Our original assumption was that there may be distinctive patterns between groups, based on occupation, education or qualifications. However, the survey and interview findings found very little distinction in responses according to these variables. All groups cited the devastating effects of closure upon staff. These effects apply to staff from across the age range and with a range of occupational backgrounds, qualifications and service records. Notwithstanding these uniformities, there were some identified differences: long service staff in the older age range were not surprisingly concerned about their immediate financial situation and responded less positively to retraining and redeployment opportunities. Successful transferees indicated age and length of service as relevant factors in
respondent willingness to seek alternative employment, coupled with the view that few older staff (in support services) were mobile in terms of car ownership.

There are advantages and disadvantages of an extended closure programme. On one hand staff have time to adjust in a number of ways to a radically changed situation: conversely, the protracted "slow death" may demotivate staff especially when resources tighten and opportunities for transfer become fewer and less accessible. Many of the symptoms reported in the literature review on hospital closures have been found in this study. Refusal to accept that closure is right or morally legitimate (Massey, 1991) was demonstrated through concerns raised regarding the welfare of patients and the impending loss of community. At present a number of staff, some who have had close contact with patients over a number of years, feel that patient care is being compromised by the retraction. It is believed among some staff that this is an issue that management are either not aware of or refuse to consider.

Current levels of uncertainty concerning future employment opportunities were rife across all groups which for some is providing a (perhaps unconsciously) justification for inaction, which can be seen to be similar to Schlossberg and Leibowitz's (1980) "confusion" stage. There were also persistent comments that many of the staff were continuing in their current employment in expectation of generous severance or early retirement packages. An identified obstacle to staff movement is the reluctance of some (especially with long service records) to forfeit potential redundancy money if they move to employment out with the health service.

Respondents believe that negative stereotyping of hospital staff outside the trusts might constrain employment opportunities and is impacting on self-worth and self-esteem (Dominigue and Singleton, 1994). Evidence from successful transferees suggests that this may be an internalised self-image rather than a genuine significant constraint.

The literature identifies a number of stages in the "institutional loss" process. These stages involve disbelief and denial, feelings of betrayal, confusion and anger prior to arrival at resolution (Schlossberg and Leibowitz's, 1980). The findings indicate that with respondents, there still persist an amalgam of largely negative emotions concerning the closure and for many the stage of resolution has yet to be attained. This is despite the varied and extended efforts of management to inform and consult with staff. Arguably, resolution will only come when staff know what their likely outcomes will be in terms of continued employment, severance packages and early retirement terms. Over one-third of respondents claimed not to have been informed at all about future provision and three-quarters not to have been consulted over this critical issue.

Staff shortages, coupled with reportedly growing levels of absence and sickness, were compromising efforts to redeploy and retrain staff. Many respondents were not actively pursuing training or employment opportunities, for any of a combination of the reasons outlined above.

In addition, the availability and utility of specific information and devices were questioned. This is resulting in staff being disinclined to use many of these facilities. Although there were no real criticisms of secondments and training conceptually, staff identified a number of practical or operating constraints acting against their effectiveness, including inadequate resources, especially staff shortages, and insufficient contact and support.

The most intractable factor, from which a number of sub-factors extend, concerns the morale of staff and their motivation to take positive steps to withdraw from the hospital. Evidence from diverse sources confirms that morale and motivation of staff are at low levels. The old psychological contract based on security and continuity still resonates for many staff whose careers and lives are integrally mixed both with the hospital and their local community. Both these life-enhancing symbols are in a state of fracture as a consequence of the retraction.

Success in securing alternative employment appears to be positively related to personal initiative in seeking and pursuing opportunities, displaying an internal locus of control (Crodwer and Pupyn, 1993). All these respondents considered that they had been successful primarily through their own efforts, and whilst the hospital may provide channels for matching or retraining, these will be of little use without the initiative and effort of individuals.

The group interviews confirm a number of the issues raised in the survey. Whether the negative aspects identified above through the staff interviews were completely accurate reflections of the situation or not are in some ways irrelevant. People's behaviour will be related to their perceptions of situations and it is clear from our findings that these perceptions were affecting staff orientations towards the retraction programme. Whilst there is evidence of convergence of views between staff and management respondents, there are signs of a gap in perceptions, especially over the extent to which staff should take responsibility for their own advancement or should be guided and assisted by the hospital. As one manager put it: "We have 150 qualified nurses, but there aren't going to be 150 posts for learning disabilities nurses either in the community or the hospital. People have to get that through their heads and realise they're going to have to think about transferable skills" Other managers offered similar dependency culture views along the lines of: "People have to focus on what they are going to do for themselves" and: "Some people are quite innovative in what they are doing, others want to be spoon fed.. the Trust has a responsibility to do that, but I think there's an onus on them as well".
Conclusions

The study has demonstrated that even with a well-resourced programme with which employees are familiar and to which they are generally positively inclined and exercised with obvious goodwill by senior staff, the management of a major retraction programme confronts significant barriers. Prime among these are the social-psychological orientations of staff especially when pressures extend over a protracted period of time. There does appear to be individual characteristics, centred on the concept of 'locus of control' which are important in helping to determine staff outcomes. Whilst it is impossible to discern the reasons why some individuals display more of these qualities than others at any one time, or whether these are inherent or learned, the hospital is attempting to activate these individual characteristics among its staff. This is important as our evidence indicates that staff who do pursue alternative opportunities tend to be successful, at the very least, in obtaining interviews. One of the key issues to emerge from this study is the importance of understanding the profound emotional influences of closure/retraction on individuals. It would appear that a structured perspective was taken to the implementation of support mechanisms, with less attention being paid to confronting the devastating emotional consequences of their well-intentioned programme. This unintentional neglect is resulting in incomplete realisation of the programme.

This research makes a contribution to HRD in a number of ways. First, the findings from this case study can be used to inform other HRD directors in the health services sector who are likely to face or to implement retraction. Second, it adds to the literature on barriers and motivation to learning, by taking a focus on provision of training and development in a traumatic context, providing scope to develop our understanding of the emotional dimensions of motivation. It can also make a contribution to the work on barriers and facilitators to organisational change, through identifying key emotional intrinsic orientations of staff potentially affected by change.

A Qualitative Study of Nonexempt Employees: Careers or Jobs?

Kimberly S. McDonald
Linda M. Hite
Brad Gilbreath
Indiana University-Purdue University Fort Wayne

This qualitative exploratory study investigated career development activities, concerns, and needs of nonexempt employees. The study focused on work and career satisfaction and the potential role of career development activities. Results revealed a continuum of needs and interests regarding career development and reinforced the importance of further research on this key population. Nonexempt employees are the lifeblood of organizational output. Therefore HRD practitioners are urged to devote more attention to the career development of these often-overlooked employees.

Key words: Nonexempt Employees, Career Development, Human Resource Development

Despite apparent similarities in subject matter between human resource development and traditional career development theory, there has been little crossover in research or in practice (Boudreaux, 2001). Typically, much of the research that has been conducted regarding career theory has focused on career choice, developmental stages, and environmental influences; while the majority of career development studies in HRD have concentrated on the career progression of those in managerial and/or professional positions (Allred, Snow, & Miles, 1996; Wentling, 1996) or on early career goals and aspirations.

There are some similarities between the work of career theorists and HRD researchers. Both, for example, have begun to explore gender differences in careers, which has led to recognition of the influence of family responsibilities on career choices and progress. However, few studies in either field have focused on the career development of blue-collar and nonexempt employees (DeSimone, Werner, & Harris, 2002) and even fewer have examined the impact of HRD initiatives on these individuals’ careers. The purpose of this study is to explore how nonexempt employees perceive their careers and how HRD/CD initiatives may influence their careers.

The lack of attention to the career concerns and needs of nonexempt employees is puzzling. Nonexempts comprise more than half of the workforce for many organizations. Moreover, they often produce the organization’s products or provide its services, making them the closest link to the customer base. Traditionally, managerial talent, particularly at the highest levels of the organization, has been viewed as the most valuable human resource, and therefore the focus of most HRD initiatives. More recently, however, a competitive global marketplace and changing economic conditions require organizations to attract and retain the best employees at all levels. Front-line employees increasingly are asked to take on more responsibilities to ensure product and service quality, efficiency, and innovation. As a result, organizations are beginning to recognize the nonexempt workforce as a potential source of competitive advantage. Leibowitz, Feldman, and Mosley (1992) reinforced this thought when they wrote: “In an era when ‘working smart,’ flexibility, and efficiency are prized characteristics of any workforce (blue-collar or white-collar, manufacturing or service), organizations cannot afford not to examine more closely the career development needs of their nonsalaried workers” (p. 334).

The paucity of substantive research on this segment of employees suggests that they have been ignored or overlooked in most HRD efforts. As compelling as the argument is that organizations need their nonexempt workers for economic success, an equally important consideration involves reciprocity and fairness. For example, Wooten and Cobb (1999) argue for integration of organizational justice literature into career development theory and research. They write:

By its very nature, CD involves basic issues of fairness over the allocation of CD resources, the policies and procedures used to decide who receives them, and the interactions between those who provide and those who not only receive CD rewards but also experience its losses (p. 173).

Clearly, nonexempt employees are stakeholders in their organizations, as are their exempt and managerial associates, yet they typically have fewer opportunities for enhancing their skills in current positions or for career development. The paucity of substantive research on this segment of employees suggests that they have been ignored or overlooked in most HRD efforts. Respondents to a survey conducted by the American Society for Training and Development indicated that only 36% of hourly employees were covered by their organizations’ career development systems (Gutteridge, Leibowitz, & Shore, 1993). Leibowitz, Feldman, and Mosley (1992) wrote:
In these fast-paced times it is not difficult to find organizational career development programs that address the increasingly varied career needs of executives, managers, technical and administrative professional employees... The same cannot be said, however, of the nonexempt population in many organizations... These employees' career development concerns have not typically been the focus of intensive examination by HR professionals; indeed, the tacit assumption in many organizations appears to be that this population has no significant long-term aspirations that need to be addressed by the organization's career development staff (p. 324).

Thomas (1989) concurred that this population has been neglected by organizations and suggested "few organizations subscribe in practice to the idea that low-level, non-supervisory employees have or even want careers" (p. 354). However he believed organizations should be concerned with "blue-collar careers" because these workers do "accumulate skills . . . over time and are concerned about the meaning of their work experiences" (p. 355).

HRD professionals are in a position to advocate for increased emphasis on the development needs of nonexempt employees. However, they need more information to draw from if they are realistically to consider investing HRD resources into the large and varied group that are categorized as nonexempts. One goal of this study is to add to the small body of knowledge currently available.

Theoretical Framework

To more clearly understand the careers of nonexempt employees, it is important to look at their job expectations. Only a few studies have examined what blue-collar or nonexempt employees want from their jobs. Loscocco (1990) found that both blue-collar women and men ranked job security and good pay as the most important of eight job characteristics. HR professionals have indicated that strong work relationships positively influence job satisfaction for nonexempt employees (Leibowitz, et al., 1992). These HR professionals also perceived many nonexempts as being frustrated with their careers - citing issues such as perceived lack of mobility, lack of knowledge regarding ways to improve their careers, and the inability to think about career options. However, it is important to note that the Leibowitz et al. study represented the view of HR practitioners rather than direct reports from nonexempt employees.

Several studies have suggested that HRD initiatives can assist employees in their career development. For example, managerial men and women frequently cite the importance of mentors to their career advancement (Gordon & Whelan, 1998; Ragins, Townsend, & Mattis, 1998; Wentling, 1996). Tharenou, Latimer, and Conroy (1994) found that training opportunities led to promotions. Informal learning opportunities such as "stretch assignments" or overseas experiences also have assisted managerial men and women to advance in organizations. However, little is known about the impact of HRD interventions on nonexempt employees. In their study of women employed in trades, Greene and Stitt-Gohdes (1997) noted that "formal career education and/or counseling was not a factor in participants' decisions to choose the trades" (p. 274). Hite and McDonald (2001) found few HRD initiatives cited by women in front-line positions as assisting them in their careers. Olesen (1999) indicated that employees who move from blue to white-collar positions typically do not receive training about adapting to their new cultures.

Both Green and Stitt-Gohdes' (1997) and Hite and McDonald's (2001) studies were qualitative in design, grounded in emergent data. Jerich (2000) conducted a quantitative study assessing the professional development needs of secretarial employees at a large university. These employees indicated a need to develop business and budgetary skills to advance in their careers as well as a need to continually update their computer and technology knowledge and skills. Additionally, these secretarial employees cited time as the greatest barrier to their professional development. While this study focused on perceived needs and barriers to professional development, it did not examine the impact these interventions might have on secretarial employees' careers.

Case studies of successful career development programs for nonexempts suggest that the programs have been successful. For example, Russell (1984) reported that evaluation data regarding Lockheed's career development program indicated improvement in work quality and quantity, morale, and communication with managers and co-workers. Leibowitz, et al. (1992) cited data from an employee survey indicating improvement in the career planning process to argue for the effectiveness of Corning's career development program for nonexempts. However, both of these reports provide anecdotal information and report the data from HR's perspective.

Situated within the larger context of HRD research and practice, our study is an attempt to contribute to a better understanding of how white-collar dominated views of careers mesh with the experiences of nonexempt employees. We hope to identify ways the HRD community can better serve the needs of nonexempt employees and the organizations employing them. Thus our study is an initial step in answering a fundamental and important question:

20-2
How can HRD practitioners better meet the developmental needs of the nonexempt workforce?

Research Questions
This study explored the career experiences of men and women in nonexempt positions. The lack of established scholarship on nonexempt employees led us to other sources of inquiry. As a result, the questions developed were based on a review of the few studies that have targeted non-managerial employees as well as extrapolation from research on those in management positions. The questions posed were focused on what nonexempts want from their work and what activities have helped them in their careers. The term "career" used in the questions was defined to the participants as referring to paid or unpaid work. The following questions were addressed:

- What is important to you in your work?
- Looking back over the jobs you have had, are you satisfied with where you are now? Why or why not?
- What activities have you participated in to help in your current or future work?
- What has been the effect of these activities on your current work experience or your plans for future work?
- What additional activities would be most helpful for your career?

Methodology

We employed focus group discussions to gather data related to nonexempt employees' career development. Limited research data in this area necessitated a qualitative approach. Focus group methodology is recommended when the study is exploratory and when "factors related to complex behavior or motivation" are being examined (Krueger, 1994, pp. 44-45). We wanted to obtain data that "emerges from the group" (Krueger, p. 45), rather than imposing our own frame of reference on the data. Focus group discussions provide a forum where subjects can interact with one another in a non-threatening and candid manner (Lederman, 1990).

Human resource representatives from three organizations solicited volunteers to participate in this project, with the only parameter being that the potential participants be nonexempt employees. Three focus groups involved men and women employed in a large financial company, two consisted of employees in a mid-size manufacturing company, and the final group was nonexempt employees of a state university.

Each focus group began with a brief overview of the purpose of the discussion and our definition of careers. The five major questions listed above were presented.

Brotherson and Goldstein (1992) recommend using multiple researchers as a "form of triangulation" when using focus group methodology (p. 337). Therefore, at least two researchers were present at each focus group discussion. One researcher served as moderator, while the other took notes. Throughout the discussion, both the moderator and note taker verified participant responses using clarifying questions, additional probes and paraphrasing. Additionally, the note taker summarized the responses for each question before the facilitator proceeded with the next query (Krueger, 1993). Participants were instructed to clarify or correct any misinterpretations. Immediately following each discussion, a debriefing between the moderator and note taker took place to discuss "first impressions" and to compare and "contrast findings from earlier focus groups" (Krueger, 1994, p. 128). The discussions were tape recorded for review and preparation of complete transcriptions. Each researcher analyzed the transcripts independently to determine patterns emerging from the six groups. We used the constant comparative method (Merriam, 1998), comparing comments within and between focus groups to develop tentative categories. The researchers then shared their observations and findings.

Demographics

Each focus group in this study had 6-10 participants, for a combined total of 49. Within the 49, we had a small amount of racial/ethnic diversity: 14% of participants self-identified as black, 80% as white, and 6% did not respond. The total group included 33 women and 16 men. Not surprisingly, the financial institution had more female representation, and the manufacturing company included more males.

Participant ages ranged from 18-62, with nearly half (49%) in the 31-50 range, 27% under 30 years of age, and 22% at 51 or older (2% did not respond). Over 60% of our participants had been with their companies for ten years or fewer. At the other end of the spectrum, approximately 10% indicated employment of over twenty years.
A query about educational background indicated that 37% had completed high school or a GED. Nearly equal numbers had completed post high school education (22%) or associate degrees (24%). Fourteen percent held bachelor’s degrees.

At the end of each focus group session, participants were asked to respond in writing to brief statement sets about careers and career planning. The percentage of participants responding is listed to the left of each statement. The first set inquired about how (or if) the current job fits into a career plan:

- 27% I have a job, but I don’t think of it as a career
- 29% I am in this job for now, but I have other plans for my career
- 43% This job is part of a career path I have chosen to follow
- 1% No response

The second set of items asked how much thought respondents had given to careers:

- 22% I have not done much thinking about my career direction and plans
- 78% I have done a lot of thinking about my career direction and plans

A rough correlation can be made between these two groups of questions, noting that 72% of the participants think in terms of a career plan when considering their current jobs and 78% report having given thought to career direction. These results are particularly interesting in light of assumptions often made about nonexempt employees’ lack of career awareness.

Results

It is clear from our interviews that psychologically enriching work is important to many nonexempt employees. Important factors mentioned were: knowing one has done a good job, gaining a feeling of accomplishment, being appreciated, as well as having challenge and task variety. Not surprisingly, nonexempts often mentioned income and security as being important. They noted the importance of having a job that permits taking care of self and family, offers good benefits, and provides job security.

The respondents told us that liking your work and enjoying co-workers is important, as is having fun and working in a positive social environment. These values are not new among the workforce, as indicated by Kornhauser (1965), who found that many employees regarded good personal relations with their co-workers as a principal source of pleasure at work.

Issues related to job control were raised by several respondents, as in being empowered and having input and autonomy. Other factors included meeting performance standards, quality, and doing one’s best. Some stressed the importance of teamwork.

If one were to categorize what was important to nonexempts, three themes seemed relevant: the work itself, climate issues, and security/compensation/benefits. The work-itself category encompassed factors such as challenge, accomplishment, variety, and autonomy. The climate category encompassed relationship issues, being appreciated, knowing expectations, social support, and having input. And the security-compensation-benefits category encompassed factors such as job security, benefits, good pay, and flexible work schedules.

Satisfaction

We asked participants if, in view of their past work, they were satisfied with their current positions. Our intent in posing this question was to discern if respondents had set and met personal work-life-related goals, and if not, what hindered them. For the most part, however, the responses did not follow that line of thought, but were more literal. Only a few mentioned career aspirations or goals when responding to this query. Respondents did however reveal a great deal of individuality in their interpretations of “satisfaction.” For some, levels of satisfaction seemed based on how closely they perceived their current jobs reflected the characteristics they had cited as important to them in their work. As one participant noted, “…the job that I have now meets a lot of my needs as a job. . . There are times when I come in an hour early just because it’s cool to be there.”

Many appeared to measure current job satisfaction by making comparisons with past work experiences, noting that this environment or position compared favorably or unfavorably with previous workplaces. For example, several agreed with the statement made by one person that “this is the best place I’ve ever worked.” Similarly, some respondents asserted that they were quite satisfied with their current positions and workplaces, and that they saw no need to consider other options. This comment illustrates that perspective:

When you talk about career goals, I think most of the people in this plant, even the majority of the ones that are in the plant in manufacturing, in the front line are happy with their jobs and as long
as the company is here, they are going to be here. They don't have a feeling or need to move up. They are making a good wage.

Responses also varied somewhat by organization. Most of the employees in the manufacturing facility indicated satisfaction based on their perceptions that they were paid well, had good benefits, were treated fairly, and made a product of use to society. The financial institution had been experiencing some changes over time, so several employees of longer tenure expressed a preference for the past over the present, perceiving that employees were treated better by the company and had more opportunities for advancement and reward in the "old days." An example offered by one respondent:

In the past, my understanding is, years ago, when people took classes, they were rewarded for it, given raises, given a $50 or $35 bonus check. They were rewarded, so most people stopped taking classes when they weren't rewarded any more.

Participants from the educational institution acknowledged low pay as something they disliked, but they saw the benefits package and job flexibility as balancing out pay concerns.

Reasons for satisfaction seemed to cluster around the nature of the work, the work environment, and perception of appropriate remuneration. Sources of dissatisfaction included failure to fulfill earlier aspirations and failure to gain advancement.

Professional Development Activities

Many responses to the question regarding activities individuals had participated in to help with their current or future work focused on traditional HRD activities. For example, many respondents had engaged in internal and external training opportunities. A wide variety of training topics were discussed as the focus of these programs including computer applications, communication skills, product knowledge, technical information relevant to the specific job, and courses that led to professional certifications or designations. Additionally, several of the participants had taken advantage of tuition reimbursement/reduction programs to pursue their college education. All three organizations provide some form of financial support for employees' higher education.

Less traditional activities frequently mentioned included serving on committees and assisting with special projects. One participant stated, "I volunteer for several things. I feel that this is probably where opportunity lies... it opens my eyes to a lot of things within the company,..." Other discussants talked about participating in team meetings and serving on safety committees or a clerical/service staff committee within their organization. Still others cited community volunteer work (i.e., United Way and Junior Achievement) as being helpful professionally and satisfying on a personal level.

In general, respondents employed by the financial service organization and the educational institution felt networking was an important career development activity. One individual discussed the importance of networking to advance in one's career, stating, "I get to know the high ups and I believe networking goes very far... ." Others mentioned increased knowledge and teamwork as benefits of networking.

Effects of Activities

Many of the effects of the activities pursued by respondents were intangible or not directly applicable to their jobs. In fact, the most intangible of outcomes was no perceived effect whatsoever. Closely related to the no-effect answer was frustration, an outcome resulting from unmet expectations. Some respondents, mostly those who had pursued higher education, had expected results (e.g., promotions or transfers into other types of positions) that did not materialize, resulting in frustration. One respondent who devoted much of her discretionary time in pursuit of a college degree expressed this poignantly: "It's like I spend all of my time in class away from my family and my kids and this degree is really worth nothing."

Some activities were not pertinent to respondents' current jobs but to potential future jobs or careers. A few of our respondents used tuition reimbursement as a means of preparing for a career in a different field. Others indicated further education was a way to increase their marketability in case they need to find another job.

Another category of effects revolved around new perspectives. A few respondents told us that their developmental activities had opened their eyes, giving them different perspectives and readjusting their ways of thinking. One person told us that the courses she had taken toward her master's degree had exposed her to how classmates view their employers, giving her more perspective with which to consider her own employer. Another said that she had gained a new perspective on her supervisor's job as a result of attending meetings on the supervisor's behalf. Understanding other people better was an outcome mentioned by some.
More confidence and enjoyment were also mentioned as outcomes. One respondent told us her developmental activities had made her job more enjoyable by allowing her to meet more people in other parts of the organization. Another respondent told us that, although pursuing developmental activities was sometimes uncomfortable, it had resulted in more self-confidence.

Although mentioned about half as frequently as intangible effects, our respondents did mention some more tangible outcomes of developmental activities. For example, one respondent told us that, as a consequence of her development, "people look to you." We were also told that developmental activities had resulted in employees gaining more responsibility.

In some cases developmental activities improved the day-to-day experience of employees by making their jobs easier and reducing their stress. Also some employees were able to apply their learning activities outside of work. Two participants had pursued developmental activities that helped them establish businesses. The driving force behind these efforts seemed to be a desire for more financial security.

To summarize, we did not hear about many effects of developmental activities from our respondents. The effects we heard about could potentially be grouped into two categories: personal and organizational. The personal category includes outcomes such as new perspectives, increased self-confidence, enhanced marketability, finding out something is not one's calling, and acquiring skills useful outside of work. The organizational category could include outcomes such as acquisition of skills useful on the job, assumption of additional responsibilities, and enhanced leadership ability. Of course, some effects could fit into more than one category, such as gaining a better understanding of others and reduced stress.

Additional Activities Respondents Thought Would Be Helpful

Respondents mentioned various formal company-sponsored activities they believe would be helpful. The first was refresher training to keep up with the latest developments in procedures and work rules. Another was exploration sessions using personality instruments to help employees learn about themselves and others. Training classes employees could leave work to attend were also mentioned. In one of the organizations, many employees pursued various designations/certifications, and structured classes were desired to help master the subject material.

Respondents mentioned a greater number of informal on-the-job activities than formal or offsite activities. For example, they indicated it would be helpful to have opportunities to see how their job fits into others, as would seeing what others do on the job. The feeling was that this would help employees more effectively work with and support each other. Shadowing others who do the same work was also mentioned as potentially helpful. In this case, the respondent seemed to be referring to counterparts doing the same work at other locations. A maintenance employee suggested it would be helpful for employees to train one another on what they know. A nonexempt working in an office environment suggested that time to study at one's desk would be helpful. A few other employees expressed a desire to engage in the voluntary community service activities their employer supports.

Respondents told us that more encouragement to learn and grow would be helpful. If employees are motivated to learn about what goes on in another part of the organization, the feeling was that they shouldn't be discouraged from doing so. Rewarding employees for completing developmental activities (i.e., courses) also was viewed as helpful.

In sum, we did not hear about many additional developmental activities that nonexempts felt would be useful to them, nor was there a lot of convergence. There was a feeling that removing some barriers to development, encouraging employees periodically to complete a course or try something outside their immediate work role, and supporting their efforts to do so would be helpful.

Other Issues

At the close of our questioning, we always asked if there was anything else relevant we should hear about from respondents. At this time we often heard about difficulties encountered by those seeking to develop themselves. In one organization where there is currently a big drive for cutting costs, respondents said they felt hesitant to ask to attend courses for which their department would be charged. As one respondent explained, "It is very hard when you are stressing cost reduction, cost reduction, and you're seeing all of these job eliminations and people are just being let go, you think that maybe I really don't want to take this class right now." Some said they were receiving cues from supervisors indicating reluctance to approve training because of the expense. Other respondents talked about work piling up while they were gone from the job attending classes, making it punishing to return to a job and confront an overload of waiting tasks. On a similar note, respondents mentioned guilt about co-workers having to cover for them while they were away at training.
This open-ended part of the focus group sessions also uncovered some eye-opening information about people who do not want to develop their careers. Respondents in one organization indicated that employees were being forced to create career development plans including goals and desired future jobs. Respondents made it quite clear to us that some people are happy where they are in the organization and do not want to move up or change jobs. They were careful to point out that this didn’t mean that they were not willing to learn what was needed to continue to perform their jobs proficiently. The point was that some employees are very good at what they do and happy doing that, and forcing them to prepare a growth-oriented career development plan was seen as counterproductive.

Another major line of discussion was around qualifications for supervision. At the manufacturing firm we visited there was a strong feeling among nonexempts that too much emphasis was being placed on college degrees as a requirement for supervision. The nonexempts felt the company was losing money by bypassing people who could be good supervisors but who were, for one reason or another, unwilling to pursue higher education. Several respondents told us they want “a go-to” person in their supervisor; someone who knows the technical side of the job and who can answer their questions. Their feeling was that some of the college-educated supervisors did not understand the technical part of the job and were not willing to learn. There was strong sentiment among respondents at this company about this issue, making it hard to dismiss it as a typical blue-collar, white-collar perceptual difference.

Conclusions and Implications for HRD

As noted in Merriam (1998), “One of the assumptions underlying qualitative research is that reality is holistic, multidimensional, and ever-changing, it is not a single, fixed, objective phenomenon…” (202). This quote was well illustrated by the data obtained from our participants. The complexity and diversity of their perspectives provided us with a wealth of material that could not be categorized easily. This study has yielded interesting insights, but at the same time, it has prompted questions; which is, of course, the “ever-changing” aspect of qualitative work.

The results of this study indicate that those satisfied with their current positions tentatively fall into two groups. One group is happy with their current positions; they do not choose additional career advancement, they like the work they do, and they perceive they are treated well by their employers in terms of pay and recognition. Members of the other group are happy with their current positions, because they like the work and see opportunities for career advancement in an organization they believe provides sufficient remuneration for their efforts.

Conversely, those dissatisfied with their current positions typically perceive that they are not being adequately rewarded for their work, and they do not see opportunity for advancement to gain additional pay or prestige. One other tentative grouping includes those who are planning for future careers unrelated to their current jobs. Some seem grateful for an opportunity to work while they prepare for their next venture; others appear eager to leave, and in fact, their choice to change careers may be a reaction to their current dissatisfaction.

Lack of tangible outcomes of career development activities was a source of frustration for some respondents. More specifically, disappointment and frustration that a college degree hadn’t resulted in promotions was a major source of complaint. There seems to be a need for more realistic expectations among some nonexempts about what a college degree can and cannot do for one’s career. Also, if there are other developmental needs or deficiencies employees need to overcome, they need to hear about these so that they can choose whether to do something about them. Employees need to be given the full picture of what is needed for higher positions along with their current strengths and weaknesses. Managers need to provide this type of developmental feedback and HRD professionals often may be able to help them with this task. The dissatisfaction resulting from unmet expectations can be severe, and much of this dissatisfaction seems preventable.

These results suggest that fairness issues may influence nonexempt employees’ career development. The perception that career development activities did not result in tangible outcomes may be both a fairness and psychological contract issue. As Wooten and Cobb (1999) note more research is needed to explore the relationship between CD and organizational justice.

HRD can play an important role in helping organizations assess nonexempt employees’ career needs and then targeting programs to meet these needs. Those individuals expressing satisfaction and demonstrating few career aspirations may benefit most from initiatives designed to update their current skills and knowledge. It is important that HRD not ignore this group, but rather use them as subject matter experts, coaches, and on-the-job trainers. Those wishing for advancement opportunities may need and desire a larger set of HRD initiatives that might assist them in furthering their careers. Informal learning opportunities, mentoring, and career planning workshops are a few examples of the activities this group of nonexempt employees would find beneficial.
The participants in this study did not mention many HRD initiatives they had participated in, nor did they mention many they felt they had missed. For example, no one mentioned mentoring or job rotation, two common career development activities. We do not know why this was the case, and that prompts further questions. For example, are nonexempt employees unaware of the opportunities available to them? Do companies limit their access to HRD programs? Is the assumption made that nonexempts are not interested in pursuing these types of activities? A more focused study, employing quantitative methods may help answer some of these questions.

We believe the HRD community should recognize nonexempt employees as both primary stakeholders and as potential allies. A better understanding of their experiences and perceptions will help meet nonexempt employees’ needs and build their capabilities. This will release untapped potential within the nonexempt workforce, thereby helping to maximize workforce performance and organizational effectiveness. It will also help the HRD profession become more inclusive in its efforts to promote personal growth and career development.

Is Work Sharing a Better Option for Organizational Development?

Steve L. Whatley
Chan Lee
Lisa Moten
The Ohio State University

To obtain first-hand information about work sharing, the authors traveled to Wolfsburg, Germany and conducted interviews with Volkswagen organizational development employees and observed workers in the work environment. The implications of this paper indicate that work sharing is successful in Germany and that human resource development professionals should conduct further research into work sharing as a viable alternative to employee layoffs.

Keywords: Work Sharing, Job Sharing, Job Security

Job sharing has grown successfully over many years in Germany. Following the lead of Volkswagen, ten German industries agreed to implement work sharing in 1995. The success in Germany raises the question as to the potential for work sharing in the United States as an alternative to mass layoffs, i.e., layoffs involving 50 or more employees. Blyton and Trinczek (1997) explained work sharing as reducing working time to prevent mass dismissals. Cummings and Worley (2001) defined job sharing as “two people sharing a fulltime job” (p. 429) and discussed using job sharing as an alternative to downsizing or layoffs. Essentially, work sharing is a trade off between working fewer hours for less money and retaining a job versus losing a job completely.

Since 1992, the United States experienced a steady decline in the national unemployment rate until the latter portion of 2000 when unemployment began a steady increase. According to the Bureau of Labor Statistics (January-August, 2001), since mid-1999, mass layoffs have increased with few exceptions during the second and third quarter of 2000.

The number of people affected by these events has doubled since mid-1999 with a slight decrease in unemployment during the second quarter of 2001. The period January-August, 2001 was significantly higher than for the same period in 2000. In August 2001, manufacturing accounted for 41% of all mass layoffs and 49% of all people laid off. Industries included electronics, transportation, etc (Bureau of Labor Statistics, August, 2001).

In September 2001, employment fell by 199,000 although unchanging the unemployment rate of 4.9% up from 3.9% one year ago (Bureau of Labor Statistics, September, 2001). A month later, job losses were spread across most industry groups, with particular large increases in unemployment in manufacturing and services. The Bureau’s report was the first since terrorists attacked the World Trade Center on September 11th. Although the U. S. economy was weakening before the attacks, this downturn was exacerbated by the event of September 11th. The lack of demand for products and services encompassed 28% of all mass layoff events. Less than two out of five employers with layoffs in the third quarter of 2001 expected recalling employees. The manufacturing industry experienced 40% of all mass layoff events up from 37% one year before (Bureau of Labor Statistics, October, 2001). In November 2001, 42% of all mass layoff events involved the manufacturing industry (Bureau of Labor Statistics, November, 2001).

Again, the extensive use of mass layoff versus the success of work sharing in the Germany raised two research questions: First, to what extent does the literature address themes and issues on job sharing to avoid mass layoffs? Second, to what extent do the factors that influence the success of job sharing in Germany, using Volkswagen as a benchmark, differ from factors concerning job sharing in the United States?

Methodology

The authors first sought to determine the extent to which the literature addressed work sharing, or job sharing, as it is known, in the United States and its application to mass layoffs. It is important to note that because of the absence of academic articles related to work sharing the authors were required to use resources from either professional or popular journals. However, to learn about work sharing firsthand, they traveled to Germany and observed the work sharing program at the Volkswagen’s headquarters in Wolfsburg in May 2001.
Findings

Literature Search

Four databases from two disciplines, education and business, were searched on October 7th. These databases included the Educational Research Information Center (ERIC), Education Abstracts, ABI/Inform Global, and Business and Industry. Two of the databases, ERIC and ABI/Inform Global, were used because of being recognized as “major resources in HRD Research Literature” (Swanson and Holton, 1997, p. 186). The ERIC and Education Abstracts databases represent the education aspects of work sharing, while ABI Inform and Business and Industry databases represent the business and industry aspects of work sharing.

Key terms used in the search were work sharing and job sharing. It is important to note that the ERIC database identified the key term job sharing as a synonym of work sharing. The ERIC, Education Abstracts, ABI/Inform Global, and Business and Industry databases were searched using each key term from 1966, 1983, 1971, and 1994 respectively.

A total of 845 articles were found in all of the databases combined. The ERIC contained a total of 82 articles. All 82 articles were located using the key term job sharing, while no records were found using the key term work sharing. The Education Abstracts search revealed a total of 42 articles. Two records were found using the key term work sharing, and 40 records were found using the key term job sharing. The search in the ABI/Inform Global database revealed 640 articles with 303 articles found using the key term work sharing, and 337 records were found using the key term job sharing. The Business and Industry database contained a total of 81 articles with 22 found using the key term work sharing and 59 found using the key term job sharing.

Type of Articles

Once the records were categorized according to key term, they were then classified by type of article: popular, professional, and academic. Popular articles were defined as articles intended for the general population. Professional articles were defined as articles intended for practitioners. Academic articles were defined as peer-reviewed articles and published in scholarly refereed journals (See Table 1).

Within the ERIC database, 63 of the records were classified as popular articles while 19 articles were classified as professional articles. The ERIC database did not contain any academic articles. Within the Education Abstracts database, 34 articles were classified as popular articles and seven were classified as professional articles. The Education Abstracts database did not contain any academic article. Within the ABI/Inform Global database, 512 articles were classified as popular articles, while 126 were classified as professional articles. There were only two academic article found in the ABI/Inform database (Blyton and Trinczek, 1997; Singh, 1999). The Business and Industry database search revealed 72 articles that were classified as popular articles, while nine articles were classified as professional articles. Again, as in the previous three databases, no academic articles were found in the Business and Industry database.

Work Sharing at Volkswagen

In the 1980s, Volkswagen’s strategy involved the introduction of new technology and process automation as the principal route to increased productivity and lower costs, a strategy widely shared in Germany during that period. However, work cycles were longer and work pace slower with the initial adoption of the technology-driven strategy resulting in little room for team and group-work practices popular elsewhere. By the late 1980s, rising labor and other costs, created internal discontent within the company and planners retreated from ambitious automation targets resulting in huge losses in 1991 and 1992 (Tolliday, 1995).

The idea of work-sharing, which is redistributing available work by reducing the working hours and pay of employees, gained an increasing profile in German industrial relations as a result of Volkswagen’s pioneering agreement with labor in 1993. Volkswagen’s commitment was to secure stable and stimulating working, learning, and living conditions for the long-term (Phillips, 1987). Management’s commitment to labor was evident during the authors’ visit to Volkswagen’s headquarters. In 1995, labor and management came to a work sharing agreement that included management’s guarantee of jobs: Positions that included 30 hour workweeks and pay for overtime. Volkswagen used 450 different work schedules to accommodate work sharing (Whatley and Lee, 2001). The adjusted workweek schedule resulted in an increase in productivity and a reduction in absenteeism (Huberman, 1997).
Interview sources were quick to point out that maintaining positive relations with labor has proven to be in the best interest of Volkswagen's stability and longevity as well as promoting the German government's policy and in fact, the German philosophy, of social partnership.

Particular characteristics appear to be prevalent throughout Volkswagen's history as they pertain to the organization's culture. Open communication, harmony, dialogue and cooperation are attributed to the overall success of labor-management relations and thus Volkswagen's success. The labor-management relationship lead to cooperation in solving some of Volkswagen's most pressing problems including improving technology at the cost of losing production jobs, lowering production costs, and implementing work sharing.

Factors Contributing To Success

There are several satisfactory reasons why Volkswagen implemented work sharing versus mass dismissal to solve over-employment problems, which also serves as bases for use of work sharing in the United States, such as: layoffs would have damage cooperative relationships between labor and management. Based on the Soziaplan in the Works Constitution Act, German companies consider social criteria like age, family status, and length of service before terminating employees. Thus, labor groups in Germany have inherent power unheard of in the United States. Conversely, management in the United States, has virtually unlimited power to effect mass layoffs rather than seek other alternatives that could prove just as beneficial. In essence, the process employing the best person, the appropriate number of employees and using an effective employment process becomes less important and employees become expendable.

Since the local government of Lower Saxony is the primary stockholder in Volkswagen, it is doubtful that a mass dismissal plan would be implemented. These reasons do not mean work sharing is negative. Work sharing has provided several advantages to the company including saving labor costs of 1.6 billion DM in 1994 (Blyton and Trinczek, 1997). Even if Volkswagen saved these labor costs by mass dismissal, it would eventually acquire recruitment and training costs in the future, as is experienced commonly in corporate America. However, because of work sharing, Volkswagen has maintained quality standards by retaining existing work groups. Also, since Volkswagen guarantees job security, it assists in raising productivity; otherwise, workers would hesitate to suggest ideas for improving processes because of fear that their ideas may reduce the number of jobs (Blyton and Trinczek, 1997; Whatley and Lee, 2001).

Consideration for Work Sharing in the United States

Organizations across the United States have engaged in downsizing, most recently referred to as "rightsizing". Regardless of the term used, rightsizing in many situations is nothing less than mass layoff. Organizations have taken this "developmental" approach to streamline their organization by ridding itself of multiple layers of management no longer seen as necessary or useful.

In the process of rightsizing, organizations may in effect reduce overhead as it relates to labor costs, however, losses are also experienced by the organization as well. Organizations lose experienced workers, who possess core competencies for future growth, but also at some point need to be replaced and retrained for the positions once held by the "rightsized" employee (Cummings and Worley, 2001). Stated differently, positions once eliminated are restored.

Rightsizing creates problems within the organizational climate by creating distrust with employees who question their future with the organization. In other words, employees not knowing about the longevity of their employment may be apprehensive about offering their continued loyalty to an organization that may or may not demonstrate its loyalty by providing continued employment. In the long-term, "rightsizing" begs the question: Is rightsizing developmental? Therefore, work sharing should be considered as a better alternative rather than rightsizing for organizational development.

Implications For Human Resource Development

Human resource development implementation of work-sharing at Volkswagen demonstrates not only maintenance of the primary work-sharing ground rules such as reduced working hours, decreased income, and guaranteed job security but also essential compromises with its union in recompense for the job security and hourly wage increases.

However, there are several important points to consider for the successful transferability of organizational
change in Volkswagen or in organizations in the United States: First, the employer's approach to solve over-
employment problems is critical. Even within the German auto-industry, Daimler-Benz has continuously worked on
mass dismissals because of management's belief that work sharing like Volkswagen's case would just delay problems
rather than solve them.

Second, employees at Volkswagen already had been paid relatively high wages before implementing
organizational change strategy. It would be much more difficult to make an agreement with workers in lower wage
companies. Third, even if work sharing at Volkswagen functions as a short-term solution, it does not guarantee job
creation (Heuser, 2000). Although having a part-time job is better than not working at all, it is still not an ideal
alternative.

Conclusion

Two major themes concerning work sharing aimed at organizational development have been raised in this paper: the
absence of HRD research concerning work sharing and the limited use of work sharing as an alternative to mass
layoffs in the United States.

The limited use of work sharing in the United States may link directly with the absence of HRD research
concerning work sharing, thus, verifying a gap between HRD research and practice. The literature on work sharing is
limited to either professional or popular journals rather than academic sources. Though there is difficulty because of
the absence of academic research on work sharing issues, HRD professionals should focus on work sharing/job
sharing to support organizational development efforts in becoming more "developmental" rather than "detrimental."
Further research should focus on the planning and implementation process of work sharing to provide empirical
validation of HRD role in organizational development.

Identification of Key Predictors of Rapid Change Adaptation in a Service Organization

Constantine Kontoghiorghes
Oakland University

Carol Hansen
Georgia State University

This exploratory study attempted to identify key predictors of rapid change adaptation in a service organization. The results of this study suggested that rapid change adaptation will be more likely to occur in an organizational setting within which there is an emphasis on process and quality improvement, innovation, rapid technology assimilation, and internal customer focus.

Keywords: Change Adaptation, Innovation, Quality Management

As organizations begin the 21st century, change appears to be everywhere. As organizations transform the way they produce goods and modify the way services are delivered, numerous social, economic and technological pressures bombard them. To name a few, they include market fragmentation, shrinking product lifetimes, global production networks, workplace diversity and mobility, simultaneous intercompany cooperation and competition, and the business process reengineering movement (Oden, 1999). Given the intensity of these challenges to organizational survival and competitiveness, it is not surprising that most organizations find themselves operating in more complex, unpredictable and dynamic environments (Lewin & Johnson, 2000). To cope, most organizations consider themselves to be in a state of continuous improvement where they must accelerate the pace and effectiveness of their change strategies (Oden, 1999). The contemporary significance of organizational change is indicated by the recent proliferation of terminology such as, organizational transitioning, organizational renewal, organizational effectiveness, organizational improvement, and so on (Lundberg, 1999).

Felkins, Chakiris and Chakiris (1993) define the management of change as an interactive process that links daily work practices with strategic, directed change programs and performance goals. Pettigrew, Woodman and Cameron (2000, p. 698) elaborate "Change should refer to sequences of individual and collective events, actions, and activities unfolding over time in context." French and Bell (1999) note that inquiry about organizational change is founded in organization development theory and practice. They join the two constructs by defining organizational development as planned change in an organizational context. These definitions call to mind issues of process, pace, people, and environmental context. The focus on process contrasts with earlier views that change is a discreet movement from one state to another (Lewin, 1951). The assumption that change is continuous rather episodic suggests that change is ongoing, evolving, and cumulative in its attempt to yield a new pattern of intentions (Orlikowski, 1996). The role of people in these definitions suggests that an organization's members both shape and are shaped by change (Lundberg, 1999). Finally, the importance of organizational context and its impact on change is reflective of socio-technical systems theory (Pasmore, 1988).

While ways of thinking about change have, over time, evolved, differences persist in how scholars view its unfolding and management. Variance in perspectives range from a fairly mechanistic approach, whose principles assume an objective reality to a more dynamic and interrelated view of organizational behavior, based on participation, dialogue and teamwork. These worldviews can be categorized into a typology of four perspectives; behavioral, critical humanism cultural and systems theory (Felkins, Chakiris, & Chakiris, 1993). Behavioralists see change as a rational, measurable, and directed process with clear predictable and manipulable causal relationships. Critical humanism as a change perspective is centered on experience and encourages individuals and their organizations to question dominant ideologies. A cultural approach to change suggests an interpretive sense of reality where change occurs through social interaction based on cultural norms that are unique to a given group or organization. The systems approach places an emphasis on the gestalt of interdependent processes that respects the complexity of organizational relationships and structures. It is the last two perspectives that have most informed the study reported in this paper.

French and Bell (1999) note that as the history of organizational development has matured, certain change models advanced the practice. For example, Lewin (1951) introduced the idea that change is a three-stage process where behavior moves from one state to another and where change results from interplay with opposing forces. Kilman (1989) specified a total change system that consisted of critical leverage points within five sequential states.
The notion of first (transactional) and second (transformational) order changes was the basis for the Burke-Litwin model of organizational change (1994). The thinking was that transactional changes that impacted the work climate were easier to than deeper transformational changes designed to impact the deeper layer of the organization’s culture. Porras and Robertson’s model (1991) describes change as part of a system in interaction with its environment. They offered the premise that organizational development interventions alter features of the work setting which impact an individual’s behavior and lead to individual and organizational improvement. This evolution in perspectives and practices formed the foundation for a current breed of change models that emphasize the integration of social and technical systems in supporting the continuous process or change.

**Socio-Technical Systems**

The sociotechnical systems approach is based on the notion that organization survival requires systems that are open and able to interact with their environment. Oden (1999) portrayed opens systems theory as:

“A dynamic relationship with its environment, receiving various inputs, transforming them in some way, and producing outputs. Receiving inputs in the form of material, energy, and information, along with feedback regarding outputs, allows the open system to offset the process of decline. Moreover, the open system adapts its internal processes and structures to its environment as the need arises.” (p.14)

The organizational system can be divided into two subsystems: the social and the technical. This perspective assumes that the two factors of technology and people are essential to the change process. Neither alone is the driver of change. Oden described the application of social change without technology is merely automation and the application of technical reengineering is merely reorganization.

Lunberg (1999) offered an interesting view of how the social side of the socio-technical systems perspective works through his theory of social rules. This theory views organizations as social systems, composed of members who are agents with varying degrees of influence. Rule systems govern the transactions among members of the social system by sharing the nature, impact, content and outcomes of interactions and relationships. As these rules are created, learned, maintained and modified by individuals within the organization, its members also develop distinct identities and associated capacities to influence social rules in varying contexts. An additional assumption is that rules can be both a positive and negative force. While rules are necessary to make social transactions easier and more predictable, they also serve as barriers to change. The notion of social rules is reflective of culture theory as cultural norms are socially learned and reinforced (Spradley, 1979). Blumer (1969) noted that it is the social process that creates and upholds the rules and not the rules that invent group life.

The technical side of socio-technical systems theory can be linked to an interest in reengineering, which emerged in the early 1990’s as a relatively new management approach. In general, the first step in a reengineering effort is to rethink the organizational system in terms of its key processes and the technology available to carry them out. After the necessary process and technology related changes are introduced, the focus shifts to how the organization is managed and structured (Lawler & Mohrman, 1998). Lawler and Mohrman note that it is mostly top down process, which requires significant redistribution of power and authority and significant investment in information technology. According to French and Bell (1999) reengineering “does not appear to pay much attention to the social system of organizations relative to change processes and the redesign of work.” Yet, reengineering has failed to produce the desired outcomes in terms of competitive advantage. “Recent reports, supported with the viewpoints expressed by the founders of this movement, claim that more than 70 percent of reengineering efforts have failed to achieve their purposes” (Lawler & Mohrman, 1998, p. 205). High failure rates may be attributed to that to many people reengineering means downsizing which according to numerous studies rarely accomplishes its goals (Lindsay & Petrick, 1997). Such dismal outcomes appear to confirm the need for both a social and a technical perspective in achieving effective change through practice and research.

**The Context of Quality and Change**

TQM can be characterized as a people –focused management system whose philosophy and guiding principles for continuous improvement are based on teamwork and employee empowerment (Harvey & Brown, 2001; Lindsay & Petric, 1997). Through well structured processes, TQM aims to create an environment that encourages people to grow as individuals and learn to bring about both small but continuous (Kaizen) and drastic or breakthrough improvements” (Dervitisiotis, 1998; p. 112). What differentiates TQM from reengineering is its focus on cultural empowerment and an attention to change in small and continuous increments. TQM, interventions tend to fail when implemented, similar to reengineering, as top-down programs that assume neither an upward flow of involvement nor consensus decision-making (Hammer & Champy, 1993).
The role of management is key to understanding TQM. According to the TQM philosophy, most quality-related problems in the organization are caused by bad management and the systems that managers create and operate (Deming, 1986; Lawler & Mohrman, 1998). Likewise, the power of management in fostering quality driven cultures is in consonant with the organizational culture literature. This stream of study finds that management, in particular, executive management creates and maintains the cultural values of their organizations through the work models that they reward (Hansen & Kahnweiler, 1997; Schein, 1985; 1990).

