v2.0.

Tripod

Why not Virtual Reality?:
The Barriers of Using Virtual Reality in Education

Naglaa Ali
University of Florida
United States
naglaa@ufl.edu

Dr. Richard Ferdig
University of Florida
United States
rferdig@coe.ufl.edu

Abstract: In the near future, distance education has the potential not only to effectively deliver instruction than is done today, but also to bring people more closely together than traditional classroom education (VanderVen, 1994). Virtual Reality (VR) brings to distance education exciting possibilities that were once considered science fiction (Rigole, 1996). It has been used for years in military, government, medicine, psychology, industry, and networked entertainment programs, but it is fairly a new concept in education (Montfort, 2000). This paper explores various aspects of Virtual Reality including its definition, inception, current capabilities and future possibilities. This paper will also describe barriers of using VR in education and suggest new ways for integrating VR into teaching and learning. First, the paper will define the concept of Virtual Reality and its different types. In order to understand the implications of this technology, one must first understand the concept. Second the paper will address the benefits of using VR. I will describe what makes a good virtual environment, what prevents teachers from using this technology in their classrooms, and what recommendations exist for facilitating VR in classrooms. Finally, an example from education will be described highlighting the use of VR in teaching and learning.

Virtual Reality (VR) can be described as a multi-sensory highly interactive computer based environment, where the user becomes an active participant in a virtually real world. Freedom of navigation and interaction are essential for a computer environment to be characterized, as a VR environment system must offer an extension of our normal experiences, thus allowing as many degrees of freedom as possible to perform a given task (Whitelock, 2000). There are many types of VR systems, which are generally classified according to the types of technology employed to implement the system. Those systems include simulators and emulators, telepresence systems, CAVE systems, fully immersive systems, augmented systems and desktop and Internet VR systems (text-based VR and graphic-based VR). Depending on the level of the user’s participation and interaction with the virtual environment, VR applications are also subdivided into passive (learners have minimal control over the training event), explorative (enables students to explore and construct their own learning) or interactive environments (allows the learners to immerse themselves in the subject matter) (Whitelock, 2000). For purposes of this paper, the definition of VR is limited to the desktop and Internet graphic based VR. There are two types of desktop and Internet graphic-based VR:

1) VRML: (Virtual Reality Modeling Language) is a language for describing three-dimensional (3-D) image sequences and possible user interactions to go with them. Using VRML, you can build a sequence of visual images into Web settings with which a user can interact by viewing, moving, rotating, and otherwise interacting with an apparently 3-D scene. For example, you can view a room and use controls to move about the room, as you would experience it if you were walking through it in real space. Here are some websites that can give you more clear ideas about VRML while exploring some environments by yourself:
   - http://caad.arch.ethz.ch/~dave/heritage/world.wrl
   - http://www.finearts.art.vcu.edu/VRML/vrmlanintro.html

2) QTVR: QuickTime Virtual Reality (QTVR) is an Apple technology that allows users to explore virtual reality. QTVR developers can create and display 360-degree views of objects or panoramic scenes that can be manipulated and navigated. With this technology, it is possible for teachers and students to share classroom projects they can rotate and examine. It is also possible for users to look at various environments (e.g. a classroom, a different country, outer space.) without the need to actually be there. Check these website for more clear idea about the QTVR concept.
   - http://www.lib.uiowa.edu/commons/skillvr/background.html
   - http://www.terraouest.com/galanagos

Both types are important in education and serve as powerful tools for teaching and learning. Using the capabilities of VR technology allows people to expand their conceptions of the real world in ways that were previously impossible (McLellan, 1998). This power of VR technology provides several possible ways in which it can facilitate learning. It allows students to:
- Visualize abstract concepts.
- Observe events at atomic or planetary scales.
- Visit environment and interact with events that distance, time or safety factors make unavailable.
- Master, retain, and generalize new knowledge when they are actively involved in constructing that knowledge in learning by doing situation.
Develop participatory environments and activities that can only exist as computer generated worlds (thin gs and places with altered qualities).

Interact with a model that is as motivating or more motivating than interacting with a real thing. (Whitelock, 2000)

With all the benefits of VR technology, still there is still limited classroom use. Busy classroom teachers resist another instructional tool without appropriate provisions for training, preparation, implementation, and so forth (Auld, 1999). Teachers must understand the VR implications, and formulate a vision of where they want to go with it to enrich their own curriculum and their students' learning. School administrators must figure out the optimal application of virtual reality for each situation, while at the same time not falling into the trap of buying new technology for the sake of having new technology. Full of promise and excitement, using virtual reality in schools is a great challenge, but one that must be pursued (Sykes, 1999).

Even though teachers and administrators should learn the value of VR in classrooms, there are many reasons that limited the use of it:

- Teachers do not know how to implement the VR applications in their classrooms.
- The considerable gulf between educators and those who create the software and hardware they use.
- The cost of the VR hardware and software.
- The shortage of training workshops that train teachers how to create and use the new technologies in their classrooms.

Although these reasons limit the use of Virtual Reality in the classrooms, they are not impossible to overcome. Creating a simple VR environment is not a hard job. To create a VR environment:

1. Teachers must know what make a good virtual environment. A good Virtual Reality environment, is the environment that can (Follows, 1999):
   - Provide the learner with a reason to learn.
   - Provide the learner with context for the learning process to take place.
   - Allow the learner to control the learning process.
   - Develop the learner's ability to solve high-level problems.
   - Make learning a personal experience for the learner.
   - Model the complexities and uncertainty of working in the real world.
   - Accommodate a wide range of learning styles.
2. Select between the available types of VR systems that match their needs and capabilities and have a good impact in teaching and learning.

There are many ways that teachers can build a VR environment without the need of the expensive hardware and software. One of these ways is Using QTVR. QTVR software allows teachers and students to construct three-dimensional representations of objects from two-dimensional photographs. QTVR is a wide reaching educational tool that can be used not only in a large variety of locations, but also in a large variety of situations to attain multiple educational goals. Teachers can create their own VR environments that match the objectives, the curriculum, and their students' learning styles. Teachers can create these VR environments with their students. In this case the students can learn while engaging in the developing process.

One example of the development of virtual reality in education is the creation of the Educational Technology Department at University of Florida. Using QTVR, we created an online source for students, faculty, and visitors to explore the Educational Technology Department. The goal was to create an interactive web site that would allow users to view the department, and get information about it. One of the unique features of the virtual visit is the use of VR. Using a map, the user can click a VR location and explore it. We found motivation and learner interest increased using realistic, navigable VR environments. The low cost of creation and playback, as well as the broad installed user base of quick time, makes video-based QTVR technology a reasonable choice for education and training materials (Mohler, 2000).

Abstract: This paper describes a web-based Synchronized Multimedia Integration Language (SMIL) Tutorial that provides an interactive online guide which uses a learning-by-example approach to teach SMIL programming. It includes thoroughly explained sample code segments and a comprehensive example that integrates many of the media components that can be synchronized using SMIL. These components are illustrated graphically and by the code.

Introduction

This paper describes a web-based Synchronized Multimedia Integration Language (SMIL) Tutorial that provides an interactive online guide for SMIL programming. SMIL is a markup language that lets you control the location, timing and sequence of still images, video, and sound for use in web-based applications. It was developed by the World Wide Web Consortium (W3C) and enables Web developers to create multimedia content for delivery over the Internet. Typical uses of SMIL include applications such as Intranet/Internet training, marketing, real estate house tours, and distance learning.

This tutorial uses a learning-by-example approach to teach the SMIL specification. All the sample code segments written in SMIL are thoroughly explained. In addition there is a comprehensive example that integrates many of the media components that can be synchronized using SMIL. These components are illustrated graphically and by the code. Although the tutorial is considered to be a SMIL tutorial it covers more than just the coding. There are major portions of the tutorial that address the issues of capturing various types of media that one can include in a SMIL presentation.

The address of the SMIL Tutorial is http://138.87.169.67/smil. This tutorial is intended to provide an easy-to-follow, step-by-step tutorial for novice SMIL programmers. The SMIL Tutorial introduces SMIL syntax and the basics of SMIL programming. Using an interactive style, this tutorial provides fully commented easy to follow examples, and programming techniques. Both linear and random navigation are provided on every page so the user can easily find topics of interest.

Contents of the Tutorial

The SMIL Tutorial consists primarily of textual content explaining the basics of SMIL programming. SMIL is based on the eXtensible Markup Language (XML) and consists of files and streams of audio, video, text, or image content. These media elements are transmitted separately over the Internet providing more economical and efficient use of resources. Yet they are presented as an apparent seamless multimedia stream to the viewer.

The SMIL specification consists of XML tags that allow the definition of windows, multimedia elements, and their synchronization in time when displayed in a SMIL capable browser. There are a variety of applications that support the SMIL specification. One of the most popular is the RealPlayer by RealNetworks, which is the default player for this tutorial. SMIL requires a number of specific file types in order to support multimedia in the RealPlayer. These file types are thoroughly addressed in the tutorial and include the following: .rm (real media), .rp (real pix), .rv (real video), .rt (real text), and .smil (synchronized multimedia integration language).