Studies that have focused on the link between culture, work models, and TQM indicate that, in general, that a participative, flexible, risk-taking, team-based, and quality driven organizational culture positively supports TQM efforts (Detert, Schroeder & Mauriel, 2000; Fiorelli & Feller, 1994; Kontoghiorghes & Dembeck, 2001). Thus a company's prevailing cultural characteristics can inhibit or defeat a change effort before it begins. “Companies with a top-down management style, a short-term orientation that keeps them exclusively focused on quarterly results, and a bias against conflict may be uncomfortable challenging long-established rules” (Hammer & Champy, 1993, p.207). Detert, Schroeder & Muriel (2000) identified a set of 8 specific value dimensions that appear to theoretically lead to quality cultures: Management should be based on facts; long term planning and goal setting is preferable to a short term orientation; the sources of problems should be searched for in processes not in people; a premium is placed on change (as opposed to stability); the purpose of the organization is to achieve results that its stakeholders consider important; collaboration and cooperation is preferable to working alone; the vision, goals and responsibilities of the organization should be shared; success ought to be judged against external benchmarks.

Meanwhile, Detert et al. (2000) call for more studies by arguing that this is an area that has been inadequately explored. For instance, Olson and Eoyang (2001) state that there are over fifteen group methods that can guide change in organizations. The authors further state that “this variety produces a kind of cacophony that defies integration and does not allow any one voice to stand out as a logical alternative to the traditional explanations” (p. 6). Scholars and practitioners, on the whole, acknowledge the need for more research in organizational change. However, a recent review of the literature finds that the quality of data has advanced little in the past 25 years (Pettigrew, Woodman & Cameron (2001). Pettigrew et al. characterize current knowledge as too antitodal, containing few theoretical propositions and based on studies that are lacking in rigor. They call for a new pluralism between the social science and management scholars that entails a new dedication to time and history and a willingness to reveal the relationship between change processes and outcomes by portraying changes as continuous processes and not just detached episodes. The authors suggest that the literature is underdeveloped regarding these six interconnected analytical issues: multiple contexts or levels of analysis; time, history, process and action; linking process to outcome; international comparative research; receptivity, customization, sequencing, and pacing; linking scholarship and practice.

Problem Statement

Given the limitations and lack of rigorous research pertaining to change in organizations, the main purpose of this empirical study was to identify, prioritize, and describe the most important work environment variables in terms of rapid change adaptation in a health insurance service organization. The work environment was assessed in terms of the following learning and organizational dimensions: learning climate; management practices; employee involvement; organizational structure; communication systems; reward systems; job design; job motivation; organization commitment; job satisfaction; innovation practices; technology management; teamwork climate; ethical work culture; and process improvement climate. The dependent variable used for this study pertained to the extent to which the organization can adapt to changes instantly.

Research Questions

This main research questions for this study were as follows:
1. Which of the organizational variables incorporated in the study are highly associated with rapid change adaptation?
2. Which of the organizational variables incorporated in the study can serve as predictors of rapid change adaptation?

Methodology

Instrument. The instrument of this study consisted of a 108 Likert item questionnaire, which was designed to assess the organization in terms of the earlier described dimensions. Many of the dimensions and indicators were assessed with scales that were used or described in previous literature or research (Buckingham & Coffman; 1999; Hackman & Oldham, 1980; Kontoghiorghes, 2001a; Kontoghiorghes, 2001b; Kontoghiorghes & Dembeck, 2001; Lindsay & Petrick, 1997; Macy & Izumi, 1993; Pasmore, 1988; Whitney & Pavett, 1998), while several were custom-designed specifically
for this and other studies. In all, the questionnaire attempts to determine the extent to which the organization is functioning as a high performance system and according to TQM and sociotechnical systems theory principles. Further, the instrument assesses the extent to which the organizational environment is conducive to training transfer and a continuous learning culture.

The instrument utilized a six-point scale that ranged from "strongly disagree" to "strongly agree". The first version of the questionnaire, which consisted of 99 Likert items, was originally pilot-tested on a group of 15 participants for clarity. Furthermore, a group of seven experts in the organization development, human resource development, or quality management areas reviewed the instrument for content validity. Upon revision, the instrument was then administered to a group of 129 members of five different organizations. Reliability tests were conducted and the instrument was further refined and expanded. As stated earlier, in its final format the instrument consisted of 108 Likert items. The reliability of the instrument was measured in terms of coefficient alpha and was found to be 0.98.

Subjects. The sampling frame of this study consisted of 256 employees of a large organization in the health care insurance industry. The instrument was administered in one division of the organization in order to determine the extent to which it was functioning as a high performance unit. The employees were given the survey instrument at scheduled staff meetings over a period of two weeks. 192 out of the 256 employees returned the survey and the response rate was calculated at 75%. In all, 86.4% of the respondents were females and 13.6% males. In terms of position held in the organization, 4.1% of the respondents were identified as either a vice president or director of the unit, 4.1% as managers, 11.6% as supervisors, 65.7% as salaried professional, 12.8% as administrative personnel, and 1.7% as hourly employees.

Data Analysis. Based on the gathered data, a correlational analysis was used to describe the extent to which the organizational variables incorporated in the study are associated with rapid change adaptation. Further, through a stepwise regression analysis the most important predictors of rapid change adaptation variable were identified.

Results and Findings

Correlational Analysis. In total, change adaptation was found to be positively and significantly correlated with 99 of the other 107 variables incorporated in the questionnaire. These significant correlations ranged from 0.152 to 0.664 and reflected all learning, sociotechnical, and quality management dimensions assessed by the instrument. This finding in essence validates the systemic nature of rapid change adaptation and thus its reliance on multiple organizational dimensions for successful implementation. Given the large number of significant correlations and the fact that the main purpose of this study is to identify the stronger predictors of change adaptation, only those that were found to be 0.4 or higher are listed in Table 1.

As shown in Table 1, change adaptation was found to be moderately to highly associated with 29 organizational variables which in turn represented the sociotechnical, quality management, and learning environment dimensions. A closer look at Table 1 will reveal that most organizational variables represent the sociotechnical and quality management dimensions and range from 0.400 to 0.63. It is worth noting that none of the training transfer climate variables were found to be highly associated with rapid change adaptation. This finding suggests that successful change interventions depend more on the design, operational, and cultural characteristics of the organization rather than the skill level and expertise of the workforce.

In terms of the sociotechnical variables, the correlational data in Table 1 reveals that change adaptation will be more likely to occur on a more rapid basis if introduced in a participative and non-bureaucratic work environment within which there is constant communication and no boundary interference between departments. Other work environment variables that were found to be moderately to highly associated with change adaptation were: strong organizational commitment toward the employees (r = 0.46; p < 0.01), encouragement by the organization to have a healthy balance between work and life obligations (r = 0.45; p < 0.01), and the extent to which the organization is characterized by high ethical standards (r = 0.44; p < 0.001). Collectively, these work environment variables describe a non-bureaucratic and ethically driven system, which promotes employee involvement and well being.

With regard the job and team environment, change adaptation was found to be more highly associated with a high performance team environment within which team members are deeply committed to one another's personal growth and success (r = 0.48; p < 0.01), are willing to put in effort above minimum required in order to help the organization succeed (r = 0.44; p < 0.01), and have personal influence over their own work (r = 0.42; p < 0.001). In other words, rapid change adaptation is more likely to occur in a true team environment within which employees are deeply committed to the success of the organization and each other and enjoy autonomy on how to perform their jobs. These results demonstrate the importance of designing organizations that promote employee commitment and teamwork. Hence, paying close attention to the needs of the social system is still very important when rapid change adaptation is a desired outcome.
As far as the dimensions dealing with innovation, technology, and rewards are concerned, the correlations in Table 1 make it apparent that rapid change adaptation is more likely to occur in an innovation driven system within which risk taking not only is not punished, it is expected. Moreover, within such an environment new ideas are constantly sought and rewarded. This kind of work environment is in direct contrast to the bureaucratic model of management, which in turn advocates strict adherence to rules and regulations while at the same punishes or drives out of the organization those who challenge it. It is not by accident then that bureaucratic organizations have such a hard time coping with today’s rapidly changing times and often rely on drastic reengineering efforts in order to address their numerous and stagnation related problems.

**Correlation is significant at the 0.01 level (2-tailed). Listwise N=159**

The data in Table 1 also suggests that rapid change adaptation is highly associated with rapid technology assimilation (r = 0.56, p < 0.01), frequent technology introduction (r = 0.47, p < 0.01), and the use of technology as a primary support in the organization’s quality efforts (r = 0.43, p < 0.01). This finding is not surprising, given that the more rapidly the organization assimilates frequently introduced technologies the quicker it adapts to the related changes. Another implication of this finding pertains to the validation of the importance of sociotechnical systems theory. More specifically, the findings described in this technology related section in conjunction to those pertaining to the need of a highly participative, committed, and team oriented social system, demonstrate that organizational renewal and success do indeed depend on the optimization of both subsystems, the social and the technical. This finding is important in the sense it reinforces the fundamental premise of STS theory of “joint optimization” of both subsystems, while at the same time highlights the importance of systemic solutions when it comes to creating flexible and adaptive systems.

In terms of rewards, rewarding new ideas (r = 0.50, p < 0.01), profit sharing (r = 0.48, p < 0.01) as well as rewards for learning (r = 0.40, p < 0.01) were found to be positively and significantly correlated with rapid change adaptation. This finding suggests that when the employees believe that positive organizational outcomes will result into personal
gains then the employees will be more motivated to adapt the introduced changes. The positive association between rewards for learning and rapid change adaptation indicates that a reward system that is also based on pay for skills and knowledge does indeed offer the organization an advantage when it comes to change adaptation. However, given the high correlation between rewards for new ideas and change adaptation, special attention should be paid to the rewards for new ideas component. The effectiveness of a rewards for new ideas system can be exemplified by the fact that last year alone, employees at the Toyota plant in Georgetown Kentucky provided the organization with more than 70,000 new ideas. The payoff for these ideas was about $3 million. The instituted changes in turn saved the organization $28 million (Toyota Information Seminar, 2001). It is important to note that aside from the gains stemming from improvements, rewarding new ideas assists the organization in creating a more participative system which in turn, as it was found by this study, is also highly associated with instant change adaptation ($r = 0.60, p < 0.01$). Lastly, another very important outcome of such a rewards system is the fact the change process itself is owned by those who actually implement the changes which in turn is critical when it comes to successful change interventions.

With regard to quality management (QM), the correlations in Table 1 indicate that rapid change adaptation is highly associated with a quality driven culture. As shown, the correlation between change adaptation and the extent to which the structure of the organization facilitates focus on process improvement ($r = 0.63, p < 0.01$) was by far the highest in the table. Other QM variables that were found to exhibit a Pearson correlation of 0.40 or higher were: internal customer focus ($r = 0.55, p < 0.01$), quality measurement ($r = 0.52, p < 0.01$), excellence commitment ($r = 0.52, p < 0.01$), emphasis on doing things the first time ($r = 0.45, p < 0.01$), the extent to which quality improvement is a primary focus for the organization ($r = 0.41, p < 0.01$), and the extent to which quality improvement is a high strategic priority ($r = 0.41, p < 0.01$).

The last group of variables to be discussed under the correlational analysis are those belonging to the learning environment. A close look at the learning related variables in Table 1 will reveal that rapid change adaptation will be more likely to occur in an environment within which employees are committed to continuous learning ($r = 0.50, p < 0.01$), are rewarded for their learning ($r = 0.40, p < 0.01$), and share their knowledge and expertise with others ($r = 0.40, p < 0.01$). Collectively, these three variable demonstrate that a continuous learning culture can indeed act as a catalyst to organizational change and renewal.

**Stepwise Regression Analysis.** The results of the stepwise regression analysis of the change adaptation variable are summarized in Tables 2 and 3. As it is shown in Table 2, the produced regression model accounted for 59.5% of the total variance of the dependent variable and it incorporated in its design 11 independent variables. At 4.0%, shrinkage of the $R^2$ value can be considered very small.

*a* Dependent Variable: Instant change adaptation; *N* = 176

*c* $F = 24.46, p < 0.001$

Accounting 38.9% of the total variance, the variable pertaining to the extent to which the structure of the organization facilitates focus on process improvement was found to be the strongest predictor of change adaptation. The second and third predictors selected by the regression model, which accounted 6.2% and 3.7% of the total variance respectively,
were rapid technology assimilation and internal customer focus. The remaining predictors selected by the regression model were: a) profit sharing; b) awareness of how work unit processes fit with those of the other work units; c) few restrictions to innovation; d) product/service quality is measured at every step of the way; e) supervisory feedback on performance; f) personal influence over one's work; g) decisions on quality improvement are based on objective data; and, h) people in the organization are willing to put in effort above minimum required.

Summary and Conclusions

In short, the correlational analysis of this study found rapid change adaptation to exhibit a correlation of 0.5 or higher with the following organizational variables: participative organization; the extent to which there is no boundary interference between departments to solve joint problems; few restrictions to innovation; the extent to which risk taking is expected; the extent to which risk taking is not punished; the extent to which new ideas are rewarded; quality measurement; organizational commitment to excellence; and, the extent to which the employees of the organization are committed to continuous learning. At the same time, the stepwise regression model identified the following variables to be the most important predictors for rapid change adaptation: the extent to which the structure of the organization facilitates focus on process improvement; rapid technology assimilation; internal customer focus; and, profit sharing.

Collectively the correlational data and the independent variables in the regression model suggested that rapid change adaptation would be more likely to occur in an organizational setting within which there is an emphasis on process and quality improvement, employee participation, rapid technology assimilation, innovation, and internal customer focus. Within such a participative system quality measurement is made at every step of the process, there are few restrictions to innovation, and the organization shares its profits with the employees. Furthermore, within such a system risk taking is not only not punished, is expected. New ideas are constantly sought and rewarded while employees enjoy task autonomy, put in effort above the minimum required, are genuinely committed to each other's success and growth, and receive supervisory feedback on their performance.

In all, the findings of this study highlight the importance of STS theory and demonstrate that rapid change adaptation is more likely to occur in an optimized sociotechnical system for which employee involvement, commitment, and empowerment are of great importance. Given the high correlations between several TQM variables and change adaptation, one can further conclude that rapid change adaptation is significantly facilitated by an environment for which quality, excellence, and continuous improvement are a strategic priority. This can be considered an important finding because as of late some have questioned the effectiveness of total quality management in today's rapidly changing world. The new argument is that organizations need large and drastic changes in order to cope with today's fast changing environments. Thus, advocates of the reengineering approach claim that TQM, which relies on small but continuous changes, cannot be an effective approach to drastic changes. The results of this study prove otherwise. In general, companies that function under a continuous improvement mode do not need to make drastic changes in order to cope with the demands of the external environment. In fact, it is frequently the continuously improving companies that make it necessary for the competition to implement drastic changes in order to bridge the corresponding performance gap. Hence, the results of this study further suggest that unless reengineering efforts are accompanied with cultural changes that transform the organization into an innovative and non-punitive entity, the organization will still find itself having difficulty adapting to changes in a rapid manner and thus being subjected to periodic and unproductive drastic changes.

Implication for Human Resource Development and Limitations of the Study

This study has significance for HRD practitioners who serve as change agents. In this capacity, they must foster a philosophy of open systems where transformation considers both the social as well as the technical side of change. By helping organizations embrace the sociotechnical doctrine, they enhance their ability to foster the predictors of instant change adaptation identified in this study. Key to an organization's readiness and willingness to accept the quality of this perspective is their organizational culture.

Cultural norms are deep, difficult to see and for most, impossible to articulate. It is the role of HRD, given the field's philosophical commitment to people and people-focused management, to uncover and provide guidance in interpreting these belief systems. In particular, help is needed to understand how an organization's culture supports or hinders the principles of total quality management and continuous improvement. Given serious support from top management, HRD practitioners can work with individuals to reshape inappropriate reward structures, managerial practices and work models. By transforming these factors, a culture of excellence, synergy and innovation can emerge through new systems designed to favor employee empowerment, teamwork, and an openness to continuous learning. In short, the social rules can and must change. Without a supportive culture, the potential for effective and rapid adaptation drops dramatically, as the organization becomes a candidate for yet another failed reengineering attempt where there is little or no sustainable impact to bottom line performance.
In terms of future research, the main limitation of this study was that its data was gathered from a single source and was conducted in a service organization. Replicating this study in other industries and environments will help determine the extent to which the presented results can be generalized to other settings.

Research and Theory - Internationalization of Organization Development: Applying Action Research to Transnational Health Organizations

Carol Pavlish
College of St. Catherine

The well being of people around the world are increasingly dependent on effective transnational collaboration in health policy making and strategic planning. By facilitating transcultural interaction and planning, consultants in Organization Development (OD) can contribute significantly to managing issues of great human concern. This paper addresses the cultural competencies OD consultants need as they implement action research and work with transnational health organizations to construct a more socially just and healthy world order.

Keywords: Culture, Action Research Model, Organization Development

Virtually all organizations are coping with the concept and impact of globalization either as part of the context in which they function or as part of their internal operations and strategic management. In particular, international health organizations are struggling with the need to establish collaborative transcultural relationships to address the challenges of infectious diseases such as tuberculosis, AIDS, and hepatitis as well as the health consequences of population shifts, rapid social change and political violence. These complex health and social issues affect most societies and, therefore, require transnational analysis and solutions. After studying the history of international public health, Walt (2001) concludes that the current trend in globalization creates the challenge of international health cooperation in developing global health policy and forming more public-private partnerships to address global, national, and local health concerns.

Increased collaboration between national and international health organizations clearly establishes the importance of considering how cultural differences impact working relationships. As new alliances and partnerships are formed and different cultural beliefs and values intersect, professionals in Organization Development (OD) must be prepared to work within, among, and between cultural value systems that are not only internal (organizational) but also external (national and ethnic). The primary focus of this paper is to examine the impact of ethnic cultures mixing in transnational organizations and alliances that form to address global health concerns. Specifically, this paper explores the need for OD professionals to develop an international mindset and then presents a reconceptualized model for action research based on cultural inquiry and transpection. Cultural implications for each step of the action research model (ARM) are explored and some cultural competencies for OD consultants are suggested.

An International Mind Set

Paige and Mestenhauser (1999) claims "Leadership in the 21st century will require more than new knowledge; it will require new ways of thinking" and suggested that all professional disciplines develop an international mind set (p. 501). Currently, the most common approach to internationalizing a discipline is simply to add knowledge on various cultural traditions. However, the authors claim that this manner of internationalizing is far too simplistic and does not result in a fundamental change to the discipline. They define internationalization as "a complex, multidimensional learning process that includes the integrative, intercultural, interdisciplinary, comparative transfer of knowledge-technology and the contextual, and global dimensions of knowledge construction" (p. 504). All of these elements work together to construct a new mental model of what all professional disciplines including OD seem to need in this global era of profound changes and interrelated, interdependent cultural systems. Internationally minded OD consultants still consider the internal organizational issues that require change but these consultants are also driven by higher goals such as peace, social justice, sustainable development, human rights, and international and intercultural collaboration (Paige & Mestenhauser, 1999).

Copyright © 2002 Carol Pavlish

21-2
These goals seem particularly significant in the development of TNHO because the World Health Organization describes the following conditions as prerequisites for health: “freedom from the fear of war; equal opportunity for all; satisfaction of basic needs for food, water, and sanitation; education; decent housing; secure work and a useful role in society; and political will and public support” (Ruzek, Olesen & Clarke, 1997, p. 14).

The internationalization process is the focus of research conducted by Anderson and Skinner (1999). They claim that internationalizing a business is dynamic and fraught with uncertainty which often has negative consequences for small and medium-size organizations. Anderson and Skinner discovered that a significant factor in determining the degree of success is the extent to which the organization is ready to learn; they state, “Revision of underlying beliefs, assumptions and values held by members of the internationalizing company is crucial and the encouragement of learning, and the sharing of that learning within the organization, are fundamental for the effective operation of an international venture” (p. 236). In testing a four-stage model of the internationalization process, they conclude that participants inevitably experience the first three stages (prospecting, introduction, and consolidation) but that the fourth stage (re-orientation) is not inevitable. Re-orientation “requires a reconceptualization of the dominant logic and generative learning by the company as a whole” (p. 254). Therefore, one of the primary changes that OD consultants must help develop is a new mental model for the organization with which they work. A new mental model for TNHO seems particularly significant as members shift away from the concept of health within a cultural or geographic boundary and re-orient themselves toward the concept of global health.

For OD consultants working with TNHO, the transition from local thinker to global thinker must be deliberate and seems more complex than simply being culturally aware and sensitive. In an effort to learn what an international mind set means to OD, a cultural perspective will be applied to each step of an action research model (ARM). At the conclusion of this exploration, a clearer understanding of the international competencies for OD consultants will hopefully emerge.

An International Concept of the Action Research Model

Rothwell, Sullivan and McLean (1995) suggest an ARM that OD consultants can utilize when helping organizations cope with and adapt to change. The greatest benefits of this model are its open, participatory nature and its easy, flexible application. OD consultants working with TNHO must approach their work in an inquiring manner and the ARM frequently cycles through phases of gathering information to be used in planning. For OD consultants, the model also provides specific guidance that can easily be applied in different contexts without imposing a prescription for action. This flexibility acknowledges differences in organizational as well as ethnic cultures and allows those differences to create innovation without a restrictive structure. The following section of this paper explores cultural implications for each step of the ARM as originally described by Rothwell, Sullivan, and McLean (1995).

Entry and Start-Up

Rothwell, Sullivan and McLean (1995) described the first two steps in the ARM as a phase of inquiry. The OD consultant researches the organizations, as well as the context in which they operate, and discusses the demand for change with key decision-makers within the organization. The result is a “tentative, flexible, written plan for guiding the change effort” (p. 56). Initial contact with people in the organization is extremely important – and even more so when the cultural backgrounds differ as occurs in TNHO development. Two theoretical perspectives are particularly helpful in analyzing potential issues and conflicts during startup and entry: intergroup attribution theory and path dependence.

According to Ting-Toomey (1999), Intergroup Attribution Theory suggests that different social and cultural groups possess preconceived notions regarding characteristics of their own (in-group) and other (out-group) social groups. These preconceptions are based on “implicit assumptions, beliefs and categorizations of what human nature or human behavior is all about” (p. 152). Because of the uncertainty and heightened anxiety of working with strangers, attribution biases become prevalent in early encounters. For example, people often utilize negative stereotypes when interacting with out-group members and actively seek confirmation to substantiate those early judgments.

Intergroup Attribution Theory is important to OD consultants as they work in all phases of AR but seems especially significant in the early phase. First, OD professionals must be acutely aware of their own perceptions regarding in-group and out-group membership and must also be aware of their positionality in relation to all groups. OD professionals must also reflect on their prior interactions and experiences with people from the cultures with
whom they are working and carefully monitor how those past experiences impact the current situation. OD consultants must also recognize that when members of organizations from different ethnic groups/countries initially meet, the members' minds are already set in many ways. Unconscious biases and stereotypes will prevail unless OD consultants initiate activities to "undo" them. These activities must occur early in the ARM so stereotypes do not permanently establish themselves in the new relationships that form.

Another aspect to consider in entry and start-up pertains to the concept of path dependence as described by Eriksson, Majkgard, and Sharma (2000). Their research suggests that organizations' past experiences in the international market are critical to the knowledge they need when venturing into foreign markets (path dependence). The authors claim that the degree of cultural difference between the home and foreign market determines the amount of internationalization knowledge an organization needs. They also assert, "The initial steps in the internationalization process shape the business, institutional and internationalization knowledge the firms accumulate. The latter also forms the assumptions, beliefs and future absorption capacity [learning] of the internationalizing firm" (p. 30). Therefore, as members of TNHO begin working together, early experiences are very important to subsequent operations and activities.

OD consultants are key people in the initial phases of newly formed alliances between organizations. Educating organizations about internationalization process and transcultural competence needs to start early. Assessing prior experience with international organizations is also important at this stage. If a large cultural difference exists between members, then OD consultants must be particularly aware of the need for people to learn about cultural norms, customs, beliefs, and values in interpersonal interactions and health practices. All subsequent steps are dependent on how effectively OD consultants conduct the entry and startup phases when working among groups from different cultures.

Assessment and Feedback

The concept of cultural value orientation provides a helpful perspective for OD professionals to apply during all phases of ARM but is especially relevant during assessment and feedback. OD consultants employ a variety of data collecting techniques to formulate a better understanding of organizational issues affecting and being affected by the need for change. Cultural values will partially determine how the data is collected and what meaning is attached to the data. Therefore, in this phase of ARM, consultants must be aware of their own cultural values and assumptions as well as the various value orientations of the people involved. Finding assessment tools that reliably test value orientations seems an important part of assessment. Validity and reliability of the data and accuracy of the conclusions are dependent on an understanding of different cultural value orientations.

A classic framework of value orientations proposed by Kluckhohn and Strodtbeck (1961) provides a description of how ethnic cultures vary in their arrangement of complex principles “which give order and direction to the everflowing stream of human acts and thoughts as these relate to the solution of human problems” (p. 4). With an emphasis on problem solving, this framework seems particularly helpful for OD professionals working with TNHO. For example, according to Kluckhohn and Strodtbeck (1961), people vary in their primary orientation to relationships. All cultures have elements of individualism, family (lineality), and community (collaterality) as members develop relationships; however, certain cultures tend to favor one orientation over another. Cultural groups who primarily value individualism may be very willing to offer honest information to OD consultants in focus groups; whereas cultures favoring collaterality might be less likely to offer honest information in focus groups because their value orientation tends toward group cohesiveness. In addition to becoming aware of variations in value orientation among organization members, OD consultants must also be aware of their own value orientation and how values affect their choice of data gathering techniques. More research is required before accurate conclusions about how different cultural values impact the effectiveness of data gathering techniques can be drawn. In the meantime, value orientations can be a helpful guide for OD consultants when considering which techniques to use.

Data analysis following data gathering is another potential source of cultural bias. A degree of ethnocentrism will most likely be present, and OD consultants must be constantly aware of their positionality (race, class, gender, culture) in relation to the people on whom they are analyzing data. Tisdell (1998) discusses the concept of positionality in the classroom and claims that positionality affects what is seen and what is constructed as truth. To counteract the possibility of bias, she suggests seeing with a third eye which “is to recognize that the self constructs knowledge in relation to others, and both the self and others are situated and positioned in social structures where they are simultaneously privileged and oppressed” (p. 150).

OD consultants for TNHO must be constantly vigilant about their cultural positionality in order to avoid ethnocentric assumptions during data interpretation and analysis. For example, silence is often interpreted from a
Western perspective as a lack of “voice” which is metaphorical for lack of knowledge or empowerment. However, many cultural groups appreciate silence in a vastly different way, and the diversity in value orientation about silence could result in misinterpretation. When working with TNHO, consultants cannot assume they know what silence means; instead they must ask questions about what is “underneath silence” (Tisdell, 1998, p. 151).

Feedback follows data gathering and analysis. How OD consultants offer feedback to members of the organization is once again partially dependent on value orientations. In addition to the list of useful feedback characteristics proposed by Franklin (1995), OD consultants need to add a characteristic about cultural sensitivity. For example, feedback is offered using the principles of mindful intercultural communication. Mindfulness is the “readiness to shift one’s frame of reference, the motivation to use new categories to understand cultural differences, and the preparedness to experiment with creative avenues of decision making” (Ting-Toomey, 1999, p. 46). Many cultural implications exist for the feedback phase. By remaining tentative about conclusions drawn from the data and actively seeking input from participants to explore new perspectives—especially cultural perspectives—OD consultants can become more effective in providing feedback to members of TNHO.

Action Planning

The primary perspective in the action planning phase of ARM is to be inclusive and encourage widespread participation especially during the initial stage of TNHO development. Multiple cultural and interdisciplinary frames of reference are necessary to compose an ethical and effective plan for change. As Eriksson, Johanson, Majkgard, and Sharma (2000) found in their study on knowledge development in the internationalization of businesses, when first going abroad organizations are likely to be ethnocentric “because their absorptive capacity [determined by past experience] is domestic-market based” (p. 319).

Members of TNHO are especially likely to start their work together from an ethnocentric viewpoint. Perspectives on concepts such as health and disease causality as well as who is entitled to provide care and what intervention strategies work effectively are derived from cultural values and norms. Lacking awareness of other cultural perspectives in the early phases will severely limit collaborative visioning and problem solving. OD consultants perform a vital role in creating safe environments and providing opportunities for members to comfortably discuss their cultural perspectives. In order to address global health issues, members of TNHO must recognize their own differences and then work toward incorporating multiple perspectives into meta-models for collective problem solving to improve the health of the world’s people.

Bennett (1993) proposed a developmental model that depicts growth from ethnocentrism to cultural relativism; he describes the process of development as “the construction of reality as [people become] increasingly capable of accommodating cultural difference” (p. 24). Organizations by their very nature often attempt to instill commonality among members—perhaps a commonality of purpose through common norms and standards. Differences are sometimes overlooked as people within the organization strive toward achieving a common set of goals or missions. Thinking in terms of cultural differences and valuing diversity of traditions require a new mental model for organizations.

Adler (1980) describes “cultural synergies” as the differences that people bring to intercultural experiences. He claims that acknowledging cultural differences can potentially lead to better outcomes than if those differences are avoided. By creating a global mindset that accommodates cultural differences, OD consultants for TNHO can enhance development toward cultural relativism. Bennett (1993) offers several cultural adaptation strategies such as structuring opportunities for difference-seeking and promoting examination of profound cultural contrasts.

As people move toward cultural diversity and greater awareness of differences occurs, ethnic conflicts often emerge. Anticipating these conflicts ahead of time is an important consideration for OD consultants working with a TNHO. Palich and Gomez-Mejia (1999) claim that “Cultural diversity may indeed bring together divergent perspectives...but global firms may find that these benefits are more than offset by the drawbacks of unmanageable levels of diversity” (p. 15). Contrary to popular support for “value-in-diversity” the authors contend that global firms must exercise caution when entering diverse markets and at the very least must take into account the inevitability of cultural conflict. Palich and Gomez-Mejia (1999) state, “Since globalization requires managers to coordinate the efforts of groups from different national cultures, disproportionate levels of misunderstanding and conflict are likely to attend these efforts” (p. 13). OD consultants who work with TNHO need to implement strategies that prevent cultural clashes. They must also recognize the early signs of cultural conflicts and be prepared to provide the necessary leadership in managing them.

White and Rhodeback (1992) question the assumption that OD ethical standards for professional conduct are transferable to other countries. When researching cultural variation in analyzing and resolving ethical dilemmas, White and Rhodeback found significant cultural differences in OD professionals’ perceptions of ethical consulting.
behaviors; they state, “implicit in this difference is the potential for otherwise successful working relationship to be soured by a lack of sensitivity to a difference in expected standards of conduct” (p. 668). Both researchers conclude by imploring the OD profession to more explicitly integrate international diversity into the Code of Ethics.

The Preamble of the “Statement of Values and Ethics for Professionals in Organization and Human System Development” as reported by Rothwell, Sullivan and McLean (1995) clearly indicates that the authors of the Preamble recognize their Western perspective. The Preamble authors state, “Since this Statement has been developed from within the cultural perspective of the United States...we recognize that it includes concepts, beliefs, assumptions, and values unique to the country’s culture” (p. 566). This awareness is a significant first step in acknowledging that cultural differences and conflict potential co-exist. Another significant step occurred as Aragon and Hatcher (2001) compiled a casebook for OD professionals to use as an “ethics and integrity resource” (p. 6).

Perhaps, the next step is more research on the nature of cultural dilemmas that OD consultants encounter and effective methods of working through the dilemmas. For example, how are human rights interpreted within a collectivist versus an individualistic society? Should some ethical principles be universally applied? What methods are effective in helping transcultural groups manage conflict? Research of this nature could provide more guidance for OD consultants as they internationalize their mindsets and work globally.

**OD Interventions**

During the intervention phase all previously discussed concepts seem to converge. Mindful cultural communication, diverse value orientation awareness, conflict management, and intergroup attribution theory seem necessary in shaping the perspective of OD consultants during the intervention phase. Lau and Ngo (2001) who researched the effect of culture on OD interventions echo the complexity of this issue; they tested competing hypotheses by questioning whether the usage and effectiveness of OD interventions in multinational organizations are related to the organizational culture in which they occur (cultural influence) or the cultural context of the country-origin (isomorphic influence). The researchers discovered that the cultural adaptation issue “is much more complicated than it was thought...[and] that some OD interventions are culture-free and some are not” (p. 109). They conclude that the organizational culture perspective is more pertinent to the implementation of OD interventions and that the isomorphic (country-culture) view is better in understanding OD effectiveness.

The controversy of how much influence the country-culture has on OD interventions continues to be explored by some OD researchers. For example, Golembiewski (1993) compared the success rate of OD interventions in Western settings versus non-affluent countries. The results of his studies indicated that OD interventions in Western settings had a 41% success rate in achieving “substantial proportion of intended effects” whereas only a 16% success rate was reported in non-affluent settings (p. 1674). A 56% success rate was reported by non-affluent countries and a 43% success rate was reported by Western countries in the category of “some intended effects achieved” (p. 1674).

Golembiewski (1993) cautions against OD consultants being too restrained in implementing OD interventions in low-income countries; he argues that OD, by its very nature, is sensitive to cultural differences and that ARM is designed to assess and diagnose those differences. He asserts that “OD consultants can (and frequently do) make reasonable situational adjustments to the cultures in which they operate and that OD technology has powerful generic features that facilitate adaptation to the idiosyncrasies encountered in all organizations in all settings” (p. 1673). However, the low success rate of OD interventions in low-income countries must be addressed with more research as the OD profession internationalizes. This research would be particularly helpful to TNHO working on health issues where human lives are at greater risk if collaboration fails. Since many serious health risks exist in low-income countries, the importance of developing research-based OD interventions that work effectively cannot be overlooked. By avoiding assumptions about OD effectiveness in low-income countries and producing workable models, OD researchers could contribute significantly to correcting the large and complex health disparities that exist between low-income nations and the more economically developed countries.

Green (1993) described his experience as a non-governmental participant at a United Nations (UN) conference on aging. His observations led to several suggestions for OD consultants working toward global change. For example, he notes that the practice of Theory X and the centralization of decision-making are common in many nations abroad. Theory Y with its more participatory management practices is more novel – especially with developing countries (Green, 1993). This anecdotal report lends support to the argument that country-culture has an impact on OD practices and that OD consultants working with TNHO must consider how to most effectively work within a broad range of cultural contexts.

Although some OD researchers claim that cultural sensitivity is an inherent feature of OD, there seems to be a need to enhance the effectiveness of OD interventions in developing countries. In addition to deliberately applying
a cultural perspective to existing OD interventions and testing interventions in various cultural contexts, new interventions that deliberately acknowledge and bridge cultural differences must be developed and researched. Many diversity training techniques are available, and they often result in increased cultural awareness. However, culture should also be an integral part of system level interventions. Rather than being compartmentalized as a subject of training, culture could be woven into every aspect of OD intervention.

There appear to be no prescriptions for success when implementing OD interventions in TNHO. Therefore, when determining how to conduct interventions, OD consultants must consider multiple cultural contexts and how they impact the development of organizational culture as well as the many issues that pertain to cultural adjustment and firm effectiveness. Perhaps, the best guide is for consultants to proceed with interventions by using contingency planning which stresses flexibility, probabilistic planning which accepts multiplicity and uncertainty, and futuristic planning which maintains a vision of possibilities. This planning needs to be accompanied by a spirit of inquiry, optimism, and confidence as OD consultants work to balance power among participants, plan effective ways to manage different cultural perspectives on global health concerns, and maintain hope in goal achievement.

Evaluation

In the evaluation phase of ARM described by Rothwell, Sullivan and McLean (1995), OD consultants return to data gathering except this time the data pertains to outcomes. A series of questions such as “what benefits have been achieved by implementing OD interventions” and “how are they valued by different cultures” need to be asked. Assuming a cultural perspective is integrated into the evaluation plan, the actual implementation of evaluation measures must also exemplify cultural sensitivity. Mindful cultural communication avoids bias in the interpretation of data, incorporates multiple ways to examine data, and conveys respect for differing values regarding outcomes. By exemplifying the continuous nature of evaluation, reflection-in-action is an effective perspective for OD consultants during this phase.

Schon (1987) discussed reflection-in-action as the process of fluid inquiry and continuous frame analysis; he describes how reflective practitioners are patient as they engage in reflective conversations with the situation allowing conclusions to be tentative as more perspectives are sought and continually incorporated into the emerging and ever changing situation. OD consultants engage in reflective practice to learn about the effect of interventions as well as the process for subsequent steps. Wide participation is assumed as multiple cultural frames are sought. As novel situations present themselves, reflective practitioners by carefully analyzing the subtle similarities in situations and the many shades of differences make wise use of past experience. Even though Schon (1987) does not specifically discuss the cultural implications of reflection-in-action, the process seems to be helpful in cross-cultural encounters. OD consultants working with TNHO need a reflective rather than just a technical process during evaluation. By its very nature, evaluation requires careful and complex thinking that usually occurs while the professional is in the situation. The next steps of ARM are dependent on this very important reflection.

Adoption and Separation

OD consultants have been planning this stage of ARM from the beginning. Two concepts seem pertinent for transcultural organizations – agency and community. Agency refers to the “ability of actors (persons, groups, organization) to make decisions and act out of their own interests,” and community refers to the “participation of actors in interdependent relations” (Rousseau & Arthur, 1999, p. 8).

Transnational collaborators in health planning seem to need both concepts. OD consultants need to prepare representatives from different cultures to act partially out of their own national interest (agency) and out of an interest in the common good (global community). Once these concepts are balanced, adoption and separation can occur more successfully. Having prepared members of a cross cultural group to appreciate both threads of similarity and shades of difference, to interact effectively, to work synergistically, to manage conflict productively, and to maintain resilience in an ever-changing context, OD consultants can slowly withdraw their help. How this separation is best managed in TNHO requires research since there is currently a lack of published studies that examine the separation phase of action research. More information about how cultural value orientations impact adoption and separation and about which techniques work best is also needed. This type of research would advance an international mindset for OD consultants.

Competencies for OD Professionals in International Work

Wigglesworth (1995) describes several competencies for professionals working in international OD. These include competencies such as self-awareness, linking skills, interaction skills, and tolerance of ambiguity. He describes various researchers who have studied cultural differences and presents some excellent suggestions on how OD
professionals should behave in international situations. However, an international mindset seems to require a
different way of thinking—not just an enhanced set of skills. Yershova, DeJaeghere, and Mestenhauser (2000)
suggest that an international mindset requires “thinking not as usual” (p. 39). This section of the paper suggests
three “not as usual” thinking competencies for OD consultants who work with transnational organizations.

Comparative thinking is the first competency. Yershova, DeJaeghere, and Mestenhauser (2000) state,
“International experts and consultants are known to make comparative assumptions about problems that appear
similar to those of their own cultures, and to offer instant solutions without first analyzing these problems” (p. 57).
Comparative thinking is the process of relating what is known to what is unknown and discovering and analyzing
assumptions about both. Comparative thinking is a method used in a variety of contexts—as explanations,
persuasions, and understandings. The key feature in sound comparative thinking is a careful exploration of the
cultural elements being compared.

In the multicultural context etic and emic perspectives need to be compared. The etic perspective is viewing a
culture from the outside; the emic perspective is viewing the culture from within (Cutz & Chandler, 2000). When
thinking comparatively, OD consultants should be able to shift emic and etic perspectives as the situation demands.
Without comparative thinking, people tend to use the emic perspective about their own culture and etic perspective
about other cultures. However, working effectively across cultures requires an ability to explore, compare and
analyze both etic and emic perspectives of multiple participants. Reflection, correlation, cultural transpection, and
imagination characterize comparative thinking.

Contingency thinking is a second competency. The complexity of working across cultures requires a certain
confidence in the unknown. Those who can think about multiple, interacting, and cascading variables are better able
to work transnationally. Similar to systems thinking, contingency thinking requires OD consultants to see the “big
picture” and recognize that outcomes are partially dependent on unknown factors. Unforeseen problems will arise
and are viewed as new opportunities for novel discoveries and improved planning. Flexibility, openness, and
creativity characterize contingency thinking.

Global thinking is the third competency and requires OD consultants to consider how worldwide economic,
political, and sociocultural trends impact transnational organizations. The world is viewed as a singular, complex
system where decisions influence the future of the world community. Microlevel analysis is consistently
contextualized as OD consultants consider macrolevel impact. Citizenship in the world community requires an
analysis of issues as they impact all people—not just those (such as the wealthy and educated) who have a voice but
also the meekest and weakest citizens. Individual and community responsibility is seen in light of social justice and
transcultural consciousness. Connection, context, equity, and empathy characterize global thinking.

Conclusion

ARM as described by Rothwell, Sullivan, and McLean (1995) is a very helpful process for OD consultants but
seems to require greater acknowledgement of cultural differences. Researchers who believe culture is quietly
inherent in the current practice of OD seem to overlook the complexity and tenacity of cultural values. More
research about how differences in cultural values impact transnational organization development is needed in order
to improve the health of the world’s people. More explicit emphasis on cultural values throughout the action
research process is required for TNHO to discover effective ways to change the significant health disparities that
exist between developed countries and low income countries. More attention to OD interventions that facilitate
transnational collaboration is necessary for analyzing and addressing specific global health concerns such as
environmental degradation and food production, civil unrest and the suffering of refugees, and economic and health
care access disparities among the world’s people. As the OD profession enters the global era, an international mind
set seems important. In addition to the well publicized list of OD competencies, thinking “not as usual” in the form
of comparative, contingency, and global thinking is required—especially if the OD profession wants to exert
effective leadership in making this world a more socially just, environmentally healthy and tranquil place to live.

The Design and Development of an Instrument to Measure Organizational Efficacy.

James G. Bohn
The University of Wisconsin–Milwaukee

Organizational Efficacy is the perceived ability of an organization to work together and persist regardless of obstacles. While researchers have recommended a tool to assess Organizational Efficacy, to date no instrument makes this claim. This research developed the Bohn Organizational Efficacy Scale, using two studies to assess validity and reliability. The studies revealed a three factor solution as predicted by efficacy theory, .93 alpha coefficient, and strong correlations with customer focus and employee satisfaction.

Keywords: Organization, Efficacy, Measurement.

Organizations require empirically based tools to effectively analyze the reasons for poor or strong performance (Connor & Lake, 1994). This research developed and tested a tool to measure Organizational Efficacy, which has been theorized as an aspect of organizational performance (Bandura, 1997). The purpose for understanding organizational efficacy is to assess organizations that are low in efficacy, and develop means to improve efficacy and thus improve performance. The aggregated performance accomplishments of every employee in an organization drive organizational performance (Bandura, 1997, p. 472). In other words, organizational performance is more than the sum of its parts, it is the output of coordinated effort among many people. Shamir, (1990) in his analysis of employee motivation within corporations, made the following statement:

In the case of collective tasks whose accomplishment depends on collective efforts, it is not rational to make an effort if collective efficacy is perceived to be low, because no matter how strong the perceived relationship between rewards and collective accomplishments, the chances of such accomplishment and therefore of obtaining rewards, are perceived to be low. Hence, a cognitive calculative formulation of collectivistic motivation must include the individual’s subjective probability that the collective efforts will result in collective (organizational, departmental, or team) accomplishment" (p. 316).

Thus aggregated individual perceptions of the organizations’ capabilities are critical to the overall success and performance of the entity. Tools for measuring that capability have been elusive to this point. Observers of organizations know there are some organizations have a "feel" about them that exudes efficacy, where a “can do” attitude pervades the halls of the organization (Kotter & Heskett, 1992). We know that other organizations have less of the attitude, where people have less “fight” in them (Ryan & Oestrich, 1998). Conversely, in organizations that appear highly efficacious, people believe they can do anything set before them (Kotter & Heskett, 1992). These organizations are not afraid to take risks (Truske, 1999). Does this belief of organizational efficacy necessarily translate into financial results? At this time we cannot assert a direct causal relationship between the two factors, but we do know that self-efficacy is a cognitive apparatus which supports behavior (Reeve, 1996). Thus the overarching thesis of organizational efficacy theory is if strong self-efficacy beliefs sustain individual persistence (Sadri & Robertson, 1993), then perhaps organizational efficacy beliefs will sustain organizational persistence to accomplish organizational goals and increased organizational performance.

How Are Organizations Analyzed Today?

Organizations study culture, teamwork, employee benefits and other factors to influence performance (Truske, 1999) but an overall metric of organizational efficacy in the business community is not currently available. Organizations are analyzed for their morale, their climate, their culture (Robbins, 1998).

They have also been analyzed for their capacity to learn (Senge, 1990), and their ability to create Organization Based Esteem (Pierce, Gardner, Cummings & Dunham, 1989). These components by themselves are useful, and have value. Yet it seems logical that a coherent, unifying sociopsychological theory that subsumes these elements and which has stood the test of time would be useful in analyzing organizations at a much higher level.

Theoretical Framework

An overarching organizational research question that continues to this day is "What contributes to organizational performance?" Perhaps the question is being asked incorrectly, and thus is giving us a tangential answer. Perhaps the question should be "What gives an organization the capacity to perform at peak levels?" Thus an instrument to assess employee perceptions of organizational efficacy would be useful. As far back as 1987, Marilyn Gist argued for this concept, "By using a valid instrument, research may show that group perceptions of efficacy are related to group performance" (Gist, 1987, p. 482). Thus the theoretical approach used to develop the instrument in this study is efficacy theory. Albert Bandura wrote in 1997, "Analyses of the determinants of perceived organizational efficacy can make a valuable contribution to the understanding of organizational performance (p. 476)." Using Bandura's theory as a structure for organizational analysis seems fitting, since both the therapeutic, educational and management literature for the past three decades abound with empirically validated references to self-efficacy. Bandura (1997), reported that "Although perceived collective efficacy is widely recognized to be highly important to a full understanding of organizational functioning, it has been the subject of little research" (1997, p. 468). Recent forays in the educational community by Schwarzer, Schmitz & Daytner (1999) however, are showing success in measuring collective teacher efficacy. Yet an instrument to assess organizational efficacy designed specifically for the context of business organizations has been lacking in the literature thus far.

Self-efficacy

A brief explanation of self-efficacy is essential for understanding organizational efficacy. Self-efficacy is a belief in one's ability to generate effort to overcome obstacles and persist in the performance of tasks or activities (Bandura, 1986). Bandura tells us that "Among the different aspects of self-knowledge, perhaps none is more influential in people's lives than conceptions of their personal efficacy" (1986, p. 390). Gist adds (1992) "Self-efficacy may be thought of as a superordinate judgment of performance capability that is induced by the assimilation and integration of multiple performance determinants" (p. 188). Self-efficacy is central to the motivational core of human action. There is a proven relationship between efficacy and action (Bandura, 1980). Gist emphasized this when she wrote "The predictive validity of self-efficacy is well established" (1992, p. 187). Efficacy is an empirically proven psychological construct. Yet efficacy goes beyond the individual; it also influences groups of individuals, including teams (Spink, 1990; Carron, Widmeyer, & Brawley, 1985) and organizations, which are the focus of this instrument.

Organizational Efficacy

The focus in organizational milieus has been the individual, to the exclusion of understanding how individuals perceive the collective efficacy of the organization. Yet people are not islands in organizations: they act together, and they have a sense of the capabilities of others to perform work (Zaccaro, et al, 1995, p. 305). People have a sense of being part of something larger than themselves. In organizations with high levels of organizational efficacy, people should function differently, work differently, and the outcomes should be different than organizations where organizational efficacy is low. Many definitions of collective efficacy echo that statement. "Collective self-efficacy deals with a group's beliefs in its competence for successful action" (Schwarzer, et al, 1999). Zaccaro, Blair, Peterson & Zazanis (1995) define collective efficacy as "a sense of collective competence shared among individuals when allocating, coordinating, and integrating their resources in a successful concerted response to specific situational demands" (p. 309). It also involves individuals' perceptions regarding the group's performance capabilities (Kozub & McDonnell, 2000). Finally, "Collective efficacy refers to individual's assessments of their group's collective ability to perform job-related behaviors..." (Riggs, et al, 1994, p. 794).

In other words, people can sense the capability of a group to perform actions. We sum up with a statement from Bandura's recent work (2000) on the subject, which reflects his thinking over the past 15 years as follows. "People's shared beliefs in their collective efficacy influence the types of futures they seek to achieve through collective action, how well they use their resources, how much effort they put into their group endeavor, their staying power when collective efforts fail to produce quick results or meet forcible opposition, and the vulnerability to discouragement that can beset people taking on tough social problems" (p. 76). In this research, collective efficacy is refined in the context of organizations, hence the term organizational efficacy. Though we are limited by
the space constraints of this paper, the OD/HRD literature supports the following three factors of organizational

efficacy:

Sense of Mission or Purpose – Do we know where we’re going?
Sense of Collective Capability – Can we work together to accomplish the goal?
Sense of Resilience – Are we capable to stay the course in the face of obstacles?

Organizational Efficacy is defined as follows:

Organizational efficacy (OE) is a generative capacity within an organization to cope effectively with the
demands, challenges, stressors, and opportunities it encounters within the business environment. It exists
as an aggregated judgement of an organization’s individual members about their (1) collective
capabilities, (2) mission or purpose, and (3) a sense of resilience.

Research Question #1

Can an instrument be developed to measure the construct of organizational efficacy in a reliable and valid manner,
consistent with the proven principles of instrument development?

Construction of the Bohn Organizational Efficacy Scale

The construction and validation of the BOES followed the general sequential procedures for developing self-
report scales of individual differences (Jackson, 1971; Jackson & Paunonen, 1980). Items are rationally derived
from theory; the item pool is reduced and refined through various empirical procedures that maximize internal
consistency and convergent and divergent validity while minimizing the influence of response styles associated with
item variability, agreement-disagreement wording, gender bias, and other factors. 37 items were written for the
BOES utilizing these procedures. They were derived from multiple sources including: the authors’ extensive
conversations with people in organizations (Pierce, Gardner, Cummings, & Dunham, 1989), open-ended sentence
completion exercises (Bandura, 1997, p. 43), organizational observations (Kraut, 1996), and interviews (Edwards,
Thomas, Rosenfeld, & Booth-Kewley, 1997) focusing on the three proposed factors of organizational efficacy: Sense
of Mission; Sense of Collective Capability; and Sense of Resilience.

Sample Items

While the entire Organizational Efficacy Scale is not presented, one item from each theorized factor is
presented to give readers a sense of the questionnaire, and the Likert scale used in the research.

Sense of COLLECTIVE CAPABILITY
1. People in this organization can take on any challenge.

Sense of MISSION/FUTURE
2. This company has a strong vision of the future.

Sense of RESILIENCE
3. During an economic downturn, this organization will come out strong.

Research Question #2

Will the instrument demonstrate convergent validity with existing instruments that measure collective efficacy,

Two existing scales were used to assess convergent validity: Schwarzer’s Collective Teacher Efficacy Scale
(adapted) and Riggs Collective Efficacy Belief Scale. Schwarzer, et al, has conducted research on collective teacher
efficacy which items were reworded to derive convergent validity with organizational efficacy items. Schwarzer’s
scale (1999) had a Cronbach’s alpha of .91, and .92, respectively. Test-retest reliability resulted in .77 (N = 197) for
the period of one year. Riggs, et al (1994) developed a Collective Efficacy Belief Scale, with alpha scale reliabilities

21-3
ranging from .85-.88. It was hypothesized that the Organizational Efficacy Questionnaire would correlate highly with the items from both these scales.

Research Question #3

Will the instrument demonstrate discriminant validity with constructs that are dissimilar, specifically self-efficacy, as measured by Schwarzer, and Organization Based Esteem, as measured by Pierce, et al (1989)?

Individual Self-efficacy

The generalized self-efficacy scale of Ralf Schwarzer at the Freie Universitat of Berlin was used to assess discriminant reliability (1997; 2000. The German version of this scale was originally developed by Matthias Jerusalem and Ralf Schwarzer in 1981, first as a 20-item version and later as a reduced 10-item version (Jerusalem & Schwarzer, 1986, 1992; Schwarzer & Jerusalem, 1989). It has typically yielded internal consistencies between alpha = .75 and .90. All the items from the Schwarzer self-efficacy scale were included in the testing of the organizational efficacy instrument, and aggregated as one individual efficacy score per respondent.

Organization Based Esteem

It was hypothesized that organizational efficacy is not organization-based self-esteem (Pierce, Gardner, Cummings & Dunham, 1989). Thus all the items on the organization based self-esteem scale were used to check discriminant reliability. All the items from this scale were included in the testing of the organizational efficacy instrument, and aggregated as one Organization Based Esteem score per respondent.

Research Question #4

Will the instrument show criterion validity with measures normally used in a business setting, specifically Customer Satisfaction, as measured by Kotter and Heskett (1992), and Workplace/Job Satisfaction as measured by Buckingham and Coffman, (1999)?

Customer Satisfaction

Kotter & Heskett, (1992) studied 207 organizations, ranging from airlines (Northwest) to breweries (Coors), to car manufacturers (Nissan) and concluded that adaptive cultures have a “feeling of confidence: the members believe, without a doubt, that they can effectively manage whatever new problems and opportunities come their way” (p.44-45). This is a statement of organizational efficacy. Thus one item on customer focus was used to assess criterion validity.

Workplace/Job Satisfaction

Items measuring employee satisfaction are critical predictive factors, since it seems employees would be satisfied in an organization that is highly efficacious. Thus we employed two questions from Buckingham & Coffman’s questionnaire (1999) specific to employee satisfaction.

While the research may be challenged for common method variance because the same method used to measure organizational efficacy was also used to customer and employee satisfaction, there is evidence from the literature (Dawes, 1999) that subjective evaluations of performance correlate strongly (.51, p<.05) with objective evaluations of performance.

Study #1

A study was conducted from February through April of 2001 to test the discriminant, convergent, and criterion validity of the scale. Eight companies were contacted for the study, only seven participated in the study. A total of 432 questionnaires were distributed, and 142 were returned, yielding a return rate of 32%. The companies are in the southeast Wisconsin-Northern Illinois Area of the United States. Guaranteed anonymity requires that the companies not be listed in this research. The seven companies yielded 30 different departments, ranging from Accounting to Warehouse. Gender response was nearly even with 46% female and 51% male, and 3% refused to identify gender. The majority of people in the study were Caucasian 78.9% with Hispanic 15.1% as the second largest category.
Results of Convergent and Discriminant Validity from Study #1

Table 1 depicts correlations between the Bohn Organizational Efficacy Scale (BOES) developed in this research, against two measures of convergent validity, and two measures of discriminant validity.

<td>1.000</td>
</tr>
</tbody>
</table>

All correlations are significant at the 0.01 level (2 tailed).

All items on the scales were computed together as one score for each participant. The BOES converges strongly with both the Schwarzer Collective Teacher Efficacy Scale (r=.857, p=<.01) and the Riggs Collective Efficacy scale (r=.613; p=<.01). There is a modest correlation (r=.387; p=<.01) between Organization Based Esteem (ORGESTEEM) and the BOES, indicating some overlap in the constructs. There is no correlation at all between SELFEFF (Self-efficacy) and the Organizational Efficacy Questionnaire, as predicted.

Criterion Measures

</table>

Table 2 shows the correlation between the BOES and Customer Focus, as compared to Organization based Esteem and Customer Focus. Customer Focus is more highly correlated with Organizational Efficacy (r=.564; p=<.01) than with Organization Based Esteem (r=.183; p=<.01). A z-test showed that the difference is statistically significant.

</table>

Table 3 shows the relationships between the Buckingham and Coffman questions and the BOES. Satisfaction with the place of work (Q53) is more highly correlated with BOES (r=.659; p=<.01) than with Organization Based Esteem. Conversely, (Q54) "At work I get to do what I do best every day." is more highly correlated with Organization Based Esteem (r=.599; p=<.01), than with the BOES. This is to be expected, since esteem is more job specific and individual. However when employees assess workplace satisfaction they take into account the organizational efficacy of the entire system.

Conclusions from Study #1
Study #1 showed that the Organizational Efficacy Questionnaire (BOES) was not measuring Organization Based Esteem or Self-Efficacy. In addition, the criterion measures of Customer Focus, Employee Satisfaction with workplace, and Employee Satisfaction with Job showed expected relationships.

**Study #2**

The second study was composed of 619 respondents from seven companies, with 75% male and 25% female. 89.6% were Caucasian, 4.0% African American, and 1.8% Hispanic. They represented 26 different departments, and 5 different roles, ranging from executive to line worker. In study #2, the 23 item scale was presented to seven different companies to access a large enough sample to conduct proper factor analysis, which requires a minimum of 10 respondents per item. The response of 619 people exceeds the 230 needed to justify the factor analysis. The BOES was reduced to 17 items after further statistical analysis.

**Alpha Levels and Factor Analysis**

Alpha level for the entire Bohn Organizational Efficacy Scale (recoded) was .93, Sense of Mission/Future subscale (.80); Q11, 14, 15, 16, Sense of Collective Capability Subscale (.92); Q1-7, 9,10 and Sense of Resilience Subscale (.88) Q18-21. Thus all the subscales and the overall scale meet or exceed .8 alpha.

Table 4 shows that Items 1-7, 9 and 10 comprise factor 1 (COLLECTIVE CAPABILITY); Items 11, and 14-16 comprise factor 2 (SENSE OF MISSION OR FUTURE); and items 18-21 comprise factor 3 (SENSE OF RESILIENCE). Factor 1 derived an Eigenvalue of 7.898, accounting for 47% of the variance; Factor 2 Eigenvalue = 2.021, 11.9% of the variance; and Factor 3 Eigenvalue = 1.128, 6.63% of the variance. The three factor solution was validated.

**Figure 1. Organizational Efficacy Across 14 Companies**

Figure 1 shows the total Organizational Efficacy Scores for all 14 companies in the study. As can be seen from
the bar chart, the scores vary widely across companies, though no company reached the maximum score of 102 (17 items x a maximum score of 6 per item). Company 13 has the best overall score, while Company 4 shows the greatest need for improvement. Table 5 shows that Organization accounts for nearly 16% of the variation in organizational efficacy, and the F ratio is significant at the .001 level.

Findings and Conclusions

The combined studies showed that Organizational Efficacy can be measured, and that the instrument showed expected discriminant and convergent reliability. The instrument derived three factors as theorized from the literature, specifically Sense of Mission or Future, Sense of Collective Capability, and Sense of Resilience. The alpha levels for the overall scale and the individual scales of each factor were at or above .80. Common criterion variables for business, including both Customer Focus and Employee Satisfaction were shown to be positively correlated with the BOES. Table 6 shows a moderately strong (r=.540 ; p<.01) correlation between perceived Organizational Efficacy and perceived Customer Focus, a strong (r=.702; p<.01) correlation between perceived Organizational Efficacy and Workplace Satisfaction, and a moderate (r=.486; p<.01) correlation between perceived Organizational Efficacy and Job Satisfaction. These are significant and important findings for all organizations interested in employee perceptions of customer satisfaction and workplace satisfaction.

** Correlation is significant at the 0.01 level (2-tailed).

Other statistical analyses showed statistical significant differences between organizations at the organizational level, but not at the department level. Thus the 17 item Bohn Organizational Efficacy Scale has passed the fundamental statistical tests for reliability and validity, and positively answered the four research questions.

The Relationship of Individualism and Collectivism to Perceptions of Interpersonal Trust in a Global Consulting Firm

Ghazala Ovaice
University of Illinois at Urbana-Champaign

This study explored the national culture values (e.g., cultural syndrome) of Individualism and Collectivism and their relationship to interpersonal trust which was defined as consisting of Reliability, Openness, Concern, and Competence. Cultural syndrome was found to have a significant relationship with perceptions of trust in the manager and in the work team. The major implication is for the building of awareness around the notion that trust in workplace relations varies when considering a multinational workforce.

Key Words: Individualism, Collectivism, Interpersonal Trust

The notion of a global workplace is one that is commonplace in today's business environment. Organizations are realizing that their workforce is rapidly becoming multinational due to increases in globalization, mergers and acquisitions, and joint ventures (Marquardt & Engel, 1993). As organizations continue to employ workers from different national cultures both domestically and internationally, HRD is now pressed with a new dilemma in improving performance at the individual, team or organizational levels with a global focus. That is, HRD professionals are now being asked to consider effects of cultural tendencies (which includes values and beliefs) on their performance improvement initiatives. Relationship building is foundational to successful business performance. Interpersonal trust is one workplace dimension that should be viewed as the baseline for successful relationship building, especially in a global environment.

Summary of the Problem

Trust is an interpersonal dynamic that has received a great deal of attention in the organizational sciences recently (Kramer, 1999). While there is research looking at the moderators, mediators, and outcomes of the construct of trust, a large gap exists in the trust literature regarding the antecedents of trust; especially the cultural dimensions as possible antecedents. The limited extant literature on culture as an antecedent of trust inhibits HRD professional's ability to effectively analyze, design, develop, implement, evaluate and manage performance improvement or promote organizational learning in a global arena. That is, in order to continuously improve performance and learning in an efficient and effective manner, empirical organizational research is needed to clearly understand the implications of cultural differences in interpersonal dynamics.

Purpose of the Study and Research Questions

The purpose of this research was to investigate the relationship, if any, between culture and trust in a multinational work setting. Culture (e.g., Individualism and Collectivism) and trust (e.g., Reliability, Openness, Concern, and Competence) were operationalized into several subcomponents and it was the relationship and/or interaction between these variables that this study was interested in determining. Trust was examined as relating to two primary workplace relationships: between employees and their primary manager as well as between employees and their primary work team. The research questions guiding this study were as follows: (1) Does a significant relationship exist between cultural syndrome and propensity to trust?, (2) Does a significant relationship exist between cultural syndrome and a trustor's tendencies toward various components of trust in the primary manager?, and (3) Does a significant relationship exist between cultural syndrome and a trustor's tendencies toward various components of trust in the primary work team?

Studying the cultural syndromes of employees in a multinational organization is an attempt to make the best multinational uses of varying employee dispositions (Davison, 1994). The ability to understand relationships between cultural syndromes (i.e., collectivistic and individualistic tendencies) to the construct of trust is vital. As organizations continue to move into different countries and set-up offices around the world, the need to understand varying cultural perspectives on trust becomes paramount. Trust has been found to be an important aspect of relationships since it leads to "a constructive dialogue and co-operation in problem-solving, facilitates goal clarification, and serves as a basis of commitment to carry out agreements (Schurr and O'Zannem, 1985, in Shaffer & O'Hara, 1995, pp. 9)." Consequently, HRD professionals must understand the cross-cultural implications of trust.
both within and between organizations, especially in such unstable environments as that of a recently merged or acquiesced corporate culture. In order for such partnerships to be successful employees must feel a sense of trust with their work group, their manager, and the organization as a whole. In attempting to maximize performance and human potential of such employees, HRD professionals will need to be knowledgeable of the relationship between culture and trust amongst work related values; for it is these same work related values that will ultimately influence the productivity and performance of an organization.

Theoretical Framework

Building on Ajzen & Fishbein (1980) Theory of Reasoned Action and their decision model, a few trust researchers (i.e., Currall & Judge 1995 and McKnight, Cummings & Chervany 1998) have suggested frameworks for intentions to trust. These researchers purport that an individual's attitudes, beliefs, and cognitions will shape his intention to trust, ultimately moderating whether that individual engages in trusting behavior. Similarly, this study proposes that an individual's cultural syndrome (i.e., their individualist or collectivist tendencies) serves as an antecedent to their propensity to trust (see Figure I). That propensity to trust will then moderate their perception of (i.e., their intent to) trust based on the individual's knowledge of the trustor's reliability, openness, concern, and competence. This perception of trust in the primary manager or primary work team then results in specific organizational outcomes as suggested in the trust literature (see Anderson & Narus, 1990; Barney & Hansen, 1994; Bromiley & Cummings, 1995; Kramer, 1999; Lawler, 1992; McAllister, 1995; Mayer, et al., 1995). This study investigate the relationship of culture as an antecedent to trust. The relationship between trust and organizational outcomes was out of the scope of this study but is depicted in this model to illustrate the overall picture of interpersonal trust in the workplace.

Critique of Relevant Literature

Limited extant literature exists regarding the relationship between cultural syndrome and trust. Shaffer and O'Hara (1995) found that individuals from low Individualism countries would express less trust of a service professional than persons from high Individualism countries. Consequently, Shaffer and O'Hara (1995) have found that trust varies along low and high Individualism countries. Shaffer and O'Hara (1995) argued that differences in perceptions of trust may be partially attributed to national differences in the bases for trust by utilizing Hofstede's (1991) argument that in small power distance and Individualism countries "the main sources of power are one's formal position, one's assumed expertise, and one's ability to give rewards (p. 12)." Also, based on their findings Shaffer and O'Hara (1995) concluded that for clients from small power distance/high Individualistic countries "providing evidence to establish one's expertise, competency, and ethical orientation during initial encounters may enhance perceptions of trust (p. 12)." Shaffer & O'Hara (1995) have found that high power distance and high Collectivism show a strong distinction between in-groups and out-groups. They go on to state that in these countries
trust is essentially based on in-group membership. Hence, in “collectivistic countries in-group membership and ultimately trust may take longer to achieve... In individualistic countries business is conducted with whole companies, in collectivistic countries business is conducted with individuals (who are members of one’s in-group; therefore the relationship is then with one person and not the entire company p. 13).”

Shaffer and O’Hara’s (1995) discussion of cultural syndromes and trust is focused on a country level analysis of Individualist and Collectivist countries. Other studies have looked at the relationship of cultural syndromes and trust at the individual level of analysis. For example, Yamagishi & Yamagishi (1994) studied trust between American and Japanese citizens. They found that Japanese citizens reported lower levels of trust compared with their American counterparts. This appears to be a rather surprising finding given the expectation that Japanese culture is often identified with “close, stable, long-term social relations (Kramer, 1999, p. 10).” However, Yamagishi & Yamagishi (1994) noted that in actuality Japanese culture could be distinguished by high stability whereas American culture does not have a comparable sense of stability and social uncertainty. Therefore, when in a situation of instability Americans are more concerned with reducing the stability and uncertainty through personal knowledge of the trustor as well as reputational information, whereas the Japanese rely on assurance of predicted stability of interpersonal and inter-organizational relationships (Kramer, 1999).

Nicol (1994), in his study of American and Mexican students found that trust is in fact a multidimensional concept that serves as a foundation for assessing cultural influence on trust. Nicol found the application of the trust concept “to differ systematically along cultural lines (p. 101).” Specifically, he found that the more collectivist culture would place a higher emphasis on the relationship dimension of trust, while the more individualistic culture placed a higher emphasis on the institutional agent and caution dimensions of trust.

Methodology

Smith Consulting consults globally on human resources issues. They have representation in all geographic regions around the world. Given the global focus of the organization, Smith was well suited as the population from which the sample was drawn. The unit of analysis was the individual employee. The sample was a stratified sample representing various global locations (including the U.S.) and multiple lines of business. A total of 627 employees (from over two dozen countries around the world) responded to an online survey resulting in a 67% response rate. Twenty-four surveys were dropped because they were deemed unusable. The cultural syndrome (e.g., Individualist or Collectivist tendencies) for each of the respondents was then determined based on their responses to the INDCOL scale items. Cultural syndrome was determined by the category in which they had the highest total score. Thus, amongst the remaining 603 respondents, there were a total of 393 collectivists and 210 individualists.

The stratified random sample was considered to have yielded respondents who were representative of the firm’s demographic make-up. Demographic data were pulled from Smith’s internal employee database in order to describe the respondents. Overall, there were more females (56.8%) than males (43.2%) amongst respondents. Age data were only available for North American employees. Therefore, of the 425 North American employees that responded to the survey almost half were between the ages of 25 and 35 (49.6% of respondents). Concurrent with the overall respondents, there were more collectivists in all age groups than individualists. Of those respondents who were in management roles, there were more collectivist (61.1%) managers than individualists (38.9%). The total percentage of respondents in management roles (11.9%) was considered slightly smaller than the overall percentage of Smith employees in management roles, but within sampling error. Employee tenure data indicated that two-thirds of respondents had only been employed at the firm for less than 3 years (66.6%). Almost one-third of these respondents had been at the firm for less than 1 year (29%). These percentages are considered to be somewhat higher than the tenure of overall Smith population. However, the differences fall within normal sampling error and do not affect the generalizability of study results.

Items from three existing instruments were utilized for this study. First, Triandis’ (1995) 32-item INDCOL measured Individualism and Collectivism at the individual level (as opposed to the cultural level) with published alpha coefficients of .71-.80 (Singelis, Triandis, Bhawuk, and Gelfand, 1995; Probst, Carnevale, & Triandis, 1999). Second, Mishra & Mishra’s (1994) 16-item measure of trust looked at four components of trust (Competence, Reliability, Openness, and Concern) with a published alpha coefficient of .93. Third, Mayer et al.’s (1999) 8 questions on propensity to trust were adapted for the purposes of this study with published alpha coefficients of .55-.66. Finally, the instrument also included a demographic section (for data that could not be obtained through the employment database system at Smith). The three instruments plus the demographic instrument were converted into one web-based questionnaire. In addition, the instrument was translated into Spanish, Portuguese, and French.
Each one of Smith's global locations had access to the internet and was able to link to the questionnaire through a hyperlink in an email message sent to each participant. (It is important to note that in this organization, online data collection was considered common practice as all employee surveys were administered in this fashion.) Once at the website, participants were given directions for filling out the instrument, as well as the option to pick the language in which they chose to complete the questionnaire. Once participants submitted the instrument, data were automatically transported into a MySQL database on the University of Illinois server and then converted into an SPSS database for data analysis. Descriptive and inferential statistics were then used to analyze the data from the questionnaire. The primary method for data analysis was the use of a Multi-variate Analysis of Variance (MANOVA) with follow-up Regression Analysis, MANCOVA, and Repeated Measures Analysis.

Limitations of Research

As with most research studies, there were some limitations. The Latin American (47% compared to 70%, 72%, and 66% in the Asia-Pacific, Europe, and North American regions, respectively) portion of the sample revealed lower response rates compared to other regions. This lower response rate was explained, however, due to traditional low response rates from the region in all employee surveys, limited local support for such initiatives, and varying organizational structures (e.g., having different ownership structures due to joint ventures or acquisitions). Also, while all Latin American employees have access to a computer they do not necessarily have their own computer; thus accessibility to technology could also be a factor. Another limitation to the study is the low reliability of the Mayer and Davis (1999) propensity to trust items (.53 alpha coefficient). However, published reliability data for the Propensity to Trust items found Cronbach alphas ranging from .55 to .66 (Mayer & Davis, 1999). Finally, this study was limited to employee perceptions of trust in their primary manager and primary work team; thus, implications are limited to these workplace relationships.

Results

The first research question addressed whether a significant relationship existed between a trustor's propensity to trust and their cultural syndrome. Propensity to Trust, the dependent variable, has been defined as an inherent willingness to trust (Schoorman, Mayer, & Davis, 1996). The trust literature suggests that individuals differ in their disposition to trust (McKnight, Cummings, & Chervany, 1998; Mayer, Schoorman, & Davis, 1999), that is, the likelihood that they will display trust in a given situation. The independent variable, Cultural Syndrome, has been defined as the elements of culture that are organized around a central theme. Specifically, Triandis (1995) described it as an individual's tendency towards Individualism or Collectivism. The central theme of Individualism is organized around the individual as the unit of analysis and the orientation is to the self. The central theme of Collectivism is organized around the team as the unit of analysis and the orientation is to the group. Findings from an ANOVA suggest there was no significant relationship between cultural syndrome and a trustor's Propensity to Trust (F=2.25; p=.135). Therefore, Individualist or Collectivists tendencies do not effect disposition to trust.

Research question two addressed the relationship between cultural syndrome and trust in the primary manager. The dependent variables for question two were the four trust components (Mishra, 1992): Reliability, Openness, Concern, and Competence. Again, the independent variable was cultural syndrome. Cultural syndrome was found to have a significant relationship with all trust variables when looking at trust in the primary manager (Reliability F=10.44; p=.001; Openness F=11.56; p=.001; Concern F=8.14; p=.005; and Competence F=9.56; p=.002). Research question three addressed the relationship between cultural syndrome and trust in the primary work team. The dependent variables for research question three, as in research question two, were the four trust components; the independent variable was cultural syndrome. Again, cultural syndrome was found to have a significant relationship with all trust variables when looking at trust in the primary work team (Reliability F=12.81; p=.000; Openness F=16.00; p=.000; Concern F=11.73; p=.001; and Competence F=12.29; p=.001).

Overall there appeared to be a larger number of Collectivists (n=393) than Individualists (n=210) amongst respondents (even from those countries that have been traditionally identified as Individualist). Triandis (1995) believed that individuals actually have tendencies toward both Individualism and Collectivism and that these constructs are, in fact, contextual. Triandis' explanation lends itself to the conclusion that this particular global consulting firm is potentially promoting a collectivistic organization culture that, in turn, could potentially be overriding some traditional national culture value in the context of this particular workplace.

Through a comparison of mean scores for each component of trust, findings from this study could be further explained to trust in the primary manager (see Tables 1 for means and standard deviations for trust in the primary manager and primary work team by cultural syndrome). First, Collectivists had overall higher perceptions of trusts than Individualists on all four trust variables across workplace relationships (e.g., primary manager and primary work team). Second, the Competence variable had the highest rating for trust in the primary manager and primary work team. Third, Openness rated the lowest for trust in the primary manager while Concern rated the lowest for trust in the primary work team. However, fourth, Individualists and Collectivists have the greatest differences on trusting their manager's and team member's Openness characteristics; with Collectivists having more trust than Individualists on their primary manager's and team member's Openness. Fifth, trust in the primary manager had overall higher mean scores in comparison to trust in the primary work team. Sixth, trust in the manager rated higher than trust in the work team regardless of cultural syndrome or trust component (see Table 1). Often times, managers are the individuals in an organization that hold power due to their formal position, have some sort of expertise, and have the ability to give rewards. Therefore, by virtue of their role in the organization, they may command trust from their subordinates. However, this does not mean that trust in the manager is certain or unconditional rather the suggestion is that, given the nature of their relationship with employees, managers tend to be perceived as having higher Reliability, Openness, Concern, and Competence compared to an employee’s team members. The role of management in an organization can account for some of this behavior. Creed and Miles (1996) have suggested that management actually institutionalize their collective view of trust and trustworthiness by enacting the organizational context for exchanges, communication, and fair dealings.

Finally, there was a main effect (see Table 2) for trust along the various trust variables where the highest mean score was for Competence (C 22.50; I 21.26), followed by Reliability (C 22.08; 20.73), Openness (C 21.02; I 20.19), than Concern (C 21.02; I 19.78). Thus, though Collectivists emphasize relationship building, in general, it is evident that decisions to trust are based more on cognitive aspects of trust (e.g., Competence and Reliability) than on affective or relational aspects of trust (as evidenced by lower ratings for Openness and Concern). Similady,
Individualists predictably placed emphasis on cognitive aspects of trust. Therefore, manager and team member ability, knowledge and skills as well as their performance over time effect will effect employee perceptions of trust.

Discussion

Implications for Practice: Managers and HRD Professionals

Given the findings of this study, several implications arise for managers as well as for both HRD and OD practitioners. Findings from this study revealed that Collectivists had overall higher trust scores than Individualists and there were more Collectivists in the sample than Individualists (even from traditionally Individualists countries). The major implication here is that organizations are fostering and promoting open cultures, rewarding teamwork, information sharing. Thus, organizations are advocating collectivist behavior. Managers then need to be cognizant of the differences between individualists and collectivists, as well as foster an open culture in order to achieve higher levels of mutual trust. Findings from this study also revealed that Competence and Reliability tend to have higher ratings then Concern and Openness when looking at trust in managers and teams. Therefore, managers need to not only continually develop their own knowledge, skills, and competencies but also foster that continuous learning environment with their workforce (thus, enhancing the Competence component of trust). Consistent behavior over time by managers who “walk the talk”, will likely result in employees who perceive their managers as being more trustworthy due in part by setting examples of consistent, reliable performance and behavior. In a related concept, managers must be aware of cultural variances on perceptions of trust when considering internal communications. For example, it is important to consider communicating competence and reliability up front to individuals with whom they embark in a trusting relationship.

In reference to trust and culture awareness on the individual level, managers also need to understand the effect of organizational trust and organization culture. As Creed and Miles (1996) have stated, “management institutionalized its collective view of trust and trustworthiness by enacting organizational contexts for intramural exchanges, communication, and fair dealing (p.35).” Hence, the extent of trusting behavior exhibited by a manager is likely to be reciprocated by his employees. Consequently, managers then need to understand their work team culture as well as organizational culture in relation to how they support and develop the various components of trust especially in the context of a multinational workplace. As Triandis (1995) has noted, individuals have tendencies toward both Individualism and Collectivism, yet in instances were the organizational culture is strong enough, it can override the national in the workplace context. Furthermore, trust has been proven to being context specific as well (Kramer, 1999). Therefore, managers have a real opportunity to establish and cultivate a trusting organizational culture through open communication, consistent and competent behavior, awareness and knowledge of both trust and culture variances (especially as discussed in this study), and effective relationship building. Accordingly, Barney and Hansen (1994) suggested that trust can affect transaction costs consequently providing a source of competitive advantage. In addition, Davis, Schoorman, Mayer, & Tan (2000) indicate that employee trust for the general manager is an internal organization characteristic that provides a competitive advantage for the firm.

Just as with managers, several implications exist for HRD professionals in relation to the findings of this study. The implications discussed above can be considered a micro-level discussion regarding trust and culture. Implications for HRD professionals will take a macro-level view in respect to the entire organization. Managing the change, learning, and performance of a multinational workforce is grounded in effective relationships with HRD clients. Trust, as noted earlier, can be considered to be foundational to the successes of these relationships. Given the multinational nature of the workforce, HRD professionals would be better served through first enhancing their own learning and development around the areas of trust and culture. Findings from this study also indicated that at Smith Consulting, there were more Collectivists than Individualists (even from those countries that would traditionally be considered individualist). The practical implication for HRD/OD practitioners is then to (1) consider the cues in their organizational infrastructure that support such a group oriented environment (i.e., there may be a great deal of collective behavior that is being reinforced by pay structures, work design, etc), (2) ascertain whether such an environment is strategically aligned with goals and vision of HR as well as that of the larger organization, and (3) determine whether continuing to foster collective behavior (e.g., orientation is to the group as opposed to the self, employees are interdependent, and group goals drive behavior) is the most appropriate culture to cultivate given the organization’s mission, structure, and culture. It is not in the best interest of HRD professionals to simply assume that a collective environment is the best environment, especially bearing in mind that individuals actually have tendencies toward both Individualism and Collectivism. Such considerations will then have implications for work design, pay structures, and development initiatives, to name a few.

HRD professionals who understand that trust in managers and work teams varies by cultural syndrome (e.g.,
collectivists have higher trust in workplace relationships), can than work with their lines of business and internal clients to consider communication, management and team development, collaboration and satisfaction issues. As a result, they will have the potential to effect cooperation, problems solving, and facilitate goal clarification (Schurr and Ozannem, 1985, in Shaffer & O'Hara, 1995). For example, cultural differences depending on cultural context and job context can effect methods of training with specific implications for the rigor of training, cognitive involvement and participation of the audience, status of the trainer, and trainer competencies (Thornhill, 1993). These training design, development, and delivery factors fall into the competence and reliability components of trust. Thus, awareness and skills around the cultural aspects of trust building can enhance an HRD professional's effectiveness by establishing trust early in the relationship through highlighting competent and reliable behavior.

An HRD professional's role is often to understand and anticipate the pulse of an organization. Awareness, cognizance, and skills around the organizational dynamics of interpersonal trust and culture will allow HRD professionals to better serve their ever changing organizations. This holds true especially when considering the unstable organization cultures of newly merged or acquired firms, dealing with changes in the external environment, as well as for new organizations that are starting to make their mark. In all of these organizational structures trust is critical. Specifically, HRD professionals can work with their internal clients to plan for changing structures through successful establishment and maintenance of trusting work relationship, advise clients on development opportunities (especially for global managers and expatriate employees) in the areas of cultural awareness), and potentially work with executives and leaders in the firm to foster an organization culture that essentially "brands" trust as a value.

Implications for Future Research

The findings from this study point to several implications for future research. First, are implications for theory building research that focuses on developing a new reliable Propensity to Trust instrument. Researchers have purported that Propensity to Trust is an antecedent or even moderator to trust (Mayer, Schoorman, & Davis, 1995; McKnight, Cummings, & Chervany, 1998). Yet, Propensity to Trust was the only dependent variable that did not have any significant differences between Individualists and Collectivists. Coupled with the creation of a new instrument, is the need to explain the potential mediating relationship of Propensity to Trust between cultural syndrome and trust in the manager or work team. In addition, this study found a significant relationship between cultural syndrome and trust in the primary manager as well as primary work team. Future research should consider in depth exploration of one or two of the trust components at a time (e.g., concern or competence) for the development of a model and/or theory of cultural based trust. Implications for applied research include further investigating the differences between trust in the manager and trust in the work team (as well as other workplace relationships). This study looked at perceptions of trust in a given moment. Future research should look at the relationship of cultural syndrome in actual trust building as the natural next step in this strand of literature. Several organizational dynamics (e.g., teamwork, cooperation, decision making, satisfaction, performance etc) have already been proven to be antecedents, moderators, mediators, and outcomes of trust. However, these existing findings need to be further investigated with the effect of cultural syndrome on these relationships. This study was a quantitative study. The findings from this study and future research could be enhanced with support from more qualitative or naturalistic findings. The purpose of this research was first to establish that a relationship does, in fact, exist between cultural syndrome and interpersonal trust. Future research should then consider other research methods when investigating this phenomena. Finally, the population for this study was a company with a strong corporate culture. Hence, the ability to replicate these findings in a manufacturing environment or that of a new product development team, for example, must be considered. Corporate culture, industry, and external environments all have the power to effect employee perceptions of trust. Yet, the nuances of how and to what extent differences in perceptions of trust could arise based on these moderating variables prove an intriguing question for future research especially when coupled with variances in cultural syndrome.

The Effect of Organizational Support, Management Support, and Peer Support on Transfer of Training

Susan E. Cromwell, Ph.D.
Judith A. Kolb, Ph.D.
The Pennsylvania State University

The intent of this study was to examine three specific work environment factors (organizational support, management support, and peer support) that affect transfer of training in a supervisory skills training program at one-month, six-month, and one-year points. The findings indicate a positive correlation between management support and transfer of knowledge and skills at the one-year time frame.

Keywords: Transfer of Training, Management Support, Organizational Support

HRD professionals continue to struggle with the reasons why a higher percentage of the skills and knowledge acquired during training programs do not transfer to the work environment and why transfer appears to diminish over time. Many organizations spend a significant amount of time and money on training. It was estimated that in 1998 the average United States employer spent well over 10% of payroll on education and training (Bassi & Ahlstrand, 2000). Yet, in one study, researchers found that HRD professionals believed that only 40% of the program content of a management development program was transferred to the work environment immediately after the program ended, about 25% was still being applied six months later, and a mere 15% was still being used at the end of one year (Newstrom, 1986). To a large extent, HRD practitioners have emphasized and developed sophisticated delivery devices at the expense of building the critical connection between the training site and the work environment (Brinkerhoff & Montesino, 1995).

A significant amount of research has been conducted to identify the effects of supervisory behavior on the level of productivity in an organization. After research identifies effective supervisory behaviors, training programs are designed and developed to teach supervisors and managers the skills and knowledge they need to know to increase employee productivity, job satisfaction, and organizational commitment. Many individual and organizational factors affect transfer of this training. Factors include individual motivation of trainees, training program design and delivery, organizational climate, and the person to whom the trainee reports.

There have been several efforts to expand the training perspective (Tannenbaum & Yukl, 1992). As early as 1980 (Wexley & Latham), “probability of transfer” was mentioned. Researchers (Baldwin & Magjuka, 1991; Hicks & Klimoski, 1987; Noe & Schmitt, 1986) have recognized the importance of several environmental characteristics and have examined variables outside the immediate training program that may be important to the success of the training effort. Broad and Newstrom (1992) identified barriers to transfer and discussed strategies to address these barriers. Factors affecting transfer include individual trainee characteristics, training program design and delivery, and work environment factors such as organizational support, trainee supervisor support, and peer support. Work environment factors influencing transfer of training are the focus of the study reported here.

Although there are several definitions of transfer climate, we draw on Broad and Newstrom (1992), Goldstein (1993), and Baldwin and Ford (1988) to define transfer climate as work environment factors perceived by trainees to encourage or discourage their use of knowledge, skills, and abilities learned in training on the job. Case studies reported by Broad (1997) indicate an increased emphasis by companies on building a climate that supports training transfer. Several researchers (Holton, Bates, Seyler, & Carvalho, 1997; Kozlowski & Salas, 1997; Rouiller & Goldstein, 1993) have examined specific aspects of transfer climate.

Baldwin and Magjuka (1991) examined the effects of three organizational “signals” on subsequent training outcomes. The pre-training signals examined were course information provided to trainees, accountability to the supervisor, and program status (mandatory or voluntary). Their study showed that when trainees received relevant information before the training program, recognized that they would be responsible for learning, and perceived the training to be mandatory, the trainees reported greater intentions to transfer the learning back to their jobs.

Another work environment factor that influences transfer is support of the trainee’s supervisor (Broad, 1982; Huczynski & Lewis, 1980; Michalak, 1981; Nadler, 1971; Tannenbaum & Yukl, 1992; Zemke & Gunkler, 1985). Tangible and/or perceived support of the manager can be influenced before and after the training intervention.

Copyright © 2002 Susan E. Cromwell and Judith A. Kolb
Cohen (1990) found that employees were more motivated if their supervisors were supportive and if attendance is perceived to be voluntary rather than mandatory.

In today’s team-centered work environment, co-worker support also might be important for transfer of training. Although considerable interest has been focused on supervisory support, less has centered on peer or co-worker support. Pea (1987) found that perceptions of support from both supervisors and co-workers contributed to transfer of training. Bates, Holton, Seyler, and Carvalho (2000) found that peer support was a significant predictor of learning transfer. Ford et al. (1992) found that work group support was relevant for affecting the opportunity to perform and a significant predictor in the performance of more complex and difficult tasks.

Understanding the variables that influence transfer of training can assist HRD professionals, managers, and organizations in selecting the appropriate techniques for facilitating the application of newly learned skills, knowledge and behaviors back on the job. The intent of the study reported here was to examine the work environment factors that affect transfer of training in a supervisory skills training program. If barriers to the transfer process are identified and supervisors are able to utilize and apply a higher percentage of knowledge and skills, then the potential exists for increased rate of return on the time and money invested in such training.

Research Questions

RQ1: What are the differences between each of the following work environment factors: organizational support, management support, informal peer support, and use of a formal peer support network, and perceived transfer of training?

RQ2: What are the differences between work environment factors and perceived transfer of training at the following points of time: one month, six months, and one year after completion of a supervisory skills training program?

RQ3: What similarities and differences exist in the perceptions of managers and trainees regarding organizational support, management support, and transfer of training?

Methodology

Sample

Seventy-five front-line supervisors from one unit of a large northeastern university participated in this study. This target group was selected because at the time of the study all front-line supervisors in this unit had completed a supervisory skills training program within the past year. The range of supervisory experience within this group ranged from less than one year (1.6%) to more than 20 years of experience (11.1%). Trainees were nominated either by their department head or through self-nomination and represented a cross section of colleges and administrative units throughout the university. In this unit, the trainees serve as peers to each other.

Procedures

Two questionnaires were used to examine the transfer of key skills emphasized in the supervisory training program and the perceived amount of management, peer, and organizational support given to the trainee regarding transferring skills into the work environment. Transfer behaviors were assessed using an instrument with a 6-point Likert-type scale ranging from a low of 0 (not at all) to a high of 5 (very frequently). The instrument was modified with permission from one developed by Rothwell (1996). Readers wanting a copy of the questionnaire should contact the first author.

Questionnaires were administered at meetings that were held at times convenient for trainees. Trainees were given the questionnaires and asked to return them to the researcher at the end of the meetings. A similar approach was used with each trainee’s supervisor. The information gained was used to measure perceptual differences between the amounts of support received/given.

The data analysis for this study was done using quantitative statistical techniques. The statistical analysis was completed through applied statistics and SPSS. ANOVAs and correlations were conducted relevant to trainees’ perceived use of the knowledge and skills learned during training, perceived level of support by peers, and managers, and perceived level of organizational support, and use of the peer support network to enhance the transfer process. All short answer responses were analyzed using open-coding techniques (Strauss & Corbin, 1990).

In addition, following the open-coding guidelines (Strauss & Corbin, 1990), clusters of items within the questionnaire were identified. The clusters identified were performance feedback, coaching, rewards and
recognition, and follow-up. Analysis of the clusters was accomplished using ANOVAs and correlations to determine
the trainee's perceived level of support.

Limitations

This study was a study of perceptions. Perceptions of transfer of training may not equate to actual use of skills on
the job. Second, data collected on a specific group of employees working in a union environment may have
influenced the results of the study. Last, the design of the study called for the creation of sub-groups and clusters
within categories, which reduced the n for several analyses.

Results and Findings

Research Question 1. What are the differences between each of the following work environment factors:
organizational support, management support, informal peer support, and use of a formal peer support network and
perceived transfer of training?

Transfer of training level for application of knowledge and skills was grouped as follows: Low (<40%); Moderate (≥ 41% to 80%), and High (>80%). The rating scale measuring application of skills ranged from 1—not at all to 6—most of the time. Table 1 presents the mean, standard deviation and ANOVA results for work environment factors.

Note. Low(<40%), moderate(41- 80%), and high (>80%) groupings of perceived application of knowledge and
skills a Sheffe post hoc analysis revealed significant differences exist within organizational support, management
support, and peer support between the low and moderate application groups and between the low and high
application groups for all four factors. No significant differences exist between the moderate and high application
groups for the four work environment factors.

Significant differences were found in transfer of training between groups in organizational support,
management support, peer support, and in peer support network. The Sheffe post hoc test was used to identify areas
of specific differences. For the four work environment factors, the high level of application group had significantly
higher means than did the low application group. Trainees who reported receiving higher levels of organizational,
management, and peer support also reported applying, to a higher extent, the knowledge and skills learned in the
supervisory training program.

Note. Low(<40%), moderate(41- 80%), and high (>80%) groupings of perceived application of knowledge and
skills a Sheffe post hoc analysis revealed significant differences exist within organizational support, management
support, and peer support between the low and moderate application groups and between the low and high
application groups for all four factors. No significant differences exist between the moderate and high application
groups for the four work environment factors.

Significant differences were found in transfer of training between groups in organizational support,
management support, peer support, and in peer support network. The Sheffe post hoc test was used to identify areas
of specific differences. For the four work environment factors, the high level of application group had significantly
higher means than did the low application group. Trainees who reported receiving higher levels of organizational,
management, and peer support also reported applying, to a higher extent, the knowledge and skills learned in the
supervisory training program.
The organizational support and management support factors were examined by clusters. The three clusters examined for organizational support were performance feedback, coaching, and rewards. The four clusters examined for management support were performance feedback, coaching, rewards, and follow-up. The Scheffe post hoc analysis revealed significance difference in the organizational support cluster of coaching between the low and high application groups and in the organizational cluster of rewards between the low and moderate application groups. The Scheffe post hoc analysis revealed significance difference in the management support clusters of performance feedback, coaching, rewards and follow-up between the low and moderate application groups and the low and high application groups.

Specifically, trainees who reported receiving a higher level of support (performance feedback, coaching, and rewards) from the organization and a higher level of support (performance feedback, coaching, rewards, and follow-up) from their supervisors also reported a higher level of transfer of training.

Research Question 2. What are the differences between work environment factors and perceived transfer of training at the following points of time: one month, six months, and one year after completion of a supervisory skills training program?

Significant differences were found between application groups in organizational support, management support, and peer support only at the one-year time interval. The Scheffe post hoc test was used to identify specific areas of difference. For each of the work environment factors (organizational support, management support and peer support) the high level of application group had significantly higher means than did the low application group. No significant differences were found between groups in the peer support network.

For organizational support, the high application group reported an overall mean of 2.60 (SD = .608) as compared to the mean of .93 (SD = .662) for the low application group. For management support, the high application group reported an overall mean of 2.99 (SD = 1.18) as compared to the mean of .44 (SD = .509) for the low application group. For peer support, the high application group reported an overall mean of 2.90 (SD = 1.30) as compared to the mean of .007 (SD = .116) for the low application group.

The investigators examined specific clusters relative to time—one month, six months and one year—by perceived transfer of training. Again, only at the one-year time frame was the relationship significant between trainees reporting receiving higher levels of support and trainees reporting higher transfer of training.

Research Question 3. What Similarities and Differences Exist in the Perceptions of Managers and Trainees regarding Organizational Support, Management Support, and Transfer of Training?

The summary index for the three variables reflects the combined perception of application of skills (17 statements from survey), management support (18 statements from survey) and organizational support (10 statements from survey). No significant differences were found between the perceptions of managers and trainees regarding organizational support, management support, and transfer of training (See Table 2).

Management support was the only variable that approached statistical significance (p = .072). In the management support clusters, no significant differences were found between the perceptions of managers and trainees regarding the performance feedback, rewards, and follow-up clusters. The management support coaching cluster was the only variable that was statistically significant (p = .001). For the management support coaching cluster trainees reported an overall mean of 2.88 (SD = 1.43) as compared to the mean of 3.78 (SD = .732) for the managers.

Analysis of the data revealed no significant differences between the perceptions of managers and trainees regarding transfer of training and two of the work environment factors: organizational support and management support. No significant differences were found between the perceptions of managers and trainees regarding organizational support clusters and transfer of training. In the management support clusters, no significant differences were found between the perceptions of managers and trainees regarding the performance feedback, rewards, and follow-up clusters. The management support coaching cluster was the only variable that was statistically significant (p = .001). For the management support coaching cluster, trainees reported an overall mean of 2.88 (SD = 1.43) as compared to the mean of 3.78 (SD = .732) for the managers.

</table>

The examination of clusters relative to similarities and differences in the perceptions of managers and trainees regarding the two work environment factors revealed no significant differences in the organizational support clusters. In the management support cluster, coaching was the only variable that was significant. In the coaching cluster, managers perceived that the level of coaching given was significantly higher than that perceived by trainees.

Conclusions and Recommendations

Trainees who reported receiving higher levels of support in the work environment indicated they were applying, to a higher extent, the knowledge and skills they learned in the supervisory training program. In addition, certain support actions by the organization and management appear to provide a higher level of application, knowledge, and skills than others. More specifically, the results suggest that particular actions such as coaching may play a significant role in the transfer of training.

Empirical research has been limited regarding the effect of peer support and transfer of training. The results of this study indicate that peer support does influence transfer of training. Trainees who perceived higher levels of peer support throughout the training program indicated they were applying, to a higher extent, the newly learned knowledge and skills. Peers in the organization under study completed the supervisory training program in a short time frame (one year), so trainees were able to share and apply the information learned more readily. In addition, supervisors who attended the program may have served as supervisors to others who attended and thus, were able to provide support both as a peer to others and as a manager. However, results suggest that the utilization of the peer support network did not affect transfer of training.

The results also revealed that the time element is an important factor to consider when measuring a trainee's application of knowledge and skills and perceived support. No difference occurred during the one-month and six-month periods. Limited research has been done examining the effects of work environment factors on the transfer process over longer periods. Several possibilities exist as to why differences were revealed only at the one-year time frame. If trainees did not have opportunities to utilize the knowledge and skills when they first completed the training program, then trainees might perceive they were not supported by the organization, their supervisor, or their peers due to the fact that other priorities may have infringed on the opportunity to use the skills. In addition,
organizational incentives, such as promotional opportunities or salary incentives may have more impact at the one-year time frame than at the one-month time period.

The results of this study reveal that no significant differences exist between trainees and managers regarding two of the work environment factors: organization support and management support. It was interesting to find that when clusters were examined relative to similarities and differences, differences did exist in the management support coaching cluster. Managers perceived that the level of coaching given was significantly higher than what was perceived by the trainees. One possible explanation for the fact that no differences were found in the organizational support clusters and management support clusters of performance feedback, reward, and follow-up is due to the small sample size and the fact that 70% the managers who responded to the survey had also participated in the supervisory training program.

Implications for HRD

Evidence exists that work environment factors support transfer of training. It is recommended that HRD professionals focus not only on the individual trainee and training program content, but also on organizational support factors that influence transfer. Organizations should take steps to assure that full support is given to professional development efforts. In order to identify whether or not an organization is supportive of professional development efforts, HRD professionals first may need to assess the transfer climate.

The significance of management support and its effect on transfer provides strong support for implementation of processes that will assist managers in collaborating with trainees as they participate in training programs. In the study, the importance of coaching by the manager enhanced the application of knowledge and skills. A technique that could be utilized includes requiring trainees to meet regularly with their managers to discuss action plans and on-the-job application of skills. Another technique that could be used involves structuring pre-training course sessions for managers, where managers could learn about the content of training courses being provided for their direct reports and actions managers might take to support trainees throughout the training program.

The finding that peer support affects transfer of training has implications for HRD professionals. While further research is needed in this area, support mechanisms can be developed to enhance peer support. In this study, the use of a peer support network did not prove to be significant; however, the concept of providing such a mechanism for peers to interact, share ideas and information may be useful if the network were structured differently. One idea is to establish peer group meetings after the training is over. This would provide peers the opportunity to share additional information and/or address lingering questions.

Recommendations for Future Research

With the amount of funds allocated toward training in organizations today, a careful examination of how to gain a better return on investment in training is important. This study can help organizations assess their work environment and design interventions that will better utilize the training dollars spent.

The focus of this study was to examine the effect of work environment factors (organizational support, management support, peer support, and the use of a peer support network) on transfer of training. The design allowed for examination of those factors over three periods: one month, six months, and one year. Ns were quite low; however, for some clusters. Examination of a larger group size would benefit future studies. Given the findings of this study and the extant literature on transfer of training, continued research is needed to examine the role of the work environment on the transfer of training. Since the findings indicate that work environment factors do influence the application of knowledge and skills, future research should examine more specifically the types of actions that bring about the highest impact for the trainees.

Research on the question related to timing of support actions would provide useful information. Specifically, does the timing (before, during, and post) of such support actions hinder or help the transfer process? If certain support actions are timely, and recognized by both the manager and trainee as significant to the trainee’s participation in the training program, then would that hinder or help the transfer process? There appears to be a need to measure transfer over longer periods. Measuring transfer over a one- or two-year period would provide trainees a greater opportunity to apply the knowledge and skills they learned during training and would provide opportunities for organizations to plan for supportive actions to enhance transfer.

Another area for future research involves the ability of trainees to distinguish between the many types of support actions provided to them in the work environment. Do trainees distinguish between the support actions as an organizational action, management action, and peer action, or do they view all support actions as one entity?
Clarifying how trainees view work environment factors would be beneficial to help define the impact of specific factors and transfer of training.

Future research with a larger size group to determine the impact of peers would be beneficial. More specifically, what are the specific actions peers take that affect transfer over longer time periods? Do peers recognize the informal conversations they have regarding the training as supportive actions or do they only recognize specific supportive actions such as assisting with work responsibilities while the trainee attends the training program?