A developer must devote the time to learn the language. In order to assist interested developers, this tutorial has been structured to not only address the syntax of the language but also to discuss other development issues. Some of the topics covered in the tutorial include:

- Acquiring media resources
- Converting various media elements to streaming media.
- Learning SMIL syntax
  - Adding text to a SMIL application
  - Adding audio to a SMIL application
  - Adding video to a SMIL application
  - Exemplifying the use of SMIL tags
- Putting it all together to create a multimedia presentation

The sections about acquiring media resources discuss creating visual and sound elements. The section about visual elements covers acquiring/creating pictures, animation, video and colors. Within this framework, there is information about creating the visual elements with a still camera and scanner, a digital camera, a video camera, or graphics programs. The section about sound elements covers acquiring/recording voice and music. It addresses the process of creating the accompanying sound elements by recording voice transcripts with a microphone and sound card, adding background music, or creating synthetic sound.

One section of the tutorial is devoted to the explanation of the process of converting traditional media files into streaming media files using Real Producer. The next section introduces/exemplifies SMIL syntax and provides numerous demos that showcase the capabilities of SMIL (See Figure 1). Finally, the major contribution of the tutorial is the section, which explains and demonstrates in detail the process of creating a SMIL application. This section presents a planning methodology, discusses the issue of bandwidth considerations, depicts the components of a SMIL application including all media resources and code, and demos the completed application.

![Figure 1: Tutorial Example Of The Use Of Tags](image)

**Tutorial Design**

The Tutorial is partitioned into the following 6 main sections: Introduction, Creating Visual Elements, Creating Sound Elements, SMIL File Types, Tags, and Putting It All Together. As the user proceeds through the Tutorial, these 6 choices are always available on the navigation panel at the left side of the screen. With the exception of the Introduction, each section has subtopics that show on the navigation panel when the user is in that section. Additionally, there is a menu bar at the top right side of the screen that offers the user the option of seeking supporting information. Specifically, the choices are as follows: Introduction (to the tutorial), a Site Map (for the tutorial), a Search function, a Glossary, Links to related sites, and Demos that are used in the tutorial (See Figure 2).

![Figure 2: Interface of the Web-Based SMIL Tutorial](image)

The final section presents a SMIL application that has been segmented into its various components. In order to provide easy access to the files and media resources, an image map has been included. This map gives the tutorial user an overview of the application components and provides an opportunity to examine each component in detail (See Figure 3). This SMIL application is also included as a demo. The user can invoke this demo on demand to visualize the synchronization of the different components (See Figure 4).

Enhancing the Classroom Through Video Technologies
A Proposal for a Video Festival Presentation
Submitted by Bob Boston

Since the invention of the motion picture, film and video have found a place in every classroom from Kindergarten to the doctoral graduate class. Most of us can remember the chatter of the 16mm projector in the back of the room, or taking a turn narrating a filmstrip. We all have memories of our favorite — and least favorite — educational presentations. Film and video have found a place as an effective tool used to supplement classroom instruction.

Today’s technology offers teachers and student great versatility and creative opportunity. We can still watch pre-produced documents, but with the availability of quality and increasingly inexpensive video production tools, we can take that experience a step further. Teachers and students alike can create customized, sophisticated presentations with limited experience and funds.

This video presentation will show clips used in elementary schools, special education, and university distance education courses to demonstrate the effectiveness and advantages of using video in the classroom. This format can excite and invigorate your lessons. Watch how students involve themselves in group activities, demonstrate teamwork and problem solving as they produce their own music video or record their class plays for prosperity. See examples from our own studios of effective presentation styles and techniques used in reaching students at distant locations. All of this can be accomplished with a home video camera, computer, and a little imagination.

Educational video has taken a step into the future and it stars you, the teacher, or the student, or the principal.
Using Advanced Screen Capture in Support of Educational Technology Instruction

John Bryner, Southern Utah University, US
Matthew Nickerson, Southern Utah University, US

Abstract

Among the many burgeoning "support" applications that can enhance the technology training of preservice teachers there is new group of simple and inexpensive “advanced screen capture” programs that should not be overlooked. Also referred to as video screen capture or moving screen capture they perform a rather simple yet powerful service. Like “older” screen capture applications, video screen capture can record whatever is displayed on a computer monitor but instead of a single “screen dump” video screen capture allows the user to record the monitor’s image over time and create, as the name implies, a movie of what is happening on the screen.

There are several advanced screen capture applications currently available with a wide range of pricing. Some of the more popular applications are:

1. HyperCam, (Windows), Hyperionics, $30.00
2. SnagIt, (Windows), TechSmith, $39.95
3. SnapzPro, (Mac), Ambrosia Software, $40.00
4. ScreenCam, (Windows), Lotus, $86.00
5. Camtasia, (Windows), TechSmith, $149.95

Southern Utah University’s educational technology program uses Apple Macintosh computers reflecting the preference of the vast majority of public schools in Utah and so we use SnapzPro from Ambrosia Software. All of the applications mentioned above are relatively simple to operate and SnapzPro is no exception.

Software

SnapzPro® can be activated with a short cut command key at any time. The short cut immediately opens the SnapzPro® window offering a choice of four capture area options: 1) the entire screen, 2) a single window, 3) preselected items, or 4) a user defined area. In addition to the area option, the user may also set the file format with the Save As option. SnapzPro® offers a range of formats including: .gif, .jpg, .pict, .png, .tiff, and .mov. All but the last option support the capture of a single image. It is the .mov option allowing the user to record all screen actions over time that we are highlighting here.

When the .mov (movie) option is selected form the Save As pull down menu the user may then define other properties peculiar to movie capture such as frame rate, scale, sound capture (internal sounds), and microphone capture (narration). Once all the setting are in place the video capture is initiated with a command key and the application begins recording the desired screen actions. A repeat of the command key halts the recording and the capture file is saved to the desktop or other selected drive/folder.

Narrative
This interactive session will demonstrate our use of this software in support of our educational technology course. At present this tool is helping in three important areas: 1) it supports faculty and lab assistants in teaching the basic software applications required for information literacy, 2) it enables teacher candidates to create powerful artifacts for their electronic portfolios, and 3) it introduces a new tool for K-12 teachers.

Educational technology faculty first used SnapzPro® in support of basic software training. There are several software applications that are covered in all sections of the course and instructors are anxious for their students to master the basics as quickly as possible so the important issues of integrating technology into teaching/learning can be discussed and practiced. As reported throughout the country and in the literature, students are coming to college with a wide range of information literacy and computer skills. While some arrive having already mastered many productivity and Internet applications there is still a significant percent that come with considerable reluctance where computers are concerned and with few or no computer skills.

In an effort to reduce class time devoted to software basics and to support intimidated or less prepared students the faculty have created small video vignettes using SnapzPro® that demonstrate basic operations for each of the principle software applications used throughout the course. These vignettes, or video tutorials, are saved as Quicktime® movies and made available to students through the Internet via online course syllabi. Students who are struggling or who just need a simple reminder can open the video tutorial whenever they need assistance. This is especially helpful when the teacher or lab assistant is not available. The tutorials open in a small display window and can be viewed simultaneously with the application they are learning for quick and easy reference. The Quicktime® format allows students to pause, reverse or fast forward the tutorial in order to view the exact process in question and to view it as many times and at whatever speed they wish.

Reports in the literature attest to the successful use of similar video vignettes to support classroom instruction in a variety of different disciplines. Their use in training teacher candidates is proving equally successful. The ISTE standards are a prime focus of our educational technology curriculum and as candidates progress through their course of study they not only learn and practice the use of technology in the classroom, they are also mastering the tools necessary for creating and maintaining an electronic professional portfolio. SnapzPro® is proving very useful in preparing artifacts for their portfolios that demonstrate competencies described in the ISTE standards. For example, a student can create a screen capture “movie” documenting their step by step creation of a PowerPoint® presentation. Because this advanced screen capture application includes a synchronized microphone capture option, candidates can narrate the process and add important pedagogical notes and/or personal reflection to their computer demonstrations that are destined for their portfolios. Even more powerful is the use of the microphone capture to record a candidate’s lecture synchronized to the presentation slides demonstrating their skills of appropriate use of presentations in the classroom.

Every hardware, software, or Internet application introduced to our candidates is taught and practiced at four levels: 1) basic functions of the application is demonstrated by the instructor, 2) candidates demonstrate basic mastery through projects that require direct application to a teaching problem or situation, 3) use of the application in the classroom is modeled by the instructor, and 4) candidates demonstrate appropriate use of the application in the classroom via individual or group projects (most often these projects reflect their emphasis or major area of study.)

Educational technology faculty at Southern Utah University are pleased with the teaching/learning outcomes resulting from our ongoing use of SnapzPro as a part of our educational technology repertoire. Online tutorials, creating portfolios and modeling new teaching strategies make advanced screen capture software a very useful tool and we encourage educational technology faculty to consider this inexpensive and easy-to-use application as part of their instructional strategy.
eBooks for Education

Cathy Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, Jacksonville, FL USA.
cavanau@unf.edu

Abstract: An eBook is a form of publishing in a digital medium. Because reading is a basic component of most educational activities, providing alternative formats and supports for reading activities becomes necessary to reach all students, especially special need students and distance learning classes. Digital or electronic text offers options such as Text-to-Speech that provide users additional modalities for receiving the information. New tools now allow readers to interact with the text to the extent of taking notes, marking, highlighting, drawings, bookmarks, searching, and even interacting with associated dictionaries. With modern editors eBooks can be easily created from web or word-processed documents. By creating their own eBooks and using available online libraries, instructors can expand the accessibility and ease of use both for themselves and their students.

The eBook

eBooks are text documents that have been converted and “published” in a digital format that display on specialized reading devices or computers. eBooks have two basic components, hardware and software. The hardware, known as a reader, is a special computer style device or program that displays the “book” on a screen, and the software contains all of the content: text, pictures, and other information. Today there are many online libraries of electronic text and online sellers of electronic books. eBooks can be purchased and downloaded to an eBook reading device. While competing formats exist, the capabilities of eBook readers and creation programs have expanded and improved. Initially an eBook was a single web page read by scrolling. Today’s eBooks, some of which are still published in “classic” pure text or html formats, have exceeded that single page design. Today’s eBook formats and their “readers” present text in a more user-friendly style. eBooks and readers display book content page by page in a portrait orientation, allow users to adjust text size, remember where reading stopped to enable continuation from that point, allow readers to take notes within the book, highlight portions of the text, add drawings, look up definitions, and read the book aloud. The books are no longer limited to computers connected to the internet, but can also be stored and read on laptops, pocket computers using Window’s CE and Palm operating systems, and eBook reading devices like the RocketBook and eBookMan from Franklin. The variety of reading devices allows people to access eBooks anywhere. It is possible for a person to carry his or her own personal or professional library in a pocket for anytime access, storing the books on a computer chip.

The ability of some eBooks to use Text-to-Speech programs offers users an additional modality for receiving the information. According to CAST (Center for Applied Special Technology), in order “to reach learners with disparate backgrounds, interests, styles, abilities, disabilities, and levels of expertise” educational materials should be flexible and adaptable for all learning styles (1998). Studies have found advantages of using electronic text technology applications with struggling readers because of the nature of electronic text over paper-based (McKenna, Reinking, Labbo, & Kieffer 1999). Anderson-Inman and Horney (1998) indicated that students benefit from the scaffolding advantages of voice output, online dictionaries, and note taking offered by electronic text to achieve success in learning. Standard print text can create a barrier for dyslexic and visually impaired students. Ebooks make information more accessible to students with disabilities. Material in digital form offers many advantages for students with or without disabilities.

Unique features
EBooks have features that traditional paper books do not—users can control the look and feel of the eBook, and also save notes, highlights, and drawings within the eBook. Another advantage is size; the amount of text in a book takes no additional space in an eBook, and the only limit on the number of books that can be stored is the memory available. A study conducted by Simmons College researchers found that the average weight of a backpack in middle school was twenty pounds, and that more than half of the participating students carried loads that were heavier than 15 percent of their body weight (Petracco 2001). Doctors suggest that to avoid injuring the body, never carry more than ten percent of bodyweight (ICPA 1998). The ability to carry many books, references, and resources electronically allows users to make better use of the information, with just-in-time educational advantages. According to one eBook company, using the PDF format a gigabyte of storage could contain over “200 illustrated college reference books, or 350 legal volumes, or about 2,500 600-page novels” (Munyan 1998). The eBook system allows users to have volumes of information either at their desktop or within their pocket. Distributing paper documents among colleagues or students traditionally requires expense in both time and money. EBook files can easily be sent through e-mail or made available on the web.

**Education applications**

Using an eBook in the educational setting is no different than using a printed material. Electronic text can be books, documents, articles, reading lists, reference material, anything that is usually printed on paper. EBook files can be distributed to students through a variety of methods including internet and discs. Instructors could compile student reading material from a variety of sources such for students’ access on either handheld devices or computers. The use of handheld devices adds a level of mobility and access to reference that was heretofore impossible, which makes this format ideal for distance education students, or students who cannot otherwise use paper-based materials. The eBooks and reader can act as a personal reference library for students, allowing constant access to resources. Currently numerous online libraries and bookstores distribute freely or sell eBooks which range from copyright-free texts that include much of classic literature, science and philosophy to current best sellers, reference books, and instruction manuals. Instructors can add notes, advance organizers, comments and questions to the texts before converting them to eBook format. As the material is in electronic format, students can copy and paste information to use in reports, to take notes, or for analysis. Some readers allow annotations, enabling a student to take notes within the book, allow bookmarking of locations within the text and have interactive dictionaries for just-in-time learning. Instructors could distribute annotation files for texts that make adaptations for special needs students, such as highlighting and providing graphic organizers, or the annotation file could contain specific questions for students to answer and return.

EBooks allow instructors to carry with them and have at their desktop or handheld computers a professional library, with texts, sites, articles, and writings. Instructors could carry all their course syllabi, along with course packets, and possibly textbooks and reference materials, available at an instant’s notice anywhere. Educators can easily create and carry with them their own professional portfolio or could convert a student’s work into an eBook for portability, then evaluate or edit it by making comments using the annotation features and send it back to the students with the annotation file for review. An instructor can read a book, highlighting important sections, adding comments, book marking important locations and then have the student read that book, with the instructor’s annotation file providing the student with an advance organizer including comments and directions.

**EBook formats**

EBooks come in a variety of formats, some of which are platform or device specific, while others are cross platform. HTML or text-based eBooks are ready to use in standard browsers and users can adjust text styles, size, and colors. With HTML or text it is possible to search within the book, and copy and paste selected text to other programs. Adobe PDF eBooks are accessible to most operating systems, including Macintosh and Windows, for viewing and printing. The PDF format allows for page navigation, multiple viewing options, adding bookmarks, and searching. Many consider the Adobe Portable Document Format (PDF) a standard for electronic distribution worldwide, as PDF files are compact and can be easily shared, viewed, navigated, and printed using a PDF reader such as Adobe Acrobat. Palm eBooks can be read on Palm handheld devices and
their format allows for various fonts and font sizes, controlling the amount of text on the screen. Microsoft Reader eBooks are compatible with Windows (95+) operating systems for desktop and laptop computers as well as handheld devices. Microsoft Reader uses a technology called “ClearType” to make words on screen appear more like print. The MS Reader’s navigation system allows for multiple methods of page navigation and will remember where readers have stopped. The MS Reader allows creation of annotation files for the text that allows various colored bookmarks and highlights, searching, and dictionary lookup features. MS Reader’s current desktop and laptop versions can also read text aloud.

Making and finding eBooks

Many tools are available at no cost to convert existing electronic text into eBook formats for use on readers. Microsoft distributes for free a plug-in for MS Word 2000 that allows users to change any MS Word document into eBook format for the Microsoft Reader. Palm has DropBook, which is a program for Windows and Macintosh that allows conversion of a text file to the Palm Markup Language for reading with the Palm Reader. Another program, ReaderWorks, allows users to convert documents, publications, web pages, and books into MS Reader (.lit) format. There is even a form of ReaderWorks online which users can access to convert their documents and then download the new reader files. Also there are many free libraries and other organizations that contain and make available a large number of eBooks. One is Project Gutenberg, which is the oldest of the online book repositories with over 4000 copyright free publications, and University of Virginia’s EBook Library which distributes on average over 9000 eBooks per day.

The future

The electronic book is by no means finished in its development. Hopefully in the future there will come a time when one content format is finally agreed upon. Currently companies are working on adding audio, video, and text-to-speech components for eBook software. Online bookstores are expanding their holdings of eBooks, with some of the college bookstore organizations including eBook forms of texts. As handheld computing devices continue to improve in their abilities and continue expand their market, it is expected that eBooks will expand with them.

Building a Statewide K-12 Digital Library

Cellestine Cheeks, Towson University, US

A majority of academic and public libraries have formed partnerships and established some of the most dynamic networks in the history of libraries in the United States (Carver, 1999; Okerson, 1996; Uball, 1994). This major achievement has been accomplished in several states because of the concerted efforts exerted by librarians, educators, and legislators to provide equity for all students (Olsen, 2001). Colleges, universities and public libraries recognize the potential of being able to deliver access to research information to all clients upon demand (Pearlmutter, 1999; Walters, 1998). Libraries in K-12 schools should be considered essential to the success of any school, given mandated state proficiency tests in many states. Students need resources, and libraries are the places for these resources. This paper proposes to describe the process that is being used to build a strong statewide digital library collection.

The strategy used to design the planning for a statewide K-12 digital library system relied on the research conducted for college and university networks developed in the states of California, Illinois, Michigan, North Carolina and Wisconsin, and the state models involving school libraries existing in the states of Alabama, Ohio, Delaware, and Texas. The concept of defining a digital library, why it is needed as well as why a state network is necessary is presented. The role of the collection development team, technology support team, the political support, as well as the negotiations with vendors to put this project into action is detailed.

This paper presents the challenges faced by a collection development team in the process of building a statewide digital network in the K-12 community, as well as the positive impact of team collaboration to the success of the project. The goal of this project is to provide equity to all students at the K-12 level so that when they reach the college and university level they will be able to utilize digitized images, audio and video in existing network collections.
Media Makers Produce Career Commercials: The Softer Side of Technology

Professor Joanne Clemente
School of Education
New York Institute of Technology
Marlene Natale
Sewanhaka School District
United States
jclementa@nyit.edu

Abstract: What motivates a young woman to choose a particular career path? Are glass ceilings yet shattered? How can we use the allure of television commercials to interest the next generation of young women to expand their horizons, perhaps choose careers outside their visible range? This community service project focuses on the utilization of NewMedia skills to develop career “commercials” with auxiliary web content for display at a local Children’s Hospital. This project, then serves three purposes: developing young women’s awareness of career choices; developing young women’s technology skills to encourage higher education and career choices in Science, Engineering and Technology; to provide community service and career counseling to an underserved population at the Hospital.