Examining the potential to utilize a formal peer support network and assess the utility of this device would be beneficial to organizations. Are there different types of networks or mediums that can be utilized to provide peers the support they need before, during, and after training to enhance the transfer process? Does the use of technology, the Internet and e-learning change the types of peer support needed?

Future research would also be valuable in examining the impact of organizational barriers and constraints facing organizations today and in assessing the total impact of these barriers (time constraints, union contracts, lack of funds, and resources) on the transfer process. This study was conducted in a non-profit organization with limited resources for rewards and recognition. Does this limitation prohibit an organization from truly enhancing the transfer process, despite the attempt to provide organizational, management, and peer support? Finally, can the day-to-day barriers and constraints reported by trainees be controlled by the organization to ensure adequate transfer of training?

The Impact of Workplace Design on Training Transfer

Virginia W. Kupritz  
The University of Tennessee-Knoxville

Tharulatha Y. Reddy  
Former UTK graduate student

The present study investigates the impact of workplace design on training transfer and where the physical environment fits in with other organizational factors impacting transfer. Tentative findings indicate that trainees perceive workplace design to be an important organizational factor impacting transfer. Utilizing an ethnographic approach, cumulative frequencies for elicited responses about organizational factors were highest for workplace design perceived to impede transfer and second highest for workplace design perceived to facilitate transfer.

Keywords: Workplace Design, Training Transfer, Organizational Factors

This study examines workplace design as an organizational factor impacting training transfer. While HRD research recognizes the importance of organizational context in influencing worker ability and opportunity to transfer (Roulier & Goldstein, 1993; Tracey, Tannenbaum, & Kavanaugh, 1995), the physical environment has been overlooked as a potential contributor. None of the fifty-eight studies included in the most comprehensive reviews of the transfer literature (Baldwin & Ford, 1988; Ford & Weissbein, 1997) examines workplace design, yet the physical environment is an integral part of organizational context (Sundstrom & Altman, 1989; Sundstrom, De Meuse, & Futrell, 1990).

HRD initiatives that take workplace design into account support HRD's mission to provide the best opportunity to perform efficiently on the job. A 30-year established body of Environment and Behavior (EB) knowledge documents workplace design as an integral part of organizational context that can enhance or inhibit individual, group and organizational performance (Becker & Steele, 1995; Brager, Bauman, Heerwagen, & Ruland, 2000; Brill, Keable, & Fabiniak, 1999; Brill, Margulis, Konar, & BOSTI, 1984,1985; Brill, Weidemann, & the BOSTI Associates, 2001; Brookes & Kaplan, 1972; Crouch & Nimran, 1989; DeMarco & Lister, 1985; Ellis & Duffy, 1980; Hedge, 1982; Kupritz, 1998; Marans & Spreckelmeyer, 1982; Springer, 1982; Vischer, 1996). EB studies, however, have not approached work performance from a training and development perspective. The present study draws from this EB knowledge in its examination of the impact of workplace design on training transfer. The application of EB theory to human resource development needs allows the disciplines to examine workplace design from a multi-disciplinary perspective. The objectives of the present study were to identify design features that facilitate and impede training transfer and to determine where workplace design fits in with other organizational factors impacting transfer.

Why HRD Professionals and Organizations Need to Pay Attention to Workplace Design Issues

Even though HRD professionals do not have control over the physical environment, they need to understand the vital role that workplace design plays as an organizational factor in training and development. Conversations with M. Lawer (personal communication, September 30, 1998), a training specialist at a major university, point to performance difficulties attributable to workplace design:

Quite frequently, in at least half of the [training and development] workshops I present, the discussion turns to difficulties attributable to workplace design. For instance, in a recent workshop on delegation skills, a supervisor cited her office’s physical layout as an obstacle; in her opinion, the extremely open nature of the office makes it difficult to give effective feedback to employees, as other employees as well as students can hear all that is said. Similar stories, detailing the effects of physical design on routine work activities, are recounted weekly.

Kupritz (2000b) highlights important reasons why HRD professionals should pay attention to design features impacting privacy in training and development whose reasons are just as valid for workplace design features at large. First, understanding the ramifications of the physical environment is crucial for helping trainees develop personal action plans that include potential physical obstacles and opportunities and helps trainees systematically
think through which aspects of the training realistically can be used within these physical constraints. Action planning identifies organizational constraints (such as design limitations) and opportunities to perform learned behavior on the job that allow trainees to return to work with a realistic and workable action plan. This activity helps workers maximize their opportunities to perform efficiently on the job and starts the important process of training transfer (Cheek & Campbell, 1994). From the larger organizational perspective, action planning empowers individuals and groups by giving people some control over decisions affecting their work. Research has demonstrated that worker control over their work environments—both actual and perceived—can enhance physical health and offset the stressing effects of heavy workloads and a fast work pace (O'Neill & Evans, 2000). O'Neill and Evans determined that training workers on how to use their adjustable workstation designs reduced stress and enhanced motivational performance. The adverse effects of job-related stress are well-documented (Kahn & Byosiere, 1992; Karasek & Theorell, 1990).

Secondly, understanding the ramifications of the physical environment is crucial for designing a training environment psychologically and physically that simulates workplace design conditions in the application environment. Instructional design models stress that transfer is more likely to occur when learning conditions approximate the application environment (Clark & Voogel, 1985; Laker, 1990). The need for trainers to approximate the actual conditions created by design limitations and design opportunities holds true for all training experiences, be it a noisy office environment to an extreme environment such as a military maneuver in desert-like conditions. For example, O'Neill and Evans (2000) staged interruptions during training as trainees practiced certain tasks to approximate office conditions these learners encounter on the job. Simply put, sound training may not occur in a quiet atmosphere if in fact the actual workplace is noisy, filled with distractions and interruptions any more than military training would occur in jungle-like terrain for desert warfare (see the National Simulation Center for live, virtual and constructive training, 1999).

The physical environment is not under the control of the trainer, but the conditions under which the training experience occurs are. To this end, Kupritz (2000b) suggests that trainers can simulate uncrowded or crowded conditions that approximate the density of the trainees' actual work environment. Mock set-ups of workspaces that facilitate or hinder work processes can also be incorporated into the training experience. Further, trainers can simulate visual and acoustical distractions and interruptions by introducing pedestrian traffic, incorporating background noises (e.g., office equipment) and conversations, and staging interruptions. Kupritz concludes that trainees are better prepared to cope with the physical environment through training that approximates the physical conditions and action planning that helps trainees identify physical constraints and opportunities to support learned behavior on the job.

Thirdly, understanding the ramifications of the physical environment addresses another dimension of organizational context that may improve transfer. The multi-dimensional nature of training transfer presents a formidable challenge to organizations. Corporate America continues to spend billions of dollars annually on training, much of which has either failed to transfer or has been extinguished over time (Broad & Newstrom, 1992; Foxon, 1993; Georges, 1988; Grabowski, 1983; Kelly, 1982). This failure to transfer has particularly happened with training in problem solving, management development and interpersonal skills (Foxon, 1993). Holton and Baldwin (2000) cite a common estimate that only 10 percent of training actually transfers to job performance, but caution that this has not been empirically documented. Enough empirical evidence exists to document that transfer is extremely low even though the precise figure may not be known. While HRD research continues to seek solutions that improve transfer, much of the transfer research has focused on factors within the formal training context (Holton & Baldwin, 2000). A stream of research, however, has evolved that examines the importance of organizational factors in the work environment to support learned behavior on the job (Rouillier & Goldstein, 1993; Tracey, Tannenbaum, & Kavanaugh, 1995). This stream of research targets organizational factors such as level of management and collegial support, availability of resources and technology to support transfer, timeliness of training to try out new learning, training relevance, potential application of training on the job, and transfer climate (see the review by Ford & Weissbein, 1997; also Foxon, 1993).

Although progress has been made in understanding organizational factors impacting transfer, Kupritz (1999, 2000a) proposes that workplace design has been neglected as another organizational factor that can enhance or inhibit the ultimate success of a training intervention. Kupritz synthesized EB theory for workforce training and development to examine workplace design that impacted older and younger worker performance. The Kupritz studies, however, did not measure the impact of training-specific situational factors on newly acquired skills. To this end, the present study measures trainee perceptions about the impact of organizational factors on newly acquired supervisory skills. This type of approach supports Tracey, Tannenbaum and Kavanaugh's (1995) contention that measuring situational factors that are training-specific can help move beyond the question of whether training works to why training works.
Research Methodology

The study participants (sample) consisted of 24 office workers who are actively involved in supervisory duties within the same major university. The office workers participated in a training workshop for supervisory skills within a four-month period and were now on the job. These employees attended one of three supervisory training programs with similar training skills taught by the same trainer at the university. The training skills included encouraging upward communication, disseminating information effectively, delivering unpopular messages, effective feedback strategies, mastering listening skills, identifying basic requirements for performance and evaluation, maintaining high morale, and understanding team influences.

The study utilized the first phase of the Heuristic Elicitation Methodology (HEM) to interview the 24 office workers. The first phase of the HEM is qualitative and is designed to exhaust the range of respondent perceptions concerning the variables being examined. As a cognitive ethnographic method, the basic assumption of the HEM is that it is possible to match particular items and attributes with particular cultural values (Harding & Livesay, 1984). Ethnographic procedures such as the HEM help to establish authenticity through the nature and format of the questions asked, followed by content analysis techniques (see Denzin, 1978; Denzin & Lincoln, 1994; LeCompte & Schensul, 1999). The ability to establish validity, especially internal validity, has been regarded for some time as a major strength of ethnographic procedures (Goetz & LeCompte, 1984; LeCompte & Schensul, 1999). HEM stimulus materials are respondent-generated rather than investigator-generated. Similarly, data is respondent-categorized rather than investigator-categorized. This procedure preserves the language and conceptualizations of respondents and decreases the likelihood of overlooking significant attributes of a domain being examined (LeCompte & Schensul, 1999; Spradley, 1979; 1980).

Structured interviews were conducted with each office worker over a 30-60 minute period. The structured interview is the first phase of the HEM, called the Domain Definition. The Domain Definition is an open-ended interview in which the language of the respondent is used in a series of interlinked questions, with answers recorded verbatim. Using the respondent’s own language in the questions helps to establish a shared meaning of language. The interviews reveal the range of items and attributes of a well-defined domain relatively quickly (Harding, 1974; Harding & Livesay, 1984; Kupritz, 1998). The HEM consists of several elicitation phases, however, any elicitation phase can be used individually and stand alone as a separate investigation (Harding, 1974). The methodology is predicated upon the idea that "language provides a powerful entry to cultural meaning structures" (Harding & Livesay, 1984, p. 75).

The Domain Definition identifies domains through semantic relationships in terms of behavior, artifacts and knowledge that people have learned or created. A “domain” is a set of categories organized on the basis of a single semantic relationship (e.g., “X” is a kind of “Y”; “X” is a way to do “Y”). The research instrument for this study was designed to elicit information primarily about organizational factors perceived as facilitating and impeding training transfer. The 10 questions asked avoided “referential meaning” by asking for “use” through contrast, similarity, uniqueness and the ideal in an effort to exhaust a domain (LeCompte & Schensul, 1999; Spradley, 1979; 1980). Three of the 10 questions are presented below, illustrating the nature and format of the questions used in this study:

Q. What skills learned in this workshop are you now using on the job? [Answers = "X"]
Q. When "X", what conditions, or office features, or situations make it easier to "X"? [Answers = "Y"] PROBE: What else might make it easier to conduct "X" other than "Y"?
Q. When "X", what conditions, or office features, or situations make it harder to "X"? [Answers= "Y"] PROBE: What else might make it harder to conduct "X" other than "Y"?

The investigators conducted domain and taxonomic analyses utilizing content analysis procedures (see Spradley, 1979). These analyses involve sorting through interview responses and identifying patterns, categories, or themes. A tabular worksheet was developed that displayed semantic relationships. Possible cover terms and included terms (i.e., items and attributes) that appropriately fit the semantic relationships were searched for in the data. Making systematic use of this kind of worksheet helps to uncover domains embedded in the interview responses (Spradley, 1979). For example, included terms dealing with effective interpersonal communication were grouped as items and attributes under the same cover term, positive management support. Each item and attribute included under this cover term fit the semantic relationship, "X" (e.g., listen more collectively) is a kind of positive management support.

Items and attributes were respondent-generated and respondent-categorized to preserve the language and conceptualizations of respondents. Each item and attribute was represented in some domain category. Key participants reviewed the domain categories for accuracy and gave positive feedback (see Creswell, 1994; Merriam,
1988). Following the content analyses, cumulative frequencies for similar types of items and attributes were calculated to determine how often similar types were elicited. Quantifying included terms in domain categories allowed the investigators to determine included terms elicited most frequently and to gain a beginning understanding about the distribution of beliefs across domain categories. A system of cultural meanings was uncovered that these office workers use to denote and connote organizational factors impacting transfer.

Findings

Elicited responses by the office workers revealed four main organizational factors as facilitating transfer: positive management support; supportive workplace design; availability of technology and equipment; and positive coworker support. Elicited responses also revealed four main organizational factors as impeding transfer: unsupportive workplace design; lack of management support; lack of coworker support; and lack of time in general (but not perceived as caused by management). Table 1 reports cumulative frequencies computed for each of the main organizational factors. Cumulative frequencies for elicited responses were highest for positive management support perceived to facilitate transfer, followed by workplace design.

</table>

Elicited responses for positive management support perceived to facilitate transfer included:
Listen more collectively; open environment, personnel would be welcome to make comments; try to be available; make sure they [employees] are appreciated; try to recognize when people express interest; not want to openly chastise them in front of their peers; [manager] leads and takes the lead; should always be an open door to express concerns, whether negative or positive; encourage diversity [in opinions]; being allowed a flexible schedule; [providing] regular staff meetings; have staff meetings on a regular basis, if there is a problem you can talk about it right away; management not restricted by deadline; fully staffed; if we can hire somebody at rush [time] in the middle of the year; not to have so many [hierarchical] layers; opportunity for cross-training; a pay raise; [employees] need to have a purpose and a goal.
[verbatim responses by office workers]

Elicited responses for supportive workplace design perceived to facilitate transfer included:
An office with less people; if we had less other offices in this unit, it would create unity; if it [workspace] is quiet; if you were set up in cubicles with the door closed, then it is private; should be offered some sort of withdrawal if you are dealing with sensitive matters; walls to go to the ceiling; I wish I had an office with a door, you need to talk privately; having my own office would be ideal so you can concentrate on that thing at one time; go to a place where you are uninterrupted, need to be away from the environment, the everyday environment; if there are no interruptions; close proximity; being close together; good working space to get things done; office environment plays a role, [it] puts the team in a better frame of mind; an office with adequate workspace and facilities; environmental things add or take away from one's motivation; communal area for team meetings [is needed]; as far as efficiency and morale, a nicer environment; have to be comfortable—a desk, chair and climate [like we had] in the old building; an office with windows to see outside.
[verbatim responses by office workers]
Cumulative frequencies for elicited responses were highest for workplace design perceived to impede transfer, followed by lack of management support. Elicited responses for unsupportive workplace design perceived to impede transfer included:

Too crowded up here; overcrowding; don't have my own office, keeps me distracted; I am sitting there with no privacy—often times I can hear the other person on the phone; don't have room for cubicles physically, find yourself listening to others' conversations and it breaks your concentration; the break room is right there, the room is very disruptive, you don't feel free to talk; sometimes people congregate around the phone, makes it hard to hear on the phone; the nature of the business by virtue of the physical structure where my office [is] and there is a physical line to allow the employees to stop by; constant interruptions; too spread apart; a lot of skills I cannot use because I am so far moved; if my office were closer, the physical part; the environment does not set up for impromptu; harder down here because of the layout of the facility; cubicles, the problem is you have to physically get up [to] ask them [employees].

verbatim responses by office workers

Elicited responses for lack of management support perceived to impede transfer included:

Other priorities, don't have one-on-one interaction; some of our supervisors get stuck in the old way of thought; difficulty communicating upward; overbearing supervisor; a supervisor who interrupts all the time; time management, it is hard to service three locations; office schedules are different; time sometimes, things go unattended; being short-handed does something to morale; to go through so many [hierarchical] layers to get things approved; no training; an employee who has no skills, you need to have opportunities; highly specialized activities, very compartmentalized; when you are bombarded with three or more people busy telling me things to do, they all want an answer right away; lack of priorities; don't show that much recognition when someone does something good; recognition needs to come higher; no management support for team.

verbatim responses by office workers

Cumulative response frequencies were then broken down to examine the distribution of beliefs across similar types of items and attributes for each organizational factor. Table 2 reports response frequencies computed across items and attributes for the top four organizational factors elicited as impacting transfer. Items and attributes dealing with effective interpersonal communication were elicited most often as facilitating transfer among all organizational factors. Items and attributes dealing with workplace design features that did not support privacy needs were elicited most often as impeding transfer among all organizational factors.

As stated earlier, no inferences can be made at this time about the strength of association or the relative weighting of importance for these elicited items and attributes and their domain categories.

Implications

The theoretical considerations presented in this study, though still in their formative stage, provide a beginning knowledge base about the impact of workplace design on training transfer. The study indicates that trainees perceive workplace design to be an important organizational factor in facilitating and impeding transfer for supervisory work practices. The findings reveal that unsupportive workplace design is foremost in the minds of trainees when discussing organizational factors impeding transfer for supervisory skills and, pending further research, may contribute to the 10 percent low transfer record commonly cited for work practices at large. HRD professionals, therefore, cannot afford to ignore the vital role that workplace design may play in transfer, especially considering ASTD’s 2001 report that corporate expenditures for managerial and supervisory training are at "fairly high levels" worldwide (Marquardt, King, & Koon, 2001, p. 10). For example, Canada and Australia/New Zealand in 1999 spent 22 and 21 percent of their training budgets, respectively, on managerial and supervisory training.

The findings also reveal that supportive workplace design may improve transfer. Unfortunately, the reality is that most people work in distraction-porous workspaces—filled with interruptions, acoustical and visual distractions, etc.—all of which contribute to unsupportive workplace design (Brill et al., 1999). This means that HRD professionals need to acknowledge the pervasive mismatch that exists between the quiet, structured classroom-type training environment and the noisy, interruption-filled "real world" work environment. Brill et al. (2001) describe this work reality, based upon an extensive study of some 13,000 American office workers:

Of all their time, people in all job types spend by far the most doing quiet work. Supporting quiet work is one of the two top productivity enhancers and job satisfiers. However, two-thirds of those in open offices (the most prevalent workspace type) are "often distracted by others' conversations" and can't do undistracted work. (p. 32)

Instructor-led classroom training continues to predominate training delivery globally, ranging from 56.2 % to 84.5% with the United States at 79.9 % (Marquardt, King, & Koon, 2001). This high percentage emphasizes the need for training to approximate physical conditions of the work environment more closely during the classroom experience, and to incorporate potential design obstacles and design opportunities into action planning so that trainees can return to work with a realistic and workable action plan.

The detail gained from this initial study warrants further studies that examine the impact of workplace design on other types of training skills and where workplace design fits in with other organizational factors for these training skills. It may be that workplace design is an important organizational factor impacting transfer for some work practices but not for others. Workplace design, on the other hand, may be important for transfer across the board. The ethnographic nature of the present study did not allow the investigator to prioritize the relative importance of workplace design compared to other organizational factors. Future studies can measure the relative weighting of importance given to organizational factors by respondents and the strength of relationships between organizational factors and acquired training skills.

Transfer Of Learning: How Managers Develop Proficiency

Michael D. Enos
Clark – Bardes Consulting

Marijke Kehrhahn
University of Connecticut

The purpose of this study was to expand the theoretical framework for understanding the transfer of learning by investigating the relationship between transfer of learning, proficiency, work environment variables, and informal learning; and to contribute to the existing theory of informal learning by investigating the role that informal learning plays in the development of managerial skills.

Keywords: Informal Learning, Transfer of Learning, Metacognition

Corporate managers require complex cognitive skills in order to work effectively with highly technical systems; interpersonal skills to be able to work competently in work teams; and leadership skills to effectively manage. A few decades ago, the solution to manager proficiency problems was to send people to formal classroom training (Wexley & Latham, 1981). Now, formal training programs are being criticized because they do not prepare employees to keep pace with the constant change that occurs in today’s workplace, do not provide employees with sufficient “real world” experience to develop proficiency (Sheckley & Keeton, 1999), and are not adaptive and meaningful to employees (Poell, Van Der Krogt, Wamerdam, 1998). This study investigated the relationships between managerial proficiency, transfer of learning, the means by which managers develop proficiency, and the transfer climate in the work environment. Understanding these complex relationships is valuable because it will help organizations to capitalize on their learning programs, reduce costs, ensure a more productive workforce and, ultimately, enhance their competitive advantage.

Problem statement

In 1998, an estimated 5.3 million managers were sent to formal training, resulting in 166.2 millions hours of managerial training (Bassi & Van Buren, 1999). While formal classroom training is one way for managers in organizations to learn, it may not be the most effective or most widely used learning method. According to Day (1998), 70% of learning in companies occurs informally from activities that take place outside of the classroom setting. Despite the prevalence of informal learning in the workplace, research has focused primarily on the transfer of skills learned during formal training (Rouiller & Goldstein, 1993). Due to the lack of research on what facilitates the application of skills learned informally, human resources practitioners are left with unanswered questions about ways to ensure that employees apply what they learn informally.

Theoretical Framework

Proposition 1: A Manager's Level Of Proficiency is Positively Related to the Transfer Of Learning. Sheckley and Keeton (1999) defined proficiency as the ability to skillfully apply knowledge within a particular domain. Research suggests that individuals who are proficient within a particular skill domain have an extensive and well-organized knowledge base that is built from experience (Chi, Feltovich, & Glaser, 1981; Kraiger, Ford, & Salas, 1993). When a knowledge structure is robust, strong links between problem types and specific solutions exist, thus enabling transfer of learning. For example, Gick and Holyoak (1983) found that 58% of individuals with better quality schemas (an indicator of a well-organized knowledge base) were able to solve a target problem compared to 29% of subjects who had poor schemas. The association between managerial proficiency and the transfer of learning has not been investigated in past studies. Based on the research addressed above, it was expected that managerial proficiency would relate positively with the transfer of learning.

Proposition 2: Managers Learn Mostly Through Informal Learning In The Workplace. Although formal classroom training is the most widely used mode of instruction to develop managers in today's corporations (Bassi & Van Buren, 1999), research suggests that most managerial learning takes place informally (Lowy, Kelleher, & Finestone, 1986; McCall, Lombardo, & Morrison, 1988). Informal learning strategies include job experience.
Proposition 3: Skills Learned Through Informal Learning Will Be Transferred More Readily Than Skills Learned During Formal Training. Proposition 3 is underpinned by common elements theory which holds that when individuals are able to make connections between past experiences and current problems, transfer of learning is likely to occur (Butterfield & Nelson, 1995). A premise of this study was that skills learned informally are more likely to share similar features with transfer tasks in terms of context and content. Therefore, skills learned informally are more readily applied than skills learned formally. Yorks, et al. (1998) found that 80% of employees who interacted with the managers who attended an action learning reflection program that required managers to work on real-time problems as a learning mechanism reported that they saw noticeable differences in the managers' behaviors after training. Further, Stolovitch and Yapi (1997) found large effect size differences in transfer between subjects who participated in a case study method of training and a control group who did not participate in case method training (d = 2.4). Past research on how the similarities between learning situations and transfer tasks increases the likelihood of transfer of learning formed the basis of this study.

Proposition 4: A Supportive Work Environment Facilitates the Transfer Of Learning Over the past decade, a number of studies were conducted that investigated the relationship between work environment factors and the transfer of training. Rouiller and Goldstein (1993) conducted the study that provided the best support that work environment factors relate to the transfer of training. In their study, the researchers found that transfer climate (an aggregate measure of work environment factors) explained 36% of the transfer of training variance. Several studies (e.g., Brinkerhoff & Montesino, 1995; Facteau, Dobbins, Russell, & Kudisch, 1995; Foxon, 1997, Tracey, et al., 1995; Xiao, 1996) have measured the relationship of specific work environment variables (e.g., coworker support, supervisor support, organizational support) with the transfer of training. The studies that have been conducted to date have examined the relationship between work environment variables and the transfer of learning from formal training programs. A gap in the literature remains concerning the role that work environment factors play in the transfer process when skills are learned informally. The results of this study were expected to show a positive relationship between work environment variables and the transfer of learning.

Methodology

Setting. This study was conducted in 1997 with managers who worked at a large subsidiary of a 100 year old Fortune 100 company located in New England. The company, a leading provider of insurance products that employed approximately 20,000 employees, was experiencing rapid growth, deep change, and extensive mergers. The sponsoring company valued effective management education and provided a wide variety of formal training programs for managers centered on developing proficiency around several core leadership behaviors. Further, informal learning was recognized by senior leaders, and the organization at large, as a purposeful activity. The extent and frequency of informal learning in the organization cannot be stated with any degree of certainty since the company did not have any formal metrics in place that measured informal learning.

Participants. A sample of 188 managers was identified by the company’s HR department from a larger population of managers as potential participants for the study. Of the 188 managers who were invited to participate in the study, 45% (84) took part by completing a questionnaire. All participants were notified through informed consent that their participation or non-participation would not affect their status as an employee of their company, and were ensured of confidentiality. The respondents included 60 (71%) women and 24 (29%) men. Respondents were on average 42 years old, ranging from 25 to 61 years, with an average of 10 years of managerial experience. Thirty percent of the managers had 1-5 years of managerial experience, 38% had 6-10 years, 16% had 11-15 years, and 16% had more than 16 years of managerial experience. Most participants (43%) had earned a Bachelor’s degree while 17% held a Master’s degree, 14% an Associates degree, 13% a High School diploma, 6% a Ph.D. or M.D.

Instrumentation. The questionnaire developed for the study consisted of three sections. Section I of the questionnaire consisted of 20 items that pertained to core leadership behaviors identified by HR professionals in collaboration with a number of managerial employees one year prior to the study. Managers were asked to rate the core leadership behaviors in three ways. First, managers were asked to self-report how they learned each of the 20
Research Question 2. Research Question 2 posed the question: To what extent do self-reported Proficiency scores, Informal Learning, Supervisor Support, Coworker Support, and Organizational Support scores explain variance in self-reported Transfer of Learning scores? The results of a preliminary residual scatterplot suggested that...
all of the assumptions for normality, linearity, and homoscedasticity were met, however, casewise diagnostics results suggested two outliers. After the removal of the two outliers, the hierarchical regression analysis to test Research Question 2 was applied. The order of entry of the independent variables into the regression equation was based on the correlation with the dependent variable. Proficiency (r = .64), was entered as the first step, followed by Organizational Support (r = .18), Coworker Support (r = .15), Supervisor Support (r = .11), and Informal Learning (r = .01). At the final step, with all variables entered, the regression explained 55% of the variance in Transfer of Learning scores. Proficiency explained 54% of unique variance (L = 9.1, p < .01), while 1% of unique variance was accounted for by Coworker Support (L = 1.2, p > .05). The other variables entered into the regression equation did not explain any unique variance (see Table 1).

** p < .01

A post-hoc correlation analysis showed that Informal Learning was negatively correlated with Organizational Support (r = -.46), Supervisor Support (r = -.26), and Coworker Support (r = -.15). A hierarchical regression analysis was conducted to clarify the relationship between the variables. Informal Learning was entered as the dependent variable. At the final step, with all variables entered, the regression explained 22% of the variance in Informal Learning. Organizational Support explained 21% of unique variance (L = 22.4, p < .01), while 1% of unique variance was accounted for by Supervisor Support (L = .84, p > .05). Coworker Support did not explain any unique variance (L = .58, p > .05). In sum, the results indicated that Organizational Support had a medium effect size inverse relationship with informal learning, suggesting that managers who perceived lower levels of Organizational Support perceived more of their learning to be informal.

Conclusions. Two conclusions were drawn from Research Question 1 results. First, managers learned managerial skills predominantly through informal learning. Second, “interactions with others” (e.g., interacting with supervisors, coworkers, and subordinates) was the informal learning activity that managers used most to learn managerial skills. Four conclusions were drawn from the results of Research Question 2. First, Proficiency explained 54% of the Transfer of Learning variance. Second, Informal Learning did not explain a significant amount of variance in the Transfer of Learning. Third, elements of the work environment did not explain a significant amount of variance in the Transfer of Learning variance. Fourth, a lack of Organizational Support explained 21% of the variance in Informal Learning.

Conclusions and Recommendations

Two assumptions of the study — managers’ proficiency would be strongly related to transfer of learning and managers learn mostly through informal means, were supported by the findings. However, the lack of support for the other two assumptions — that transfer of learning would be strongly related to work environment and that skills learned informally would transfer more readily — prompted a rethinking of our model of managerial learning. This reconceptualization led to the development of a new model (Figure 1) and a new set of propositions concerning the development of managerial proficiency. As outlined in Figure 1, managers in this study developed proficiency through a dynamic, ongoing informal learning process that entailed engaging in job experiences, interacting with others, observing others, and reflection. Informal learning resulted in tacit and explicit knowledge that contributed to well-structured domain knowledge. In the absence of support from the work environment, managers relied on their metacognitive abilities to help regulate participation in informal learning activities. Managers planned, monitored, and evaluated their learning behaviors in relation to their current domain knowledge, and were able to regulate their actions in such a way that enabled progress towards the achievement of their learning objectives (e.g., strategies to
Proposition A: Informal Learning is a Continuous Cycle of Challenging Experiences, Action, and Reflection. Following Watkins and Marsick’s (1992) theory of informal learning, an argument can be made that the informal learning activities that managers specifically reported were elements that facilitated a broader informal learning process that included both explicit and implicit learning. For example, “job experiences” cited by managers provided specific and challenging work problems which required necessary actions to resolve. Further, “interactions with others” and “watching others” promoted “reflection” and helped managers to make sense of their experiences. These conscious activities were embedded in a deeper, ongoing series of experiences that promoted learning.

Proposition B: Informal Learning is a Social Process. The most prevalent learning activity (44%) that managers reported to build proficiency was “interactions with others” in the workplace. While prior research (e.g. Billet, 1994) has suggested that interaction with peers, supervisors, and subordinates in the workplace are strategies for informal learning, the results in this study are unprecedented due to the wealth of learning that managers reported through these types of interactions.

The tenets of social practice theory help to explain why and how managers in this study learned through their “interactions with others” in the workplace. Lave and Wenger (1991) purported that learning is a social process of participating in work activities and interactions with others that do not exist in isolation, but are part of an integrated set of relations that take on meaning and are situated in the work setting. According to Billet (1994), learning can occur as a result of close guidance from others in the course of work activities. Choo (1998) argued that knowledge can be shared explicitly and implicitly among employees who interact with each other and with the social dimensions of their work tasks and organizational setting. Thus, by observing, assisting, and copying behaviors of experienced practitioners, managers can develop an understanding of the “norms” of a company, and a tacit and explicit understanding of these “norms” can be transferred from one manager to another. The conceptualization of
Today's companies rely mostly on formal training to develop the proficiency of managers. Unfortunately, the use of formal training programs to develop the proficiency of managers has not paid dividends, as most skills that are learned during formal training are rarely applied on the job (Pfeffer & Sutton, 2000). Based on this study's findings, social practice theory girded by the comments from participants in this study has two important implications for informal learning theory. The first implication is that informal learning is a social process that is largely dependent on social interaction with other individuals in the workplace and is situated in the organization. The second, and perhaps more important implication, is that actions, in concert with interactions with others in the workplace, serve as an important vehicle in which domain-specific knowledge is generated, articulated, and dispersed throughout an organization. This implication suggests that neither action nor interaction alone will result in the building of domain knowledge necessary to become proficient; an integration of action and interaction must exist.

Proposition C: Transfer is a Component of Informal Learning that is Embedded in the Process. The lack of a significant relationship \( r = -.01 \) found in this study between informal learning and the transfer of learning raises questions about the actual relationship between the two phenomena. As described by Holton, et al. (1997), transfer of training occurs when a learner is able to take what is learned during formal training and successfully apply it on the job. As evidenced in this definition, a clear demarcation exists between learning (that takes place during formal training) and transfer. But, what is the role of transfer in an informal learning system? When learning is a continuous cycle of challenging experiences, actions, and reflection when does learning stop and when does transfer begin? Results from this study and past research help to provide insight into these questions.

Yelon, Reznich and Sleight (1997) proposed that "a law of exchange" characterizes the transfer process, that is, with each application, a learner gathers new knowledge from its implementation, which in turn is used for future applications. In essence, the study suggested a dynamic process of transfer that entailed individuals learning informally from their applications. If the contention that transfer is a component of the informal learning process stands, why wasn't such a relationship demonstrated by the results of the study? Similar to past studies (e.g., Rouiller & Goldstein, 1993; Tracey, et al., 1995) transfer of learning in this study was measured as a one dimensional "product." The single dimensional approach used to measure transfer made it difficult to detect differences in transfer associated with learning methods.

Proposition D: Metacognitive Skills Moderate Informal Learning and the Application of Learned Skills. Contrary to past research, the results of this study suggested work environment factors did not play a significant role in how managers learned and transferred skills. If learning and transfer were not influenced by external factors, what internal mechanisms enabled managers to learn and transfer skills? Ertmer and Newby (1996) argued that self-regulation involves the recursive and interactive process of identifying actions to facilitate the achievement of a task (i.e., planning), paying mindful attention to the strategies that are employed to achieve a task (i.e., monitoring), and assessing the outcomes of the actions that are deployed to achieve a task (i.e., evaluation). The self-regulation process is guided by metacognitive knowledge. Metacognitive knowledge entails individuals' awareness of their strengths and weaknesses as learners, requirements to succeed in a task, obstacles in the environment that might interfere in accomplishing a task, and cognitive strategies that might lead to success (Ertmer & Newby, 1996). Metacognitive knowledge and self-regulation work together in a dynamic fashion to produce effective learning. Metacognitive knowledge provides individuals with information about a specific task, its demands, and what it will take to accomplish the task. Self-regulation, on the other hand, serves as a mechanism that controls the application of metacognitive knowledge and helps reduce the gap between an individual's current and desired abilities (Ertmer & Newby, 1996).

Two results from this study allow for speculation that metacognitive knowledge and self-regulation played roles in how managers learned and transferred learning. First, the results of a post hoc analysis showed that an inverse relationship existed between organizational support and informal learning \( \beta = -.46 \). In the absence of organizational support (i.e., supplies, learning aids, and rewards to assist in the transfer of learning), participants made a deliberate effort to engage in informal learning activities to achieve the knowledge and proficiency necessary to carry out required job tasks. Following this interpretation, managers' metacognitive knowledge may have helped them to detect a discrepancy between the managerial tasks they needed to accomplish, their current abilities to accomplish the tasks (i.e., domain knowledge), and the support that their environment provided to carry out these tasks. In order to reduce the gap between their current domain knowledge and required knowledge, managers may have actively sought out, created, and recognized informal learning opportunities (i.e., self-regulation) to develop their managerial proficiency.

Practical Implications for HRD Practitioners

Today's companies rely mostly on formal training to develop the proficiency of managers. Unfortunately, the use of formal training programs to develop the proficiency of managers has not paid dividends, as most skills that are learned during formal training are rarely applied on the job (Pfeffer & Sutton, 2000). Based on this study's findings,
two implications are offered for HRD practitioners who face the challenging task of developing the proficiency of managers in their organization.

Implication 1. Shift the focus away from formal training of managers and develop more realistic expectations concerning the application of what is learned through formal training. Recognize and leverage the abundance of informal learning opportunities that managers experience and focus on developing managerial proficiency and expertise.

Opportunities for informal learning such as interactions with others in the workplace, observing others, and challenging job assignments must be harnessed and leveraged. In addition to developing explicit and implicit knowledge, these types of activities over a period of time are more apt to result in the development of proficiency. In order to facilitate managerial proficiency in the workplace, managers need to be in an environment where informal learning is encouraged and strategies and activities that promote informal learning (i.e., reflection and challenging experiences) are made available (Sheckley & Keeton, 1997).

Implication 2. Develop the metacognitive skills of managers.

Managers that have superior metacognitive skills will be more likely to engage in and seek out informal learning opportunities and effectively transfer skills that they have learned. Past research supports two approaches to developing self-regulation (Smith, et al., 1997). The first approach is to give the learner control over the content, sequence, and pace of learning. Sternberg (1989) argued that giving learners control over their learning can lead to a more motivated and involved learner. A second approach to promoting managers’ self-regulation is generating a mastery orientation. Mastery orientation differs from a performance orientation in that the focus of learning is on developing proficiency of a skill, not on outperforming peers (Smith, Ford, & Kozlowski, 1997).

How This Research Contributes to New Knowledge in HRD

The fast pace in which corporations operate today, and the need for companies to remain competitive, has unloaded a heavy burden on organizations, managers, and HRD practitioners. The prevailing belief among organizations and HRD practitioners today is that increased spending on formal training will result in more effective managerial performance and ultimately, increased revenue for the company (Bassi & Van Burren, 1999). While there is some evidence that shows that companies that heavily invest in training are more successful than those that don’t (Bassi & Van Burren, 1999), this study demonstrated that formal training is not the ultimate source of learning and the transfer of learning.

Organizations and HRD practitioners would be well-served to rethink their approach to managerial learning and proficiency. This study suggested that managers learn mostly from informal learning, proficiency is the product of informal learning, and that self-regulation moderates informal learning and the transfer process. In light of these findings, companies should harness and leverage informal learning and cultivate the metacognitive abilities of managers, as opposed to increasing spending on formal training programs. By applying these approaches, companies may save money, develop more proficient managers, and gain a competitive advantage.

Through a critical literature review and comparison of CPE curricula offered by medical and legal professional associations, this study examines ways in which political, cultural, and institutional practices within the professions and their associations support or injure various groups. This exploratory study begins the examination of one of four research propositions composed to stimulate new questions and research in CPE, focusing on the relationship between CPE and social justice.

Keywords: Continuing Professional Education, Diversity, Social Justice

This study reexamines traditional approaches to continuing professional education (CPE), but in a different way from other recent calls for scrutiny and subsequent reframing (Mott and Daley, 2000). The professions, originally designed by and for the privileged, in many ways still function as elite groups. In stark contrast to a uniform profile of the highest status professions (medicine, law, engineering) as white males from privileged backgrounds (Eraut, 1994), today's professionals are increasingly differentiated in social background, race/ethnicity, gender, disability, lifestyle, and sexual orientation. This has resulted not only in the emerging diversity of the professions, but also in the proliferation of young professionals who challenge traditional values, assumptions, and conventions.

The CPE curricula of mainstream professional associations are composed primarily of updates on content knowledge, which are presented as “scientific,” hence value neutral. The extent to which this knowledge is Euro-centered and excludes the contributions of women and non-Whites is left unexplored.

Two recent commentaries on the state of CPE (Cervero, 2000, and Queeney, 2000) do not include increasing diversity in the professions themselves as one of the current challenges, trends, or critical issues. We assert that the traditional view of CPE based on an objectivist theory of knowledge is inadequate to enhance competence for (1) successfully relating to an increasingly diverse professional community; (2) reframing policies, practices, and barriers to entry in the professions; and (3) using specialized knowledge for treating people, not as collections of needs, but as whole human beings (McKnight, 1995, p.39).

Problem Statement and Research Propositions

The mainstream approach to CPE disregards the critical literature that questions the concept of professionalism as an ideology. If we are to create a theory of communicative action (Habermas, 1999) for professions that is centered on communities of difference, we must turn to a body of knowledge that has hitherto been ignored. The research propositions stated below and the specific question this study addresses, are framed differently from many found in the literature on CPE. Rather than focusing on measurable educational outcomes of learners, they call attention to the structures and processes of the professions (including CPE) intended to improve the professional practice of their constituencies.

Traditionally, the ideal profession is depicted as a category or a distinction in which individuals recognize others as they recognize themselves promoting an ideal of community that is unable to accommodate plurality, difference, and different realities (Young, 1990). This approach is a conceptual straitjacket for researchers, rendering many questions “unaskable” because they cannot be accommodated within traditional methodologies. By denying plurality, differences, and different realities, membership in a profession (and development of professional expertise) appears to require the erasure of identities arising from race, class, and gender.

Much of the current literature focuses on a long list of ills that plague CPE, but makes few recommendations on how to build professional membership and competence that truly addresses the challenges of the 21st century. Collins (1991, 1998) informs us, and Eraut (1994) concurs, that CPE needs more emancipatory strategies and practices.

As Foucault (1977) noted, “Knowledge derives not from some subject of knowledge, but from the power relations that invest it . . . All knowledge is political” (p. 220). Foucault, among other critical theorists, viewed power as being embedded in existing social structures and discourse, rather than the possession of those who then
use it to regiment and control other hegemonically. Hence, knowledge construction, through research methodologies that have the potential for being emancipatory rather than oppressive, provides rational grounds for:

1. Requiring that differences in gender, race, ethnicity, religion, and sexual orientation become central to the concerns of the professions, i.e., in the day-to-day life of a professional, the impact of practices on different groups and the implications of these practices for whole communities must be considered.

2. Directing us to examine the particular ways in which political, cultural, and institutional practices within the professions support or injure various groups.

3. Questioning professional knowledge in such a way that the institutional structures associated with housing bodies of expert knowledge (hospitals, school, courts, professional associations), that are organized on the basis on the dominant cultures values and norms, are examined for their commitment to social justice.

4. Becoming border crossers; that is, “to understand Otherness in its own terms” (Giroux, 1992, p. 23). This is made possible by exploring and articulating the obstacles erected by power, authority, membership in professions, and control over resources.

In 1988, Cervero asserted that the critical viewpoint was crucial to sound practice in CPE because it holds ethical and political considerations alongside technical expertise as equally important dimensions of continuing professional education and development. Further, adult educators who design and deliver CPE courses in a variety of settings should have little difficulty in incorporating sessions for attendees in which they are asked to critically reflect upon the questions. “Am I doing good (for society)? Or, am I doing well (for myself)?” Given the prevailing view among many adult educators that knowledge is socially constructed, serious reflection on one’s contribution to the growth of civil society while seated in rows of a well chilled meeting room for CPE updates seems almost ludicrous (Boud and Walker, 1998). Perhaps it is time to give up the notion that knowledge is “constructed” and replace it with the idea that the products of culture (knowledge is one of them) are the results of a negotiation with a lifeworld of which we are a part. Further, the various group identities that evolve out of these negotiations inform us that classrooms that don’t include our lifeworlds and the power relations that exist within them do little to support reflective dialogue on our knowledge constructions (Collins, 1998, p. 71-72).

Research Question

Two aspects of Cervero’s articulation of current trends and issues in CPE hold particular significance for this inquiry: (1) increased collaboration among providers such as universities and workplaces, often in partnership with professional associations; and (2) the incorporation of continuing education as part of state regulatory mechanisms of licensure/certification (2000, pp. 6-8). Both of these trends highlight the reality that CPE is now highly corporatized, institutionalized, and regulated – no longer part of many practitioner’s lifeworlds (if it ever was) and carried out with the precision of technical rationality.

To begin the exploration of just one of the research propositions noted above (#2), we investigated: In what ways and to what extent do professional associations and their CPE curricula support cultural reproduction, social integration, and socialization to an objectivist view of the professions?

Theoretical Framework

A major premise underlying the research propositions and the exploratory research question stated above is that a theoretical framework for researching the ways in which CPE and its diverse providers (with the workplace and professional associations as the most prevalent suppliers) is lacking. Although critiques that have contributed much to the topics of professionalism, CPE, and program planning exist such as, Illich et al., 1977; Cervero, 1989; Cervero & Wilson 1994, 1996, 1998; Collins, 1991, and McKnight, 1995, they tend to fall into two categories. First, Illich et al. (1977), Collins (1991), and McKnight (1995) provided very useful critical treatises on the meaning of professionalism as an ideology and its effects on modern society. Second, Cervero and Wilson (1994, 1996, & 1998) focused on the negotiation of power and various interests in responsible program planning. Eraut’s work (1994) bridged the gap a bit more in terms of empirical research on how professionals construct knowledge to improve practice (often through CPE) but it did not satisfy the need to look across professions as most of his research
examined the staff development of K-12 teachers. It also did not examine the broader societal implications of CPE practices in terms of cultural reproduction. The primary goal then of these four propositions and the exploratory research question is to stimulate new empirical research on the ways that business-as-usual CPE practices improve practice, not only by steadily advancing technical expertise, but also by examining the ways in which that expertise contributes to social justice. If this goal is achieved, it may provide the foundation for a more comprehensive theoretical framework.

Data Collection and Analysis

First, literature not routinely considered in researching professional associations and CPE was reviewed and the findings are presented here in the section titled, Critical Literature Review. The purpose is to present a “counter-story” to the idealized notion of the professions as it relates to health care in the United States. Counter-stories, as Haraway pointed out “… are not any more ‘real’ than those widely circulated on an everyday basis, (but) they do engender situated knowledges that offer different values, perspectives, and understanding of everyday reality” (1996, p. 255). And, as Shank noted, “The most important reason to adopt new research methods is to open up the inquiry process” (1994, p. 349).

Second, a web-based document content analysis and phone follow-up was undertaken to compare CPE curricula of associations whose membership comprises a variety of diverse interests within the professions of medicine and law. These two professions provide a purposive sample in several ways. First, they share a similar historical developmental path including the timeframes within which they founded professional associations, adopted licensure requirements, standardized curricula, and limited entry to the profession members of marginalized groups and subsequently modified those practices (Illich et al., 1977; McKnight, 1995; Foucault, 1984). Further, their professional associations are “resource rich” in comparison to many others and therefore maintain regularly updated, highly sophisticated websites where members and the public-at-large may view their benefits and conference programs. These two professions’ associations are identically structured in terms of the mainstream associations (beginning with the name “American”) and their “National” affiliates comprised of numerous groups organized around their ethnic, racial and/or gender group identity. Finally, as Eraut (1994) pointed out, these two professions enjoy a shared perception in the public eye as the true professions, to which all other aspire. These shared characteristics facilitated an exploratory comparison.

In terms of limitations of these findings, given that the purpose of this literature review and exploration of CPE curricula is to stimulate new dialog among CPE and HRD scholars with the hope of fresh theory generation, generalization of the results to modify current practice lies outside its scope. Accordingly, what follows was informed by the work of Brookfield (1993, 1995) in which he built on the ideas put forth by the contributors to the Frankfurt School of Critical Social Theory (Habermas, Adorno, Horkheimer, Marcuse,) and the “pedagogy of hope” proposed by Freire (Freire and Faundez, 1989). Consistent with these frameworks, the purpose of this review is to open up spaces in which dominant ideas and unfair practices can be contested. As Brookfield noted (1993), “Sometimes all we can do is focus on how the damage inflicted by a program, policy or practice can be kept to a minimum. At other times we have the chance to develop new structures that seem more democratic or to create spaces in which open, critical conversation can take place” (p. 79). But, first we must ask the questions and understand what we find.

Critical Literature Review

Politics, economics, and medicine share a long history that can be traced back to the eighteenth century in Europe. Foucault’s (1984) review of the politics of health in eighteenth century France examined how two distinct strands of healthcare—the private, market enterprise of the doctor/client relationship and the political/governmental goals to control the health of the labor force—converged, transmuting Western medicine into the system today. Medical expertise was a valuable skill during this era in France and Europe. Government power coalesced, and ‘the public’ became a defined entity to be studied, examined, and controlled. Overseeing the health of the working class was an important function for doctors in the eighteenth century. They assumed administrative positions within the power structure, dispensing advice to the work force on personal hygiene, healthy eating, and living habits. Doctors were not merely becoming separated from the working and marginal classes. They became the “overseers” (p. 171). Today, the healthcare hierarchy is well entrenched. Those with a ‘doctor’ appellation occupy the top rung, followed
by nursing and the allied health professions. Those who ‘diagnose’ control entry into the healthcare delivery system while nursing and the allied health professions exist in a subordinate position of an authoritarian system.

The Effects of Oppression on Healthcare Professionals

Freire (1988), noted that one major characteristic of oppression is that the values and norms become internalized in those they dominate. The oppressed become ‘hosts’ of the dominant society’s ideology. In most cases of oppression, the dominant group looks and acts differently from the subordinate group—male doctors versus female nurses, male dentists versus female dental hygienists, male psychiatrists versus female social workers—and the characteristics of the subordinate group become devalued. He asserted that, “Submerged in reality, the oppressed cannot perceive clearly the ‘order’ which serves the interests of the oppressors whose image they have internalized. Chafing under the restrictions of this order, they often manifest a type of horizontal violence, striking out at their own comrades for the pettiest of reasons” (p. 44).

Freire further posited that this process of internalization leads to personality characteristics of self-hatred and low self-esteem in the dominated group. Individuals feel hostility toward the powerful, but those experiencing the effects of this hierarchy are not able directly to express it. The oppressed complain vociferously to each other, but react submissively when confronted with power. Unleashed aggression within oppressed groups can manifest in self-destructive behaviors. These characteristics stem not only from dependency, but also from hatred of their ‘own kind’ and a desire to be like the oppressor. As Freire concluded, “it is the rare peasant who, if promoted to landowner does not become the tyrant of the peasant” (p. 28).

The Business of Continuing Professional Education

Expanding technologies, information about disease, and new treatment modalities are increasing exponentially. Practitioners who have been in the field for years can be so far behind the times as to be dangerous. Hoffman (1980) described continuing education as a component of adult education, and further defined continuing education within the healthcare delivery context as a system of education that is a subsystem of the health system, because its clients either support or deliver health care services. Similarly, licensed professionals view CPE as an integral part of being a professional, however, not everyone voluntarily seeks further education. Practitioners, therefore, turn to the state for assistance in requiring it. Since a primary responsibility of the legislature is to protect the health, safety, and welfare of the public, legislators conclude that they are fulfilling their duty to the public by requiring continuing education. State laws are amended requiring licensees to accumulate mandatory continuing education (MCE) hours during each licensure period (Houle 1980, p. 59). MCE has been a financial boon to the professional associations. Associations lobby the state legislature to require continuing education. After amending the laws or even promulgating new rules, the legislature or similar regulatory board creates a list of ‘approved providers’ of CPE. Besides educational institutions, local, state, and national level professional associations are typically approved providers. The associations can benefit from MCE because non-voluntary attendance in CPE courses provides virtually guaranteed revenue.

Another issue for professional associations surrounds the educational viewpoint of their CPE courses. Cervero and Wilson (1994) distilled the various views of program planners into three common views, the classical, naturalistic, and critical viewpoints (p. 14). From the perspective of CPE, the critical viewpoint has only recently emerged and it argues for the abandonment of the idea that there is consensus regarding professional quality. As Cervero asserted, “Because there is a lack of consensus in most situations, the purpose of continuing professional education is to help professionals understand the ethical and political, as well as the technical, dimensions of their work (Cervero 1989, p. 519). Given that the leadership within professional associations often are the primary authors of policy and programs, associations will have difficulty planning courses that challenge the status quo and, therefore, the leadership. For CPE practitioners within professional associations there are major hurdles to overcome in constructing programs that will support critical thinking that leads to self-reflection, and ultimately to improvement of practice not just instrumentally, but democratically. As Cervero and Wilson (1994) pointed out “It is especially difficult to envision how program planners might practice this [critical] viewpoint in organizations that are not committed to the particular political and ethical agenda espoused in the theories, a common situation for many educators of adults. For example, how are educators who are personally committed to these goals to plan programs in the face of an organizational mandate to make a profit?” (p. 24). Although program planners would do well to consider grass roots members and nonmembers when constructing CPE courses, current association
partnerships and allegiances to regulatory and accrediting bodies, make this unlikely. Education policies need to be grounded in the goals and concerns of those 'at the bottom' of the association hierarchy because the leadership in oppressive groups may not represent the grass roots. Freire (1988) noted that this phenomenon is consistent with oppressive theory, "As the oppressor minority subordinates and dominates the majority, it must divide it and keep it divided in order to remain in power" (p. 122). Divide and rule are destined to be the outcomes of leadership selected from the elite. Another dimension of divisive leadership is the current practice of leadership training for association officers and board members. Again, Freire suggested:

The same divisive effect occurs in connection with the so-called 'leadership training courses', which are (although carried out without any such intention by many of their organizers) in the last analysis, alienating. These courses are based on the naive assumption that one can promote the community by training its leaders—as if it were the parts that promote the whole and not the whole which, in being promoted, promotes the parts. (p. 123)

Associations plan programming based on policies adopted by the leadership; however, profitability is a primary consideration in course planning. Course planning that authentically responds to the concerns of grass roots professionals should be supported, but as Brookfield (1985) cautioned, “It is naive to presume that because adults are gathered in a class that critical adult learning is being facilitated” (p. 47). Whether CPE courses that create critical learning environments will lead to liberation for healthcare professionals is unknown. To date, liberation has not been achieved by the absence of critical learning within CPE.

**Results: CPE Curricula Comparative Analysis**

Annual conference programs provide a fascinating snapshot of the role of CPE in relation to professional association member interests. Revenue from conference registrations provides over half of the annual income for many associations making the match between member interests and needs and CPE offerings a financial imperative. Although the critical literature review focused only on healthcare, we broadened the CPE curricula comparison to medicine and law to add to the knowledge of CPE trends and practices across professions.

A comparison of the annual conference programs over the last two years (2000-2001) for the following professional associations (see Table 1) was completed through a web-based search.

Information gleaned from all the CPE program coordinators from the affiliated National Bar Associations, and two from the affiliated National Medical Associations indicated a growing desire to standardize program formats into “Tracks” identified with a common nomenclature. This member-requested initiative is designed to help members (many of whom belong to several of the National affiliates) quickly analyze sessions of interest.

Although the annual conference CPE curricula of the AMA and ABA are also organized by tracks, (see Tables 2 and 3), the track titles indicate different emphases from those of the National Association affiliates of both professions.

* All new developments across medical/surgical areas are handled as “Breaking News.”

The organizing principle used to create Tables 2 and 3 was ease of access. In other words, sessions were attributed to various associations' conference programs when they appeared to clearly relate to a particular track both in terms of the session description and the organization of the program. Conference programs that now feature a “Cultural Competence Track” included a description of the track as a whole and some statement indicating the previous year's interest in these topics. It is important to note that the CPE curricula of both the AMA and ABA include sessions on diversity but they tend to focus on the needs of diverse clients, not those of the professional membership. Also, these sessions are subsumed under broader concerns around clinical issues, such as the study of diabetes within a certain population or how the death penalty impacts various minority groups.

Phone interviews revealed that program planners are responding to the tragic events of September 11, 2001. Visits to the homepages of the ABA and AMA revealed position statements and anticipated additions to the 2002 conference programs related to “Disaster Response.” A slightly different response emanated from several of the
National Association affiliates (medical and legal). While position statements and messages of sympathy are all but universal, phone follow-up with program coordinators of the National Bar Association affiliates confirmed that their programmatic thrusts would be on the effects of racial profiling—a repeat topic for several years now, but even more critical since September 11.

With regard to the Professional Development Tracks, the ABA and AMA session descriptions indicated a “one-size-fits-all” approach regardless of the topics (mentoring, financial planning, career planning, etc.). Alternatively, Track descriptions for the National Medical and National Bar Association affiliates feature the particular minority group interest and position the session topic within that context. Disturbingly, the ABA annual meeting program runs concurrently with the ABA Commission on Racial and Ethnic Diversity (not shown on Table 2) and this special interest group’s program includes many sessions that are very similar to the ones found on the conference agendas of the National Bar Association affiliates. However, attendance at these sessions precludes attendance at the general membership sessions, many of which are devoted to technical updates presenting an unfortunate dilemma for conference attendees. When asked about this conundrum, the ABA program coordinator acknowledged the decision point but noted that the previous solution (a pre-conference) did not generate enough attendance to be continued and the concurrent programs seemed to be the “perfect” solution. Further, the coordinator noted that, “there really is no problem because members who miss technical update sessions can always purchase audio and video tapes of the sessions.” Scheduling decisions driven by the desire to optimize conference revenue, at the expense of other outcomes, create conditions of de facto segregation in this example. To the extent that conferences create spaces for dialogue among participants, the politics of scheduling play a substantial role in enabling or preventing inter-racial and cross-cultural communication. Brookfield has devoted considerable attention to the need for adult educator’s (and we include CPE practitioners among them) to examine the hegemonic aspects of their practice and calls for an examination of the ways in which practice perpetuates inequities and the ways in which it is discriminatory and anti-democratic (1995). Conference programs provide an important publicly available framework for undertaking this examination.

Conclusions, Implications for Research, and Contributions to HRD

Returning to the research question, In what ways, and to what extent do professional associations and their CPE curricula support cultural reproduction, social integration, and socialization to an objectivist view of the professions? Annual meeting programs reveal a color-blind stance on the part of the AMA and ABA. Placement of the ABA Commission on Race and Ethnicity program as a concurrent offering presents disquieting evidence of the degree to which CPE practitioners are complicit in cultural reproduction. Partially in an attempt to offset asymmetrical power relations, the National (Medical or Bar) Association affiliates offer racially and ethnically sensitive CPE and explicitly promote a social justice agenda through their mission statements and their annual meeting programs. Continuing analysis of both professional association educational programs and membership demographics will help reveal the extent to which the association agendas are “preaching to their own choirs.”

The purpose of presenting the initial stages of this research is to call attention to the issues raised in the four propositions posed early in this paper, particularly in relation the second proposition. There is a paucity of research that investigates CPE from a structural problem-posing rather than an instrumental problem-solving stance. Both conference programs and conversations with program coordinators (in mainstream and minority-focused associations) confirmed that sessions are selected and agendas are assembled with some attention to the association’s mission, but with an overarching goal of maximizing attendance, hence revenues. And, it appears at least from session titles, that the National (Medical and Bar) Association affiliates experience social justice issues as more central to their practice than do the American (Medical and Bar) Associations.

Recently, Cervero (2000) posed the following question as the number one critical issue facing the field of CPE. He asked, “Continuing education for what? The struggle between updating professional’s knowledge versus improving professional practice” (p. 8). Somehow, the professional obligation to update knowledge, improve practice, and commit to a more just society through practice have become competing rather than synergistic goals. This competition is institutionalized by the market-driven forces that retain sessions and topics based on attendance.

The problems posed by this analysis are closely aligned to those facing the AHRD Task Force on Standards and Ethics and the consideration of the role of such codes in improvement of practice. Currently, scholar/practitioners engaged in CPE affiliate with organizations within their individual professions, thus dividing the field of CPE into many diverse units. There is a need for a national and international affiliation where CPE providers and researchers can come together to share research and practice ideas. Ruona and Rusaw (2001) envisioned AHRD as a space for
creating shared vision and values, fostering changes in behavior and conduct, creating rewards and incentives for ethical conduct, and promoting and disseminating basic and applied research (p. 227). To the extent that this space can be extended to the research and practice of CPE, the potential exists for a richer consideration of HRD through the narrower lens of CPE.

The Ambushed Spirit: Peace, Violence, Downsizing, and Implications for HRD

Daniela Truty
Northern Illinois University

The purpose of this study was to investigate the phenomenon of downsizing from the perspective of the person who was separated from the job, and to explore its connection to violence and peace. Findings suggest that the experience of downsizing is not uniform among affected employees; rather it is dependent on contextual factors and other constitutive elements of what it means to be a person in the workplace.

Key Words: Downsizing, Violence, Peace Studies

This paper is part of a larger study I plan to complete in Spring 2002. I was one of 1,100 white-collar employees in a large midwestern automotive manufacturing firm, separated from the job at the beginning of an industry downturn in August 2000. From my perspective, this downsizing was an act of violence as real as other types of workplace violence. I questioned whether anything existed in the literature to support my perception of downsizing as violence, if my colleagues described experiences similar to mine, and how it was that organizations were permitted to downsize in this way with virtual impunity from employees, lawmakers, and the general public. As an HRD professional in a corporate or academic environment, what did the realization that downsizing could be perceived as violence mean for my work?

Questions and Theoretical Framework

I approached this study with the following questions: From the perspective of the person separated from the job: How does he or she describe the experience of downsizing? What is the relationship between his or her downsizing and violence? And how is it that downsizing appears to have become so accepted? To frame this study, I consulted four main bodies of literature: downsizing, violence, peace studies, and organizational studies.

Downsizing

News, commentaries, and stories about involuntary job loss, mergers, acquisitions, takeovers, re-engineering, reorganizations, reductions in force, firings, and layoffs, abound in the media, popular press, and investor web sites. A review of the literature on downsizing resulted in a plethora of work viewing downsizing from different perspectives and grounded in disciplines including Human Resource Management (HRM), Human Resource Development (HRD), Labor and Industrial Relations, Business Ethics, Applied Social Psychology, Philosophy, Management Studies, Family Counseling, Career Development and Counseling, Economics and Finance, and Religious Studies. Subjects of this writing have been professionally, racially, ethnically, and otherwise diverse.

Interest has focused on coping with downsizing and reemployment, particularly as the two intersect with other variables, i.e. health and demographic, for example. Most of the writing glosses over felt experiences, concentrating on how to downsize the "right" way. Writing about victims of downsizing has been descriptive, or analyzed from a clinical, psychoanalytical standpoint. While the employees' words provide the content for these analyses, there appears to be a separation between researcher and researched, subjects and objects, observer and observed, interviewer and interviewee. The literature stops short of in-depth exploration of differences in the way downsizing is experienced. None overtly connects downsizing with the discourse of violence and peace studies.

Violence

The literature on violence, except for a cursory remark by Stanage (1974), has not been explicitly conjoined with the experience of downsizing. For the most part, writers have been preoccupied with defining violence, situating it within the context of evil (Karake-Shalhoub, 1999), the Myth of Satan (Hallie, 1974 & Rubinoff, 1974), and even the Holocaust. It appears that what constitutes violence for one individual may not for another, with the exception of blatant acts like murder; rather, definitions seem to be dependent upon individual perspective (Stanage, 1974, 1981). In spite of the difficulty involved in arriving at an acceptable definition, it is important to define violence within the complexity of human experience, so that its occurrences can be reduced, if not eradicated as "forms of human bondage" (Stanage, 1974, 1981).

Copyright © 2002 Daniela Truty
Violence has been discussed in terms of workplace violence, domestic violence, street violence, as well as armed violence. Usually violence is portrayed as physical violence, although psychological and emotional violence are sometimes cited, such as in the areas of child, family and spouse abuse, and psychological warfare, i.e. PSYOP. Rarely is violence analyzed holistically, affecting mind and body simultaneously; yet, Stanage (1974) holds that it seems unlikely that one could violate one’s body and not affect the mind.

In the workplace, violence is presented as a risk management, legal, and HRM concern. It is associated with harassment, stress management, drug and alcohol abuse, disgruntled employees, and spillover effect from a turbulent home life. When violence is coupled with downsizing, it generally refers to hurt and angry employees who seek revenge against those who terminated the relationship.

It is possible to find some work on institutionalized violence although it tends to be mixed with discussions about violence as armed conflict (Arendt, 1970; Downs, 1995; Rubinoff, 1974; Stanage, 1974), domestic abuse, or philosophical investigations of evil, harm, force, authority, power, and strength (Arendt, 1970; Stanage, 1974). To my knowledge, this study is among the first to situate violence within the context of downsizing as perceived by those who were separated from the job—not as a response to downsizing, but in the practice of downsizing itself.

As I situate violence within the context of downsizing, I consider the social context of this workplace operating according to its constructed civil order. Stanage (1974) cites Berger and Luckmann when they assert that: “Man is biologically predestined to construct and to inhabit a world with others. This world becomes for him the dominant and definitive reality” (p. 215).

Pivotal to this study are Stanage’s (1974) definition of violence “...as an ‘out-of-order’ act or event” and the Theory of Violatives. “These violatives are phenomenological distinctions within occurrences of violence—distinctions that are articulated by our language when this language is carefully explored...” (p. 208). According to Stanage (1974), occurrences are classed as violative when perceived to dis-order the civil order within a given society. One learns about violent events by situating, or locating, them within a given social context (pp. 209-10).

The phenomenon of violence can be explored according to its instrumentality within a social context. Gradations of violence can be situated along a continuum between civility and barbarity, keeping in mind that violence can be constructive or destructive in outcome or intent. When an occurrence is perceived to dis-order the civil order of a social group toward civility, the occurrence is described as constructive; conversely, when the civil order is dis-ordered away from civility and toward barbarity, it is destructive (Stanage, 1974, p. 215).

Stanage unveiled the Theory of Violatives in 1974. In 1981 he developed it further to include ways in which violative occurrences can dis-order the civil order as defined by a person’s or social group’s “proprietary relevancy structures.” He called these unwelcome occurrences “thrusts”, and names them distrusive, intrusive, obtrusive, retractive, and subtrusive, i.e. DIORS (pp. 92-4). Together with the Theory of Violatives, the DIORS violatives extend the vocabulary of violence within the context of human phenomena, providing a commonly understood language with which to understand and discuss more precisely the different gradations of violence.

Peace Studies

Important to this study was the work of Johan Galtung, founder of the International Peace Research Institute in Oslo. In order to understand peace, Galtung claims, it is imperative that one study violence, since violence is the absence of peace, and, peace the absence of violence (Galtung 1969). Violence refers to the gap between potential and actual satisfaction of four basic human needs. Phenomena that widen that gap constitute violence. Through extensive research, Galtung concluded that these four human needs consisted of survival, well-being, identity, and freedom needs (Galtung, 1990).

Originally, Galtung’s typology of violence had six dimensions: personal/structural, direct/indirect, and physical/ psychological. In 1990, Galtung added a seventh, cultural violence. Cultural violence is comprised of institutions that make violence seem all right, or at minimum, not so bad. Examples of contributors to cultural violence include religion, ideology, language, formal science, law, and the media.

Organizational Studies

Institutional theory was particularly relevant to this exploration of downsizing. Institutional theory suggests that isomorphism is a major characteristic of organizational behavior and definition, resulting in organizations becoming increasingly similar to each other, adopting homogeneous norms of behavior and structure. Di Maggio and Powell describe three types of isomorphism: coercive, mimetic, and normative, i.e. when organizations impose specific structures or rules for behavior, when organizations mimic each other’s strategies, usually in response to the nebulous or unknown, and when organizations adopt or accept structures or strategies because powerful actors

**Method**

I designed a qualitative investigation to address my research questions. Twenty-eight white-collar employees participated in this study, including myself. We were separated from the same organization, within the August 2000 timeframe, and represented seven company locations in this midwestern metropolitan area. Recruitment occurred through activities sponsored by the outplacement consulting firm, contracted by the organization to assist separated employees during the transition. Outplacement staff guarded identity and numbers of people who were downsized; however, I was able to generate a “Colleagues in Transition” list, which included approximately 67 employees. All were invited to participate in this study; 28 elected to do so. Candidates were limited to this metropolitan area because of ease in arranging meetings, and to minimize potential impact of dissimilar job markets on re-employment.

Data were derived from multiple sources, including a one-on-one in-depth conversation with each participant lasting from 1.5 to 4 hours, demographic profile form, two participant journals, my own field notes, two descriptive documents prepared by two participants, electronic communication with some of the participants, the company’s annual report, as well as corporate news and comments from the company’s investor message board.

Conversations were face-to-face at a location of the participant’s choice. Three were held by telephone. I maintained written field notes throughout the conversation process, and soon after transcribed the taped conversations verbatim. Following each transcription, the document was submitted to the participant for verification of accuracy, editing, or additions. Conversations were influenced by the phenomenological method (Stanage, 1987). Moving back and forth eductively and constitutively, we sought to arrive at an in-depth understanding of content and intent, particularly of what constituted the relevance structure of each of the participants, and how they perceived order and dis-order within their work communities. Conversations began with a broad question, i.e. “bring to mind your stay at the company, and tell me the story of your downsizing”. I used four prompts, “I” language, “v” violence, “sc” social construction, and “p” person to guide the discussion toward specific questions, if the conversation hadn’t addressed them already.

**Analysis**

Analysis was influenced by hermeneutics, because it allowed for an interpretative process, inclusive of my own biases, experiences, knowledge, perspective, and understanding of the literature (Thompson, 1997; Thompson & Haytko, 1997; Thompson, Locander, & Pollio, 1990). Hermeneutics makes no claim of objectivity, generalizability or replication of these findings. Themes emerged from multiple readings of texts and transcripts, moving iteratively from part to whole to the larger whole, to the total and back again (Cotte & Ratneshwar, 1999; Glaser & Strauss, 1967), frequently refining my interpretation of what the participant was trying to say. Other written documents were analyzed in similar fashion. I wrote ideographic summaries per participant, returning to each as needed for further clarification (Cotte & Ratneshwar, 1999). I paid particular attention to the language used by the participants in describing their experience, highlighting words, phrases, and sentence constructions suggestive of the violative nature of downsizing (Stanage, 1969), from which I would develop Stanage’s Theory of Violatives (1974). The demographic profile forms were useful for checking age distribution, longevity, as well as diversity.

**Findings**

It quickly became apparent that in order for the participants to tell their stories, they needed to contextualize them within the employment relationship. A temporal downsizing horizon emerged including Before, During, and After for everyone, and an Interim for some. “Before” applied to the most recent job with the company, sometimes earlier than that, and set the stage for the perceived impact of the downsizing event as well as the sense making activities that would ensue. Job experiences ranged from “a difficult stay” (Dale) to a “job of convenience” (Steve).

“During” referred to the downsizing event itself, from official notification of dismissal to final exit from the company. Participants spoke of three components, the anticipatory period, selection criteria, and the process, i.e. mechanics. Of these, the selection criteria appeared to be most troublesome. Reactions were mitigated in part by whether the selection was expected or unexpected, well communicated or not, fair or unfair, and credible or not.

“After” comprised the period from final exit to the day of our conversation. Activities during this time included sense-making, healing, learning, retiring, and seeking.
The official or unofficial “Interim” was common to few employees. Official interims began with an explicit notice of impending termination, not necessarily occurring on the designated downsizing day, and usually extending from “D-day” (Steve) through January 2001. Unofficial interims began prior to the official downsizing date, and consisted of indirect statements or managerial behaviors that unquestioningly meant downsizing to the participant. Of the 28 participants, the interim was relevant to five. The interim experience was characterized either by struggle to stay on or anticipation of something better to come.

Three different reactions to the downsizing emerged: “Layoff was a godsend to me” (Dale), “It happened: move on” (Peter), and “We were hurt” (Patrick). People with the first two reactions would have preferred to stay until they decided to leave “if they had their druthers” (Bob). Those for whom the layoff was a godsend described their most recent job as difficult, so much so that they suffered psychosomatic symptoms that would be resolved only upon severing the relationship. They saw no choice but to leave the company, had they not been downsized.

Those with the second reaction appeared to be less severely impacted, either because the job was not challenging enough in quality and/or quantity; they believed that they were undervalued by the company; or because the downsizing was accepted as a neutral event in their work lives. They saw downsizing as change, a needed transition to a different professional phase, or an opportunity to retire early, especially since economically they had no difficulties. People in this group tended to linger on the job because it was comfortable for them, so why not.

Of the 28 participants in this study, approximately 20 perceived their experiences as hurtful. People in this group could be evenly divided into two groups. One group wanted to stay with the company even though they were aware of interpersonal or professional problems with their immediate boss or boss’ boss, the organizational structure, or other job related issues. The employee’s desire to stay with the company superseded the challenges he or she was experiencing, hoping, sometimes struggling, to resolve the difficulty. The second group wanted to stay with the company, and was unaware of bothersome issues. Of these, some described recent organizational/structural changes, such as a new director of their functional unit, who brought new philosophical and operational preferences to bear on the job. Even though they were aware of the differences between the past and the present, these participants did not equate them with the necessity for their downsizing. Others did not expect to be selected at all, their downsizing had come “out of the blue” (Trinity), were happy with the job they were doing, and saw no reason for their demise. This group was searching for meaning.

The selection process resulted in ruminative activity among most participants. Perceived reasons for selection included: boss or boss’ boss did not like me; my performance did not meet with their expectations; my project was discontinued due to budget cuts and restructuring; my department had to cut numbers, my job was divided among others, and my position was eliminated; the company did not have any or enough work for me to do; they made a mistake: the decision makers did not know me; new organizational reporting structure with new philosophies; I spoke up when something seemed wrong to me, and/or I did not comply with their wishes to transfer to another department; and my position was never slotted as an FTE (Full Time Equivalent).

Participants referred to their experience using different terminology, including downsized, laid off, axed, severed, cut, and separated. Regardless of which word was selected, I believe that a common connotation of each was that a union had been divided or dissolved, that something had changed, that order had been dis-ordered, that dis-order had been re-ordered, and a connection had been dis-connected, i.e. separated. These expressions demonstrated transitive grammatikal structures, suggesting that subjects, known or unknown, had acted upon objects. In this case, the “objects” were once employees. Issues of power, control, freedom, and agency are located in this concept. The stories of these 28 participants suggest that they were unwelcomely separated from relationships, belonging, identity, this job, daily structure, career trajectory, and security. For Dale and Alexandra, however, the downsizing was preferable because of the toxicity of the jobs. For all, perceptions of the downsizing experience appeared to be dependent upon personal perspectives and individual life contexts.

“Perspective” is derived from the Latin that means looking through, in this case, looking through the lenses of that which is important to individual persons. Examples of perspectival and contextual factors that influenced unique experiences of downsizing included personal values, upbringing, age at time of downsizing, family and/or personal health concerns, perceived and/or reported job performance, longevity with the company, continuation of benefits, perceived fairness of the decision and selection criteria, quality of stay, job search skills, issues of race, class and gender, developmental life stage, transferability of job skills, and personal sense of self.

Language

Stanage (1969, 1987) refers to linguistic phenomenology as a heightened awareness of the language used by persons to reveal themselves to others. Without claiming to be a trained linguist or discourse analyst, I noted the language used by the participants to tell their stories. The language tended to be vivid, filled with transitive
constructions, invoking words commonly understood in U.S. culture as connotative of violence, and figurative expressions consisting of similes and metaphors. Participants used words such as hurt, shun, cut, devastate, sever, whack, pluck, crush, axe, fire, and tear; transitive constructions including, I was laid off, I was separated, I got whacked, I was fired, and we were hurt; similes such as, I felt like a criminal, I felt like an idiot, like you were being ripped apart inside, I was like a walking dead man, ghost-like, like the death of a parent, like an outcast from society, I was like a bug in a jar, it felt like a gut shot; and metaphors like, when the hammer fell, the chain around my neck, Ole Nellie was a good ole horse, we were huddled together in the foxhole, you flunked and we didn’t, I was a stigma to them, the bullet hit me, and my magic shield did not protect me this time. Linguistic constructions like these betrayed the suddenness, abruptness, unexpectedness, unwelcomeness, and the physical and psychological pain of this experience.

Those for whom downsizing had been a godsend expressed themselves in words, phrases (and gestures) of elation, like Thank God, it’s over, the downsizing was a godsend to me, or a victorious Yes! With arm raised high. These revealed a sense of relief from a trying experience, a re-ordering of dis-order.

At times, the language suggested a disparity of power, coercion, finality, reification, and deception, i.e. there is nothing you can do, it’s a done deal, the decision was made, no matter what I did or said it wouldn’t change their decision, who knows what the real truth is, it’s a game, if you destroy anything on the way out you will not get your benefits, got rid of, I was expendable, and you’ll never know. Some participants spoke of assaults on their identities, using words such as humiliated, embarrassed, and insulted. Others mentioned words of alienation, such as excluded, I was left out of, I felt alone, and I am no longer a part of. Some used this language deliberately, carefully selecting the words and expressions to convey their desired messages. Others appeared to be less conscious of having chosen these words and why. Some used words that they had heard others speak in similar situations. Others transferred words from a large city’s neighborhood in which they had grown up. Some drew from their interest in competitive sports, i.e. references to game and competition. Others selected words from history, particularly military history; or from movies, like “Braveheart”. All appeared to reach for words outside of the whitewashed vocabulary of downsizing, re-engineering, restructuring, delayering, rightsizing, reorganizing, and other examples of corporate speak. No one used the word peace; no one used the word violence (as I had expected), even though the language used and the experiences described suggested gradations of violence.

Long-term employees reported that they had witnessed approximately seven downsizings since 1975. Most participants believed that the decision makers knew that the downsizing would negatively impact their lives, and that they did not care. How was it then that the organization downsized anyway?

Few problematized the decision to downsize, some even defended it—even after describing personal experiences ranging from unpleasant to painful. This reaction was contrary to my expectations, since I was certain they would view downsizing more critically as a result of their experiences. Perceived reasons for this downsizing included, for example: pre-emptive move for survival; it was easy and quick; in response to the stock market; to cut costs; to ensure or enhance executive bonus; because of uncontrolled growth in the boom time; re-build damaged credibility from the 80s; mismanagement; everyone else is doing it; reduced costs easily visible to the financial community; low sales mean low funds available for people; lack of proper planning; lack of fiscal responsibility in the good times; not smart enough to think of another way; employees viewed as filling positions instead of as persons; consultants persuaded people in power that this was the right decision; if people in power decided to downsize, managers beneath them would not risk a good job by challenging; company needed to look good for the competition; old leadership bearing old baggage; and they’ve done it like this before, it worked, so why not do it again.

Among perceived reasons for general acceptance of downsizing were: that’s the way it is; it’s like a death, it happens to everyone, it is inevitable; this is an At Will State; it’s purely business; no more lifelong jobs; people move from job to job to make more money faster, grow their careers, and make up for benefits no longer provided by companies; frequency of media reporting that makes it routine; companies must show a profit; and either some lose the job or all do.

Some individuals volunteered alternatives to downsizing on their own, while others considered them only on probing. Most had not thought about ways to downsize costs without separating people from the job. Suggested alternatives included: talk to individuals first to see who plans to leave anyway; hiring freeze; no raises for a while; make processes more efficient; cross-functional training for breadth, not just depth, so that employees can move to different jobs within the company; look for where the real costs are for reduction, usually in overhead and not in people; balance the workloads, preventing hoarding, so that more people will have jobs; look for ways other than downsizing; shelf new product development until the economy is better; and sometimes just gotta bite the bullet.
So, What Does All of This Have To Do with Violence?

Stanage (1974) defines violence as the dis-order of order. An individual or a group of individuals according to what he, she, or they consider to be important constructs the order to which he refers. Stanage envisages a continuum spanning between order and dis-order, or civility and barbarity. He holds that it is possible to identify gradations of violence by positioning commonly understood verbs in the English language along this continuum, according to their connotation. In developing the Theory of Violatives, Stanage selected a list of verbs from the Oxford English Dictionary (OED), and added the -ive ending transforming them into nouns, suggesting that certain phenomena have the qualities of or tendencies toward whatever the verb meant. Examples of violatives that he selected include: Abusives, Breakives, Woundives, Thwartives, Ceasives, Damagives, Stopives, Spoilives, Embarrassives, Interruptives, Perturbives, Harminives, Humiliatives, Forcives, Fearives, Perturbives, Maltreatives, and Defeatives (1974, p. 230). This is an incomplete list, and Stanage challenged his readers to develop the theory by situating other violative phenomena within it. I have elected to situate downsizing within the Theory of Violatives, expanding the vocabulary with words used by participants in this study.

Violence can be constructive or destructive. Constructive phenomena move the civil order closer to civility, or order; conversely, destructive phenomena toward barbarity or dis-order. Stanage (1981) posits that violative phenomena can be said to have directionality, depending on their outcomes. For example, if a phenomenon results in the absence of something that was expected to be present, it is a distrusive, e.g. downsizing takes away a job that one expected to have until retirement. If the phenomenon is an unwelcome intruder into someone’s or some group’s constructed order, it is an intrusive, e.g. one’s expectations for the job may include getting it done no matter what, which may intrude upon one’s personal activities. When a phenomenon is thrust upon a civil order such that advances, pace, and so on are occurring so rapidly that it is difficult or impossible to keep up with them, it is said to be an obtrusive, e.g. the downsizing decision was made and implemented so rapidly that employees did not have an opportunity to learn a new skill and thus were downsized. A phenomenon that is thrust upon the social order with the outcome of negating the past or present and starting anew, often engaging in similar activities, it may be said to be a retrusive, e.g. a mid-life woman who started a career “late”, after raising her children, then was downsized, may find that she has to begin a career all over again, the vertical climb having been truncated. When phenomena are thrust into a social order so that they cause one to think or behave differently than how one perceives oneself, they are known as subtrusives, e.g. a middle manager struggles with terminating employment of one of his or her team members, but does so anyway, because it was mandated by a higher level boss and to challenge it would be risky. Stanage calls these the DIORS violatives, an acronym for the various directionalities.

Careful attention to the language and expressions used by the participants in this study and a deep understanding of each person’s relevancy structure extend the vocabulary of violence as well as the Theory of Violatives (Stanage, 1969). As a result of this study, for example, it is possible to position the participants’ experiences of downsizing along Stanage’s continuum, using words and concepts they have selected. We can now say that for some people downsizing is a shun-ive, cut-ive, rip-ive, flunk-ive, whack-ive, devastate-ive, crush-ive, concern-ive, worry-ive, devalue-ive, disrespect-ive, and so on. Accordingly, it is possible to say that if one’s experience of downsizing makes it a betray-ive or disappoint-ive, it could also be a distrusive; if a strain-ive, obtrusive; and if a cut-ive, intrusive.

Galtung (1969) uses different terminology, and defines violence as an unwelcome gap between potential and actual satisfaction of four basic human needs: survival, well-being, identity, and freedom. If one accepts that the realization of human needs constitutes order and civility, then peace and social justice could be used to name the same end of the continuum as Stanage’s civility and order—likewise for the absence of these and the opposite end of the continuum, i.e. violence, social injustice, dis-order, and barbarity. If the violative phenomenon suggests a subject-verb-object construction, where the subject is readily identifiable, it constitutes personal or direct violence. If the subject is vague, the phenomenon constitutes structural violence. Sometimes participants referred to their boss or boss’ boss as the person who selected them for downsizing, resulting from a personal or professional vendetta. Survivors called this a “political assassination”. Other times, participants alluded to “they” or “the organization” when attributing accountability for their downsizing, perhaps referring to indirect or structural violence rather than personal or direct.

Participants recounted the history of a company that had been in existence for over a century and that managed to survive near bankruptcy in the 1980s. Engaged in a cyclical industry, organizational leaders responded to each downturn by downsizing in this way. Employees came to know that if more than three years elapsed without a downsizing, something was amiss. In spite of the human hardships wrought by the downsizings, they seemed to become, in this company, an ever-looming possibility whenever a downturn was imminent. Characteristic in part of isomorphism, i.e. mimicking, organizational leaders seemed to join major competitors in the industry in shedding...
employees. An internal bureaucratic and political culture of “compliance and regimentation” (Patrick) coupled with external competitive pressures made it possible for this downsizing to occur.

I suggest that a possible interpretation of the acceptability phenomenon is the cultural violence of which Galtung speaks, that makes the downsizing seem all right, or certainly not so bad (1990). Cultural institutions, such as Law (articles of incorporation, Employment at will), Ideology (capitalism, the supremacy of the shareholder), Religion (rooted in dualities, the relationship between wealth and chosenness), Formal Science (financial reports and benchmarking), Language (The corporation as active subject, headcount, they had to do it, business/personal), and the Media (commonplace through routine reporting) make personal and structural violence possible. These participants’ stories of their downsizing experiences are consistent with Galtung’s typology of violence, complete with its dimensions, and violations against potential realization of the four basic human needs.

Conclusions

Findings from this study point to the following conclusions: People experienced their downsizing differently based on individual perspective and context; When the downsizing was perceived as deliverance, it functioned to re-order the system, i.e. a transition toward healing and restoration of health and well-being, because the job itself had been oppressive; When the downsizing was perceived as a “neutral” event, the participants were financially secure, viewed the job as a stepping stone in their careers and were planning to move on anyway, or perhaps felt powerless and had been conditioned culturally, philosophically, or experientially to accept their fate within the capitalist system; When the downsizing was experienced most severely, participants did not expect to be selected, did not think they deserved it, perceived breach of reciprocal implicit contract, perceived that this was an opportune thing the company did, that the downsizing was not justified economically, that their ideas were negated, that they had been shunned by the organizational culture and workplace community, that they were immediately “othered”, and experienced a deep sense of loss; Most employees affected by the downsizing believed there was nothing they could do to alter the decision; Experiences of downsizing describe a gap between potential and actual realization of one or more basic human needs; Stories of the downsizing suggest corroboration of personal, structural and cultural violence to render it acceptable; and Language used to describe gradations of violence can be positioned along a continuum between violence and peace, dis-order and order, social injustice and social justice, barbarity and civility, according to the way in which the downsizing was perceived.

Implications, New Knowledge for the Field of HRD and Directions for Future Research

Implications of this study for the field of HRD might include: HRD professionals who prepare management scholars within academe could develop a curriculum that includes a critique of corporate practices and contemporary issues in order to understand their impact on other people; HRD professionals might consider developing and implementing a curriculum for innovation, so that new business ventures can be developed as others become obsolete; and HRD professionals could assist organizational leaders and employees to identify, design, and implement a curriculum for employability, so that employees are encouraged to keep skills up to date and be more mobile within the organization.

Findings from this study challenge the HRD practitioner to exit the silo of implementer of strategy, and to expand our sphere of influence as change agents to the larger society. If downsizing has the potential of violence for some employees, should we not be involved with policy studies, revision, creation, advocacy, and enactment?

This study invites us to regularly reflect on what it means to be an HRD professional. As we carry through each of our assignments within a fast-paced and demanding environment, we might pause to ask ourselves the following questions: Where exactly are we rushing? To what end? For whose benefit? Who is included? Who is excluded? And most importantly, is this what we ought to be doing? How can we influence decision makers within the organization, as well as society and our government, to protect those whom we call “human resources”, co-workers, partners, clients, and friends? Given what this study has revealed, what are peaceful ways to interact with all stakeholders of the workplace, including employees? Are we committed to working for peace within the workplace, or are we selective about which peace, where, how, for whom, and to what degree?

If we have become HRD professionals because we perceive ourselves to be “people-persons”, drawn to a helping profession, we must be vigilant about being utilized to further business ends at the expense of people ends. As people persons, we have the power to reach and communicate on an interpersonal level, a very effective characteristic for furthering workplace values, persuading, and fostering a sense of family, for example. We must ask ourselves, and ask workplace leaders, to what end? What will happen in a downturn? What will happen to these
values? When HRD professionals not only reflect upon but also guide the discussion to those kinds of questions, we become proactive in changing the course of strategy.

While this study raises the HRD practitioner's consciousness of the violative potential of downsizing, the following research agenda might be influential in abolishing it altogether:

- What is the impact of repeated downsizing on learning and knowledge management in the workplace?
- What is the importance of commitment and relationships within the workplace as demonstrated in bottom line results?
- What must be done in order to enact policy, insuring portability of benefits? and
- What are successful alternatives to downsizing without forced separations?

Family, Culture and Community Work: A View From the Margins

Phyllis Cunningham
Regina Curry
Matthias Hawkins
Northern Illinois University

We critique the limited concept of work that is confined to the production of commodities. We accept the analyses that technical rationality has colonized our life world. Utilizing participatory research and study circles with our community co-learners, we analyzed life-affirming work in the Calumet Communities Empowerment Zone. Three types of life-affirming work were found: mother work, cultural work, and community work. AHRD personnel, it is concluded, need to critique corporations who are socially irresponsible and enlarge their definition of work.

Key Words: Life-affirming Work, African-American, Participatory Research

In 1999 we attended the Academy of Human Resource Development's (AHRD) annual meeting. We were impressed with the energy and commitment of industrial training personnel and university professors who run graduate programs that prepare and provide research to "learning organizations" and their human resource developers. We experienced highly articulated discourses on the technology, the meaning, and the spirituality of work engendered by this group. We also experienced an alienation from many of the assumptions, activities and goals that drove their knowledge production and applications.

In this era of the micro chip it would seem that all citizens could have more disposable time while doing less work. Contrary to this we note the following: 1) the economic differences between the rich and the poor are increasing, 2) the state and civil society are threatened by the market 3) mobile capital seeks out and exploits global sites with the least social and economic protection, and 4) materialism has displaced and contorted our value system. In addition, most work places are increasingly characterized by worker alienating practices such as contingency work, outsourcing, "just-in-time", and perpetual downsizing (Brecher and Costello, 1994; Cunningham, 2000; DeOliveira and Tanden, 1994; Hart, 2002; Korten, 1995).

We have been doing participatory research (Hall, 1997) over the last five years on the far south side of Chicago in the Calumet Communities where work, as defined by AHRD, has left the neighborhoods, and taken with it, most of the "workers" within those industries. The former steel capital of the world, initiated in 1875, is located in Calumet. In 1974, this was a thriving community of 90,000. It now has a population of 43,000 residents, reflecting the national decline from 570,000 steelworkers' jobs in 1953, to 200,000 jobs in 1982. Currently, about 25% of steel produced in the U.S. comes from here (Center for Neighborhood Technology, 1998).

The Pullman Community, also part of this area, housed a company town built by George S. Pullman who not only manufactured luxury sleeping cars, but also held the monopoly of their national distribution through leasing them to railroad companies. He also employed and leased the services of porters and maids for these cars. The Pullman community was self contained on 250 acres with over 5,000 workers living in row houses with a church, hotel and park owned by Pullman situated around the factories and wheel works. In 1894, the "Pullman Strike," a bloody and violent strike between labor and the company occurred that resulted in the state using anti-trust legislation and federal troops for the first time against a union on strike. It was also the place where the first Black labor union, The Sleeping Car Porters, was started by A..Phillip Randolph. The Pullman Community gradually became a decaying neighborhood with an outmigration of whites replaced by African-Americans (Hughes,1998).

The far south side of Chicago housed much of the industrial production which supported Chicago. Today, the "brown fields" in South Chicago look surreal where the lead from Dutch Boy paint, and the slag from the steel mills, create super-fund clean up projects. It is in this community that we begin our analysis of work through the eyes of the residents. A team of over 20 graduate students and university faculty teamed with six community organizations to mobilize and develop leadership from the bottom up. The goal was to provide leadership in six areas as called for in the Empowerment Zone mission: economic revitalization, youth futures, environmental cleanup, cultural activity, health and human services, and affordable housing (Lopez, 1998). The strategy was to utilize participatory research, popular culture
and study circles to effect this goal. Taped interviews with community leaders were made of each of the six community based organizations with whom we worked. Community residents identified problems, generated action and reflected on that action. We found that Calumet Communities residents, regardless of formal employment status, work hard.

In this paper, we examine traditional definitions of the concept of "work, in order to reveal their definitional narrowness. In addition, the authors, and our co-learners in the Calumet Community, offer alternative definitions of work that are more comprehensive, inclusive and accurate.

Its All In The Definition

According to the Encarta Encyclopedia(1998), work is defined in the form of a verb, a noun, a transitive verb, an adjective, a phrasal verb, and as an idiom. The two major modes of usage, as a verb and as a noun, have twenty-seven and fifteen meanings respectively. Further, the verb category for the usage of the word "work" is divided into transitive (12) meanings and intransitive (15) meanings. Then there is the set of phrasal meanings (19) and the idiomatic meanings (7). In total, there are 68 ways to define work listed in this one reference. Clearly work is a key code word within our culture based on its linguistic elaboration.

What is clear to us is that work driven by the bottom line of private profit is based on concepts such as commodity production, objectification, rationality that are embedded in productive processes. These concepts and processes have, in Habermasian terms, "colonized our life world" (Welton, 1997). Enveloped in a life view that our God has commissioned us to dominate the environment, we have indeed been stood on our head by our own ideology. For it is science that dominates and controls us while we triumphantly assume we are dominating the rest of creation.

What is the big deal in all this, you ask? For an answer we look at how this monopoly on defining work by business, industry and science may crush out the vitality of society, the informal terms of solidarity and exchange between members living within a common geography, a common government, and a set of common goals. For what is left out of these definitions of work is the work of women (mother work, other mother work, community mother work), cultural work and community work. The erosion of the informal culture by a narrow definition of work creates a default environment where rational definitions of work are imposed upon the vulnerable, often unemployed, marginalized members of our society. In other words, if one does not have a degree and/or a job, it is impossible to meet the conditions of a meaningful definition of work according to the society in which one lives and identifies. This ingrained attitude of contempt contributes to the erosion of the marginalized group's political identity. In this conceptual scheme the concept of unemployment quickly turns into unworthy (Bell, 1992).

"Work" with the greatest impact on and the most relevance to the goals of this democratic society should be that work with the greatest potential worth to its members. The importance of self-definition of words like work and worth is apparent when we realize that language is the frontline of the war against alienation, marginalization, and polarization—the enemies of effective, participatory democracy. This being said, we want to bring you definitions of work from the urban community perspective after we first examine some definitions of work that contrast with the views of the modern "human resource developers".

Alternative Views Of Work

E.P. Thompson (1967), the great English adult educator who spent his life thinking about work, the making of the working class, and the appropriate education for workers, noted that industrial capitalism separated work and life. This is the seminal concept that is basic to several authors thinking.

Hart (1994) picked up this theme recognizing that today it is only those who produce commodities for money that are officially counted as workers, she champions subsistence workers (those who produce life substances such as food) and mothers (who produce the workers) as doing creative and essential work. Though they are the workers who create and sustain life these are the very persons who are often excluded by the official definition of work. Rather their work is devalued and they are often dismissed as naive peasants or merely homemakers. Hart argues that both work and education should be for life. Further, Hart (2002) in an extensive study of African-American women in an urban setting found that mother work was vital to maintaining one=s family in the changing rules of welfare and work. As for the production of commodities, she notes that this activity is not production but simply transformation of materials, thus it should not be privileged over life producing activities. If anything, we should be privileging life affirming work.
Haymes (1996) picks up this analysis focusing on race; he notes that the issue within black urban communities is survival. The learning needed is how to survive scientific rationality, since the rationality of capitalism marginalizes and defines the community invidiously as "the other". Haymes, in a careful analysis of African-Americans and their "work" contribution to the physical and cultural growth of urban areas, recognizes that Eurocentric gentrification and economic redevelopment seeks to negate this work and further marginalize Blacks by displacement. For Haymes, the hope of the African-American is the "pedagogy of place". Haymes recognizes the importance of contextualizing work by invoking the meaning found in "place". But Haymes' inferred definition of work is not about leaving the community to find economic stability. He does not emphasize science, rationality, production quotas, and the "meaning" of work or spirituality within the factory as do those in HRD. In fact, he mounts a daunting critique of how African-American's culture as well as their very blackness has been pirated and commodified by capitalistic entrepreneurs. Accordingly, Haymes defines the work of urban blacks as taking back their culture, taking back the urban spaces that they have constructed and in which they have found meaning, to relearn their strengths and to revalidate their accomplishments. He notes that they have kept their communities viable under egregious conditions and must now resist the entrepreneurial cultural voyeurism which has the potential to destroy the very meaning they have constructed.

Interestingly enough, Jose Lopez, a Puerto Rican "independentista" on the near north side of Chicago, proclaims that same ideal (Community Hearings, 1998). Lopez, sees the "work" of the urban Puerto Rican community is to take back their "place" not only in Chicago but as a nation. His concept of cultural work is political. At both ends of Division Street in their Humboldt Park community fly two fifty ton Puerto Rican flags made of pipe. The pipe symbolizes the work place in which many Puerto Rican workers historically found employment in the steel mills as pipe makers. On each side of the street the lamp posts are etched with symbols of Puerto Rican history and culture. Between these symbolic gates on Division Street stand numerous Puerto Rican cultural entities: Puerto Rican restaurants, the Boriken Bakery and Café, La Casita de don Pedro Albiso Museum of Puerto Rican History and Culture (including a park with a statue of this leader for Puerto Rican independence and the casita, a small one-room wooden residence and garden typical of Puerto Rico), the Vida-SIDA health education center, the Isabel Rosado Galleria (art), La Municipal Market (fronted by a façade of the El Morro Castle located in Puerto Rico), the Margaria de Cayey Theater of the Oppressed and permanent tables to play checkers with chairs embedded in the sidewalk. Murals of Puerto Rican "political prisoners" and leaders are pictured in outdoor murals; the annual Puerto Rican People's Parade and Fiesta Boricua are celebrated here, and a Sonde Barrio salsa band was organized to provide Puerto Rican music for the community. In the immediate area is the alternative school, Pedro Albiso Campos, which for over 25 years has provided both an alternative high school and adult education in a Puerto Rican context (Ramos-Zayas, 1998). What is the definition of work for these people on whose island Columbus landed? Did not this "discovery" signal the conquest of the new world for the market and the resource hungry industrial old world? Lopez's response to this Eurocentric interpretation is a call to Puerto Ricans to take back their "work places", both the "island" as well as the diasporic islands within the continental U.S. After all, Puerto Ricans labored to build this country at the same time their culture was being devalued.

To summarize, we reject a narrow definition of work that relies on technology and rationality as the wellspring that defines our activities. But we do not reject rationality. We agree with Hart that education and work is for life and cannot be measured only in economic terms. We agree with Haymes and Lopez that marginalized groups must first reorient themselves in their own cultural context. Further, that urban persons should reclaim their "place", revise inaccurate histories with their structured silences denying their work contributions, and legitimize their own knowledges.

A Closer Look from the Bottom Up: Life Affirming Work

In this section, we will discuss three major areas of human activity that we observed in the Calumet Communities and show how this unpaid work is both necessary and appropriate: mother work, culture work, and community work. We have made a conscious effort to avoid examples that lay outside the realm of legality; we also reject the deficit discourse that is utilized by so many professionals in discussing the poor (McKnight, 1995).

Mother Work

Lowden Homes parent's challenge of mother work include safety issues as well as food, clothing and shelter. A great deal of energy is expended keeping their children safe in the midst of violence. To ensure safety for children to travel back and forth from school, they formed a parent patrol. The women formed a group of parents that would be
available during school time hours and alternated their services. Each member of the parent patrol wore bright orange vests as a symbol to let the children know they could come to them if they did not feel safe. We see this as an example of community mother work; mothers in Lowden Home look after all of Lowden Homes' children.

Another example of mother work that was apparent in our research was the activity that surrounded food. In most households the budgeted amount for food was inadequate. The parents had to seek out places within and outside the community to supplement their food budget. Supplying food for the family was a monumental task. The community grocery stores were not appropriate either in prices or quality of food. Churches established food pantries but one had to find them, note their schedules and then get there to pick up food. Many parents used the bartering system by exchanging some of their talents/skills to negotiate transportation. Bartering services in the urban setting becomes life sustaining work. Interdependent liaisons were developed to help one another over the tight spots.

Children have to be reared to understand the politics of their environment while being taught to be a good citizen. In the absence of competent legal counsel, potential interactions with police housing and welfare authorities demand significant time and energy. Young adults and children need information to develop appropriate and realistic views of the negative power that these persons hold over them--interactions with authorities should often be avoided. This requires the development of informal policy, the elaboration of informal physical boundaries, and the sharing of consequences gleaned from past encounters. This need to protect their children from "public servants" is a social cost for the poor parent.

Supplementing income is another objective of mother work. A resident gets a job and this means someone else can earn some money by caring for her children after school. Some mothers buy snacks and pop at the wholesaler and sell it out of their homes for profit. This trading of services or goods become a way to augment the family budget. In addition, to the bartering of services, residents charge affordable fees for hair braiding, sewing and catering.