Research Background:

The Commission on the Advancement of Women and Minorities in Science, Engineering and Technology Development states, “As we enter the twenty-first century, U.S. jobs are growing most rapidly in areas that require knowledge and skills stemming from a strong grasp of science, engineering, and technology. In some quarters—primarily information technology—business leaders are warning of a critical shortage in skilled American workers that is threatening their ability to compete in the global marketplace. Yet, if women, underrepresented minorities, and persons with disabilities were represented in the U.S. science, engineering, and technology (SET) workforce in parity with their percentages in the total workforce population, this shortage could largely be ameliorated. Now, more than ever, the nation needs to cultivate the scientific and technical talents of all its citizens, not just those from groups that have traditionally worked in SET fields. Women, minorities, and persons with disabilities currently constitute more than two-thirds of the U.S. workforce. It is apparent that just when the U.S. economy requires more SET workers, the largest pool of potential workers continues to be isolated from SET careers.” The report goes on to say, “Active discouragement and the dearth of out-of-school SET experiences and role models contribute to girls’ lack of interest in SET careers.”

The report also cites another problem, “The public image of scientists, engineers, and technology workers is often both inaccurate and derogatory. In addition, women, underrepresented minorities, and persons with disabilities are not adequately portrayed by the media as participating in SET careers.” The commission offers many recommendations, including:

- High School: “The Commission recommends the expansion and institutionalization of successful school-based and nonschool-based enrichment programs to (a) identify—through the use of authentic, nontraditional assessments that account for the differential experiences of students—potentially able students from underrepresented groups that have been plagued by inadequate educational opportunities; and (b) enroll them in accelerated academic preparation programs. Federal, state, and local partnerships should be established to identify and fund these intervention programs at an appropriate level.”

- Financial Support: The Commission recommends that the federal and state governments significantly expand financial investment in support of underrepresented groups in SET higher education

In another, more recent, source, the Report from the Council of Economic Advisors Opportunities and Gender Pay Equity in New Economy Occupations of May 11, 2000, two problems are mentioned: employment gap and pay gap. “However, an important gender employment gap exists in these IT [information technology] occupations. Women are currently underrepresented, making up only 29 percent of these occupations, compared with 47 percent of the workforce in the general economy”...There is also a gender pay gap within IT occupations. A woman with median earnings in IT earns about 22 percent less than a man with median earnings....Part of this gap stems from
differences in age, education, race, and occupational composition. Taking these factors into account lowers the gap to 12 percent—a gap similar to that estimated for the labor market more generally..... The gender pay gap narrows sharply for women in IT who have higher levels of education." The report further states, "Policies that assist women in their career development, such as on-the-job training and mentoring, can also enhance women’s investment in these occupational skills and their retention rates, and can thus be expected to help close the gender wage gap.

Description of Project:

This proposal describes the collaboration between New York Institute of Technology, the Sewanhaka School District and Montefiore Children's Hospital. Through the collaborative efforts of undergraduate/graduate and high school girls, this project focuses on developing the skills necessary to produce non-broadcast television commercials and auxiliary web content on careers, including interviews, educational advice and expert mentors. These “CareerCommercials” and web sites will “air” at Montefiore Children’s Hospital bedsides where there are installed, state-of-the-art, plasma screens at each bedside. Montefiore Children’s Hospital services an underserved population. This project will address the need to encourage these young patients to pursue higher education, as well as to inform them of the many career choices currently not emphasized in minority communities. This project provides the important benefit of encouraging high school girls to pursue college educations, science and technology careers, and community service. Standards involving the integration of technology, using technology as a tool and research using technology are integral to this project. Rubrics will promote uniformity in evaluation and quality.

In their own words, the students involved in this program will virtually or physically present to the audience why they wanted to participate, what information they needed to know, and how they went about researching and presenting such information. Presenters will show documentation of their progress and report on their attitudes, skill development and career consciousness at each stage of the process. Using technology as a tool, young women seek to satisfy their own quests for information and produce a tangible result that will benefit other students, male or female as well as underserved hospitalized students. Additionally, since products are web-based, its continuous availability assures that hospitalized children, even when released, will have further access to the same content. Products from this project will be displayed and described.

Those attending this presentation will be encouraged to join this project in order to make this a national effort that reaches out to all high school students, to expand their knowledge of career choices, and in particular, encourages underserved populations to seek additional educational opportunities. While this project will initially focus on encouraging young women to acquire SET skills, any student will be encouraged to participate.

This program serves many objectives:

- High school girls will be exposed to college attendance, additional career choices and technology through their relationships with college students and professors and through their participation in this project.
- College Undergraduate/Graduate students will develop leadership as well as technology skills through their involvement in this project as mentors.
- Participants will gain experiences in the use of technology both as resource and as tool and will be better prepared for possible SET careers.
- Participants will gain professional skills and add to their "portfolio" of work, useful for future education or employment.
- The image of Science and Technology Professionals can be enhanced using the media to demonstrate Women in SET careers.
- NETS standards are the guiding principles used to integrate technology into this project.
- Rubrics will guide additional participants to produce career commercial and auxiliary web content.

The Internet Textbook: Change and Opportunity

Tim Collins, National-Louis University, US

Abstract

Textbooks in one form or another have been a part of education since the written tradition began. Nevertheless, textbooks have changed drastically over the years in response to technology and changing needs, and textbooks will continue to change as society redefines its needs and uses new technology to better achieve those needs. The Internet now offers the potential of remaking textbooks completely. Though it is certain that the Internet will change textbooks, it is difficult to predict exactly how they will evolve. Nevertheless, it is possible to discern factors that will influence their future direction and development. This paper focuses on three major factors that will drive the development and evolution of the textbook in the twenty-first century: (1) the scarcity model for publishing and information technology, which was the foundation of traditional print publishing and current copyright law, is no longer appropriate for Internet publishing; (2) interactive, Internet-delivered textbooks will truly honor multiple forms of discourse, in many cases forms of discourse that are not currently validated by the academy; and (3) the multiplicity of skills and content expertise required to create these textbooks will cause the roles and functions of author, editor, and so on to change.

In the words of Yogi Berra, “Making predictions is hard, especially when they’re about the future.” This statement is especially true of the impact of technology on our lives. Though it is virtually certain that technology will change our lives, the outcomes are not yet clear. Hundreds of innovations, such as widely available hand-holds, new kinds of wireless connectivity, universal Internet access, and wide access to broadband connectivity, have the potential of transforming our lives in ways that many of us never imagined even a few years ago.

This paper focuses on the impact of technology on one key artifact of the educational system: the textbook. Textbooks in one form or another have been a part of education since the written tradition began. Nevertheless, textbooks have changed drastically over the years in response to technology and changing needs, and textbooks will continue to change as society redefines its needs and uses new technology to help better achieve those goals.

The comprehensive textbook, with illustrations, ancillaries (such as workbooks, study guides, audio programs, flash cards, manipulables), and teacher’s editions, is a relatively modern invention. The earliest textbooks were probably scripture, since in most societies, scripture was the most universally accessible, if not the only accessible written text. Many subsequent early textbooks incorporated selections from scripture in them, too, since one of the most culturally important reasons for becoming literate was in order to be able to read scripture. The first graded, or multi-level, textbooks, such as the McGuffey’s Readers series, emerged in response to universal public education, when industrial models began to be applied to mass education and children were expected to enter school at a certain age and progress though grades of instruction on an annual basis until they finished. The first comprehensive teacher’s editions, which gave teachers detailed instructions on how to work through each page with students, were developed in the early 20th century by the first publishing company to focus exclusively on the educational market, Scott, Foresman and Company. This company’s series of readers, including the Dick and Jane series, were the first true basal reading series with comprehensive teacher’s editions published in the United States. This company’s products set the standard for basal textbook publishing in all disciplines and were imitated by a host of competitors. In college textbook publishing, a similar series of developments took place, as companies developed textbooks for the major college courses and progressively added ancillaries for competitive reasons.

Technology played key steps in each stage of the development of the textbook. As printing and typesetting technology improved, companies found that they could produce books with added features such as full color illustrations. Development of sound recording made possible recorded audio programs, key ancillaries for foreign language and music series. Faster and cheaper ways of setting type (such as the demise of hot metal and its replacement with cold type and later with electronic typesetting and page composition) also dramatically lowered costs and time to market, which allowed for shorter production times and more up-to-date content. Companies also began introducing software supplements, such as test generators, computer simulations, drill-and-practice software for math, reading, and language arts, and even Internet sites.

Now the Internet has the potential of allowing us to remake textbooks completely. It is difficult to predict how textbooks will evolve, but it is possible to discern some of the factors that will influence their development. Three major trends will drive the development of the textbook in the twenty-first century.

1. The scarcity model for publishing and information technology will no longer be appropriate.
2. Textbooks will truly honor multiple forms of discourse.
3. The multiplicity of skills and content expertise required to create books will cause the roles and functions of author, editor, and so on to change.
First, traditional publishing has been based upon an information scarcity model that is not appropriate to Internet publishing. Copyright laws essentially grant a monopoly to the owners of intellectual property that allows them to charge as much as the market can bear for their products. This has ultimately created a vicious cycle in which, at least in the college market, price increases drive increases in used book sales, which drive further price increases and faster revision cycles, which in turn drive additional used book sales. In fact, statistics from the Association of American Publishers indicate that nowadays many students are failing to buy a book at all because of cost. Most other students keep their books only through the duration of the course and then sell them back to the bookstore, a sad statement of the value proposition college textbooks provide. In elementary and high school publishing, high prices drive many less affluent school districts to put off new book purchases for as long as possible, leading in some cases to situations such as one that happened a number of years ago in Texas, in which textbooks then in use indicated that the Soviet Union was still in existence, when in fact it had been dissolved for several years.