Safety, food, and citizenship work takes a lot of energy from the "normal" running of a household. In addition to the aforementioned tasks, the parents in Lowden Homes spend inordinate amounts of time at health facilities. Based on the research conducted at both Lowden Homes on the south side and the Henry Horner Homes on the west side, these communities experienced the highest rates of children with asthma, far above national norms. There are different schools of thought as to why these numbers are so high, but the bottom line is that these parents are frequent visitors at health facilities where the waiting time is often proportionately long. One area of human activity that consumes significant amounts of non-economic resources (time and energy) is the defense against chemical/environmental contamination and its subsequent non-diagnosis and misdiagnosis. Impact of these two community threats were immediately apparent amongst the very young and very old, the most vulnerable people of poor communities. In Lowden Homes, residents are exposed to the emissions of over 320,000 automobiles daily (Trkla, 1993); auto emissions that contain Nitrous Oxide, Carbon Monoxide, Benzene, Torilene, Xylene, Dioxins and Furan which can be toxic for humans (Ohio EPA, 1999). This contamination requires families to dedicate critical resources to the full time monitoring and medicating of their health. This is work for mothers caring for their children.

Culture Work

Lyn Hughes, looking for real estate investment, purchased three of the row houses in North Pullman. In the next few years she turned herself into a cultural worker within the community. She educated herself in how to organize a non-profit organization so that she could develop the A. Phillip Randolph Museum in one of the houses. This meant learning how to write grants, develop a board, keep records, engage a developer, and to run the museum. There is no regular salary for this work so recruiting community volunteers to assist her in this unpaid work was necessary. From this modest beginning of honoring the man who started the first black labor union she has:

* contracted with public schools to bring children to the museum to educate them on African-American social contributions;
* obtained a million dollar grant to turn the abandoned fire house into a cultural center complex;
* obtained national, state, and city designation for historic landmark status;
* organized and implemented a Pullman Porter travelling exhibit for the Amtrak railroad;
* consulted with Showtime on their cable TV production: "Ten Thousand African Americans called George."
* videotaped oral histories of elderly Pullman Porters aged 78 to 96 years;
* collaborated with the cultural workers in "Bronzville", "47th Street Blues group" and DuSable African American museum to tell the story of the Great Migration and African American's cultural work to make a "place" in...
Chicago.

- conducted an annual jazz festival at the museum;
- contracted with Amerail to hire 100 community young adults trained by the community college;

The vision of the Pullman community is to economically revitalize their neighborhoods through cultural tourism. Such activity provides jobs for docents, encourages development of small shops and bring economic activity into the community. At the same time a cultural center chronicles and celebrate Black Culture, provides training for jobs in the arts, technical services and cultural production.

Another organization, the Soweto Center, concentrated on educating children and youth in cultural activities. This group established a pen pal program between their children and South African children in Soweto; created art and dance sessions that were held weekly; implemented neighborhood beautification projects including planting flowers; behind one set of flowers a wall of respect was made with a figure for each Chicago child who had been killed by gunfire; once a month the community gathered to honor these children. Every year the Soweto Center celebrated Kwanza in the park, wherein hundreds of community members gathered to celebrate Africana culture. The Soweto group dreamed of getting a building where youth could become entrepreneurs by selling products or services they had developed. These young adults were taken to the community college to obtain skills needed to operate a small business. Moti’ Watson, the cultural worker with the vision received no pay for the work she did; she and her husband put their own resources into buying a building and running the program.

The Kids of the Future from Lowden Homes participated annually in the Bud Billiken parade. This unique Chicago event celebrates blackness and African heritage. The parents worked to earn money to buy uniforms for the children; they also drilled the children to not only march but perform together. After the parade, all participants returned to Lowden Homes for a barbeque. The money to buy uniforms and to prepare the meal was obtained by volunteers who worked hard to make the children proud of their culture.

In South Chicago, the Mexican Community Center organized “block clubs” which then sponsored various cultural events. The culminating cultural event took place on Cinco de Mayo when the streets were barricaded after the parade to allow various cultural and recreational activities. Again, the work was done by volunteers and community participants.

In our cultural work we brought African and Mexican Americans together for building leadership capacity through sharing experiences. In meetings where cultural performances, such as dances or popular theater were provided, we were surprised that some participants commented that they had not seen performances from other cultures. This indicates the degree to which urban cultural groups are separated and the work needed to bring them into contact. Diversity became work to segregated neighborhoods. Cultural workers seek to break down those boundaries.

Community Work

While formal social service agencies are indeed taking care of the individual case, in poor communities, we learned that much work was done with little if any material reward. For instance, in Lowden Homes, by virtue of a participatory community survey administered by residents, an acute need was identified for after school learning opportunities.

These same residents organized and conducted subsequent meetings, began to keep minutes, and, eventually came to the conclusion that they had to form an organization that would be able to administer the after school program. So, in partnership with the research team, residents went about the process of learning which type of organization was needed: a 501(c)3. After months of meeting to draft by-laws, vote on them, fill out the state and federal applications, several visits to the Internal Revenue Service, and two-hundred dollars later, L.I.N.K.-Kids of the Future was formed.

It is important to note here that the research team had as one of its objectives to ensure that the decision-making power remained with the residents and that new capacities that could be maintained were left behind once the action research project ended. Therefore, the community had to implement and administer the after school program. The next step was to fund the program.

This work began with a group writing session that produced the C.A.T.E.R. (Computer Assisted Test & Examination Review) after school program. We learned that the local government had funds that were made available by the federal granting program named the Community Development Block Grant (CDBG). We submitted a proposal to the local government and the program was approved for over $90,000.

Now, residents hired themselves and other community members to assist with implementing the program in the local community center. Soon, it became apparent that there was a need for the development of an independent site. To this point, they had worked with the local housing authority to reserve space in the community center. This arrangement
deteriorated when the local advisory council, a resident group regulated by the housing authority, and its personnel began to feud with the board of directors for the newly formed organization. Residents and community board members met with the parent patrol group to determine that several vacant housing units were being commandeered to use and distribute illegal drugs. They decided to convert these same units into a full blown computer lab and alternative community center. There were then meetings with the housing authority to get approval, develop blueprints, conduct walk-throughs, and transfer the property to the L.I.N.K. organization.

There was also the issue of the next year's funding. Again, residents researched opportunities, wrote grants, and submitted them to various agencies. This time, the State of Illinois, funded both the development of a new site and the next year's operation, which totalled over $180,000.

Shortly thereafter, there was a small grant written by two residents and a university worker and submitted for a computer literacy program that would teach residents how to use a computer for its basic applications. This grant was submitted to the Laubach Literacy organization. This grant was funded and the program was administered in the homes of residents pending the development of a new site. Residents learned together how to write resumes's, put out a monthly newsletter and write poetry.

Overall, a minimal amount of grant funds were provided initially to residents on a stipend basis. However, for the most part, the residents were required to donate their time and energy. Yet, because the need for these programs and spaces was acute, these residents did the work anyway. Crime was reduced, grades raised, matriculation rates increased, and, moreover, the intensity of some needs were relieved. However, not all community work had such positive results.

In the South Chicago community area, a small storefront, turned into an educational center, was organized by members of the Catholic church. Arnold Morales worked there as a volunteer. A graphic designer by day, he encouraged the youth to get educated, and then return, buy houses and build their community. He led the community in taking absentee landlords whose buildings harbored drug activity to court. So successful was this citizen group in closing down crack houses that a "hit" was put out on Morales. He was shot dead by a young gang member as he left the community center one night. Effective community work can have costs.

Conclusions

Poor people, "unemployed" people work. Their goal is mostly survival in a hostile environment. Accordingly, the way citizens work often demonstrated reciprocity and creativity. Work that sustains children, other adults in the community, and their culture is a priority. Hart (2002) discusses how we privilege the work being done for commodities and devalue the work done for life affirming events. It is our view that the work that goes on in Lowden Homes, Pullman and South Chicago though it does not provide economic value, is human capital rich in life affirming activity. The mother work that is required to raise a child from birth to college in the inner city is a valuable social contribution. We found that Lowden Homes' wealth was in its people and the work they do daily in service to one another.

In a more material analysis, economic activity can be calculated. Using the frequency of our meetings in Lowden Homes Computer Learning Center project alone, and the average duration of each of these meetings, we estimate that there were over 2,000 people hours donated by economically disadvantaged residents. If these hours were compensated at $10/hour, we see that the people doing this work could have earned, conservatively, $20,000 for only the time spent in meetings. If we use the formula two hours of outside work is needed per hour of community/board work, the number of hours triples to about 6,000. In total, there was work done in Lowden Homes on one project that could be valued at approximately $60,000.

What are the values of our society? Following 9/11 we note that the polarity of our value system was exposed. For our political leaders, "shop till you drop" was the admonition; clearly the assumption was a strong society is based primarily on its material economy. However, for many if not most citizens the 9/11 tragedy created new community heroes, new social solidarity, and a desire to connect more with friends and family. For us the latter reaction is a response to do life affirming work and to place commodities and their production in a proper perspective.

The solution to our systemic dilemma is to change the system. This is political engagement (Newman, 1994). For those who identify as adult educators working within HRD, we must join that struggle. Corporations that are out of control must be critiqued; progressive corporations that are seeking ways to be socially responsible should be encouraged (Davidmann, 1995). A strong civil society that fosters political debate is a responsibility of all citizens. We can learn from those who do life affirming work in the urban landscapes, many of whom are now marginalized from participation in the dominant society.
Co-learners whose work has made this paper possible are Lyn Hughes, Historic North Pullman; Deborah Hardin, Willie Cole, and Marilyn Tyler, Lowden Homes; Hank Martinez, Mexican Community Committee; Antonio Lopez, Olive Harvey College; and Motti Watson, Soweto Center.

Game Theory Methodology in HRD

Thomas J. Chermack  
Richard A. Swanson  
University of Minnesota

Two of the overriding issues facing the human resource development profession include the complexity of (1) integrating multiple theories for disciplinary understanding and in (2) fulfilling its strategic roles. Based on the literature and logical connections, game theory methodology was determined to have potential in helping the HRD profession addressing these complex issues.

Key Words: Game Theory, HRD Theory, Strategic HRD

There has been great concern that the HRD profession must become more strategic in its efforts (Gilley & Maycunich, 1998; Walton, 1999). Some have even proposed specific strategic roles of HRD (Torraco & Swanson, 1995). Furthermore, there is general consensus among scholars that the discipline of Human Resource Development (HRD) is grounded in the recognition and integration of multiple theories. Psychological, economic, and system theories are generally viewed as essential, if not core (Holton, 2001; Ruona, 2001; Swanson, 2001; Torraco, 2001). Thus, two of the overriding issues facing the HRD profession include the complexity of (1) integrating multiple theories for disciplinary understanding and in (2) fulfilling its strategic roles.

On a completely separate path, a growing number of people are recognizing the importance of game theory (Brandenburger & Nalebuff, 1996; Fundenburg & Levine, 1999). Game theory tracks how outcomes of interactions between players are affected by the rules of the game, the tactics employed, and by the players' beliefs about each other (Gibbons, 1992). Game theory sets up the interrelationships in an organization as a simple exchange, a choice. Each player will make his or her move and expect certain consequences and reactions. Game theory is also founded on economic principles (Gibbons, 1992) and has been extensively tested (Fundenberg & Levine, 1999; Levine & Pesendorfer, 2001; Wright, 2000). Brandenburger & Nalebuff (1996) simplify some of the more complex concepts and equations found in game theory and apply them to business strategy. The application of game theory to the social sciences is only beginning and this paper intends to explore the application, usefulness and relevance of game theory to HRD.

Purpose of the Paper

The purpose of this paper is to explore the utility of game theory in helping the HRD profession address the complexity (1) of integrating multiple theories for disciplinary understanding and in (2) fulfilling its strategic roles.

Research Questions and Methodology

This paper first focuses on rational for the inquiry, provides an overview of game theory (what it is, how it works, and general principals), and discusses the potential role of game theory methodology in addressing the two identified critical HRD issues. These issues, in question form, read as follow:

- Can game theory methodology provide assistance to the HRD profession in integrating multiple theories for disciplinary understanding?
- Can game theory methodology provide assistance to the HRD profession in fulfilling its strategic roles?

In that this is a preliminary investigation, the methodology used in answering these questions was a literature review along with an analysis and synthesis from the perspective of the two research questions.

Theoretical Framework and Rationale for the Inquiry

HRD has seen increasing interest in the development and application of theory (Swanson, 1996, 1998). In January 2002 the profession saw the first issue of the new HRD theory journal, Human Resource Development Review. It is being led by Elwood F. Holton (Editor) and Richard J. Torraco (Associate editor). The call for theory development in the HRD profession justifies expansive theory discussions and focused theory building research. Since 1996,
Swanson has advocated that the discipline of HRD is based on three core theories — psychological, system, and economic theories. Metaphorically, he portrayed this as a 3-legged stool with each theory domain having one of the legs. Furthermore, the proposition is made that when all three legs are called upon and are integrated, they provide the uniqueness of the profession as well as the stability and flexibility required to be effective.

Almost everyone in HRD acknowledges the importance of psychological theory to the profession. To a lesser extent there are advocates of system theory, and to an even lesser extent there is support for economic theory. As important as psychological theory is to HRD, it by itself is inadequate (Holton, 2001). Disproportionate attention to the psychological leg may limit theory growth and the strategic impact of HRD.

For example, Robert Gagne (1964) addressed the psychology of learning community in his classic keynote paper to the American Psychological Association. His paper on learning principles continues to provide a blunt challenge to those who only study learning in terms of what happens inside a person. His thesis, informed by research and experience, is that we should study what is to be learned instead of dwelling on psychological principles conceptualised apart from the learning task. Clearly, Gagne was more interested in the system requirements that the traditional psychological requirements of learning (1964).

Despite the warning for Gagne, and from even earlier works (see Dooley, 1945), the HRD profession continues its disproportionate dependence on psychological theory and its derivative—learning theory. More specifically, the discipline of Adult Education almost exclusively focuses on the internal process of the learner and not on the external context and system demands. This void is a fundamental reason why Adult Education theory in itself is woefully inadequate in responding to the scope of problems facing the HRD profession. Even when adult educators reach toward the organizational context, they remain bounded by the individual learning process. One such example from adult education is the concept of transformative learning that many HRD professionals are familiar with. While Merizow and his associates (2000) seem to pose many of the right entry questions related to change and transformation, they offer very little in terms of theory or applied tools for rigorously studying the substance and demands of the context or the basis of the learning problem. As a part of Mezirow’s (2000) edited work, Yorks and Marsick (2000) write about organizational learning and transformation. They extend themselves to groups of learners and never substantively address the substance of the group’s sponsoring organization and its context. They do allude to the idea that “the goal of organizational transformation is allowing the organization to more effectively realise its performance goals.” (Yorks & Marsick, p. 254). While performance goals are referred to, Yorks and Marsick offer nothing more on the effective realisation of performance goals in terms of ongoing analysis or verification of outcomes. The authors simply drop back into individual learning constructs—psychological theory—and ignore the promise of addressing system and economic theories in any substantial manner.

Game theory has developed out of economics as a means of addressing decision-making within complex and strategic real-life situations. It has always had an eye toward theory to practice. As game theory has matured, it has clearly gone beyond its economic roots and has expanded to embrace system and psychological realms. For these reasons, it seems worthy to explore game theory and its potential in helping the profession embrace and integrate psychological, system, and economic theories and for assessing the utility of game theory in advancing HRD strategic roles.

Overview of Game Theory: What It is, How it Works, and General Principles

Developing out of economic theory and British submarine warfare, game theory was first applied to the political sciences as a potential means for ensuring political integrity (Brandenburg & Nalebuff, 1996; Fundenberg & Levine, 1999). Game theorists thought that if they could instil in leaders a deep understanding that millions of lives are riding on the decisions and political manoeuvring of the few, powerful leaders would act in a way more beneficial to the community at large (Gibbons, 1992). When this attempt was regarded as unsuccessful, game theorists began to concentrate their efforts in parlor games, predictability, and mathematics.

Game theory is a theory of social situations (Fudenberg & Levine, 1999), or the study of multiperson decision problems” (Gibbons, 1992. p. xi). Levine (2000) defines game theory as “the mathematical study of human interactions described by rules of play and alternative choices” (p. 1). McCain, (2000) states: “Game theory is a distinct and interdisciplinary approach to the study of human behavior” (p. 2).

Economic theory has four main branches, namely, decision theory, general equilibrium theory, mechanism design theory, and game theory (Levine, 2000). There are two main branches of game theory: cooperative and non-cooperative. Non-cooperative game theory (also referred to as zero-sum) deals with how individuals interact with one another in an effort to achieve their own individual goals. In these non-cooperative games, one player wins and the other loses. These are usually simple games in which the winner takes everything. Examples include tennis, chess, and boxing. In cooperative, or non-zero sum games, one player’s gain need not be a loss for the other. Non-
zero sum games, when played correctly produce enough wins for everybody. Non-zero sum games attempt to model
the real world. Each player's interaction with another player will have effects that may seem unrelated yet are
interrelated and far-reaching.

Choices and alternatives in game theory are most commonly displayed in a table (see figure 1). From this
profile, it is easy to determine what each player's payoff is under each alternative choice. Games have been a
scientific metaphor since the work of von Neumann & Morgenstern (1947), which has been credited as the first
important and unified work in game theory.

Figure 1. The basic map of the alternatives and payoffs in a game.

<table>
<thead>
<tr>
<th>Player 1</th>
<th>Option X</th>
<th>Option Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option X</td>
<td>(Payoff for Player 1, Payoff for Player 2)</td>
<td>(Payoff for Player 1, Payoff for Player 2)</td>
</tr>
<tr>
<td>Option Y</td>
<td>(Payoff for Player 1, Payoff for Player 2)</td>
<td>(Payoff for Player 1, Payoff for Player 2)</td>
</tr>
</tbody>
</table>

The Prisoner's Dilemma

Perhaps the most notable example of a non-zero sum game is the famous Prisoner's Dilemma (Tucker, 1950).
In the dilemma, you and a partner in crime are interrogated separately. The evidence to convict both of you of the
crime is lacking, but there is enough evidence for a lesser charge, for example, a one-year prison sentence for each.
The state wants the more serious charge and pressures both of you to confess and implicate the other. A deal is
offered in which if you confess, but your partner does not, you will go free, and your partner will be sentenced to ten
years. The same deal is offered to your partner. If both of you confess, the term is three years each, and if neither
confesses, it is one year each. The options are charted in figure 2.

Figure 2. The prisoner's dilemma as an example of game theory applied.

<table>
<thead>
<tr>
<th>Your Strategy</th>
<th>Partner's Strategy</th>
<th>Stay Quiet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confess</td>
<td>You: 3 years Partner: 3 years</td>
<td>You: 0 years Partner: 10 years</td>
</tr>
<tr>
<td>Stay Quiet</td>
<td>You: 10 years Partner: 0 years</td>
<td>You: 1 year Partner: 1 year</td>
</tr>
</tbody>
</table>

Wright (2000) points out that there are two quirks in the Prisoner's Dilemma that impede intuitive
comprehension. First, in the Prisoner's Dilemma, the object of the game is to achieve the lowest score possible,
since the score represents each player's prison sentence. This can most easily be thought of as competing for the
lowest payoff, which seems counterintuitive. Second, to "cheat" is to tell the truth. These are two characteristics of
the Prisoner's Dilemma that run contrary to the majority of game theory games (Wright, 2000) and are unique to this
popular example.

Wright (2000) reveals two key features of non-zero sum games such as the Prisoner's Dilemma. First,
communication carries critical importance. If the prisoners cannot communicate, and behave logically, both will
suffer a prison sentence. When considering the possible options as a player of the Prisoner's Dilemma, the
importance of communication becomes clear. Suppose my partner cheats on me by confessing. If I stay quiet, I get
a ten year sentence. If I cheat too, I get a three-year sentence. If my partner stays quiet, I am still better off cheating
as I will go free, rather than the one-year sentence I will receive if I stay quiet too. The logic becomes irresistible:
never cooperate, always "cheat" because the outcome will be your best option every time.

If both players follow this logic, by both always cheating, both will get three years in jail. If both players stay
quiet, each receives one year in jail. The win-win outcome is, obviously, for both players to stay quiet. However, it
makes no sense for either to stay quiet unless both have been assured by the other that he or she will stay quiet too.
This is why communication is critical.

The second key feature of the Prisoner's Dilemma is trust (Wright, 2000). Players must be able to trust the
assurances of other players. If a player suspects that another player will cheat even after giving assurance, then
cheating will still produce a more beneficial outcome. This is not irrational as there is substantial temptation for any
player to cheat.
Rationality

Neoclassical economics is based on the assumption that human beings are absolutely rational in their economic choices (Becker, 1993). For use in general economic models, rationality has been a tool to limit the range of possibility and make more accurate predictions (Gibbons, 1992). Thus, neoclassical economic theory is not applicable in situations that involve restricted competition, or options that are not presented because they are irrational (McCain, 2000). In neoclassical economic theory, to choose rationally is to maximize one’s rewards. The importance of rationality is in its assumption that a given players actions are predictable, or that a player will always choose the outcome that will yield the greatest benefit. "The largest problem for neoclassical economics has been in situations that require decisions outside the money economy, because rationality does not hold" (McCain, 2000, p. 17).

What has made an impact on social science with regard to the Prisoner’s Dilemma is the outcome that if both players act rationally, or do what is in their best self-interest, they will both be made worse off in terms of their own purposes. An arms race is another example of such a phenomenon: each country acting in its own self interest will, overall, make the world worse off (McCain, 2000).

Applying Game Theory Concepts to Business

Brandenburger & Nalebuff (1996) apply the concepts of game theory to business strategy. The authors also describe the elements of game theory in business strategy by using the acronym PARTS, standing for players, added value, rules, tactics and scope, respectively.

Players

Brandenburger & Nalebuff (1996) pose the question: “if business is a game, who are the players and what are their roles?” (p. 16). To answer, they begin by offering the Value Net (see figure 3). Brandenburger & Nalebuff (1996) submit that the Value Net is a helpful tool when considering a given business situation as a game. “This map, the Value Net, represents all the players and the interdependencies among them” (Brandenburger & Nalebuff, 1996, p. 17). The vertical dimension of the value net denotes the flow of goods while the horizontal dimension identifies the competitors and complements. These terms warrant definition and differentiation. “A player is your complementsor if customers value your product more when they have the other player’s product than when they have your product alone” (Brandenburger & Nalebuff, 1996, p. 18). Complementors are the opposite. “A player is your competitor if customers value your product less when they have the other player’s product than when they have your product alone” (Brandenburger & Nalebuff, 1996, p. 18).

Figure 3. The Value Net provides a model for examining the players in a game.

Added Value

The key to understanding the power distribution in a game is in the concept of added value. Brandenburger & Nalebuff define added value as "the size of the pie when you are in the game minus the size of the pie when you are out of the game" (1996, p. 45). Simply put, your added value is what you bring to the game, or what the others would miss by not inviting you into the game. A warning here: do not expect to get more than your own added value.
value out of a game situation because once you ask for more than your added value, you are asking the others involved in the game to divide less than they would have if you had never been invited (Levine, 2000).

An excellent example of added value is seen in movie stars. Sylvester Stallone rose to stardom with Rocky, and was paid a minimal salary for his efforts in the film. However, when he signed for Rocky II, he had enormous added value, and thus, could demand and enormous salary.

Rules

An examination of the rules of the game will help to establish the limits to the negotiations. While some business deals are free form and without limits, others are strictly bounded. For example, most retail stores offer the same price to all customers. This is a rule. In some situations, cultures, or business situations, customers are not allowed to negotiate individually on the price of given goods. Other situations, cultures, or business situations rely on individual bartering.

Game theory also posits that for every action there is a reaction. Brandenburger & Nalebuff (1996) point out that this expected reaction is similar to Newton's third law in physics, however there is a critical difference: In physics, the reaction is expected to be equal and opposite. This is not the case with reactions in game theory – they are not expected to be equal or opposite – they are not limited. According to Brandenburger & Nalebuff, "You look forward into the game and then reason backward to figure out which initial move will lead you where you want to end up" (1996, p. 52).

Tactics

The job of managing and shaping competitors' perceptions is an essential part of business strategy. Buyers and sellers negotiate – sellers portray what they have to offer as valuable, while buyers might not agree on the same level. Negotiations involve, and in fact, rely on perceptions (McCain, 2001). Brandenburger & Nalebuff describe tactics as "actions that players take to shape the perceptions of other players" (1996, p. 199). There are three common tactics described here (1) lifting the fog (2) preserving the fog and (3) creating complexity (Brandenburger & Nalebuff, 1996).

A full display of capability, or lifting the fog means that a player will demonstrate full confidence in a given product, service or choice. This is commonly referred to as putting one's money where one's mouth is. "The tactic is to put on a display that impostors can't, or wouldn't dare to, match" (Brandenburger & Nalebuff, 1996, p. 203). This is a common tactic in companies that are certain of their competitiveness (Levine, 2000). For example, Microsoft has often used this tactic, as its leaders know that few companies can offer the same or similar products with any degree of success.

Preserving the fog is a risky tactic, but can be an extremely effective one. When an organization or department turns down a project or business deal, those responsible have good reason to hope the deal is never seen again. If a competitor tries it out and fails, the first company is vindicated, as the project was doomed to failure (Gibbons, 1992). However, if someone picks up the project and turns it into a success, the judgement of decision makers in the first company is seriously questioned. "If you follow the herd, you'll succeed or fail along with the herd. The fog is preserved. You'll never stand out if you're right, but you're also less likely to get eaten alive if you're wrong" (Brandenburger & Nalebuff, 1996, p. 213). This tactic is one of joining the herd.

Creating complexity is a method of confusing an opponent. "Unpredictability is sometimes the key to effectiveness" (Brandenburger & Nalebuff, 1996, p. 222). This tactic is simply used to cause confusion to other players who think they know how you function as an individual, group, or organization. For example, complex pricing schemes, product bundling, or even long distance phone bills produce confusion that obscures the real price. All of these are methods of covering or obscuring the real price of a given product.

Ultimately, the goal of any tactic is to shape people's perceptions of the game. The game is changed when perceptions of the game are changed. The key to perceptions is noting that people observe there to be several different games occurring at once, when in effect, these are all parts of the same game.

Scope

In principle, a game does not have boundaries, but a game without boundaries is also far too complex to analyze. For this reason, people draw and re-draw boundaries almost constantly. "People often talk about a national economy, or an industry, as if it were the whole picture. Of course, everyone knows that's a fiction. In reality, the
world’s economies are highly interdependent – indeed, increasingly so” (Gibbons, 1992, p. 57). Scope refers to the boundaries that are drawn in order to make sense of a given situation.

Analyzing individual games in isolation is threatening, thus “Academic game theory models are sensitive to assumptions about who knows what and when and to the structure of the game itself, but these assumptions, in isolation, are not of much use in the real world” (Bushko & Raynor, 1997, p. 4). Game theory method relies heavily on the systems view of interconnectivity, and also provides the tools to analyze complex games or situations without losing this overall context.

Results and Findings: Theory Integration Question and Discussion

The theory integration question of this inquiry is as follows: Can game theory methodology provide assistance to the HRD profession in integrating multiple theories for disciplinary understanding?

Swanson (2001) has put forth the following definition: “Human resource development (HRD) is a process of developing and unleashing human expertise through organization development (OD) and personnel training and development (T&D) for the purpose of improving performance” (p. 90). Furthermore, he provides a model of the HRD process within organization and larger environment. Within this purposeful context, Swanson’s advocates three theory legs for the discipline of HRD that are visualized as a 3-legged stool that stands on a rug of ethics. He goes on to advocate that “the whole theory of HRD is proposed to be the integration of psychological, economic, and system theories within an ethical frame” (Swanson, p. 93). He goes on to propose an overarching theory integration proposition for HRD:

HRD must integrate its core psychological, economic, and system theories into a holistic theory and model for practice. (Swanson, 2001, p. 94)

The challenge of this proposition is large. First, most HRD professionals function from principles and tools of practice with weak and inconsistent reference to any research and theory. Thus, just getting HRD professionals to clearly state a theory that explains their work is enormous. Even so, most simultaneously espouse that HRD is grounded in multiple theories while saying nothing at all about the integration of multiple theories in defining the HRD discipline and its practices.

Game theory methodology appears to provide potential for integrating and applying economic, system, and psychological theories in HRD practice. First, it fully acknowledges the three theory domains and second, its focus is on decision-making within the complex real-life situations. Game theory methodology can be utilized in analysing economic, systems, and psychological situations, thus it appears that game theory methodology might prove promising in integrating these theories of HRD. Game theory has primarily been used in decision situations and has not been used in the manner advocated by the authors. Therefore, the authors acknowledge the preliminary and exploratory nature of this proposition.

Applying game theory methodology to HRD would logically need to be confined to boundaries established by the HRD definition and purpose. Once confined to HRD, it is useful to highlight the fact that game theory methodology is best suited for addressing strategic issues and ill-defined problems. Not all problems facing HRD professional are strategic or ill-defined. Some projects contain both. For example, a major hotel chain engaged a deep analysis related to the strategic and ill-defined problem of customer satisfaction and its relationship to business success. The complex sets of system, economic, and psychological information from this analysis could be holistically thought through using game theory methodology. Once a business strategy was determined, game theory methodology would be of less value to subsequent decisions. For example, if training materials were to be designed to implement the new customer service strategy, game theory methodology would not be very useful to making training design decisions compared to the available training design methodologies.

It is our position that game theory can provide assistance to the HRD profession in integrating multiple theories for disciplinary understanding. Furthermore, game theory methodology is best be applied to the work of HRD assuming its strategic roles. A series of case studies applying game theory methodology in actual organizations would be useful in testing the theory integration proposition.

Results and Findings: Strategic Role Fulfilment Question and Discussion

The question of the added value of game theory methodology to HRD is as follows: Can game theory methodology provide assistance to the profession in fulfilling the HRD strategic roles?

Swanson (2001) asserts that HRD is of strategic value if (1) it is performance-based (2) demonstrates strategic capability and (3) responds to the emergent nature of strategy. Our position is that game theory methodology can contribute to HRD and its fulfilment of these strategic roles.
Performance-Based HRD

HRD interventions serve a broad range of interests. While HRD can serve the needs of individuals and groups within organizations, HRD that is strategic contributes to business goals and organization performance (Swanson, 1994). "Performance-based HRD must be based on a clear definition of the performance problem through accurate identification of actual and desired performance requirements at the organization, process, and individual levels (Swanson, 2001, p. 347).

Game theory methodology focuses on outcomes; thus, HRD practitioners using the methods advocated in game theory must consider the strategies and payoffs for several alternative situations before focusing in on one particular strategy. Game theory methodology aims first at understanding the game that is being played. Tools such as The Value Net (Brandenburger & Nalebuff, 1996) are useful in defining the players, the boundaries, and the stakes.

Game theory can also assist in the clear definition of performance problems. For example HRD professionals might use game theory tools in assessing the key relationships that are jeopardized by a quality issue in a specific department. These tools can also function as internal diagnostics at the interfaces between divisions (Rummler & Brache, 1995).

Demonstrating Strategic Capability

HRD provides education and learning about the nature of systems and strategy, and in many cases, HRD professionals contribute directly to the planning process (Torraco & Swanson, 1995). Education is critical in providing the systems perspective for those who set the strategic direction, while direct participation in the strategy process by HRD professionals ensures the recognition and consideration of competitive advantages achieved through the development of human expertise.

Game theory methodology is highly systemic in nature and contributes to the consideration of options prior to the decision-making process (Gibbons, 1992). Brandenburger & Nalebuff (1996) point out the need to define the scope of a game, while keeping in mind that no game occurs in isolation. That is, the effects and implications of one game will likely affect another game that is often perceived as separate. The HRD professional can use game theory tools to keep the broad perspective and examine the implications of several possible outcomes in a strategic situation.

Game theory methodology can also be used proactively to suggest possible future outcomes of given strategic options. A thorough analysis of player actions and responses can help HRD professionals anticipate possible future options and payoffs. While the intent of game theory methodology is to evaluate decision implications, its potential to predict options cannot be ignored.

Emergent Nature of Strategy

"HRD cannot add value to the shaping of strategy if the strategy is already fully formulated" (Torraco & Swanson, 1995, p. 19). For this reason, HRD professionals must find ways to embrace the emergent nature of strategy. For the HRD professional this means the constant preparation and development of employee expertise to take full advantage of business opportunities that emerge with little or no indication. Simply viewing strategy as an evolving phenomenon indicates the need for expertise at the individual, process, and organizational levels. "Academic game theory models are sensitive to assumptions about who knows what and when and to the structure of the game itself" (Bushko & Raynor, 1997, p. 4).

Game theory methodology provides the methods for assessing the interconnectedness of strategic options and situations. With useful means for evaluating the implications of strategic decisions, and their counter-decisions, game theory methodology supports the emergent nature of strategy and its wider implications. Simply charting decision options on the map presented in Figure 1, or by using the value net to assess a given situation might allow the user to see pieces of the whole situation that may have otherwise been overlooked.

Conclusions and Implications for Further Research

Based on the literature and logical connections, game theory methodology has potential in helping the HRD profession address the complexity (1) of integrating multiple theories for disciplinary understanding and in (2) fulfilling its strategic roles. It is proposed that series of HRD case studies focused on theory integration and strategy problems be conducted using game theory methodology to assess the utility and validity of the methodology.

Scenario Planning: An Examination of Definitions, Dependent Variables, and Support for Development as an HRD tool.

Thomas J. Chermack
Susan A. Lynham
Texas A&M University

Scenario planning has been receiving increased attention as a tool for considering the future in the midst of a rapidly changing business environment. This article will examine available definitions of scenario planning, analyze the espoused dependent variables of the process, set forth an integrative definition and support the further development of the process as a useful and relevant Human Resource Development (HRD) tool.

Key Words: Scenario Planning, Dependent Variables, Definitions

While the use of futuring is growing in its popularity, many of the futuring tools available to business leaders are lacking in clarity around precisely what they do and how they achieve their espoused ends (Fahey & Randall, 1998). With increasing uncertainty and an accelerating pace of change, business leaders will rely even more heavily on such tools. Many of the available futuring tools are without coherent descriptions or explicit purposes (Mintzberg, 1994) although descriptions and purposes can be helpful in explaining theories and approaches to given processes (Egan, 2001). Scenario planning is one such process. The examination of available definitions of scenario planning is important to any scholar or practitioner concerned with the development of the process (Fahey & Randall, 1998).

Research Questions

The purpose of this paper is to explore the espoused outcome variables of scenario planning and consider its significance as an HRD tool. This is an exploratory study designed to gather the available definitions of scenario planning, examine the espoused outcomes, set forth an integrative definition, and support the further development of scenario planning as an HRD tool. The following research questions serve as the basis of this inquiry:

1) What are the available definitions of scenario planning?
2) What are the outcome variables espoused in the available definitions?
3) What would be an integrative definition that captures the essences of scenario planning and its targeted outcomes?
4) What is the relevance and use of scenario planning for HRD practitioners and scholars?

Methodology

A literature review, analysis, and synthesis accomplished the purposes of this study. The predominantly available literature comes from the United States and Europe, which may limit the study. A keyword search of “scenario planning” conducted through several large search engines at a major university in the United States yielded several resources. The resulting resources were examined for their definitions and outcome variables.

History and Background of Scenario Planning

Scenario planning first emerged for application to businesses in a company set up for researching new forms of weapons technology in the RAND Corporation. Kahn (1967) of RAND Corporation pioneered a technique he titled “future – now” thinking. The intent of this approach was to combine detailed analyses with imagination and produce reports as though people might write them in the future. Kahn adopted the name “scenario” when Hollywood determined the term outdated, and switched to the label “screenplay”. In the mid-1960’s, Kahn founded
planning for Shell Oil, suggested in 1967 that thinking six years ahead was not allowing enough lead time to concepts to describe supply and demand chains. The use of scenario concepts in his project were more to develop a work for the Environmental Protection Agency with Willis Harmon, Peter Schwartz, Thomas Mandel and Richard compatible with the values that were advocated from the leader of the country (Ringland, 1998). SRI went on to do would resolve themselves. The other scenarios were given little attention once the official future was selected. The official future. This scenario suggested that issues such as population growth, ecological destruction, and dissent about the future.

"which clearly demonstrates how one man's thinking was driving a trend in corporate planning" (Ringland, 1998, p. IBM and General Motors to this line of thinking. Kahn then published "The Year 2000" (Kahn & Weiner, 1967), "which clearly demonstrates how one man's thinking was driving a trend in corporate planning" (Ringland, 1998, p. 13). Ted Newland of Shell, one of the early corporate sponsors of scenario planning, encouraged Shell to start thinking about the future.

The SRI “futures group” was using a variety of methods to create scenarios for the United States Education system for the year 2000. Five scenarios were created and one entitled “Status Quo Extended” was selected as the official future. This scenario suggested that issues such as population growth, ecological destruction, and dissent would resolve themselves. The other scenarios were given little attention once the official future was selected. The official future reached the sponsors, the U.S. Office of Education, at a time when Richard Nixon’s election as President was in full swing. The offered scenario was quickly deemed impossible because it was in no way compatible with the values that were advocated from the leader of the country (Ringland, 1998). SRI went on to do work for the Environmental Protection Agency with Willis Harmon, Peter Schwartz, Thomas Mandel and Richard Carlson constructing the scenarios.

Meanwhile, Professor Jay Forrester (1961) of the Massachusetts Institute of Technology was using similar concepts to describe supply and demand chains. The use of scenario concepts in his project were more to develop a model which would help people understand the nature of growth and stir up public debate. The results were published by Meadows in 1992 (Meadows et al, 1992).

Scenario planning at Shell was well on its way. Ted Newland and Pierre Wack, as the heads of corporate planning for Shell Oil, suggested in 1967 that thinking six years ahead was not allowing enough lead time to effectively consider future forces in their industry (Wack, 1985a). Shell began planning for the year 2000. When the Yom Kippur war broke out and oil prices plummeted, Shell was prepared. The ability to act quickly has been credited as the primary reason behind the company’s lead in the oil industry (van der Hiejden, 1997).

Shell’s success with the scenario planning process encouraged numerous other organizations to begin thinking about the future. Because the oil shock was so devastating to views of a stable future, by the late 1970’s the majority of the Fortune 1000 corporations had adopted scenario planning in one form or another (Ringland, 1998).

The success of scenario use was short lived. Caused by the major recession and corporate staffing reductions of the 1980’s, scenario use was on the decline. It is also speculated that planners over-simplified the use of scenarios, confusing the nature of story telling with forecasting (Ringland, 1998; Godet & Roubelat, 1996). According to Kleiner (1996), the time had come for managers to realize that they did not have the answers [the answers for what?]. Michael Porter led a “back to the basics” approach suggesting that corporations use external forces as a platform for planning (1985). In this time of evaluating how planning happens many consulting firms began developing scenario planning methodologies. Huss & Honton, (1987) describe three approaches of the time: 1) intuitive logics, introduced by Pierre Wack; 2) trend-impact analysis, the favorite of the Futures Group; and 3) cross-impact analysis, implemented by Battelle. Shell continued to have success with scenario planning through two more oil incidents in the 1980’s and slowly, corporations cautiously began to re-integrate the application of scenarios in planning situations. Scenario planning has been adopted at a national level in some cases, and its methods have been successful in bringing diverse groups of people together (Kahane, 1992; Van der Merwe, 1994).

Results and Findings: Examining the Definitions

The process of scenario planning is young, and many variations have been developed. This variety of approaches can also be found in the available definitions and espoused dependent, or outcome variables of scenario planning. The articles and books yielded from a keyword search were examined for their definitions of scenario planning and the espoused dependent, or outcome variables of the process that were embedded or implied in the definitions. The results of this search are presented in Table 1. Sources that did not contain a definition of scenario planning have been left out. The following eighteen definitions are a product of this keyword search.

</table>
Results and Findings: Examining the Dependent Variables

Some of the definitions examined here do not explicitly state the outcome variables of scenario planning. Many of the definitions feature imbedded outcome variables, which may support the notion that some definitions are unclear about their primary intentions. This also suggests that scenario planning professionals are just beginning to consider the importance of defining what they do and explicitly stating what they intend to achieve by doing it.

An examination of Table 1 shows that almost half of the available definitions date from 1997 to the present. The increase in recent scholarly literature around scenario planning might suggest a push to establish boundaries and begin the conversation of what it is that scenario planning purports to accomplish. This recent increase in scholarly works may also suggest that the process is developing and maturing with the help of concerned professionals (Fahey & Randall, 1998).

The outcome variables displayed in Table 1 can be grouped thematically into four major areas, suggesting four key outcome themes of scenario planning, namely, changed thinking, informed narratives or stories about possible or plausible futures, improved decision-making about the future, and enhanced human learning and imagination. These four outcome thematics are:

- Changed Thinking
- Informed narratives or stories about possible or plausible futures
- Improved decision-making about the future
- Enhanced human learning and imagination

The above themes are supported by a recent literature review (Chermack, Lynham, & Ruona, 2001). This review suggests that to inform decision making, learn through challenging the currently held mental models, enable organizational learning, and enable organizational agility, are all core aims of the scenario planning process. Of significant note is that none of the available definitions of scenario planning include an outcome or dependent variable of performance improvement.

Due to the high costs usually associated with the practice of scenario planning, it is surprising that performance improvement has not yet been made an explicit outcome of this strategic process. Perhaps it is assumed that scenario planning will result in performance improvement. However, while such an implicit assumption may be necessary, it is insufficient evidence that the practice of scenario planning actually results in performance improvement. Indeed, this lack of an explicit performance improvement outcome may point to a larger gap in the body of knowledge that is used to inform the practice and development of scenario planning. It is in the spirit of attending to these multiple outcome variables, including performance improvement that the Human Resource development (HRD) lens may have much to contribute to the development of the scenario planning process and also to future scenario planning, research, theory and practice. Primarily, the HRD lens, which is informed by the three theoretical foundations of psychology, systems, and economics, might contribute the view and theory of performance improvement (Swanson, 1999). As Swanson (1999) states "performance is the valued productive output of a system in the form of goods or services" (p.5). The push for performance based HRD has led to the development and application of theory building research methods (Lynham, 2000a; Swanson, 1999; Swanson & Holton, 2001; Torraco, 1995) that have been helpful in the growth and advancement of the HRD field. The recognition of performance (in terms of economics), in addition to learning, is a perspective that could contribute to the growth, maturity, and accountability of the process of scenario planning.

In an attempt to construct an integrative definition of scenario planning, it is important to include the thematics explicated in the examination of the available definitions highlighted in Table 1. By then adding the HRD perspective of performance improvement to these thematics, we can integrate the performance improvement component into this definition. Thus, after combining the HRD lens with the key thematics revealed by the available definitions of scenario planning, the authors suggest the following integrative definition of scenario planning: Scenario planning is a process of positing several informed, plausible and imagined alternative future environments in which decisions about the future may be played out, for the purpose of changing current thinking, improving decision making, enhancing human learning and improving performance. (Porter, 1985, Schwartz, 1991, Ringland, 1998, Shoemaker, 1995). This integrative definitional perspective of scenario planning may, in turn, further facilitate a push to evaluate and validate that the scenario planning process does indeed achieve what it purports to achieve, and that its informing theories hold up when examined against rigorous criteria for sound applied theory (Patterson, 1983).

The distinguishing factor for scenarios is that they are not predictions or forecasts. Scenarios are not concerned with getting the future “right”, rather they aim at challenging current paradigms of thinking and rolling people into a series of stories in which attention is directed to aspects that would have been otherwise overlooked (Wack, 1985; Shoemaker, 1995).
Supporting Scenario Planning as an HRD Tool

Swanson (1999) describes three branches of the systems theory foundation of HRD, namely, general systems theory, chaos theory, and futures theory. "Futures theory is critical for sustainable performance because it prepares one to recognize and cope with an evolving future state" (Swanson, 1999, p. 17). If scenario planning is founded on theories that are found to validate relationships, it may be a tool that fits in the futures theory branch of the systems theory foundation of HRD (Chermack & Lynham, 2001). No attempts have been made to evaluate theories of scenario planning against rigorous criteria for sound applied theory (Patterson, 1983). From this perspective, scenario planning is potentially a critical tool for the HRD professional because it might help practitioners and scholars recognize and cope with a rapidly changing business environment and the uncertainties in considering the future.

Cummings & Worley (2001) describe several methods of integrating strategic change. Among such methods are strategic planning, open systems planning, integrated strategic change, and transorganizational development. Scenario planning can be viewed from this perspective as a strategic organization development intervention. Swanson, Lynham, Ruona, & Provo (1998) posit the Strategic Organizational Planning (SOP) model, which integrates scenario building into the strategic planning process through a recurring divergent-convergent interrelationship: "scenario building flares out the thinking in its expansiveness and strategic planning reins in the thinking into an action plan" (p. 7).

Ringland (1998) also describes a method for using scenario stories to inform the strategy building process. Wilson (2000) outlines four approaches for using scenarios to inform business strategy and strategic decisions, namely: (1) a sensitivity/risk assessment, in which a specific strategic decision is evaluated through several scenario stories, (2) strategy evaluation in which scenarios act as "test beds" to evaluate the viability of an existing strategy, (3) strategy development (with a planning focus) which selects one scenario as a strategic starting point and uses the others to test the resilience of the strategy, and finally, (4) strategy development (without a planning focus) that assumes a goal of building the most resilient strategy for the largest variety of situations.

In recent years HRD professionals have seen an increasing emphasis on an active role in the strategy making and implementation process within organizations (Toracco & Swanson, 1999). In light of this aspired strategy-shaping role scenario planning must be seen as a tool of increasing importance to HRD research and practice in the future. As is evidenced by the examination of dependent variables of scenario planning, it is clear that one of the primary espoused goals of scenario planning is to alter current mental models of organization leaders. HRD professionals have a history and understanding of the theories of adult learning advocated by Piaget (1977) and Vygotsky (1986). Particularly the constructivist learning perspective, which encompasses theories of Piaget, (1977) Vygotsky (1986) and others (Fosnot, 1996) might inform the successful implementation of scenario planning (van der Heijden, 1997) as it attempts to alter mental models about managers' perceptions. Chermack & Van der Merwe (2001) make the connections between scenario planning and constructivist learning explicit with the intent of using constructivist learning theory to inform scenario planning practice. HRD professionals are in a unique position, with an understanding of these learning theories, to greatly improve the theory and practice of scenario planning in ways that business leaders and senior executives often overlook or are ill-equipped to do (van der Heijden, 1997).

Implications for Further Research

The conversation of boundaries and definitions is taking place in the field of HRD, and has been for several years (Holton, 1998; McLean, 2000; Ruona, 2000; Swanson, 1999; Torraco, 1998). Fahey & Randall (1998) suggest it is time that scenario planning professionals do the same and take a closer look at what they do, what they state that they do, and how they know they can achieve the results that they claim. The emerging questions concerning the outputs and boundaries of scenario planning may be a hint that scenario planning professionals may be moving in a similar direction. The further examination of these espoused boundaries, outcomes, and definitions is needed to ensure the future maturity and success of the scenario planning process. The dependent variables examined herein are labeled espoused dependent variables because there has not yet been a push or drive for evaluation in scenario planning. This lack of evaluation has been noted as a concern in the practice of scenario planning (Chermack, Lynham, & Ruona, 2001; Phelps, Chan, & Kapsalis, 2001; Gerogantzas & Acar, 1995). As an example, it is clear from the analysis of outcome variables that scenario planning aims to change managers' mindsets and improve decision-making. However, the evidence that scenario planning actually changes managers' mindsets, or improves decision-making is anecdotal (Wack, 1985a) and there have been few attempts to measure such claims. Although there are increasing efforts to evaluate the process (Phelps, Chan, & Kapsalis, 2001), there have been relatively few studies that establish the effectiveness of scenario planning.
Another concern is the theory base that informs the process of scenario planning (Chermack, Lynham, & Ruona, 2001). Dubin (1978) suggests that units, categories and themes aid in the development of theory. The themes revealed by examining the outcome variables of the scenario planning process suggest that several theoretical domains inform scenario planning. In order to establish the validity of the theories that underlie and inform the process of scenario planning, these theories must first be identified and then evaluated against some criteria for sound applied theory (Patterson, 1983). Once performance improvement has been recognized as a critical outcome variable of scenario planning the need to evaluate the process will naturally follow. As Swanson (1999) states: "Chasing after individual or organizational change without first specifying a valid unit of performance is inane. This is because change can take place while real performance declines" (p. 5). With the addition of the HRD lens, and more specifically the theoretical component of performance improvement, there would likely be a drive to evaluate not only the outcomes of the scenario planning process, but also the theory bases that inform the process. Doing so is likely to encourage and enhance more related research and theory development and, in turn, lead to better informed and improved practice of scenario planning.

Conclusions

This paper has attempted to present the available definitions and espoused outcome variables of scenario planning. This paper has also continued to support scenario planning as a significant tool for strategic HRD research and practice. Building on previous works (Swanson, Lynham, Ruona & Provo, 1998; Miller, Lynham, Provo, & St. Claire, 1997), this paper has further highlighted a number of ways in which using the theoretical foundations of HRD (Swanson, 1999), could result in improved scenario planning research, theory and practice. Specifically, this paper has identified four thematics that capture the espoused outcome variables of the scenario planning process, suggested the addition of a performance improvement outcome variable, and provided an integrated definition of scenario planning.

Appreciative Inquiry: Assumptions, Approaches, and Implications for HRD

T. Marshall Egan
Texas A & M University

Cynthia McLean Lancaster
University of Minnesota

This study examines the assumptions, approaches and implications of Appreciative Inquiry for HRD. The central purpose of this inquiry was to explore the strengths and weaknesses of Appreciative Inquiry. Comparisons are drawn between Appreciative Inquiry and Action Research. In addition to outlining reported strengths and weaknesses of AI, the study revealed that in addition to being a stand-alone intervention approach, practitioners view Appreciative Inquiry as complementary to other organizational interventions.

Keywords: Organization Development, Appreciative Inquiry, Action Research

Practitioner approaches to organization development and change are regarded as important aspects of Human Resource Development (HRD) (Weinberger, 1998). Appreciative Inquiry (AI) is an organizational intervention approach that is associated with Action Research (AR). AI has been gaining recognition in the scholarly and practitioner communities (Bushe, 1999). AI is a set of unique philosophical assumptions and practices (Gotches & Ludema, 1995). Although in some ways similar to AR, a diagnostic approach introduced by Lewin (1948), AI practices involve a socio-rationalist approach to inquiry, interaction, planning, and implementation. AI scholars (Cooperrider & Srivastva, 1987) criticize AR as being overly focused on problem solving. The AI approach rejects a problem solving orientation. "The idea is to look at an organization as a positive force, understanding its strengths, and figure out how to refine and enhance what it—or a system within it—is already doing well" (Zemke, 1999).

This paper reviews the assumptions forwarded by the AI approach, compares the AI approach to the AR approach, and reports findings from a qualitative inquiry involving AI practitioners.

Purpose and Theoretical Assumptions

This study examined philosophical assumptions, strategies and processes utilized in AI from the perspective of existing literature and experienced HRD practitioners. In order to differentiate and clarify the AI approach, comparisons between AI and AR are made. The research question utilized in this study was: What are the strengths and weaknesses of the AI approach from the perspective of experienced HRD practitioners utilizing AI?

AI was principally developed by David Cooperrider a professor at the Weatherhead School of Management, Case Western Reserve University. Cooperrider developed the AI approach along with Suresh Srivastva, Frank Barrett, John Carter, and others colleagues. They challenged the traditional problem solving approach to change management and introduced the term Appreciative Inquiry. AI has been used in international development efforts as well as within public and private sector organizations. The increased use of AI has led to its inclusion in the most frequently used organization development texts (Cummings & Worley, 2001; French & Bell, 1998). According to Bushe (1999), AI is one of the more significant innovations in AR in the past decade. Appreciative Inquiry "refers to both a search for knowledge and a theory of intentional collective action which are designed to help evolve the normative vision and will of a group, organization or society as a whole" (Cooperrider & Srivastva, 1987, p. 159).

AI has been described as a philosophy of knowing, a methodology for managing change, and an approach to leadership and human development (Cooperrider & Srivastva, 1987; Hammond, 1998). Cooperrider and Whitney (1999) provided the following “practice-oriented” definition:

Appreciative Inquiry is the cooperative search for the best in people, the organizations, and the world around them. It involves systematic discovery of what gives a system “life” when it is most effective and capable in economic, ecological, and human terms. AI involves the art and practice of asking questions that strengthen a system’s capability to heighten positive potential. It mobilizes inquiry through crafting an “unconditional positive question” often involving hundreds or sometimes thousands of people. In AI, intervention gives way to imagination and innovation; instead of negation, criticism, and spiraling diagnosis there is discovery, dream and design. AI assumes that every living system has untapped, rich, and inspiring accounts of the positive.

Copyright © 2002 T. Marshall Egan and Cynthia McLean Lancaster
Link this “positive change core” directly to any change agenda, and changes never thought possible is suddenly and democratically mobilized. (Cooperrider & Whitney, 1999, p. 10)

AI is a product of the socio-rationalist paradigm (Gergen, 1982; 1990). From this perspective, reality is a product of the moment thus open to constant change and ongoing. Cooperrider and Srivastva (1987) argued that there is nothing inherently real about any particular social form. From this perspective there are no transcultural, everlasting, valid principles of social organization to be uncovered. According to AI practitioners and scholars, “Social phenomena are guided by cognitive heuristics, limited only by the human imagination; the social order is a subject matter capable of infinite variation through the linkage of ideas and action” (Cooperrider & Srivastva, 1987, p. 139). According to Bushe (1995), “Socio-rationalists argue that the theories we hold, our beliefs about social systems, have a powerful effect on the nature of social ‘reality.’ Not only do we see what we believe, but the very act of believing creates it” (p. 15).

The AI approach often engages an entire organization (Murrell, 1999). Cooperrider offered the “heliotropic hypothesis,” which posits that social forms evolve toward the “light,” toward images that are affirming and life giving (Hammond, 1998). From this perspective of AI, groups, organizations, communities, or societies have images of themselves that underlie self-organizing processes. AI promotes the principle that social systems tend naturally toward the most positive images held by their members (Bushe, 1995).

The expanding amount of literature and training on AI suggests an expanding use as an HRD intervention (Cady & Caster, 2000). AI is often identified as being related to AR (Barret, 1995). AR was developed in the 1940s and 1950s and was focused on creating a research method that would lead to both practical results and the development of new social theory. AR was positioned as an important tool in social and organizational change (Goldstein, 1992). A key emphasis of AR has been the establishment of a co-research agenda whereby practitioners and organizational members work side-by-side to analyze, implement, and evaluate systems change. AR was and continues to be a cornerstone of organization development (Rothwell, Sullivan, & McLean, 1995).

AR has been criticized as a flawed method of organizational change and as an inadequate process for developing new theory. Cooperrider and Srivastva (1987) criticized the lack of useful theory generated by traditional AR. They contended that both the method of AR and implicit theory of social organization used by AR are to blame. The problem, according to AI practitioners and scholars, is that most AR projects use logical positivistic assumptions (Sussman & Evered, 1978) that treat social and psychological reality as something fundamentally stable and enduring, or external to the individual and organization.

AI, it has been argued, alleviates the conflict and resistance to change often identified in literature about other approaches to organization development and change (Barron & Moore, 1999). Where other organizational interventions concentrate on the problems to be fixed (Cooperrider & Whitney, 1999), AI focuses on “what’s working well.” Instead of viewing an organization as having problems, AI views an organization as doing things right, and using those right things to build the organization’s future (Hammond & Royal, 1998).

It is important to note that Burke (1982) and others (Rothwell, Sullivan & McLean, 1995; French & Bell, 1998) have argued organizational interventions should take a balanced approach. The balanced approach to investigation involves an examination of both what is going well and what are the problems or challenges being faced. Asking both questions does not fully support the claim that other approaches to organizational interventions are problem centered, but that they involve both positive results and visions for the organization as well as problems being faced by the organization (Burke 1982; Rothwell, Sullivan & McLean, 1995).

Comparing the Appreciative Inquiry Approach to Action Research

Because AI has been suggested as an alternative to AR, it is important to clarify the differences and similarities between the two approaches. References to practitioners in the following discussion refer to individuals who are involved in the implementation of an organization development and change effort. The following section will outline the AI approach and compare it to AR.

AI practitioners and authors have emphasized the importance of the appreciative interview. “We believe the seeds of change are implicit in the very first questions we ask” (Cooperrider & Whitney, 1999, p. 12). The appreciative interview and the “affirmative topic choice” have been reported to be essential parts of the initial stage of an AI intervention (see Figure 1 below). The selection of the topic for exploration is viewed as essential because AI researchers “believe the seeds of change are implicit in the very first questions” (Cooperrider & Whitney, 1999, p. 12). The step following topic identification, the discovery phase, is aimed at disclosing positive capacity regarding a chosen topic. AI researchers often recommend that everyone involved in the organization development and change effort participate in interviews “because, in the process, people reclaim their ability to admire, to be
surprised, to be inspired” (Cooperrider & Whitney, 1999, p. 14). A distinguishing characteristic of AI is that every question is positive in orientation (Hammond & Royal, 1998).

The third step is the dream phase (Cooperrider & Whitney, 1999). During this stage of intervention, insights from the first steps of the intervention are elaborated upon. From the perspective of the AI practitioner, the outlook and vision of the future for organization members is influenced by organization members’ shared review of the data gathered in the previous phase. The reported results are identified as the organization’s “dream” (Cooperrider & Whitney, 1999). The dream is often described as a compelling statement of strategic intent, a vision for what might be, or a powerful purpose.

The forth step in the AI process, the design phase, is identified as focusing on the creation of agreed-upon concepts and principles. The positive narratives collected in the discovery phase are used to create provocative questions and propositions (Cooperrider & Whitney, 1999). Because of their connections to positive stories, provocative questions or propositions are said to come from the positive core of the organization. An example of such a question provided by Cooperrider and Whitney is, “What would our organization look like if it were designed to maximize the positive core and accelerate realizing our dreams?”

When individuals come to agreement on the design stage, the AI process moves to the final destiny phase: “Originally, the final ‘D’ stood for ‘delivery’ and was dedicated to writing action plans, building implementation strategies and monitoring progress” (Zemke, 1999, p. 31). The final step in the AI process has more recently been described as focusing on sustaining the efforts of the previous stages (Cooperrider & Whitney, 1999).

AR is a framework for diagnosing, implementing, and evaluating a change process (see Figure 2 below). “It allows for collaboration between practitioner and client throughout the process in order to distribute knowledge and understanding within the organization” (Cady & Caster, 2000, p. 80). Although there are several AR approaches varying from five to fourteen steps (Argyris, 1989; Barker & Barker, 1994; Cummings & Worley, 2000; Davis & Cook, 1998; DePoy, Hartman & Haslett, 1999; Edmonstone & Havergal, 1995; Lewin, 1948; McLean & Sullivan, 1989), the general approach involves data gathering, diagnosis, implementation, and evaluation of the intervention. Figure 2 identifies the eight-step AR process presented by McLean & Sullivan (1989) (see references above for more information regarding the techniques and assumptions associated with AR). Two of the differentiating factors between AR and AI can be found in the Assessment and Feedback stage, as well as the Evaluation stage, presented in the AR model below.

As previously mentioned, those involved in AI criticize AR as a problem solving focused approach. According to the AI literature, the problem solving approach of AR limits the opportunities for organizations to be successful because it reinforces existing beliefs instead of addressing the possibilities for the creation of new beliefs. AR is additionally criticized because it keeps the organization moving from one unsolved problem to another (Zemke, 1999). According to Cady and Caster (2000), there are three main challenges facing AR: (1) AR is problem-solving oriented in comparison to the “positive process frameworks” utilized in AI, (2) AR has been left open to interpretation resulting in AR models that have become complex and somewhat intimidating for practitioners, and (3) AR has not been utilized in conjunction with other organization development and change approaches. Despite
these challenges, AR has been widely utilized for several decades (Cummings & Worley, 2000). There have been recent suggestions (Cady & Caster, 2000; Golembiewski, 1999; McLean, 1996) to integrate AI and AR approaches.

Problems with the Appreciative Inquiry Approach

AI has received criticism as an approach to organization development and change. According to Golembiewski (1999), executives tend to favor an AI approach to organization development and change over other approaches since it is more likely to heighten integrative rather than punitive impulses. If executives ask employees to think of the accomplishments of the organization and of leadership, the only option the AI process presents is positive information. Therefore, AI may be viewed as attractive to those holding positional power because it averts focus away from organizational challenges and specific performance or behavioral issues that may be of concern to employees. However, employees may become frustrated with managers and executives unwilling to discuss important challenges being faced by the organization.

Critics of AI argue that there is currently little research supporting AI or differentiating it as more favorable than other approaches. McLean (1996) stated,

"Does appreciative inquiry have anything to say to our practice of OD? Certainly. But it’s interesting how Cooperrider (legitimately) points to the paucity of research supporting the use of the AR model, yet provides no ‘proof’ (what would that look like, anyhow?) that appreciative inquiry can do any better. A synergistic approach will surely benefit all involved." (p. 3)

Golembiewski (1999) went on to say, “Social constructivism is an inhospitable foundation for anything that can be called empirical research, even loosely. And this ‘creative theorizing’ in AI takes on less the character of science than of advocacy, if not of self-serving spinning” (in Livingston, 1999, pp. 109-110).

Critics of AR have claimed that AR is an approach to organization development and change that focuses only on negative aspects or problems. A lack of a significant amount of research in support of AR opens the possibility that a balanced approach focusing on both the challenges and problem areas, organizational successes and best practices (Burke, 1982, p. 18), may be equally or more effective. An organizational intervention that includes features from both approaches may be most effective. As McLean (1996) stated:

"Appreciative Inquiry, however, seems to fall into the opposite trap of focusing only on what’s going well, but still for the purpose of improving the organization and those within it. Improvement requires an understanding both of what’s not working well and what can be built on because it is working well" (p. 2).

Methodology and Research Design

Because of the apparent lack of current practitioner-related information regarding the strengths and weaknesses of AI, an exploratory, qualitative study was undertaken. Key respondents were selected and questioned with the support of a consistent interview protocol. The data accessed from these interviews consisted of text in the form of rich oral descriptions (qualitative data). Frequencies and percentages of responses were organized to supply the reader with a summary of responses provided by interviewees. The following is a discussion of the interview protocol used to obtain more information regarding the strengths and challenges of AI.

Participant Interviews

Because of the lack of a public list of AI practitioners, a thorough literature search of HRD-related journals was undertaken. The researchers identified three professional associations that, based on available printed materials, journal articles and advertised workshops, were most likely to have practitioners involved in AI. Three professional associations (ASTD, ODI and AHRD) were contacted and asked for access to their published list of members. The identification of individuals who were known to facilitate AI was supported by cross-referencing literature from the professional associations with member listings. Assistance in identifying those professional association members involved with AI interventions was also requested from and provided by professional association contacts. The criteria for study participant identification included that they: (a) have been involved in several AI interventions; (b) had participated in AI interventions of an ongoing nature (not just a training event); and (c) had more than ten years’ experience in HRD or related area.

Seventeen HRD professionals were identified as prospective participants. After contacting prospective participants, ten participants were identified as being experienced with AI to the level desired for the study. Seven HRD professionals agreed to participate in the study. The participants in the study included two Fortune 500 corporate HRD managers, one HRD manager from a medium-sized private sector organization, and four external
HRD consultants. The participants were involved in AI interventions in a variety of private sector industries, including financial services, retail merchandising, pharmaceuticals, information technology, food and agricultural products, energy, and manufacturing. Additionally, AI consultants were involved in public sector AI interventions, including public schools, foundations, healthcare organizations, and environmental associations. The employee size of the organizations reported to be part of AI interventions ranged from 7,000 to 160,000 in the private sector and 100 to 11,000 in the public sector.

Data Collection. The data were collected through interviews. The researchers conducted phone interviews with these seven experienced AI facilitators. A semi-structured interview guide was used to organize data collection during the interview process. Semi-structured interviews were selected because they are "reasonably objective while still permitting a thorough understanding of the respondent's opinions and the reasons behind them" (Borg & Gall, 1989, p. 452). Interview questions focused on process, perceptions, experiences, current status, and outcomes. Because content analysis was the planned mode for data analysis, questions were developed with sufficient breadth so as not overly to direct the responses to specific issues. An AI approach (Cooperrider & Whitney, 1999) was used for the first half of the interview before the introduction of critical or problem-solving questions.

Data Analysis. A qualitative thematic strategy for data analysis was employed to organize and to make judgments about the meaning of the data. Content analysis is an approach utilized for the systematic examination of text from the interview data. The researchers utilized an inductive approach to the development of the coding scheme utilized to analyze participant responses (Glaser & Strauss, 1967; Lincoln & Guba, 1985).

Findings

The following sections report the findings of the study.

Contributions of AI Approach

Through participation in open-ended questions, interviewees identified contributions of the AI approach. In response to the question, "In your view, what are the strengths of the AI approach?" HRD professionals identified several areas associated with improved relationships among co-workers and between managers and employees. Each respondent emphasized the importance of the AI approach to the development of a shared sense of new possibilities for the organization. Sample comments illustrating the importance of AI to improved relationships and shared understanding included:

Appreciative Inquiry is an invitation to organization members from all levels to participate in the accessing of new possibilities for the organization and for all to engage in a goal setting process that begins with their collective imagination. Organization members discover the rich capacity of the system and the strengths of those around them.

I am impressed with the ability of the AI approach to support organization members in the development of possibilities for the future. The process allows new ground to be broken around creativity, cooperation, and a clarified vision for the future that involves everyone.

An examination of the responses from participants indicated that all identified one of the most significant contributions of AI to be the development of cooperation in conjunction with improved skill development or improved utilization of interpersonal skills. This skill development was often attributed to the impact of the discovery phase of the AI process.

I find AI useful in assisting organization members to develop a deeper understanding of one another through listening more effectively. This appreciative regard is demonstrated by listening, and responses support cooperation between employees and [between] employees and managers. This support fuels the movement toward organizational improvement and success.

During an AI intervention, and beginning with my first question of them, the culture for appreciating one another shifts. Employees listen to each another more intently and focus more on the strengths each brings to the game.

The benefits of AI discussed by HRD professionals were not unlike those described to be the benefits of AR (Goldstein, 1992) or identified as the intended outcomes of organization development (Egan, 2001). However, HRD professionals interviewed for this study emphasized many of the points found in the AI literature, particularly

24-3
accessing of the "capacities of the organization" toward a "better future." As stated by one HRD professional, "Participants in the AI process experience a shift away from the problems toward the resources available to them and their co-workers. There is movement toward a realistic, more productive future that is high performing and dynamic."

In addition to the contributions described above, sixteen themes were identified during the interview process. The themes are provided below (Table 1) with associated frequencies and percentages for each response.

The positive contributions identified by the participants are supported by the literature reviewed in this study. Participants' descriptions of the contributions of AI are found in the language and explanation of the AI process. Interviewee comments parallel those of the AI literature, such as the opportunity to be involved in the discovery phase, whereby participants access and understand their organizational capacity and share in positive organizational stories. The creation of the dream, whereby positive imagery about the organization can be developed, is also referred to indirectly through mentioning opportunities for individuals to access possibilities and create positive imagery for the organization. Additional references by interviewees that supported the concepts associated with AI included the power of the narrative or story, the heliotropic hypothesis, and the organization's inner dialogue. The themes from the discussion about AI appear to have been more about the discovery and dream stages than the design and destiny stages in the AI model (Figure 1 above). As one participant said, "Because AI is so new, it is important that we emphasize the initial stages of the AI process, so that we may better understand where it may lead. Without starting the process correctly, we may be unable to determine the long term impact of AI."

Weaknesses of the AI Approach

In response to the question, "What are the weaknesses of the AI approach?" all participants identified three challenges, including: difficult interpersonal situations may be overlooked and remain unidentified as challenges to the success of the group or organization; feelings of anger or frustration are not voiced and may become barriers for some employees; and dissatisfied organization members retreat and withdraw from the process because they are unable to feel included by the AI approach. Two HRD professionals responded as follows:

During an AI intervention it is sometimes difficult for the deeply rooted challenges between individuals to be addressed effectively. Employees may find some challenges to engaging authentically in the process when previously strained relationships show themselves in one-on-one relationships. This has been an ongoing challenge for a couple of my clients.

We want everyone to participate in the process but find that some refuse and withdraw. They don't directly impair the development of the team; they just remain passive. Some [organization members] have indicated that they feel they are unable to voice their true feelings...like anger.

Another theme from the interviews was that managers might avoid challenges by focusing on "the positive". As indicated by one interviewee, "I have been asked a couple of times by employees as to how they can be heard when their manager is not open to acknowledging when difficulty occurs." Several of the HRD professionals discussed...
their observations that managers may use the AI approach inconsistently, resulting in a lack of focus on the key messages forwarded by the AI process and the long-term commitment to AI may be more challenging for organizations than other interventions. The ten themes identified by interviewees may be found in Table 2 below.

<table>

The challenges for AI identified by interviewees reflected many of the same concerns found in the literature. Few participants felt that the lack of research on AI was an important consideration in the identification of challenges to AI. It was explained that AI is too new of an approach to have been well researched. The major concerns are associated with the challenges faced when only positive content is the focus of workplace interactions. One study participant stated, “It is difficult to watch individuals who feel they must speak in negative or critical terms; some of them seem unable at times to redirect their energy into a positive direction. We must continue to pay attention to the more subtle interactions between organization members, so that we can better understand how the focus on positive imagery and communication is or is not transferred.”

Finally, interviewees were asked whether AI could effectively be included with AR or other problem-solving approaches. Interviewees were divided in their responses. Several interviewees indicated that AI could be used in conjunction with other approaches because “it is important that the strength of AI be tapped, but it is also recognized that in some cases it is a consulting approach that can be used in conjunction with other approaches.” Others disagreed indicating that the movement toward a combined AI and AR approach was “misguided and misses the point of the approach. We need to embrace the philosophy behind AI, not just use part of it.” The mixed response to this question is similarly to the various discussions in literature about AI. (Bushe, 1995; Cady & Caster, 2000; Golembiewski, 1999; Schiller, 1998)

Discussion

This study explored the AI approach to organizational interventions and found sixteen specific strengths and ten specific weaknesses to the AI approach as reported by study participants. The participants in this study supported many of the strengths of AI reported in the literature (Bushe, 1995; 1998; Cooperrider & Srivastva, 1987; Jones, 1998). Further, this study found support for the potential limitations of AI as an exclusive organization intervention approach (Cady & Caster 2000; Golembiewski, 1999; McLean, 1996). The perspectives shared by the participants in this study further elaborate on AI as an HRD practice. Although there may be some differences in opinion regarding the exclusive use of an AI approach in HRD interventions, the uniqueness of the AI approach may be beneficial to HRD, even if merged with AR approach (see Cady & Caster, 2000). The results from this study are not generalizable, but elaborative. Future examination of AI interventions from both interpretive and positivistic research perspectives is recommended. For instance, the advantages and disadvantages of AI discussed in this study could be used as the basis for future development of a survey to be used with a large group of HRD practitioners. Additionally, comparative research, such as that performed by Jones (1998), and other case study research may be of benefit to determine the impact of AI practices. Finally, interpretive studies examining the experiences of practitioners and participants involved in AI interventions may be of benefit to scholars and practitioners.

Toward Transformational Learning in Organizations: Effects of Model-II Governing Variables on Perceived Learning in Teams

Blair K. Carruth
Salt Lake Community College

This study examined the effects of Model-II variables on perceived team learning by intervening the variables into three experimental groups. For two variables, perceived team learning was significantly lower than the control group. However, additional analysis revealed that the main effects were uncertain; regardless of which Model-II variable was introduced, perceptions of team learning may have depended on an interaction between gender and employment status and by a possible interaction between gender and education level.

Keywords: Model-II, Double-loop, Transformational

The study of learning organizations is a growing line of inquiry that has been approached from a number of disciplines and perspectives. With the decline of the industrial economy, organizations, profit and non-profit, representing all industries must seek to find and develop organizational members who have learned how to learn and who can work with other organizational members to enact systemic organizational change at an increasingly rapid pace.

It behooves organizations to understand the dynamics behind team and organizational learning so they may capitalize on interventions that produce desired learning impact. Model-II is a theory postulated by Argyris and Schönh (1978, 1996) that describes conditions upon which deep-rooted or transformational learning within organizations may take place. The model presents three governing variables: (a) valid information, (b) free and informed choice, and (c) internal commitment. Numerous studies have been performed to examine this model, mostly utilizing qualitative in-field methodologies. However, post intervention studies failed to provide evidence of sustained learning (Argyris and Schönh, 1996), rendering use of the model problematic.

Argyris and Schönh suggested a need exists to develop studies that utilize design methods that examine Model-II from perspectives different from those used in the past.

Quantitative research using experimental design methodologies is now emerging as a strategy to examine the model. Recent quantitative studies have shown evidence of transformational learning when Model-II interventions were employed (Kardatzke, 1996; Jeris, 1997; Ritchie, 1999). While these studies have made contributions to the Model-II line of inquiry, they examined the model holistically leaving one to question which parts of the model may have more impact on organizational learning.

The primary purpose of this study sought to identify the effects of each Model-II governing variable on perceived team learning. A secondary purpose of this study sought to contribute results that might be compared to future studies to either increase or decrease acceptance and subsequent use of Model-II by providing indication of the model's impact on organizational learning.

Theoretical Framework

Argyris and Schönh (1978, 1996), Argyris (1998), Marsick (1988), and Schönh (1983), discussed the need for inquiry that leads to transformational change in organizations. Argyris and Schönh and Argyris differentiated between single-loop learning and double-loop learning which may be compared to the difference between behavior based on obligation versus behavior based on beliefs and/or values. One type of learning, single-loop, may be transitory, while the other, double-loop, is transformational. Transformational learning, within the context of organizational learning, was said by Argyris and Schönh to alter traditional theories-in-use which can be defined as basic assumptions that guide practice. People within organizations need to discuss the undiscussable by challenging existing theories-in-use and questioning the assumptions upon which those theories are based.

Similarly, Marsick (1988) called for organizational members to engage in critical reflection. Critical reflection probes for assumptions, values, and beliefs that underlie action. Once these assumptions, values, and beliefs become explicit they can be tested, questioned and challenged. This process leads individuals and groups to understand the rationale behind actions, and it leads to learning that is rooted deep in values. The skill to critically reflect, and the learning which results from it, is akin to double-loop learning (Argyris and Schönh 1978, 1996) or transformational learning (Mezirow 1991, 1996).
Senge (1990a, 1990b) suggested reflective thinking causes organizational members to consider their mental models and helps them develop personal mastery that is at the heart of a learning organization. It is through such development that generative learning takes place, that is, the ability to create something new which is of value to others. Viewing the whole organization, and not looking myopically and exclusively at component parts, allows shared visions to be developed by organizational members. Such holistic thinking is at the heart of systemic thinking which, according to Senge, must be present in order for a learning organization to evolve.

Research Question

Argyris and Schöen (1996) noted that despite their efforts over years of qualitative research to find evidence of double-loop learning, such evidence occurred so infrequently, they referred to them as “rare phenomena” (p. 112). The development of transformational or double-loop learning capability is strongly advocated in the literature (Marsick, 1988; Marsick and Watkins, 1994; Senge, 1990a; Watkins and Marsick 1993). To encourage further study and to provide more substantial empirical grounding for Model-II, Argyris and Schön suggested a methodological approach different from those used in the past could be employed by engaging research that envisions and enacts organizational settings. This suggestion opens the door to examine Model-II under controlled conditions utilizing experimental designs.

In response to Argyris and Schön’s suggestion, recent studies have tested Model-II utilizing experimental and quantitative methodologies (Kardatzke, 1996; Jeris, 1997; Ritchie, 1999). These studies provide a new approach to analyze Model-II, yet much work is needed to more fully understand the model’s effects in organizations and the conditions that must be met in order to develop transformative learning capacity.

Each of the studies cited above examined Model-II in an holistic sense; they did not break the model into components to see which parts might have an impact on learning. This study continued the Model-II line of inquiry by individually testing the effects of the three Model-II governing variables by asking one fundamental question: Are there significant effects from any of the three Model-II variables on perceived team learning?

Methodology and Limitations

Overview of Methodology

To analyze the fundamental research question, a convenience sample of 80 people was drawn from a population of students enrolled Fall Semester, 2000 in the Business and Society course at Salt Lake Community College. Participation in the study was voluntary. A control group and an experimental group representing each Model-II variable were randomly selected from this sample. Each group was randomly divided into four teams of five people each. Participants were not informed that they were assigned to an experimental group or to the control group nor did they know that different groups were receiving different interventions until after the experiment was completed.

Each team met four times over a two-week period. Each meeting consisted of a 50 minute one clock hour class period. Thus, total intervention impact time was 320 clock hours (80 participants times four one clock hour meetings).

A facilitator trained in group facilitation and process implementation was hired to conduct the intervention for each treatment group. Each team within each group met in the same room. Teams among different groups, however, did not meet together. Team members had little opportunity to communicate with other teams within their respective groups, and they were instructed not to communicate with anyone about the study outside their assigned meeting times.

Each team was given a business problem to solve. The same problem was given to each team among all four groups. However, treatment between the experimental groups differed. For each experimental group team, an instrument designed to elicit behaviors associated with that team’s randomly assigned Model-II variable was used and displayed during the team’s discussions. As the facilitator worked with each team, she reminded team members of the displayed behaviors and encouraged those behaviors to surface and to be manifested in team actions.

All materials used in the experiment were collected at the end of each meeting and were redistributed at the beginning of the following meeting. At the conclusion of the last meeting all materials were gathered and kept by the researcher.

During the last meeting session, the Dimensions of a Learning Organization Questionnaire (DLOQ) (Watkins and Marsick, 1997) was administered. Construct validity of this instrument was tested and confirmed by Yang, Watkins, and Marsick (1998). The DLOQ instrument measures perceptions of organizational learning within groups (or teams) among seven dimensions. Each dimension can be scored separately, and an aggregate score can also be
calculated. This researcher was interested in how these interventions affected overall perception of team learning, therefore, this study did not examine differences between the seven dimension scores. Rather, aggregate DLOQ scores were used as the basis of comparison between and within treatment groups.

Demographic information was collected on each participant on a separate form at the time the DLOQ was administered. After group participants had completed the DLOQ they were debriefed, and disclosure was made regarding the purpose of the research and the different group treatments.

Aggregate DLOQ scores were analyzed between groups and between teams within groups through analysis of variance (ANOVA). Statistical analyses conducted for this study were performed using Statistical Package for the Social Sciences Version 8.0.

Missing Data

Missing data was minimal. Of 3440 possible data points (80 participants times 43 DLOQ items), only 12 items were not answered by participants, representing 0.35% of all possible data points. An additional three items, or 0.09% of the total, were double marked, meaning that more than one answer was given to a DLOQ response item. These double-marked entries were treated as missing data since it was not possible to determine the participants' intended answers. Missing data were replaced by the averages of individual scores for the given DLOQ items within the respective teams.

Hypotheses Tested

Hypothesis 1. There is no difference in aggregate DLOQ scores between the experimental group receiving valid information intervention and the control group.

Hypothesis 2. There is no difference in aggregate DLOQ scores between the experimental group receiving free and informed choice intervention and the control group.

Hypothesis 3. There is no difference in aggregate DLOQ scores between the experimental group receiving internal commitment intervention and the control group.

Hypothesis 4. There is no difference in aggregate DLOQ scores between experimental group teams receiving valid information intervention.

Hypothesis 5. There is no difference in aggregate DLOQ scores between experimental group teams receiving free and informed choice intervention.

Hypothesis 6. There is no difference in aggregate DLOQ scores between experimental group teams receiving internal commitment intervention.

Hypothesis 7. There is no difference in aggregate DLOQ scores between the control group teams.

Hypothesis 8. There is no difference in aggregate DLOQ scores between the experimental group receiving valid information intervention and the experimental group receiving free and informed choice intervention.

Hypothesis 9. There is no difference in aggregate DLOQ scores between the experimental group receiving valid information intervention and the experimental group receiving internal commitment intervention.

Hypothesis 10. There is no difference in aggregate DLOQ scores between the experimental group receiving free and informed choice intervention and the experimental group receiving internal commitment intervention.

Pilot Study

Prior to the study, a pilot study was conducted to provide a trial run of the procedures, instrumentation, and test statistics. The same facilitator was hired to conduct both the pilot project and the full study. The pilot project provided confidence that the procedures, instrumentation, and test statistics planned were appropriate. In addition, it
provided an opportunity to develop a method for dealing with missing data and absenteeism, established a data base format for data management, and provided a sample run of the statistics used in the full study.

Limitations

Two limitations of this study are worthy of note: (a) sample selection, and (b) impact of intervening variables and possible intervention effects.

Sample Selection. The convenience sample selection method employed in this study drew from a generally broad-based population, however, it did not represent an adult population at large. Care should be taken to not infer study results to external populations.

Impact of Intervening Variables and Intervention Effects. Four possibilities exist in considering the effects of the Model-II intervention. There is insufficient evidence to ascertain definitive claims as to which of these four possibilities occurred. First, it is possible the intervention did not impact DLOQ scores, and that any significant effects may have resulted from non-controlled or intervening variables. Second, it is possible the Model-II intervention effects may have impacted DLOQ scores in the opposite way from what was anticipated. Third, it is possible the effects of the Model-II intervention may have affected DLOQ scores as anticipated, leading to higher DLOQ scores, but that the effects of non-controlled or intervening variables were stronger than the effects of the Model-II variables, thus overshadowing evidence of Model-II impact. Fourth, it is possible the effects of the Model-II intervention were weakened by isolating the three variables into separate treatment groups, thus rendering a less effective impact on perceived learning.

Results and Findings

Analysis of Hypotheses

Each of the ten hypotheses is analyzed below. A one-way ANOVA with 4 levels, one level for each treatment group, was conducted to analyze Hypotheses 1 through 3 and 8 through 10 (Table 1). Separate one-way ANOVAs were conducted to analyze each of the remaining 4 hypotheses (Table 1). For all ANOVAs the alpha level was set at .05.

Hypotheses 1 - 3. ANOVA results indicated sufficient evidence exists to suggest there is a significant difference between aggregate DLOQ scores by treatment group, $F(3,76) = 3.622, p < .05$. Post hoc testing was conducted utilizing the Tukey Honestly Significant Difference (Tukey HSD) method. Results of these tests show sufficient evidence ($p < .05$) to suggest the mean of the valid information group is significantly lower than the control group mean and that the mean of the free and informed choice group is significantly lower than the control group mean. There was not sufficient evidence ($p > .05$) to suggest the mean of the internal commitment group was significantly different from the control group mean, although the internal commitment group mean was lower than the control group mean.

Hypothesis 4. A one-way ANOVA was performed comparing aggregate DLOQ scores between the four teams within the valid information experimental group. Results of this ANOVA indicated there is sufficient evidence to suggest the means of the teams within the valid information treatment group are significantly different, $F(3,16) = 3.688, p < .05$. Tukey HSD post hoc tests revealed significant differences ($p < .05$) between Teams 3 and 4.

Hypothesis 5. A one-way ANOVA was performed comparing aggregate DLOQ scores between the four teams within the free and informed choice experimental group. Results of this ANOVA indicated there is not sufficient evidence to suggest the means of the teams within the free and informed choice treatment group are significantly different, $F(3,16) = 1.421, p > .05$.

Hypothesis 6. A one-way ANOVA was performed comparing aggregate DLOQ scores between the four teams within the internal commitment experimental group. Results of this ANOVA indicated there is sufficient evidence to suggest the means of the teams within the internal commitment treatment group are significantly different, $F(3, 6) = 9.483, p < .01$. Tukey HSD post hoc tests revealed significant differences ($p < .05$) between Teams 1 and 3 and between Teams 3 and 4.
Hypothesis 7. A one-way ANOVA was performed comparing aggregate DLOQ scores between the four teams within the control group. Results of this ANOVA indicated there is sufficient evidence to suggest the means of the teams within the control group are significantly different, \( F(3,16) = 3.605, p < .05 \). Tukey HSD post hoc tests revealed significant differences (\( p < .05 \)) between Teams 2 and 4.

Hypotheses 8 - 10. ANOVA results show sufficient evidence to suggest there is a significant difference between aggregate DLOQ scores by treatment group, \( F(3,76) = 3.622, p < .05 \). However, in examining post hoc tests using the Tukey HSD method, there is not sufficient evidence (\( p > .05 \)) to suggest the means of any of the experimental groups were significantly different from each other.

Discussion

Results showed a significant difference in mean aggregate DLOQ scores between the control group and the valid information experimental group and between the control group and the free and informed choice experimental group. There was not a significant difference between the control group and the internal commitment experimental group. In short, for each of the three experimental groups, the aggregate DLOQ score means were lower than the mean of the control group with significant differences between the control group and two of the three experimental groups.

An underlying premise inherent in this study, based on studies by Kardatzke (1996), Jeris (1997), and Ritchie (1999), suggested that if there were a significant main effect, the experimental group means would have been higher than the control group mean. However, the opposite occurred; perceptions of team learning were lower, as measured by the DLOQ instrument, for those groups that received a Model-II intervention. Three areas of inquiry provide explanations that may account for these unanticipated differences: (a) type-I error probability, (b) internal and external validity, and (c) demographic variables. Each of these three areas is discussed below.

Type-I Error. The probability of committing a type-I error was calculated to be .017, suggesting there is only a 1.7% probability that there is no significant difference in aggregate DLOQ scores between the control group and at least one of the three experimental groups. This probability is well within the stated alpha level of .05.

Internal and External Validity. The significant differences discussed in relation to Hypotheses 4, 6, and 7 provide an indication that validity issues may have accounted for differences between teams within treatment groups. Yet in analyzing validity factors, there was inclusive evidence that such factors affected DLOQ scores.
Demographic Data Analysis. Education level, employment status, and gender data were collected on each participant. While it was not an objective of this study to measure the effects of these variables on aggregate DLOQ scores, in pursuing reasons why the control group mean was higher than all three experimental groups and significantly higher than two of the experimental groups, it was believed an analysis of these demographic variables might provide insight for this seemingly inverse relationship between treatment condition and aggregate DLOQ scores. This analysis proved fruitful in explaining possible influences on aggregate DLOQ scores.

Separate one-way ANOVAs were performed for education level, employment status, and gender (Table 1). Results of the education level ANOVA showed a significant difference between levels of education and aggregate DLOQ scores, $F(2,77) = 5.984, p < .01$. Tukey HSD post hoc tests revealed that those with bachelor's degrees had significantly lower aggregate DLOQ scores than those with associate's degrees or those with high school completion or less. It should be noted, however, that the associate's degree and bachelor degree levels had only six participants and two participants, respectively.

The ANOVA for employment status showed a significant difference in aggregate DLOQ scores between different levels of employment status, $F(2,77) = 4.008, p < .05$. Tukey HSD post hoc tests revealed participants who were employed full-time had significantly lower aggregate DLOQ scores than did those who were not employed. Further, the mean aggregate DLOQ scores across all three levels of employment status declined as employment status advanced from not employed to employed full-time.

The ANOVA for gender did not show a significant difference in aggregate DLOQ scores between males and females, $F(2,77) = 2.071, p > .05$. However, when education level and employment status were examined by female and male participants separately, significant differences were found.

For female participants, significant differences in aggregate DLOQ scores were not evidenced at different levels of education and employment status, $F(2,24) = .635, p > .05$, and $F(2,24) = .325, p > .05$, respectively. In contrast, significant differences in aggregate DLOQ scores were manifested among different levels of education and employment status for male participants, $F(2,50) = 6.821, p < .01$, and $F(2,50) = 8.534, p < .01$, respectively. In both analyses, scores for males were generally higher than scores for females. Post hoc tests could not be performed for education level when filtered for males because the bachelor's degree level had only one male participant. For employment status, however, Tukey HSD post hoc tests revealed male participants in the full-time employment category had a significantly lower mean score than male participants in both the part-time and not currently employed categories.

From this information it appears there may be an interaction between gender and education level and between gender and employment status. That is, there is evidence to suggest that the effects of education level and employment status on aggregate DLOQ scores depends on gender. To test these possible interactions, two two-way ANOVAs were performed, one for gender and education level and another for gender and employment status.

The two-way ANOVA for gender and education level (Table 2) did not suggest a significant interaction, $F(2,74) = 2.094, p > .05$, but, like the one-way ANOVA, it did reveal a significant main effect for education level, $F(2,74) = 5.709, p < .01$. However, in reviewing the interaction plot, gender lines crossed through different levels of education, suggesting a disordinal interaction. When education level was filtered by gender, a significant difference was found with males but not with females. Thus, although an interaction was not found with the two-way ANOVA, perhaps an interaction exists nonetheless. Care should be taken, however, in drawing a conclusion because the analysis presents mixed results, and there were only eight participants in the associate's degree and bachelor's degree levels.

This analysis of demographic variables may lead to two assumptions that could explain the outcomes of this study. First, the effects of education level on aggregate DLOQ scores may depend on gender. Second, the effects of employment status on aggregate DLOQ scores may depend on gender.

Data tabulated from the sample seem to support these assumptions. In reviewing cross tabulations for males by part-time employment and less than an associate's degree, the data shows the control group had higher counts of males who were employed part-time and who had less than an associate's degree than any of the three experimental groups.

Upon analyzing the two assumptions stated above within teams across treatment groups, higher mean aggregate DLOQ scores were generally found to exist among males with lower levels of education and who worked less than full-time. This may explain the significant differences found in the analyses of Hypotheses 4, 6, and 7. Further, the two groups that had significantly different aggregate DLOQ scores from the control group had fewer males, fewer people with less than an associate’s degree, and fewer people who worked less than full-time.

Conclusion

Results of this study generally found that the effects of any of the three Model-II governing variables as measured in this study are uncertain. While significant differences were found between the control group and two of the experimental groups, free and informed choice and valid information, the control group mean was higher than the three experimental group means. It was assumed that significant differences would have revealed opposite results. It is inconclusive whether the intervention affected perception of team learning to be lower than anticipated or whether other variables accounted for these results.

In examining the data, three possibilities were considered: (a) type-I error probability, (b) internal and external validity, and (c) demographic variables. Of these three possibilities, the effects of demographic variables hold the most promise for explaining significant differences between the experimental and control groups with the strongest explanation evidenced by a significant interaction between employment status and gender. Males who worked less than full time and had less than an associate’s degree generally reflected higher DLOQ scores than other participants.

Contributions

This study makes a contribution to new methods for Model-II inquiry and provides encouragement and justification for more extensive studies that employ sample selection techniques that draw from a broader-based population. The study may be used in comparison to future studies to either increase or decrease acceptance for Model-II by providing indication of Model-II impact on organizational learning, as well as the effects of demographic variables on organizational learning such as employment status, education level, and gender.

Recommendations for Future Research

Possibilities for additional inquiry are suggested below.
Replicate this study while controlling for gender, education level, and employment status to test the effects of the interaction of education level and gender and the interaction of employment status and gender on perceived team learning. Assess whether Model-II intervention effects lead to lower or higher perceived team learning scores or if there is no change in perceived team learning.

Repeat this study while drawing randomly from a broader-based population, then compare results of this study to the intervention effects of the new study.

Develop an intervention that could be applied to a sample population within an organization to test for organizational learning as opposed to organizational learning within teams.

Develop an intervention where the Model-II variables are tested in isolation from one another as well as holistically.

Conduct longitudinal studies which measure retention of Model-II impact on team and/or organizational learning.

References

Watkins, K. E., & Marsick, V. J. (1997). Dimensions of the learning organization questionnaire, Warwick, RI: Partners for the Learning Organization. [Contact Karen Watkins at the University of Georgia for information and copies of the DLOQ]
This paper describes a comparative case study among 27 organizations from the industrial and services sectors, which have introduced team-based work. Teamwork is often associated in literature with better opportunities for employee development than traditional work systems (e.g., Ellström, 1999). Variations in team training were found to be unrelated to differences in the organization of teamwork. The self-directed teams in our sample did not provide a better, or even different, training context to their members than other teams did. The study raises questions about the prevalence of teamwork as a context for learning and discusses some directions for further research.

Keywords: Team-Based Work, Team Learning, Comparative Case Study

The subject of learning and training in work teams and groups has received a lot of attention over the past decade. Groups and work teams have always been regarded as contexts for employee development in literature on organizational development (French and Bell, 1995; Brown and Keep, 1999). The topic is also an object of concern in literature on the learning organization (Watkins & Marsick, 1993). Groups and work teams are considered powerful learning environments (Tjepkema, Kessels, & Smit, 1999; Onstenk, 2001) and work is increasingly expected to be organized in teams (Ellström, 2001).

Learning in groups is often studied in an experimental laboratory setting, with groups made up especially for the experiments concerned and consisting predominantly of students (Jeris, 1998). Also, there have been studies of managerial teams (e.g., Burgoyne & Reynolds, 1997), interdisciplinary teams (e.g., Cooley, 1994), and temporary project groups (task forces). Production teams, engaged in the primary process of an organization, however, have rarely been at the focus of empirical research (Hendry, 1996; Imel, 1996; Willis & Boverie, 1998).

What we do know from empirical research, however, is that in practice groups and teams as organizational forms turn out to be less prevalent then predicted (Benders, 1999; Dankbaar, 2000; Sey, 2001). Furthermore, empirical research provides little evidence for the high expectations concerning their performance, opportunities for participation, member satisfaction and motivation (Boot & Reynolds, 1997; Poutsma, 1998; Russ-Eft, Preskill, & Sleezer, 1997). Moreover, empirical results sustaining the alleged learning potential of group work are scarce (Van Klaveren & Tom, 1995; Hoogerwerf, 1998; Willis & Boverie, 1998). NB Because of space constraints not all Dutch studies are included in the reference list. A full paper containing those will be handed out at the conference.

Theoretical Framework and Research Questions

Ellström (2001) distinguishes between traditional and learning-intensive work systems. Traditional work systems are characterized by a high degree of specialization, standardization, individualization, and supervisory control. Learning-intensive work systems, on the other hand, have integrated tasks and functions, informal communication, a team-based work structure, and a control system based on self-management (cf. Table 1). Onstenk (2001) presents similar ideas about the relationship between the characteristics of work and its learning potential.

Table 1. Traditional and Learning-Intensive Work Systems (Ellström, 2001).

In the Netherlands, team-based work has been studied intensively (e.g., Van der Klink & Ter Horst, 1988; Hoogerwerf, 1998). Team-based work has been introduced in a number of companies in the Netherlands. In 1996, the Business School of Nijmegen University carried out a structured qualitative investigation into team-based work in forty of such companies. The principal questions in this survey were: In what ways are companies implementing team-based work and what forms of team-based work are they using? In addition, the investigation contained a number of questions about the ways in which the learning of team members is organized. This paper is based on a secondary analysis of data from said investigation. It aims to study empirically the relation between the way work is organized in teams and the organization of their training. The analysis will enable us to test for the Dutch situation whether the positive expectations about the learning potential of team-based work have an empirical basis.

Team-based work comes in a variety of forms (Hackman, 1991; Van Hooft, De Nijs & Poutsma, 1997). Whereas the content and organization of work in self-directed teams are assumed to result in learning-intensive arrangements (Ellström, 2001), more traditional teams are expected to be less proactive in organizing their own training arrangements. In other words, following the ideas of Ellström (2001) described above, one expects to find at least a certain relationship between various forms of team-based work and the way in which training in these teams is organized.

The following three questions will thus be investigated in the current study:
1. How exactly is work organized in team-based work?
2. How do work teams organize the training of their members?
3. Is there a relationship between the way teams organize their work and the organization of training in these teams?

Research Methodology

Forty large Dutch companies were approached, twenty-seven of which turned out to be suitable for an analysis of training data. Among these companies twenty-two were in the industrial or manufacturing sector (e.g., energy, printing, and nutrition firms) and five in the logistics or financial services sector (e.g., banking, auction, and insurance companies).

One well-informed representative, usually the personnel or production manager, from each organization was interviewed face-to-face. Prior to these intensive interviews, the researchers had studied documents on the company and its teamwork system. During the interview, which usually lasted between two or three hours, the company representative together with the researchers completed an elaborate pre-structured questionnaire containing fifty-eight questions (some open, most of them closed but complex).

The study was designed as a comparative qualitative case study among twenty-seven organizations. The data provides a picture at a singular moment in time of the way these companies have organized team-based work and how they deal with training in their teams. Two groups of variables were constructed from the data set for this study:
1. Variables concerning the organization of work: for example, team responsibilities, co-ordination, consultation, and authority.
2. Variables concerning the organization and content of training in teams: for example, team participation in training, available learning activities, specific focus on training for team-based work, amount of training.

Analysis of the first two research questions involved frequency distributions for the main work and training variables, clustering of teams in terms of their organization of work, and clustering of teams in terms of their organization of training.

For the third research question the training clusters and variables were related to the work clusters and variables. Cramer's V was used to determine the relationship between the work clusters and the training clusters, with Monte Carlo sampling procedures to test the significance of this relationship. In order to test the relationship between the work variables and the training variables Kruskal-Wallis tests were used (test statistic H).

Results

The results section is structured along the three research questions. First, the organization of work in our sample will be presented. Second, the focus will be on training for team-based work. Third, we describe the outcomes concerning the relationship between work and training in teams.

The Organization of Work in Teams

Respondents were asked to what extent various actors were responsible for different team tasks. The various actors include team members, the team leader, and external actors (e.g., managers and organizational staff members
positioned outside the team). Their responsibilities concern three sets of team tasks related to the production process:
1. **Regulatory tasks**: taking care of technical, logistical, quality, and personnel issues.
2. **Authority tasks**: deciding about the flow of orders, means, and personnel.
3. **Standard-setting tasks**: setting team standards, both on the individual and team level.

Table 2 presents the results for this question. In our sample of twenty-seven cases, team members often have responsibility for performing regulatory tasks. In large majority, team members are responsible also for decisions about the order and personnel flows. The team leader has responsibility mostly for deciding on the order and personnel flows and for setting the team standards. Actors outside the team have responsibility mainly for the regulatory tasks of the team.

Looking at the distribution of responsibilities among the various actors, most of the regulatory tasks are the responsibility of team members as well as actors outside the team. The team leader has some responsibility for logistical and quality affairs as well. In terms of responsibility for authority tasks, once again team members and actors outside the team are dominant. On average, however, outside actors have the largest responsibility for the flow of means. The team leader is responsible, to a moderate extent, for the order and personnel flows as well. Standard setting occurs in less than half of our sample. Responsibility for it is distributed evenly among the actors as far as the team level is concerned, but for the individual level it is mainly in the hands of the team leader.

For each of the twenty-seven companies, it was then determined to what extent team members, the team leader, and external actors were responsible for performing the main team tasks described in Table 2. Based on these data, four clusters of teams were distinguished that differ in terms of the division of work responsibilities among the various actors:

I. **Independent, self-directed work teams.** In these teams external actors have delegated responsibility for the main tasks to the team members, without making a team leader responsible. This cluster contains ten cases (37 per cent).