Clearly this is not a very desirable situation: as the price of information increases it becomes less valuable to acquire. An information abundance model, therefore, would provide more acceptable results: as information becomes more accessible its value increases. Take, for example, the case of on-line journal indexes with full-text access. The ease of use, including access from any computer anywhere, makes it much more likely students will use periodical resources in electronic formats than if they were to use paper copies of indexes such as the Reader's Guide and then go to the stacks to find paper copies of the articles or, in the case of the library at one school I attended, wait for a page to retrieve the requested volumes from the stacks. Other advantages are savings in library bindings of periodicals, costs for shelving and retrieving copies, costs associated with keeping track of checked out books, and so on. Clearly, in this example, everyone wins: access to information is cheaper and easier, which motivates people to use periodical resources more than they would have than in the past, and allows libraries to use their limited resources to acquire more materials. By applying the economies and speed to market offered by online delivery of textbooks, prices would go down. Students and school districts would be more motivated to buy them, professors would be able to assign additional books because the total bill would be more manageable, and students would be less motivated to buy used books because new books could be updated each semester or year. In this situation, everyone wins.

Second, technology will motivate textbooks, and the academy, to honor multiple forms of discourse. In the past, the bellwether of a serious academic text was page after page of dense type, broken up, if at all, only by graphs, tables, and charts. One of America's most respected serious literary magazines, The New Yorker, did not publish illustrative art in its articles at all until well into the 1990s. Textbooks nowadays have copious illustrations, but technology will enable many different forms of discourse to be added to textbooks, from sound files (such as quotations from historical figures in history and political science texts and speech samples in linguistics books), to streamed media, to animated illustrations. Imagine, for instance, how wonderful it would be if a biography of Shakespeare allowed us to see and hear actors performing, take a virtual walk through a multidimensional Elizabethan theater, hear Elizabethan music, and see films of places Shakespeare probably saw. The advantages of this type of learning tool over a two-dimensional, static printed page are multiple, and to the benefit of everyone.

Finally, technological change will cause the traditional tasks and roles of educational publishing to change. Already, the changing economy has caused similar changes in other sectors of the workforce. Doctors, for example, no longer make all decisions about managing patients' health care. Health maintenance organizations and insurers have taken over much of this responsibility. The functions of author, editor, and book designer will be redistributed, and new roles will be added such as that of instructional designer. The author will be less the architect of the pedagogy and more a content-matter expert, and the instructional designer will help the author tailor the delivery of the content to the technological resources available. The editor will deal with not only words and pictures, but also have to manage the creation of multimedia. The role of editor will become more akin to multimedia project manager and less a shaper of words, and the content editing may in fact be delegated to another person in charge just of this one small aspect of something has become a much larger process. Clearly, this change implies that roles and responsibilities will be debundled and rebundled, and individuals working in textbook publishing will have to brace themselves for considerable upheaval.

Ultimately, this change will also affect the very notion of authorship. The trope of single author-single text arose during the Romantic period, and is a notion that will diminish in importance as the collaborative, team-based approach necessitated by technology takes hold. There will be more "managed books," and publishers may need to find new ways to acknowledge all of the different collaborators in a publishing project.

Technology, then, promises to change textbook publishing in a number of key ways. First, it will obviate the scarcity model on which publishing had been traditionally based, and replace it with a model in which the value of information increases as it becomes more accessible. Second, technology will result in the creation and validation of multiple forms of discourse that will enrich the educational experience. Third, because of the variety of skills and expertise needed to build interactive textbooks, the notion of authorship will change and more collaborative development models will become the norm. The net result will be as fundamental a change to the production and notion of the textbook as the changes caused by the development of movable type.
Teacher development through curriculum development – teachers’ experiences in the field-trialling of on-line curriculum materials

Tony Fisher  University of Nottingham School of Education, England  tony.fisher@nottingham.ac.uk
Tim Denning  Keele University School of Education, Keele, England  t.j.denning@educ.keele.ac.uk

Abstract: This paper reports on the experiences of teachers participating in the field trials of new on-line curriculum materials and associated technologies in the UK. During the period January to July 2001, teachers in 60 secondary schools in England participated in the trialling of on-line curriculum materials in Mathematics, Japanese and Latin. The three subject projects differed in a number of respects, but overall the teacher response was extremely positive and revealed a number of consistent trends relating to aspects of teacher development that ran across the differing subject settings.

Background

Since the early 1970’s a sequence of government initiatives can be identified, with the underlying aim of increasing the use made of computers in schools in the UK (see for instance Watson, 1997, for a summary). More recently we have seen the planning and development of the Internet-supported ‘National Grid for Learning’ (NGfL) as part of a wider strategy which also includes training for new and serving teachers, and requirements for the use of information and communications technology (ICT) within the statutory framework of the National Curriculum. Of course, though aspects of the strategy are particular to the UK, the underlying purpose has also been recognised and is being addressed elsewhere.

"The aim of many policy-makers in the UK and around the world is to encourage evolution into a learning society... one in which all people are responsible for their own learning throughout their lives. Access to information and learning will often depend on new technologies as well as on an approach to teaching which supports collaborative professional development."

Governments in Europe and around the world have already recognised the need to review educational practices and incorporate new technologies. Their view is of a vocational imperative and one in which IT will increase the quality and efficiency of learning itself." (Somekh et al, 1997)

Part of the NGfL strategy is to ensure that all secondary schools will have a high bandwidth Internet connection. This, together with internal networking in schools, will enable the use of Internet-delivered digital curriculum materials for learning and teaching within subject classrooms. It is within this developing context that the project reported here took place.

The KS3 Subjects Online Project

In 2000 the Government’s Department for Education and Employment (DfEE) invited tenders for the development of technology-based subject courses for a year’s worth of study in three subjects: mathematics, Latin and Japanese. The project sought to stimulate the development of "state of the art computer based programmes for teaching numeracy, classics and non-traditional languages; exploiting the full creative multimedia interactive potential of these technologies".

Three developers with experience in writing multimedia curriculum materials were contracted to develop materials in the three subjects and to set up field trials for the materials. The developers were under a contractual requirement to produce materials that met a number of criteria relating to technical and other aspects. Among these were that the materials should be sufficient for a year’s worth of study and should be targeted at Year 7; further, the materials should be capable of both mediated and unmediated use by learners. A further requirement on the developers was that they should set up the use of the materials in twenty schools per subject, together with use by ‘independent learners’ working in unmediated contexts, so that the use of the materials could be evaluated in a variety of contexts. In the case of mediated use in schools, which is our focus in this paper, teacher-mediators might or might not have a specialism in the subject in question.

The three individual subject projects used differing approaches to the development, dissemination and support of their particular materials. In the case of Japanese, the materials were designed wholly for on-line delivery by
means of existing technical resources and used a variety of animated cartoon characters and high quality audio to engage students in an 'immersive' approach to language development. This was complemented by on-line assessment activities. The materials required no particular input or mediating activity on the part of a teacher.

The mathematics materials were designed for delivery within an on-line 'managed service' framework, using dedicated hardware and an interactive whiteboard to support a wide variety of software-based learning activities. These were used to support whole class teaching designed to conform with the Key Stage 3 National Strategy for the development of numeracy, complemented by an on-line planning tool and mark book for teacher use, and student access to 'Sub Patrol', a Web area of mathematics activities and games. With the exception of the latter, a high level of teacher mediation was built into the approach adopted for mathematics.

The Latin project employed CD ROM technology to deliver local 'media rich' content and learning activities, including a large amount of video material, linked to on-line facilities for the management of content by the local teacher. There was also provision for electronic submission of written work to and from a designated 'e-tutor'.

The three subject projects also differed in their approach to training and support for the teachers involved in the school-based trials. In the case of the mathematics project, there were regular face-to-face training sessions for the whole group of project teachers, on-line community building and support, a help desk and regular school visits by the developers. In the case of Latin, there were two training events, technical support and visits to schools, in addition to on-line e-tutor support. In the case of Japanese, there was a launch event, regular electronic newsletters, a telephone help-desk and school visits.

Methodology and Data

The external evaluation employed an eclectic methodology including qualitative and quantitative aspects. Throughout the evaluation there was contact between the evaluators and the developers, with the evaluators providing formative feedback for later development cycles. There was also contact between the external evaluators and the internal evaluation being undertaken in each project. In addition, the evaluators were in regular dialogue with the project managers at British Educational Communications and Technology Agency (Becta), and with a project management group including representatives from the DfEE. The evaluation drew upon Robert Stake's responsive evaluation model (Stake, 1979), which makes use of a variety of methodologies as negotiated through and informed by discussion with key participants during the life of the project.

The research design made use of triangulation procedures, involving classroom observation of the materials in use by teachers and students, teacher interviews and postal questionnaires, and student interviews and questionnaires. Interviews followed a 'semi-structured' approach, and were recorded on digital mini-disk. Additional data about the background to the use of the materials, and responses to the materials themselves, were gathered by postal questionnaires completed by teachers and students. Information about the schools themselves was provided by the developers.

Interview data were collected from 44 separate school visits undertaken by the evaluators. These incorporated more than 60 staff interviews and group discussions with more than 250 students. Survey responses were received from 534 students and included nearly 500 individual comments about the resources. The main teacher questionnaire was completed by 43 teachers whilst the end of project survey was completed by 26. An established subject specialist also reviewed each of the subject resources.

The field recordings of interviews with teachers and students were subjected to content analysis. The questionnaires were subjected to quantitative analysis, supplemented by qualitative analysis of comments made in response to open questions. A final report covering the contracted evaluation aspects was produced and submitted to Becta for the DfEE.

During the field visits to schools for data collection, and through their contact with teachers, the evaluators became interested in the impact of the experience on the professional development of the teachers involved in the trials. Although this was not a major component of the contracted evaluation, it is upon this aspect of the project that we focus here.

Three illustrative 'vignettes'

Aspects of teachers' experience are illustrated by the following three vignettes, one from each of the three subjects, drawn from observations conducted during school visits. Though none is in a strict sense 'typical',
these vignettes have been chosen to give an impression of the impact of involvement in the projects on the teachers involved. In each case the teacher is referred to by an alias.

**Vignette 1**

Drew has three years' experience as a teacher of mathematics. He had not used an interactive whiteboard before becoming involved in the project, but had used powerful computers in a previous career. In the observed lesson he made extensive use of the interactive whiteboard (the only one in the school) both for direct teaching and for students to demonstrate their work. He set up a number of separate activities involving the use of three desktop workstations and a set of programmable graphical calculators. He commented that he had to invest a lot of time in preparation initially, as he was familiarising himself with the activities and the use of the technology, but he has become faster as he has become more familiar with the approach. He and his Head of Department are negotiating with the school for the purchase of another interactive whiteboard, as their evaluation of its impact as a tool to support teaching and learning in mathematics is so positive. He will train his colleagues in the mathematics department in technical and pedagogical aspects of its use. Other departments are also showing an interest.

**Vignette 2**

Kathy has been teaching English for five years. She describes herself as having been rather resistant to the use of new technologies before becoming involved in the Latin project. She has become a much more confident user of the technology. Kathy had to develop a productive working relationship with the school's ICT technical support in order to receive assistance and advice regarding local technical issues. As a trained English teacher Kathy has also had regular e-mail contact with a project 'e-tutor' who as a Latin specialist advises her on aspects of supporting learning in Latin. Kathy did not wish merely to supervise computer-based activity; rather, she saw her role as facilitator in terms of adding value pedagogically. She puts in a lot of preparation time at home on a portable computer provided by the project. Latin lessons with a volunteer group of students take place weekly after the end of the normal school day in a purpose-built computer room. In the observed session Kathy introduced the lesson and directed the students to relevant parts of the materials. Students then accessed a revision activity from among the materials which had been placed on the school's curriculum network server. Kathy concluded the lesson with a group debrief during which she used a data projector.

**Vignette 3**

Susie has five years experience as a teacher of Japanese. The observed lesson was a timetabled lesson in a school where Japanese is an established subject. Susie had tried to use the on-line materials with her whole class of 28 students, but the school's Internet connection was not of sufficient bandwidth for that number of simultaneous accesses to the materials, and download times became unacceptably slow. Susie had therefore developed an approach in which, after a whole class introduction to the lesson, she divided the group into two halves. Half stayed in the normal classroom undertaking teacher-initiated activities, whilst half went to a nearby computer room to use the on-line materials. Susie supervised activity in both locations, moving back and forth between the two. At the mid point of the lesson the two half-groups changed over, and the lesson concluded with all students in the computer room where Susie made use of an installed data projector to conduct a plenary session involving an adapted use of part of the on-line materials.

**Results**

In general the project increased the participating teachers' use of new technologies, as illustrated by the vignettes. Previous use varied from a very low base in some cases, including no previous use in the teaching situation at all in the case of some teachers. This was as a result of one or both of two factors: a lack of pedagogical confidence in the use of new technologies in the teaching and learning situation, and a lack of ready access to the necessary technological resources for the subject concerned. In other cases individual participating teachers reported a relatively high base of pre-existing use of new technologies in the teaching situation. However, in each subject all teachers said that their teaching had benefited from the use of new technologies employed by the three subject courses, and most felt that their students are motivated by the use of computers.

In terms of the development of participating teachers, several trends may be discerned. All put in additional time for planning and preparation, as they became familiar with new materials and approaches. They were given no release from other commitments in order to support day-to-day participation, so the additional time was above and beyond a full teaching load. "I've found it hard work this year and you have to put a lot of time aside for it... I wouldn't have taken it up if I didn't think it was worth it." (Maths teacher, interview)
In some cases teachers were supervising the project lessons outside normal timetabled lesson time, as this was the only time that access to the necessary computers could be arranged. This was not so in mathematics, where a dedicated, specially equipped project classroom was set up. However, in the case of the Latin and Japanese projects, many teachers found themselves competing for access to the necessary technologies. For instance, “The Languages Department at my school does not have regular (or occasional) access to the ICT suite at present and so using ICT in my teaching is limited... I have therefore been piloting the project with a small group of after school Y8 and Y9 pupils.” (Japanese specialist teacher, teacher questionnaire)

In a majority of cases teachers had relatively problem-free experiences of using the technology, though in some cases initial technical difficulties had to be overcome. The developers provided technical support to address these issues. Some teachers reported becoming much more confident, developing their own use of new technologies: “Use of this material has made me much happier to develop and experiment with other aspects of ICT.” (Latin specialist teacher, teacher questionnaire) In some cases the use and impact of specific technologies was identified, for instance “If I had to choose one thing that would change my classroom it would be the interactive whiteboard. The effect of the whiteboard is immense.” (Maths teacher, interview) Where technical problems were experienced, some teachers were cautious about using technology-based approaches; for example, “If our school network works all the time, this project will be really successful and I would like to use it for my normal lessons with Years 8 and 9 but at this moment, I cannot take a risk.” (Japanese specialist teacher, teacher questionnaire) No teachers reported a negative response to the general use of the technology; where reservations were expressed these were in the context of an overall positive response, and related to matters of detail.

Teachers in all subjects responded strongly to the new materials. This was equally the case with newly and recently qualified teachers, and those who were several years further on in their careers. “In my career in teaching Mathematics this style has had the greatest impact upon learning and motivating students in maths as anything I have experienced.” (Maths teacher, 20+ years experience, teacher questionnaire.) In some cases experience with the project materials resulted in increased aspirations for work with other groups; for example, “I’d just love to use this say once a week in my normal Y7 and Y8 Japanese lessons.” (Japanese specialist teacher, interview)

In some cases it was clear that exposure to technology-based approaches had prompted teachers to reflect on their own teaching and on how it could be supported or enhanced by the use of new technologies. For instance, “What I think I would like to use it for in the future is... to teach specific points while I’m teaching - just stop and... like “now we’re going to look at the website”... just using it as an exciting little thing that you do in the lesson.” (Japanese specialist teacher, interview)

In other cases teachers articulated a direct impact on their classroom practice: “It's less of me having to draw things up on the board and that sort of thing and I've actually got more time to do the teaching and to wander round the room - I don't have to be the one controlling that [interactive] whiteboard... it changes the focus for me and it changes the focus for them.” (Maths specialist teacher, interview) “My [project] lessons are much more structured than my normal lessons - the students are much more involved in discussing their work, strategies, misconceptions etc. The pace is much faster and interest and motivation has been higher.” (Maths specialist teacher, interview) “There are some things on there that introduce it just as effectively as a teacher working with a group... they can practise really easily... and come back and teach the rest of the group what they've been practising.” (Japanese specialist teacher, interview)

For some teachers, involvement in the project had gone so far as to have been a transforming experience: “I think it's been absolutely fantastic... I've enjoyed it, the students have obviously enjoyed it... to start off with it was "I’m just trialling these materials for [developer]," and what it’s actually become is, it’s totally changed my way of teaching so it’s actually been a development for me...” (Mathematics teacher, 9+ years experience)

**Discussion and conclusions**

Though experiences varied between the three subjects, overall the teacher response was extremely positive. Teachers reported that the experience of being involved in the field trials of the materials had been a professionally developing experience. All had become more aware of the opportunities for using networked and other technologies to support teaching and learning. They had also become more confident and competent as users of the technology required by their particular subject project. In addition, a number of teachers had quickly become adaptive users of the project materials, particularly when local circumstances made this either necessary or possible. Their pedagogical confidence and pedagogical competence (Wild, 1995) in the use of new
technologies developed through mutually reinforcing development processes. This was a powerful aspect of teachers’ experience during the projects.

Much of teachers’ learning over the course of the projects reflects notions of ‘situated learning’, where the activities resulting in the learning are embedded in the social and physical contexts where the learning is to be used (Brown et al, 1989) – in this case the teachers’ own classes. This is related to the feed-back and feed-forward processes operating in the development of pedagogical confidence and competence described above.

There are indications that teachers involved in the projects are engaging to a greater extent in broadly constructivist practices. Questionnaire responses show ‘whole class teaching’ to have been the dominant mode employed by teachers in all three subjects prior to their involvement in the project. Whilst it is not possible on the basis of the KS3 subjects on-line project to say that the use of new technologies has shifted teachers’ practice in a constructivist direction, direct observation of, and discussion with, project teachers indicate the presence of what Becker and Reil (2000) refer to as ‘constructivist compatible’ practices involving the use of new technologies associated with the subject materials. The Teaching, Learning and Computers study (Becker 2001) demonstrated that teachers with a constructivist-oriented philosophy were more likely to use computers in their teaching, and also that their practices became more constructivist as a result. Further longitudinal study would reveal if that were to be the case with the teachers in the KS3 subjects on-line project.

Becker and Reil (2000) also identify a relationship between what they describe as ‘professionally engaged’ teachers (as opposed to ‘private practice’ teachers) and the use of computers. Again, there are indications of the same relationship in this study. The teachers in the KS3 subjects on-line project were willing to engage in the trialling of new curriculum materials at some considerable cost to themselves in terms of time and extra effort. They were willing to open their practice to outside scrutiny in what was for them a relatively high risk, experimental setting involving considerable innovation and task complexity. This fits with aspects of Becker and Reil’s definition of being ‘professionally engaged’ and demonstrates aspects of what Hargreaves and Goodson (1996) describe as ‘postmodern professionalism’.

The use in two of the three subject projects of portable computers by participating teachers, enabled them to undertake considerable self-training in terms of familiarisation with the materials at home, with the portability of the computer and access to the Internet enabling a “further blurring of the spatial distinction between home and school” (Fisher 1999). This use of portable computers to support self-driven teacher development is consistent with the findings of the earlier Multimedia Portables for Teachers Pilot. (Harrison et al, 1998)

More Than A Movie: Using Animation to Promote Learning of Complex Subject Matter

Joseph Frantiska, Jr. Ed.D.
Visiting Lecturer
Computer Science Department
Fitchburg State College
USA
jfrantiska@aol.com

Abstract: The field of New Media allows for the examination and greater understanding of complex possibly arcane subject matter. One such type of subject matter is tornado formation. This area of scientific information is filled with misconceptions and myths. An animation is a means by which the internal mechanism of tornado formation can be explained. Through such an examination and manipulation of an animation it can be ascertained not only that there is a specific sequence of events of tornado formation but also that there exists distinct stages of the developmental process. The word "manipulation" is important since the learner can view the animation either as a flowing series of images or as distinct images each of which can be individually examined as to its contribution to the process. This is a subtle yet important empowerment of the learner who is able to perform self directed learning within a structured environment.

Introduction

The stages of tornado formation are unveiled to be themselves as collections of subtle processes in a tremendously dynamic environment. In depth knowledge can be gleaned from each of the processes as individual phenomenon as well as contributors to the whole sequence. A constructivist approach can thus be used to understand this event. From a pedagogical standpoint, this can present the educator with both a unique teaching tool and a greater responsibility to fully understand and explain the phenomenon at both a macroscopic and microscopic level. The impact of this on the teaching process is also examined. The students were split into four groups based on their apparent misconceptions (internal formation process, external formation process, similar phenomenon, no misconceptions). Each group was instructed to enter the website where they saw images, sound files and text that presented counter-examples in a hope to reverse misconceptions and reinforce correct conceptions. All group members saw the animations last. All students were given pre and post-test where they wrote and drew their current understanding of tornado formation.

Theoretical Basis

Cognitive Flexibility Theory (CFT) forms the basis for this study. The main principles of CFT are that learning activities must provide multiple representations of content while instructional materials should avoid oversimplifying the content domain and support context-dependent knowledge. Instruction should be case-based and emphasize knowledge construction, not transmission of information. Knowledge sources should be highly interconnected rather than compartmentalized.

CFT supports the use of hypermedia for learning and provides several design prescriptions for hypermedia that seeks to promote flexible use of complex knowledge. Among these prescriptions are: a.) using case studies to learn abstract concepts instead of learning facts that are removed from their context, b.) presenting information from a variety of perspectives and representations; c.) stressing the complexity of knowledge over the isolation and decontextualization of knowledge, d.) stressing the network and relationships among knowledge; and e.)
involving the learner in the construction of new knowledge via problem-solving tasks rather than the recitation and memorization of facts and concepts.

In CFT, one learns akin to "criss-crossing conceptual landscapes". Issues involved are analyzed in different contexts and from different perspectives. The instructional medium makes such criss-crossing possible and knowledge representations reflect the "criss-crossing that occurred during learning". The criss-crossing nature leads to knowledge structures that can be likened to a web-like form. Hypermedia is particularly well suited as a means to impart these knowledge structures.

Hypermedia based on CFT fall under the constructivist psychological perspective. Constructivism calls for learners to actively participate in the shaping of their own knowledge structures rather than passively receiving facts and concepts. Differing perspectives on constructivism and student engagement range from mechanistic, exogenous views of dependent learners assimilating information given them to organismic endogenous views of independent learners who seek information on their own and accommodate it with pre-existing knowledge into personally relevant constructs.

Where CFT falls short of constructivism, according to Jacobson, et. al. (1996), is in the provision of social context and collaboration. At the center of the constructivist continuum lies the social, dialectical constructivist movement where interactions between the student, instructor, and environment provide the foundation for learning. According to Spiro et al. (1990), popular social constructivist approaches include cognitive apprenticeships and modeling, cooperative learning and reciprocal teaching, and scaffolded instruction in Vygotskian "zones of proximal development" as discussed by Berk, et. al. (1992).

Cognitive Flexibility-based hypermedia are computer based instructional programs that are born from CFT and are built to carry out its operations. The computer's ability to utilize the highly multi-dimensional and web-like structure in multiple ways describes this kind of an educational set-up with the term "random access instruction". According to Jacobson (1995), CFT asserts that students who develop "flexible representations of knowledge" will be able to adapt that knowledge to a wider variety of problem settings.

**Website Construction and Animation Impact**

The website developed to assess the usage of CFT for the promotion of learning of complex subject matter was composed of text, images, sound files and an animation. The students were divided into groups based upon their specific misconceptions or lack thereof. The animation was the last portion viewed by all groups. The animation is a critical piece in understanding the entire sequences of events that lead to tornado formation. While the previous portions of the treatments showed the student how a tornado forms it is only representative of the part that is directly observable. The animation shows that the formation of a tornado occurs in five distinct phases: a) criss-crossing wind currents, b) a horizontally rotating cylinder of air, c) updrafts which pull the cylinder into a vertical position, d) the transition from a cylinder to the familiar funnel shape and e) the eventual deterioration of the funnel. While of course the animation itself is a continuous sequence of images, this paper only shows the frames that depict the specific phases of formation.
Figure 1 (left) The cross currents which start the rotation. Figure 2 (right) The cross currents form a horizontally rotating cylinder.

Figure 1 starts off the animation with lines that show the direction of criss crossing air currents. These air currents exert some friction on each other as they pass causing a swirling motion. Figure 2 depicts the result of this friction as a swirling horizontal cylinder of air. As momentum increases and the density of air in the cylinder becomes greater, the cylinder takes on a more substantial form. This phase also occurs in the clouds away from direct observation with the animation being the only vehicle by which to see this portion of the formation.

Figure 3 (left) The horizontal cylinder becomes vertical. Figure 4 (right) The creation of a funnel.

Figure 3 shows the updrafts beginning to raise the horizontal cylinder to the vertical. That allows the cylinder to drop to the ground and begin to pick up debris which adds to it's mass which makes the cylinder visible. Due to the conservation of angular momentum, figure 4 shows that the cylinder is taking on a more funnel-like shape. Since the air is filled with more material, the cylinder is more massive and the laws of physics dictate that it must spin faster.
In figure 5 the tornado has reached a mature stage with a true funnel shape and reaching from cloud to ground. The last stage of dissipation will occur when either the atmospheric conditions fail to provide it with adequate energy or the amount of mass within itself decreases sufficiently.

The animation is itself a major factor and point of contention in the treatment. Specifically, does the addition of an animation with its flowing graphics and eye-catching motion overpower and minimize the impact of the text and still graphics? Having the students draw the sequence on tornado formation as well as writing about it on both the pre-test and post-tests helped greatly in this respect. Most students displayed a marked improvement in their graphical representation of the sequence of events. Lai (1998) has found that still graphics and animations can increase the level of concept learning produced by computer-based learning. Lai implies that this enforces the dual-coding theory exposed by Paivio (1990). According to the dual-coding theory, two streams of stimuli are better than one. This is in alignment with CFT’s criss-crossing landscape of multiple representations.

**Results**

The findings reveal that as expected the group with no misconceptions almost without exception maintained a correct understanding of the subject matter. Additionally, the students in the group who feel tornadoes were (incorrectly) similar to other weather phenomenon who start with a misconception and were not allowed to change their conceptual view of the phenomenon, showed a 100% occurrence of maintaining their incorrect understanding. This is in spite of the fact that like all other students they saw the currently accepted explanation and animation at the end of the treatment.

Conversely, the groups with misconceptions about the internal or external mechanics of tornadoes who also had initial misconceptions but were allowed to change their conceptual understanding relative to the material encountered had a 63% occurrence of changing from an incorrect to correct concept in the pilot phase of the study. The study proper portion of the study showed a similar propensity.

**Conclusions and Recommendations for Further Research**

This study has investigated the employment of CFT as a basis for attempting to bring about conceptual change for ill-structured, complex domains. This constructivist approach has used the students’ prior misconception(s) of the subject matter as a baseline to guide treatments and to measure the degree of conceptual change.

Guiding the student’s construction of the conclusion along thematic paths while allowing them to have a moderate amount of self-direction allows for the correction of false concepts as well as the reinforcement of
proper ones. The use of multiple perspectives of a domain in a case-based environment aids this correction and reinforcement by giving the student a number of adequately sized pieces of information allowing for the accurate, rapid construction of correct concepts. Hypermedia allows the student to be guided to a correct answer while allowing the student to largely drive his or her own discovery of the material. Teacher-led instruction can present subject matter via various forms but it can't allow students to explore their own path to the information they need to understand by the very fact that it is teacher led.

In both the pilot and study proper phases, students were able to not only look at information and draw some conclusions but to construct the portions of information that they needed to understand the phenomenon. This building block approach that is integral to any constructivistic type of instruction allowed the pilot students to achieve the main goal of understanding the main concept by first examining the various parts that make up the main concept. The students understood the main portions of tornado formation (wind shear, a rotating horizontal cylinder, turning vertical and narrowing) and were able to examine them separately when necessary. The animation allowed them to see the portions as contributing to an entire process.

Jacobson (1995) suggests "further research could collect data on the student's hypertext traversal patterns that could help clarify the relationship between epistemic beliefs, learning with hypertext, and knowledge transfer". Students with simple epistemic beliefs may be found to be struggling with complex hypertext environments as seems to be the case. Spiro, et. al. (1990) suggest that further research be conducted to "investigate how students with simple epistemic beliefs can be better prepared to use and learn from an instructional approach such as the Thematic Criss-Crossing Hypertext, which employs multiple knowledge representations and nonlinear linkages to demonstrate various knowledge component interrelationships". Also, more work needs to be done in understanding how to best combine the continuity of animations with the specific points made by images and text. Helping these different types of media to compliment each other will provide a strong yet flexible teaching and learning tool.

Abstract: Experiences showed that an advanced set of metadata has to be provided for discovery, retrieval and evaluation of Internet sources for scholar work. In this paper we describe the Quality Metadata Scheme and its implementation within the smart search system xFIND for scholar work. The proposed idea may be seen as a further step to a more semantic World Wide Web for the scholar community.

Motivation

At the IICM we had long-term experiences in the fields of web based learning systems, for example (Dietinger et al. 1998), hypermedia systems like (Hyperwave 2001), and knowledge discovery, as with (xFIND 2001). The praxis showed that common metadata fields and full-text search within the knowledge discovery process on the Internet do not meet users' needs. This led us to propose that one of the key issues of modern search systems is to provide and manage quality metadata for Internet sources.

A fast-growing number of users, applying the Internet for a variety of objectives is affected with a dramatic increase of information and services on the Internet. In consideration of that fact, shortcomings can be identified as follows: anyone can publish anything without quality control and accuracy, problem of misinformation, unauthorized users can change or even add new content on foreign Web sites, and missing meta-information about the authority and reliability of information and services. The problems stated so far have great impact at the users (students, teachers, librarians, scientists, etc.) of the scholar community.

To counteract the problems mentioned above, additional information has to be provided to improve the information discovery and retrieval process as well as the evaluation of Internet resources. We propose the compilation of descriptive and evaluative characteristics, which may describe the applicability and therefore the quality related to a particular information need. Thus, we call such a set of attributes a Quality Metadata Scheme (QMS). We advocate the opinion that in the field of scholar work a QMS has to provide - at least - information about the authority of information resource or services, the target audience, the expertise level (beginners, advanced or experts), and a standardized classification scheme. The quality metadata framework within the smart search service xFIND (xFIND 2001) is called xQMS.

xQMS: The Basic Idea and its Implementation within the xFIND Search System

The proposed framework allows managing the quality metadata physically separated from original information within the xFIND system. It is designed and implemented as a multi-level process. That means that at the first level authors, students, publishers and providers can add interesting material by submitting...
xQMS sets for an entire Web server, a Web area, a particular page or a section of a document. On the second level a "xQMS administrator" reviews the information submitted by the person of the first level and enables the resource to render them searchable. On a third level teachers, librarians and subject domain level experts can review the resources and its xQMS entities as well as add their own xQMS entities. Such an approach will allow building a growing system of relevant information for a particular lecture, a particular subject, etc. The system is designed in a distributed manner, which allows the co-operation of lectures, departments and even universities and scholar organizations. For example, authorities of lectures about national history of different universities can build up a reviewed repository of interesting Web resources for their students. Thus, the repository can be fed with interesting resources according to scholar work of students. They have to add interesting Web resources at the xQMS system and enlarge the information with a xQMS record. After the review process, other students can use the growing repository for their own scholar work. The novel idea is that existing web resources are indexed by an advanced search system (xFIND 2001) and in addition, varieties of quality aspects are assigned to the resources within a multi-level rating process. The document content as well as quality aspects can be used in combination to process queries.

xQMS enables to specify the quality of Internet resources for scholar work and consists of descriptive and evaluative characteristics. Descriptive attributes comprise information about the author, the organization and the publisher as well as information about the resource (title, keywords, description and language, type of resource). Related topics can be assigned by the usage of the Dewey Decimal Classification (DDC) code. In addition, a research community dependent classification code (e.g. ACM for computer science) allows specifying the related subjects more granular. Within the search process, either DDC or a community dependent classification code may be used to define the semantic scope of the search. Evaluative attributes comprise the diction of the resource, target audience (age of the audience, expertise level of audience), authority, depth of information and width of information. It is our opinion, that evaluative attributes represent subjective values just for a particular community (e.g. a high school, university, etc.). Thus, different communities have to be enabled to manage their own xQMS records. The xQMS framework enables to manage xQMS sets for different communities and allows to select a particular set for search requests.

To give an idea how powerful the system is, an example is stated as follows. A student can process a query to find information for beginners in computer science with easy diction and containing "mySQL database" in headings of the documents. Furthermore, the students can also be supplied with xQMS information related to the Internet resources (a first prototype is implemented for Netscape 6.x exploiting XUL functionality).

The solution introduced will improve the search process as well as help to evaluate chunks of information within the process of browsing. Scholar workers are enabled to specify query terms containing descriptive and evaluative aspects. Furthermore, the scholar community will get a useful tool to build up and maintain their meta-knowledge of online resources according to their needs.

Preparing for Digital Story Telling

Ellen Brinkley
Robert Leneway
Allen Webb
Western Michigan University

Gobles, Michigan
United States
Ellen.Brinkley@wmich.edu

Abstract: Internet II is about to become commonly available to many educational users. As Internet I turned many of us into text editors, Internet II will cry out for many of us to become video producers. How do we prepare both our student and ourselves, especially those preparing to become teachers for this brave new world of digital video? How do we prepare for a world of viewers that will expect and demand of us high impact video communications? At Western Michigan University, with much help from the K-12 community, and the Center for Digital Storytelling, we are beginning to explore how to combine the video digital technology with the ancient art of story telling to better prepare pre-service students to meet the rigors of first year teaching and veteran teachers to better prepare and share digital media of their reflective experiences as teachers.

Introduction

In five minutes L__[female] and C__[male] describe what it's like to work as first-year teachers in the same small Michigan school district where they were once students. In five minutes R__[female] and L__[female] demonstrate for pre-service teachers and others how they call upon the power of place to teach students in different rural communities to take ownership of both their writings and the places they live. In five minutes P__[female] tells the story of her lifelong journey to name herself "writer" and the impact that journey has had on teaching and learning in her high school English classroom. These teachers, all of whom serve as classroom mentors for pre-service teachers, were able to create their five-minute stories during an institute last July on the campus of Western Michigan University in Kalamazoo, MI, using a process called digital storytelling; the process combines the timeless art of storytelling with new and powerful digital multimedia tools. For these teachers, and for others who have experienced digital storytelling, it is the technology application that finally delivers to their teaching practice the real power of a computer as a teaching and learning tool.

To an audience a finished digital story looks something like a short autobiographical, documentary film. Storytellers begin the process by writing and recording a personal narrative script, which becomes a spoken-text “voiceover” for the visual (and other auditory) elements of the piece. Then, storytellers use software to layer their voiceovers with any images that help tell the story: still photos, video clips, artifacts, text and non-text animation, soundtrack, and video and audio effects. To the storyteller, a digital story is a highly personal and densely packed exploration of a topic through story. But the real power of digital storytelling is something that happens between audience and storyteller, in how the experience of digital story can bring people together for conversations about the subjects and topics a story explores and suggests. To bring audience and storyteller together, a digital story can be stored and played on any computer application that supports the software to run it: personal computers can be used for individual viewers, data projectors work for a room full of viewers, and for the world, digital stories can be carried over the internet and played on media players like QuickTime and Real Player.

From Berkeley to Kalamazoo

The Digital Storytelling Institute came to Kalamazoo when Gobles, Michigan, high school teacher and mentor teacher Corey Harbaugh made a promise in Berkeley, California, the summer before. He went out
to Berkeley in the summer of 2000 at the invitation of the National Writing Project (NWP) to make a
digital story about his work in the Rural Voices, Country Schools project—an initiative of the Annenberg
Rural Schools and Community Trust and the National Writing Project—that documented and celebrated the
success of America’s small-town schools. He had never heard of digital storytelling before accepting the
invitation, but at the end of his week in California he was so transformed by it that he promised Caleb
Paul, the Education Programs Director at the Center for Digital Storytelling, that he would find the