II. **Guided, self-directed work teams.** In this cluster both the team leader and members are responsible for the main tasks. Four cases from our sample fall into this category (15 per cent).

III. **Guided, partially self-directed work teams.** The team members and leader have responsibility for a number of tasks, however in this cluster their impact is limited by external actors. Two cases fit this description (8 per cent).

IV. **Externally directed work teams.** These teams are directed by external actors and have limited responsibility themselves for the main team tasks. This cluster contains eleven cases (41 per cent).

The Organization and Content of Training

This paragraph presents the data from our sample on team participation in training-related activities, types of training, specific focus on training for team-based work, and the amount of training.

**Team Participation in Training-Related Activities.** Respondents were asked to indicate the extent to which team members, the team leader, and external actors participate in three key training-related activities:

1. **Priorities:** establishing the priorities for team training.
2. **Needs**: determining the training needs for the team.

3. **Execution**: performing actual training activities.

Table 3 describes the results for this question. In most of the teams training issues are dealt with by team members themselves rather than by the team leader or by external actors. The latter do not participate in training-related activities at all in a majority of the cases. Team members have the largest impact when it comes to the execution of training. Both the team leader and outside actors have some involvement in establishing priorities and assessing training needs, but they play no role of importance in training execution.

Looking at the distribution of responsibility for training issues among the various actors, the execution of training seems to be a task mainly for the team members themselves (please note that no specific data are available about the participation of training professionals). Assessment of training needs and setting priorities for training occur less often, but can be the responsibility of any actor when they do take place.

Table 3. Participation of the Various Actors in Training-Related Activities (n = 25; missing data = 2).

</tbody>
</table>

For each of the twenty-five organizations, it was then determined to what extent team members, the team leader, and external actors participate in the three key training-related activities described in Table 3 (priorities, needs, and execution). Thus, a team participation pattern for training-related activities was determined in each case. Based on these data, three clusters were created that differ in terms of the way in which teams distribute the responsibility for training-related activities among the various actors:

I. **Teams with member-driven training.** In these teams the members themselves organize the main activities of establishing priorities for training, determining training needs, and executing training. The team leader and external actors are not involved in training. This cluster contains six cases (24 per cent).

II. **Teams with leader-driven training.** In this cluster the team leader sets the conditions (priorities and sometimes needs) for training. The team members are responsible for the execution of training, within the boundaries of that framework. In a few companies the team leader is involved in training execution as well. Ten cases from our sample fall into this category (40 per cent).

III. **Teams with externally driven training.** In these teams actors outside the team set the conditions (priorities and needs) for training. These external actors can be training professionals, personnel officers, and/or middle managers. The team members are involved only in the execution of training. Nine cases fit this description (36 per cent).

**Types of Training: Organization and Content.** Respondents were asked to indicate what part of team training is organized on and off the job, respectively. Table 4 shows these proportions for the teams in our sample. In only six cases (27 per cent) the proportion of off the job training (classroom based) exceeds one half. Fourteen companies (63 per cent) feature teams in which off the job activity constitutes just a small or moderate part of training. On the job training (in the workplace), on the other hand, represents a (very) large proportion of team training in thirteen cases (59 per cent), whereas only nine companies (41 per cent) report its proportion to be small or moderate. Roughly speaking, there is more on the job training in most teams than there is off the job training.

Combining the data on off and on the job training for each company, it is possible to determine whether the organization of team training is limited or multiple in character. Five companies (23 per cent) limit the organization of their team training mostly to off the job activities. In eleven cases (50 per cent) the organization of team training is limited mostly to on the job activities. A multiple organization of team training, combining on and off the job training in equal measures, can be found in six companies (27 per cent). Please note that no questions were asked about the proportion of non-formal or informal learning activities in the teams.

<td>8 (36%)</td>
</tr>
<tr>
<td>Very Large (&gt; 70 per cent)</td>
<td>0 (0%)</td>
<td>5 (23%)</td>
</tr>
</tbody>
</table>

Respondents were asked also about the content of team training, specifically to what extent team members are trained in preparation for new jobs, both initially and additionally. This can be regarded as an indication of the extent to which the content of team training is narrow or broad in nature. As Table 5 shows, 40 per cent of the companies organize both initial and additional job preparation training for all team members, resulting in a broad content profile. In 25 per cent of the cases, only some team members receive both initial and additional job preparation training ('moderate'), while 20 per cent organize only initial OR only additional training for job preparation ('narrow'). Three companies (15 per cent) offer no job-related training at all, only about specific topics (e.g., management, communication, and so forth).

<tr>
<td>Narrow (Only Initial OR Only Additional Job Preparation)</td>
<td>4 (20%)</td>
</tr>
<tr>
<td>Specific Only (Non-Job Related)</td>
<td>3 (15%)</td>
</tr>
</tbody>
</table>

Specific Focus on Training for Team-Based Work. Table 6 describes the extent to which training in our sample is specifically focused on the implementation of team-based work. In more than half of the cases only a small proportion of training has this focus, whereas just one company (5 per cent) devotes a large part of its training specifically to team-based work issues. Apparently, the implementation of team-based work does not lead to much specific training for team members.

Table 6. Proportion of Training Specifically Focusing on Team-Based Work (n = 21; missing data = 6).

<tr>
<td>Large (50-69 per cent)</td>
<td>1 (5%)</td>
</tr>
<tr>
<td>Very Large (&gt; 70 per cent)</td>
<td>0 (0%)</td>
</tr>
</tbody>
</table>

Amount of Training. Respondents were asked how many days per year their employees spend on training. As Table 7 shows, in 41 per cent of the companies employees spend less than six days on training each year. Six to ten days of training per year is taking place in another 41 percent of the cases, while the rest of the sample (17 per cent) even exceeds the ten-days per year limit.

The Relationship between Work in Teams and their Training

In this section conclusions are drawn about our three research questions and some points for discussion are raised.

How Is Team-Based Work Organized?

In our sample four types of teams can be distinguished. The largest cluster are the externally directed work teams, who have limited responsibilities for core team activities like performing regulatory tasks, authority tasks, and standard-setting tasks. Just behind in terms of numbers are the independent, self-directed work teams, where the team members have been delegated full responsibility for these tasks by managers and organizational staff members outside the team. Two smaller clusters emerged as well. First, in guided, self-directed work teams, the members themselves and the team leader share responsibility. Second, in guided, partially self-directed work teams, external actors share part of the responsibility for team tasks with the members and team leader.

It can be concluded that, even in our relatively small sample, quite a variety of different work teams can be found. This is a bit surprising, because for this survey no random sampling of companies was performed. Organizations were asked to participate if they were known to have implemented teamwork or to be well in the process of doing so. In view of this, the number of externally directed work teams in our sample is rather high. This finding is in line, however, with empirical studies by Benders (1999) and Dankbaar (2000), who concluded also that teamwork is not yet as widespread as often assumed.

How Is Training Organized in Work Teams?

Three training participation patterns were established in our sample, on the basis of the division of responsibilities for key training activities like priority setting, needs assessment, and training execution. The largest cluster are teams with leader-driven training, meaning that the team leader sets the conditions (priorities and needs) and the team members are responsible for the execution of training. The second largest group are teams with externally driven training, where managers and (probably) training professionals outside the team set the conditions and the team are involved in executing the training. The smallest contingent are teams with member-driven training,
who are fully responsible for all their own training arrangements and see no participation in training by the team leader or external actors.

There appears to be more on the job training in our sample of teams than there is training off the job. Only a small number of companies organize multiple forms of training, with significant training arrangements in place both off and on the job. Training content can be labeled broad, on average, in that a substantial number of organizations (40 per cent) offer all their team members initial and additional job preparation training. Most companies dedicate only a small proportion of their training to specific team-based work issues. The general amount of training for employees is rather large, however, ranging from six to ten days or more per year in almost 60 per cent of our cases.

It can be concluded that there is a diversity of ways in which teams organize their training. As with the organization of work, however, team-driven training is less prominent than perhaps expected. The organization and content of team training show considerable variation, in many respects, across the cases in our sample. It is not very surprising that on the job training occurs more often than off the job training, nor that few companies pay a great deal of attention to specific training for team-based work. In this connection it is good to note, however, that the survey did not contain any questions about non-formal and informal learning in teams. One would expect these activities to take place rather frequently, certainly relative to formal training arrangements (Marsick & Watkins, 1990).

Are Teamwork and Team Training Related?

This is probably the key question in the current study, and it yields quite a surprising answer. In no way have we been able to establish a relationship between the organization of work in teams, on the one hand, and the organization of team training, on the other hand. The four types of teamwork that emerge are not related to the three training participation patterns that can be distinguished (cf. Table 8). To put it differently, the division of work responsibilities among team actors is not connected to the way in which team training responsibilities are distributed. Moreover, all other training variables in our study (cf. Table 9) show no significant relationships to the teamwork clusters, either. Even when training variables are correlated to work variables at item level, results of which are not presented in this paper, only a random pattern of 'statistically significant' (but theoretically irrelevant) relations comes up.

Although surprising in view of the idea that teamwork provides a better learning environment than traditional work systems (Ellström, 2001; Tjepkema, Kessels, & Smit, 1999; Onstenk, 2001), the findings are largely in line with the small number of other empirical studies on this topic. The high expectations concerning performance, opportunities for participation, member satisfaction and motivation in teams are not met in practice (Boot & Reynolds, 1997; Poutsma, 1998; Russ-Eft, Preskill, & Sleezer, 1997). What is more, the alleged learning potential of teamwork is only scarcely supported in empirical investigation (Van Klaveren & Tom, 1995; Hoogerwerf, 1998; Willis & Boverie, 1998).

Limitations of the Study

It has to be noted that the survey used for our secondary analysis did not contain any questions about non-formal or informal learning, only about on and off the job training. For a more comprehensive understanding of the relationship between teamwork and learning processes in teams it would be good to include such topics in future surveys.

Another limitation of this study lies in the fact that the main respondents were personnel and production managers only, who were asked mainly about the system of teamwork. In order to get an in-depth view of learning taking place in teams it would be good to interview team members, team leaders, and training professionals as well, and to ask more questions about actual learning processes that occur.

Implications of the Study and Contribution to New HRD Knowledge

Even taking into account its limitations, this study raises serious questions about the prevalence of teamwork as a context for learning. First, how come work in so many teams is other than self directed? Second, why are training priorities and needs assessment the responsibility of team members in so few cases? Third, and most interesting, what does it mean that the variation in team training is not related to the variation in teamwork?

One would expect, certainly following the ideas of Ellström (2001) about learning-intensive work systems, that self-directed teams would have different, if not better, training arrangements in place. For example, extensive participation of team members in training, a multiple organization of team training, a broad training content, specific training for team-based work, a large amount of training. But none of these occur more frequently in the self-directed teams within our sample. In fact we found no differences in training variables to be related to differences in the organization of teamwork. There is no evidence, from our study, that self-directed teams provide a better, or even
different, training context to their members than, for instance, externally directed teams do. The organization of work and the organization of learning, to a large extent, have their own dynamics. Going one step further, there would be little reason to justify the implementation of team-based work solely by claiming that the learning potential of work will improve. There may be other promising ways to put 'learning' high on the agenda of enterprises. In other words, we should be more careful to proclaim teams as the work type for future 'learning organizations'.

All this does not explain why the implementation of teamwork and the organization of team training are apparently unrelated. This may have to do with the fact that in team learning literature (e.g., Ellström, 2001; Onstenk, 2001) most attention is paid to the organization of work and to the structural conditions for collaboration and communication in teams. Relatively little is known as yet about the actual processes of ('informal') learning that takes place in work teams, about the viewpoints on learning of the team members themselves, about their perceptions of learning opportunities and blockages, about the practical strategies that they employ in order to learn what they deem necessary and how they see fit. Future research should focus also on these elements to provide a richer picture of team learning in companies.

This case study explores the learning outcomes for the virtual team that planned the 2001 Future Search Conference for ASTD and AHRD. Team members completed the Global Process Team Questionnaire (GTPQ) and participated in interviews to determine effectiveness factors in team design, individual inputs, and process criteria. Results indicate that pre-existing relationships established trust in the virtual environment and supported the workload according to individual talents and interests.

Keywords: Virtual Teams, Collaborative Learning, Future Search Conference

This case study explores collaboration in a virtual team environment for the nine members who planned and organized the 2001 Future Search Conference that was sponsored by the American Society of Training and Development (ASTD) and the Academy of Human Resource Development (AHRD) in Orlando, Florida. A Future Search Conference is a large group strategic planning process that brings together key stakeholders in an attempt to get the “whole system” in the room to envision a desired future for a task of vital importance to an organization or community (Weisbord, 1992; Weisbord & Janoff, 2000).

In February 2001, the ASTD Research-to-Practice Committee, composed of a mix of practitioners, consultants, and academics, met to develop a conceptual outline for a Future Search conference to inform the HRD profession of the future of workplace learning and performance. The execution of the project was assigned to a team of volunteer ASTD members, dubbed the Future Search Steering Group (FSSG). This team, with the assistance of a Future Search facilitator, had four months to put together the conference without benefit of a face-to-face meeting. The conference was successful and currently serves as the foundation for continuing work within ASTD and AHRD. This case study describes the experiences of the FSSG team and provides useful lessons on collaboration in a virtual environment.

Problem Statement

Very little formal research has explored the effectiveness of virtual teams (Furst, Blackburn, & Rosen, 1999), even though trends towards globalization and enhancements in communication technology have made virtual teaming an integral part of most small group work (Katzenbach & Smith, 2001). Different time, space, and culture factors add to the complexity of collaboration in a virtual environment (Duarte & Snyder, 2001; Fisher & Fisher, 2001). In addition to these factors, the Future Search planning team was composed primarily of volunteers, an aspect of team participation that has received little or no attention in the research literature.

Theoretical Framework

There have been a number of theoretical frames applied to explain the functioning and effectiveness of teams, including developmental stages (Tuckman, 1965), punctuated equilibrium (Gersick, 1988), social exchange theory (Hollender, 1978), and process structuration theory (Giddens, 1984). One theoretical model, the Ginnett’s Team Effectiveness Leadership Model or TELM (Ginnett, 1996; Hughes, Ginnett, & Curphy, 2002), has been developed specifically to examine the variables impacting team effectiveness in a business context. Figure 1 provides a diagram adapted from the TELM model.

Based on the work of Richard Hackman (1990) and refined through field research at the Center for Creative Leadership, the TELM model uses a general systems theory approach in the study of teams. In a simplified version
of Ginnett's (1996) model, individual, team, and organizational factors identified as inputs to the system are displayed on the left in Figure 1. Process or throughputs (i.e. what one can tell about the team by actually observing the team members at work) occupy the center of the model; and outputs (i.e. how well the team did in accomplishing its objectives) are shown on the right side of the figure. In this model, team leadership establishes the vision (or "dream") for the work, guides the design function, and attends to development issues related to skills and process.

In this case study, we limit our focus on only those factors in the model that our experience can illuminate: two input factors (team design factors and individual inputs) and team process factors. These three areas are highlighted in bold in Figure 1 to illustrate the focus of our inquiry. The reasons for this limited focus are twofold. First, the organization inputs for a volunteer team of this nature were minimal. We had no organizationally sponsored control systems, including reward, education, or information systems other than international dialing access for teleconference calls. Five core members of the steering group and the Future Search facilitator who assisted them were geographically dispersed volunteers, including one member located in London; three other steering group members worked directly or indirectly for ASTD in the Washington, D. C. area. The six unpaid volunteers contributed more than two-thirds of the time, effort, and energy that resulted in a successful conference. Team leadership came from within the volunteer membership of the team and was not an organizationally assigned function.

Second, this is an exploration of process, individual, and team design factors that contribute to effectiveness rather than a study of team outcomes (the team "outputs" of the model). We take the effectiveness of the team to be an outcome achieved only in part, since the work of the Future Search conference is still ongoing. Conference attendees have been invited to participate in an extension of the dialogue that was begun in Orlando through online forums, and work is currently being undertaken to use the conference outcomes in the development of a book and other published materials. Instead, we focus here on factors that contributed to success in planning the Future Search conference in a virtual environment in which Email and teleconferences were our primary modes of communication.

One role of case studies is to test theory (Yin, 1994). The purpose of this exploratory study was to compare and contrast the experiences of the Future Search Steering Group to specific aspects of the TELM, using the model as a theoretical guide. Our goal was to draw some prescriptive lessons that can be applied by volunteer groups working in a virtual environment in the future. The study was guided by the following research questions:

- How did the experiences of the Future Search Steering Group fit with the TELM?
- How did team design, individual inputs, and process factors contribute to team effectiveness?

Methodology

Most case studies rely on multiple methods of data collection to ensure validity and reliability (Creswell, 1998). Two types of data were collected from the nine members of the FSSG during two months that followed the conference planning. Telephone interviews, lasting approximately one hour, covered the following: (a) the process of what makes a virtual planning experience successful; (b) individual factors contributing to motivation and commitment to participate in virtual planning; (c) team design factors, including leadership aspects of virtual collaboration; and (d) perceptions of group-level (collective) learning processes. All interviews were conducted by the same researcher, one of the paper's authors. Each team member was asked 13 open-ended questions, followed by probing questions for clarification, when necessary. All conversations were taped and professionally transcribed, resulting in 75 single-space pages of data.
Team Effectiveness Leadership Model
(adapted from Ginnett, 1996; 2002)
The FSSG members also completed ITAP International’s Global Team Process Questionnaire (GTPQ), a diagnostic instrument designed to help teams improve their effectiveness and productivity (Bing, 2001). As with all teams who use the instrument, this version of the GTPQ was customized for use with the FSSG. The instrument consisted of 19 close-ended items assessing such factors as equality of work distribution, clarity of team objectives, group communications, trust, conflict resolution, and leadership. Each item included a section for additional comments. The GTPQ questionnaire has been thoroughly tested for reliability and validity with global teams in the pharmaceutical, consumer products, and information technology fields for more than five years. For purposes of the questionnaire, a global team is one with members located in more than one country or one that has members from more than one country temporarily working in the same location (Bing, 2001). Mean scores were obtained for the GTPQ close-ended items. Transcriptions of the taped telephone interviews and open-ended comments from the GTPQ were content analyzed for overriding themes by the paper co-authors.

Results and Findings

Four major themes emerged from the interviews and open-ended comments on the GTPQ within this virtual, geographically dispersed team: (a) the importance of energizing and highly effective leadership; (b) intrinsic rewards that motivated individuals; (c) the necessity of a trustful environment, and (d) specific "enabling" virtual communication techniques and protocols. These will be described and related to three aspects of the TELM: team design, individual input factors, and process criteria.

Team Design Factors

Team design factors relevant to the TELM model included a narrowly focused task (organize a Future Search conference with 64 key leaders in the field of HRD); a tight deadline (four months); and volunteer FSSG team membership from within ASTD's Research-to-Practice committee. The nine-member FSSG team was composed of five core members, one volunteer facilitator from outside the ranks of ASTD, two ASTD research officers in liaison roles, and one member in an ASTD administrative role. A clear line of "authority" in the form of team commitment to the success of the project for ASTD and AHRD existed, although the sponsoring organizations exerted little, if any, formal control mechanisms.

Of these design factors, the volunteer composition and the energizing and shared leadership within the team were credited with successful completion of the task. At first blush, the volunteer nature of the team appeared happenstance, with one member noting that "when we put the team together we gave no real consideration to the relative strength or the working styles of the individuals." However, interviews revealed subtle self-selection criteria among those who volunteered: (a) keen interest in an intellectually stimulating project; (b) desire to contribute to the field of HRD; and (c) desire to enhance working relationships with valued colleagues.

Team members reflected on what kept them going as the project grew in size and intensity, with some spending as much as 20 hours a week outside of their regular jobs at the peak of activity. Working with respected colleagues was a key factor: "I've been more motivated by the chance to work with [team members] than I have the thought of we're going to put a fantastic book out ... I get a lot from the relationships ... on the steering group."

This desire to work with "a finely tuned team of professionals" was, for many, a compelling reason to join the FSSG, but all acknowledged that what maintained the team's momentum was energizing and highly effective leadership, a role that was shared by several team members. Early on in the project, the member who had volunteered to lead the team began clustering various tasks into "blocks" of work; team members volunteered to spearhead a block of work and were called "blockheads," a term that was one of the group's many inside jokes. Dividing up the task and then monitoring the resulting progress became a coordinating leadership role that was essential to effective team management. Team members agreed, however, that leadership actions were dispersed, with the informal leadership role within the group assumed primarily by another member of the team. Instead of vying for competing roles, team members welcomed others' leadership efforts and attributed this to the volunteer nature of the team:

"Given the nature of the project and the fact that we're all volunteers, I think you've got to have somebody who's pushing it forward all the time ... we each divide up the work and take on difference components but [team member A] invariably will jump in and do a little bit just to shove it along ... it always seems to be good stuff and it tends to make you think and keep pushing a little harder yourself."
Individual Factors

While energizing and shared leadership and the volunteer nature of the team were deemed essential team design factors, individual input factors also contributed heavily to successful task completion. The TELM model considers interpersonal behaviors as the foundation for individual inputs and a direct function of team members' interests, motivations, skills, abilities, values, and attitudes. For the members of this virtual team, individual factors provided intrinsic rewards and created a trusting environment that made success possible.

One of the GTPQ questions specifically asked about the equitable distribution of such intangibles as participation, project visibility, authorship of the book, and editorship of papers and conference articles—all motivational factors in the minds of team members. Most team members agreed that everyone had an opportunity to contribute in areas that interested them—"everyone gets a piece of the action"—while one member noted "it's not an issue of trying to be greedy and hog all the glory (none of us has time for it) ... [but] I think some of us have more visibility in certain areas ... this is a high-stakes issue because a book authorship is an extremely tangible professional accomplishment." Learning about the Future Search methodology (Weisbord, 1992; Weisbord & Janoff, 2000) and learning about teamwork in a virtual environment were motivating factors, as well:

I've also learned how an ongoing virtual conversation ... can contribute to collective efforts that far exceed what any one individual can do ... this has been a tremendous learning, for my experience in face-to-face task forces and group efforts had led me to believe that a few people usually do all or most of the work. Here the work was truly shared according to each person's ability to contribute.

An attitude of respect for professional colleagues permeated the virtual experience for team members. Each had an opportunity to contribute his or her own special interests and talents, and each trusted that others would see their portion of the work through to completion. The ability to do high-quality individual work that was then brought back to the team for discussion was a repeatedly mentioned theme: "For a project of this complexity to work, you've got to have people on the team that can run with whatever their passion is ... for the team to disperse and people to be doing their thing and bring it back and let the team crunch on it."

Good written and oral communication skills proved essential in a virtual conversation. Clearly, members realized that it was important that they make allowances for different modes of individual expression and create what one called an attitude of "slack": "There's something around creating slack ... Giving people the benefit of the doubt when they appear to be on your territory or saying something that's negative." Thus, motivated by an opportunity to work with respected colleagues, to share in tangible outcomes according to each team member's interests and abilities, and to learn from one another created the necessary trust for virtual collaboration.

Process Criteria

In addition to team design and individual inputs, our lessons learned came from many process factors, some of which we stumbled into and others that we created intentionally. The TELM model considers process criteria to be the effort expended, the knowledge and skills brought to bear, the planned strategy or techniques adopted, and the group dynamics that emerge from collective action.

Pre-existing relationships among the Research-to-Practice committee members that had been established in a face-to-face environment proved essential to commitment in a virtual one. Telephone conferences added the emotion of tone and voice to messages exchanged electronically, and, most importantly, humor created and sustained a shared group culture that grew through the weeks of conference preparation. One member referred to the "lubricant of a keen sense of humor" and noted that it was hard to get tense in a flurry of metaphors and one-liners. "I think the teleconferences ... help glue things together for us. They re-establish ...you can hear the chuckle that goes with the joke." Without the pre-existing relationships, most doubted that the team would have been able to collaborate so easily and with such clarity.

All acknowledged that more was shared in this team culture than the occasional humorous remark that lightened the workload: Each team member's commitment to the task and to the other members functioned to prop up the group as a whole and maintained a "high level of intensity" without a long lag time between virtual meetings or E-mail exchanges. Emails were characterized as "rapid fire." No sooner did a message go out than a flurry of responses picked up the dialogue exchange. While conducive to capturing the flavor of real-time conversation, this also proved disconcerting at times for our London colleague.
Every now and then I'd go to bed at ten o'clock which is five Eastern [time] having checked all my E-mails and being up to date and while I'm asleep dialogue is taking place in North America ... And I wake up the following morning ... and see that the dialogue has changed quite drastically as a result of ten different E-mails going back and forth ... I sit there and say, "I've missed this. I feel like I've got to take them back a step in order to say what I would have said..."

It was in this process area that we also recognized our most serious shortfalls. In the world of virtual teams, we were decidedly low-tech, relying heavily on E-mail and teleconferences as our primary communication mechanisms. In retrospect, all acknowledged that we could have benefited greatly by using an electronic bulletin board or some form of virtual collaboration software, such as WebEx® that provides chat rooms for synchronous conversations. The deluge of E-mail traffic was overwhelming at times: "It was tough to stay on top of them. If you took a few days off and didn't have E-mail access and you suddenly came back, you were 30 to 60 E-mails behind."

Many of the process techniques we adopted became enabling structures and protocols that evolved over time as we worked together in a virtual environment. We discovered that a pre-set agenda, sent out by E-mail the day before a teleconference, was essential to effective time management. Not only did it allow the blockheads to summarize their work ahead of time for all to read in advance, but also team members were able to pose questions for the group to consider before a scheduled call. This process allowed us to tackle a sizable number of items in an hour and a half teleconference and come to resolution on them. Dates and times for the calls were set after posing alternatives and letting the group decide on those most convenient for everyone, as opposed to a time that was established by team leadership. Teleconference calls were also planned well in advance for scheduling purposes. During the call, the formal team leader kept notes on actions agreed upon during the call, placing them right into the text of the agenda in bold highlighted text. Within minutes after completion of a teleconference, the team leader sent out a revised copy of the agenda by E-mail with the actions agreed upon highlighted. This allowed anyone who missed a call to be quickly brought up to date.

Overall, team members credit advance organization, pre-planned and electronically distributed agendas, follow-up agendas annotated with action items sent immediately after a teleconference and a lively and active interchange of E-mail dialogue as processes that enabled them to reach their goals. These enabling protocols, however, were only mechanical processes. Individual attributes, skills and abilities, shared commitment, and desire to contribute to the field provided the relational processes of virtual collaboration, and they proved to be as essential as any mechanical techniques.

Discussion

When we examine our first research question about how our experiences in virtual collaboration compare with the TELM model of team effectiveness (Ginnett, 1996; Hughes et al., 1999), we find that the three elements of team design, individual inputs, and process criteria were all essential to successful task completion. Each element functioned similarly to the model's basic design: individual inputs contributed to team design, which, in turn, affected the process criteria of effort, knowledge, skills, and strategy. These process criteria were supported by highly effective group dynamics within the team.

In contrast to the model were our experiences in organizational input factors. As a volunteer group, we came from many different organizations within both public and private sectors, and we were largely a self-directed and self-supported team. The TELM control system factors, such as reward systems, educational, and informational systems that comprise the usual organizational inputs, were missing from our collective experiences. However, we all understood that ASTD and AHRD had specific expectations for sponsoring the Future Search Conference and we acknowledged collective responsibility for delivering results that would be deemed worthwhile. In addition, ASTD provided the funds to support the conference and the administrative resources to ensure its logistical success. One of our team's members was heavily involved in administrative staff support on behalf of ASTD and two others provided key roles as ASTD research officers. Without their sponsorship, the team would not have been able to function as effectively as it did to ensure a successful conference outcome.

Our second research question asked about the respective contributions of team design, individual inputs, and process factors to team effectiveness. Among team design factors, we found that a clearly defined task with a short time frame for task completion and a high stakes outcome created compelling momentum for this virtual team. Volunteer membership permitted self-selection based on individual interests, motivations, and personal desires for professional recognition and contributions. Norms, developed through membership in ASTD's Research-to-Practice committee, already existed, and we were able to build on them, creating a shared vocabulary that formed the basis
for many humorous exchanges that lightened the workload and alleviated tension. This, in turn, sustained a healthy team culture.

The most important of individual inputs that contributed to effectiveness were team members' shared motivations to participate in the effort. Collectively, we were motivated by opportunities to work with respected colleagues, to enhance academic publishing in a variety of forums (e.g., book chapter authorship, conference presentations), and to contribute to the field of HRD in a meaningful way. We believe that the importance of shared motivations in accomplishing our task cannot be underestimated. Shared motivations created a powerful synergy among team members and encouraged individuals to contribute specific skills and abilities, including leadership talents. They formed the basis of a trusting team environment.

Among the process criteria that contributed to our effectiveness as a team, we believe that the combination of individual talents, knowledge, and skills resulted in a team culture with well-established, effective group dynamics. Team leadership was an important aspect of our group dynamics. With prior knowledge of the specific strengths and potential contributions from various members, team leadership (both formal and informal) designed strategy to utilize team member strengths fully. Shared leadership was also effective in dispersing effort among team members, so that no one individual carried the whole load.

Conclusions and Recommendations

When Future Search methodology was adopted for strategic planning to explore the future of workplace learning and performance, volunteers in ASTD's Research-to-Practice committee had little virtual team experience in collaboration. The tight four-month timeframe for organizing the conference meant that team members had to jump into the process without much pre-planning. We used the tools that each of us had readily accessible: electronic communication via E-mail and the telephone for conference calls.

Instead of the organizational reward systems typically used to enhance motivation and encourage productivity, we had our own personal interests and the support of two professional organizations that we were all committed to seeing successful in their endeavors. We saw the Future Search planning project as an opportunity to work with respected colleagues, to enhance professional relationships, to involve ourselves in an intellectually exciting learning endeavor, and to collaborate in publishing conference outcomes. These individual factors proved to be powerful motivators. They shaped the team design as a configuration of equals and gave rise to our collaborative processes. As a result, we spent more than 1,300 hours outside of our regular jobs to accomplish our task, often working late at night or early in the morning. We exchanged more than 2,000 E-mails and gobbled up more than 17 megabytes of hard drive space on each of nine computers. We experienced the frustration of a barrage of E-mail traffic that often appeared when we had the least amount of time to deal with it. With the completion of the conference event, our work was deemed successful by our sponsoring organizations. It continues to provide the organizing framework for ASTD and AHRD efforts to shape the future of workplace learning and performance.

What would we do differently next time? Certainly, more sophisticated tools for virtual collaboration exist; we regret that we did not pursue them early in our organizing processes, for they would have undoubtedly enhanced the online nature of our dialogue, saved hard drive space, and avoided E-mail overload.

What would we recommend repeating in future virtual collaborations? Volunteer membership, strong and respected leadership dispersed among team members, shared personal motivations for success, and organizing techniques such as pre-planned agendas and post-conference call summaries. Most importantly, our first-hand personal knowledge of each other allowed us to build upon our relationships when relying on virtual methods.

Contribution to New Knowledge in HRD

In an increasingly global world, organizations are likely to use advanced communication techniques to create groups that work in virtual time and space. This case study provides evidence that, in spite of today's technologically sophisticated means for virtual collaboration, human relationships are essential for effectiveness in a geographically dispersed team. Face-to-face relationships sustained our diversity in experiences, perspectives, and written and oral communication styles. Organizations need to consider how to provide a time and place to establish such relationships, or, conversely, how to take advantage of existing interpersonal relationships when establishing virtual teams. Our experience has taught us that relationships among virtual team members are essential for successful outcomes.

Learning at the Top: An Investigation of Nonprofit CEOs’ Learning Experiences

John J. Sherlock
University of Maryland University College

This study explored the learning experiences of nonprofit CEOs. Mezirow’s theory of adult learning was used as a framework of inquiry. While the CEO’s “professional context” is considered unique from other executive positions, it was unclear how that unique context might impact CEOs’ learning. The findings suggest that both the content and the processes of CEO learning are impacted in profound ways by the politically-charged context in which the nonprofit CEO must perform.

Keywords: CEOs, Nonprofit Context, Adult Learning

Executives in organizations are striving to help their organizations succeed amidst increased competition, rapid change, and increased environmental ambiguity (Kotter, 1988; Vaill, 1996). A characteristic identified in the research of executives who prosper during challenging times is the ability to learn from experience (Bennis & Nanus, 1985; Dechant, 1990; Hall, 1986; Kaplan, Drath, & Kofodimos, 1987; Kolb, 1976; McCall & Lombardo, 1983). These studies, however, have focused primarily on senior executives, not the CEO. Yet, there is considerable support for the assertion that an organization’s chief executive (CEO) plays a key and unique role in an organization’s success (Bennis & Nanus, 1985; Burns, 1978; Jaques & Clement, 1991; Kaplan et al., 1987; Yukl, 1999). Further, several researchers have found that CEOs’ ongoing learning is important to their success and their organizations (Bennis & Nanus, 1985; Goldsmith, 1996; Margerison & Kakabadse, 1984; Pincus & DeBonis, 1994; Senge, 1990).

This lack of understanding of how CEOs learn has negative workplace implications for both CEOs and the organizations they serve. It produces an information void for both the CEO seeking self-development, as well as executive development practitioners who seek to facilitate CEO development in both current CEOs and potential successors. This paper describes research that explored the learning experiences of nonprofit CEOs incorporating an adult learning theory as a framework of inquiry. The next section begins by reviewing the literature addressing the uniqueness of the CEO context, as well as particular aspects of the nonprofit CEO context. The section concludes with a description of Mezirow’s adult learning theory.

Uniqueness of the CEO Context

“Professional context” was operationalized for this study to mean serving as CEO in a nonprofit association. An individual’s professional context is an important dimension of one’s overall context, defined in the adult learning research as the personal and sociocultural factors that play an influencing role in the process of learning (Clark & Wilson, 1991; Sveinunggaard, 1993; Taylor, 1997). Serving as CEO in an organization, it is asserted, constitutes a professional context that is unique from serving in any other executive capacity. The CEO, as the highest ranking staff member in an organization, has the highest level of staff accountability for achieving organizational goals. Additionally, while non-CEO executives often have significant responsibilities in an organization, non-CEO positions do not match the breadth of the CEO position (Pincus & DeBonis, 1994; Sonnenfeld, 1988; Yukl, 1999). The uniqueness of the CEO’s responsibility and accountability for the organization’s performance produces unique power dynamics between: 1) The CEO and the staff reporting to him/her; and 2) The CEO and the Board of Directors to whom the CEO reports.

CEO-Staff Power Dynamic. As the highest-ranking individual in an organization, the CEO operates in a professional context where the power associated with their position influences the majority of their interactions with staff. Power is defined for the purposes of this study as the capacity to affect organizational outcomes (Mintzberg, 1983). Daily & Johnson (1997) assert that while top management teams clearly have organizational influence, the CEO “occupies a position of unique influence in the firm” (p.98). Mintzberg (1983) draws a similar conclusion in stating that while managers who report directly to the CEO may be the second most powerful influences in the organization, they are a “distant second” (p.126). When the CEO talks, employees have good reason to listen. Even the CEO who has little interest in exercising power cannot avoid the power issues inherent in the CEO.
position. The result of the CEO possessing this degree of power is that it has real or perceived effects on the CEO-staff relationship and creates a unique context in which the CEO must learn how to perform.

CEO-Board Power Dynamic. A CEO's unique context is perhaps most exemplified in the reporting relationship to the board. Prior to becoming a CEO, the senior executive typically reports to a single supervisor who is an employee of the organization. In sharp contrast, the CEO reports to a board of directors made up of individuals who are generally not employees of the organization. The concept of a governing board is used in almost all complex organizations, from welfare agencies and private schools, to hospitals and for-profit and nonprofit organizations (Mintzberg, 1983). While the board generally has the authority to remove a CEO, whether that occurs is often a function of influence, relationships, perceptions about performance, and political action (Alexander, Fennell, & Halpern, 1993; Fredrickson, Hambrick, & Baumrin, 1988; Weisbach, 1988).

The CEOs in this study were all CEOs of nonprofit associations. While nonprofit association structures are like many for-profit organizations where the CEO reports to a board of directors representing the “owners,” the limited research in this field suggests that the power dynamics between the nonprofit CEO and his/her board is even more intense (Mintzberg, 1983; Wood, 1996; Zald, 1965). Nonprofit associations, characterized by ever-changing volunteer board members and the lack of a primary profit motive like for-profit entities, often have decisions being guided by politics and personalities. How CEOs perceive and describe their learning experiences in this unique context was the purpose of this phenomenological study.

Mezirow’s Theory of Adult Learning and Context

Mezirow’s (1981) theory of adult learning was used as a framework of inquiry to explore the CEO learning phenomenon from an adult learning perspective. Mezirow’s adult learning theory focuses on construing meaning from experience as a guide to action. His concepts of learning are unique when compared to other theories of adult learning due, in part, to the complexity, multiple levels of learning, and integrated system of knowledge presented (Clark & Wilson, 1991). Below is a brief description of the key concepts of his theory.

Ways of Making Meaning. Mezirow describes learning as occurring within two domains: The meaning scheme and the meaning perspective. Meaning schemes are particular beliefs, value judgments, and attitudes. They are a more specific dimension of one’s broader frame of reference or meaning perspective. A meaning perspective is comprised of clusters of meaning schemes. A meaning perspective is a broad frame of reference adults use to make meaning of the world and does not change often. Mezirow refers to a change in meaning perspective as a perspective transformation. Mezirow distinguishes between learning to manipulate the environment (“instrumental learning”) and learning to understand what others mean (“communicative learning”). He points out that adult learning often involves both instrumental and communicative learning types of learning.

Role of Reflection. Mezirow regards reflection as an essential element of his adult learning theory. He emphasizes that individuals must critically reflect on the premises of their beliefs as part of the process to validate, modify, or transform them. For Mezirow, all reflection should involve a critique. Mezirow states that reflection is not the same as introspection. He argues that introspection refers to simply becoming aware of the fact that we are perceiving, thinking, feeling, or acting in a certain way. Reflection by an individual, Mezirow asserts, goes beyond awareness and involves a critique of assumptions to determine whether a belief, often acquired through cultural assimilation in childhood, remains functional for the individual as an adult. He adds that most reflection occurs during problem solving and that the most powerful learning occurs when adults reflect not on the content of the problem or the process involved in solving it, but on the premise underlying the problem.

Role of Discourse. His theory of adult learning also emphasizes the importance of discourse to making meaning. Mezirow’s thinking on the rational discourse is based in part on the notion of rationality of Habermas (1971). Mezirow (1991) describes Habermas’ thinking about rationality as the “the process of achieving mutual understanding by active participation in advancing and objectively weighing evidence and assessing the cogency of supporting arguments” (p.26). Mezirow’s concept of rational discourse has a number of ideal conditions, including that participants have accurate and complete information, are free from coercion, are open to alternative points of view, and are willing to accept a resulting best judgment. His emphasis on rationality in discourse has been criticized (Clark & Wilson, 1991; Cranton, 1994) for pursuing what is unattainable and for not acknowledging other ways of reaching understanding. Mezirow acknowledges that such conditions are difficult to attain but maintains that they are the conditions under which learning can best occur.
Role of Context. Mezirow asserts that learning can only be understood as situated in a specific cultural context. However, researchers of Mezirow’s theory have suggested that the role of contextual factors in Mezirow’s theory be explored further (Clark & Wilson, 1991; Taylor, 1997). This study, thus, not only provided a useful framework of inquiry into the phenomenon of CEO learning, but also served to develop further the role of context in Mezirow’s theory.

Research Question

Using Mezirow’s theory of adult learning as a framework for inquiry, how do CEOs perceive and describe their learning experiences?

Method

This study employed a phenomenological research design to explore how CEOs perceive and describe their learning in the CEO context. There are various techniques and variations of method within phenomenology, but all the approaches have certain commonalities (Sanders, 1982). They all are based on the premise that, for any phenomenon, there is a common underlying structure or “essence” which can be explicated from individual descriptions of those experiencing the phenomenon (Creswell, 1998).

Data Collection. This study utilized Seidman’s (1998) in-depth interview method as the primary data collection technique. Seidman’s philosophy regarding interviewing is phenomenological in its orientation and consistent with this study’s approach. Perhaps most distinguishing of all its features, Seidman’s interviewing model involves conducting a series of three separate ninety-minute interviews with each participant. The initial interview created a historical context of the participants’ learning experiences through reconstructing and describing past learning experiences up to becoming a CEO. The second interview allowed the participants to reflect on their learning experiences as CEO. The third interview was structured to allow participants the opportunity to reflect on the meaning of their learning experiences and to consider the implications of those meanings. During this third interview, CEOs were invited to reflect further on the differences between their CEO and pre-CEO learning experiences and the perceived influence of the CEO professional context on their learning. Seidman’s (1998) suggestion that phenomenological interviewers use primarily open-ended questions was followed in this study. All interviews were audio taped and transcribed verbatim. Nearly 3,000 pages of interview transcripts were generated.

Sample. This study included a sample of twelve CEOs of nonprofit associations. Despite the significant economic impact of associations nationwide, little formal research has been conducted on association executive learning. The researchers’ knowledge of and work experience with nonprofits was helpful in overcoming the typical challenges associated with gaining research access to “business elites” who serve as CEOs of their associations (Dexter, 1970). The sample was limited to individuals who had been CEOs of associations for no less than two years but no longer than seven years. These parameters on CEO experience were chosen based on comments from an expert sampling of CEOs who suggested that the time span of 27 years would be appropriate, from the perspective of both sufficient time in the job to be “settled” and recent enough CEO experience to be recalled. The final sample included eight men and four women, one of whom was a minority. This mix of gender and ethnicity closely reflects the association CEO gender and ethnic profile within the United States (ASAE, 1997).

Data Analysis. Because the research question invites analysis in two domains, executive development and adult learning, two sets of data analyses were utilized to promote the clearest understanding of the phenomenon. First, the study examined the influence of professional context on CEO learning experiences using Mezirow’s (1991) theory of adult learning as a framework of inquiry. Coding and thematic analysis techniques (Patton, 1990) were used to analyze the influence of the CEOs’ unique professional context on key dimensions of Mezirow’s learning theory. Then, employing an inductive approach, the researcher used Moustakas’ (1994) method of analysis of phenomenological data to develop a composite textural-structural description, or “essence,” of the learning experiences of the twelve CEOs studied. The method places an emphasis on the researcher first reflecting on their own experience with the phenomenon and striving to bracket out any biases (referred to as the “epoche” process) prior to analysis of participants’ data. Following the epoche process, the researcher engaged in the following phenomenological data analysis steps:

1. Considered each statement in a CEO Participant’s interview transcript with respect to significance for the description of the phenomenon of nonprofit CEO learning (i.e., “horizontalization”).
2. Formulated "invariant meaning horizons" by explicating the meaning of relevant statements. These invariant horizons point to the unique qualities of the CEO learning experience.

3. Related and clustered the invariant meaning horizons into themes of CEO learning.

4. Synthesized the invariant meaning horizons and themes of CEO learning into descriptions of the "textures" of the learning experiences for the CEO participants. The textural description ("noema") is often referred to as the "what" of the phenomenon.

5. Through phenomenological techniques of "imaginative variation," constructed the structural descriptions of the experience. The structural description ("noesis") is often referred to as the "how" of the phenomenon.

6. From the textural and structural descriptions of the participants' learning experiences, constructed a composite textural-structural description of the meanings and essences of CEO learning. This step integrates all of the other steps in the phenomenological process to produce a universal description ("essence") of the learning experiences representing the group of CEOs as a whole.

This use of two analysis types made it possible to add to our understanding of the two theoretical areas of adult learning and executive development.

Limitations. This study was based on a small sample of nonprofit association CEOs, and, therefore, the scope of the study is limited and may not be transferable. Further, the study is limited in that it relies on the willingness and ability of the participants to discuss their personal learning experiences. Efforts were made to address this limitation by conducting three ninety-minute interviews, which provided considerable face-to-face time to establish not only rapport, but also a high level of comfort with the researcher and the subject matter being discussed.

Trustworthiness. Lincoln & Guba (1985) assert that the qualitative researcher can enhance the trustworthiness of the study within the process of inquiry itself. This includes researcher actions to produce "prolonged engagement" and "persistent observation" so that the most relevant factors become apparent. Seidman's (1998) in-depth phenomenological interview method, involving three separate ninety-minute in-person interviews, provided the researcher with the opportunity for both prolonged engagement and persistent observation. Moustakas (1994) also suggests enhancing trustworthiness by utilizing participant-feedback. This procedure involves the researcher sending to participants copies of the textural-structural descriptions of their experience and the group's experience as a means of validating the data. The twelve CEOs in this study each received the textural-structural description of their individual learning experiences, as well as the synthesis description of CEO learning, and were asked for any corrections or additions. This approach is also consistent with the suggestion of "member checking" suggested by Lincoln & Guba (1985 p.313-314).

Findings and Discussion

The results of this study are presented in two parts: 1) The findings of the thematic analysis using Mezirow's theory of adult learning; and 2) The findings of the phenomenological data analysis.

Thematic Analysis using Mezirow's Theory

Nine themes emerged from the data analysis using Mezirow's theory of adult learning as a framework of inquiry. Each theme is briefly discussed.

Theme One. Power Dynamics Permeate the CEOs' Environment. This theme has two distinct parts, reflecting the two primary CEO relationships: 1) The CEO-Staff power dynamic; and 2) The CEO-Board power dynamic. Underlying both of these relationships was the CEOs' strong sense of vulnerability and a belief that there are many constituencies to please. Two critical elements of Mezirow's theory, discourse and communicative learning (a type of learning), are directly influenced by these power imbalances with the staff and board. In order for discourse to occur, Mezirow (1991) asserts there must be "free and open exchange" and equal power, yet it is clear that neither is present within the context of CEO relationships at work. Additionally, communicative learning involves learning to understand what other people really mean. With the "cleaned" language phenomenon so prevalent in the CEOs' interactions ("political correctness"), communicative learning is clearly impacted.

Theme Two. Learning How to Navigate the Political Process. The CEOs' recognition that they had so many, often conflicting, expectations placed on them resulted in a focused effort to figure out how to manage the political processes to their advantage. Consistent with Mezirow's theory of adult learning, evidences of both instrumental and communicative learning were apparent in the CEOs' descriptions of their learning about how to navigate the political processes inherent in the CEO position.
Theme Three. Learning About Self. Mezirow (1981) has suggested that the most profound learning often involves learning about one's identity and self-concept. He makes the point that such learning often occurs while trying to learn about something else. The CEO environment, with its continuous pressure on the CEOs to meet the boards' often-subjective expectations, tested the self-confidence of the CEOs and triggered self-reflection and learning about self.

Theme Four. Reflection a More Prevalent Learning Process. The CEOs in the study indicated that reflection had become a more prevalent learning process for them since being a CEO. The lack of opportunities for CEOs to have meaningful discourse clearly contributed to the increased use of reflection; however, it is also the CEOs' feeling of vulnerability with the board that triggers the CEOs' frequent reflection on their performance. It is unclear whether any of the ways in which the CEOs' described that they reflect constitute "critical reflection" as Mezirow's learning theory asserts is necessary. The reflective process described by CEOs seemed to be less of a critique of assumptions, as Mezirow suggests, and more of a mental replaying of events in hopes of improved future performance.

Theme Five. Learning More Difficult in the CEO Role. The majority of CEOs commented that they found learning in the CEO role to be harder than in pre-CEO positions. The challenges nonprofit association CEOs face often involve people and relationships, with no one right answer and a lack of people with whom to discuss the challenges. The CEOs' perception that this contributes to learning being more difficult is consistent with Mezirow's (1981) assertion that learning to understand what other people mean (communicative knowledge) can be particularly difficult because of the lack of empirical methods to determine truth.

Theme Six. Discourse More Difficult in the CEO Role. As was noted in the earlier themes, CEOs felt that having productive discourse was more difficult to attain in the CEO position than when they were in non-CEO positions. The power dynamic between the CEOs and both their staff and their board acted as a significant impediment to discourse in the minds of the CEOs in the study. The discourse the CEOs in the study did seek out, however, was discourse with their spouses.

Theme Seven. Spouse as Resource for Discourse and Learning. Mezirow (1994) describes learning as a social process. He asserts that meaning made by an individual must be validated through discourse with others. Overall, the comments suggest that the spouse was a valued resource in part because they provided a "safe" environment where the CEO could think through issues without undesirable consequences. The findings also suggest, however, that this CEO-spouse discourse does not meet the conditions for "rational discourse" that Mezirow asserts is necessary for learning as defined by his theory.

Theme Eight. Triggering Events Often Mistakes or Adversity. Mezirow (1994) suggests that the triggering events that produce the most learning are often emotionally unpleasant and even painful. This study's findings suggest the CEO context provides fertile ground for such triggers. CEOs perceive that the context in which they operate is one of intense political pressure, where there are no guaranteed formulas for success, and where a CEO's action on a given item may please a group of board members but displease another group. The CEOs, when asked about how they most often learned, mentioned making mistakes, and then learning from those mistakes.

Theme Nine. Degree of Change Varied among CEOs. Mezirow (1991) indicates that individuals rarely transform their "meaning perspectives" and that most learning occurs by through validating or expanding existing "meaning schemes." The data suggests that some CEOs experienced learning at the "schema" level, while others described learning that could represent changes in meaning perspectives. The most transformative learning experiences described focused on learning about self.

Phenomenological Data Analysis

The product of this study's phenomenological data analysis is the textural-structural description or "essence" of the phenomenon of nonprofit association CEO learning. That description was developed within the phenomenological tradition by systematically building on the findings from each step of phenomenological data analysis summarized earlier. The process required a careful working through and imaginative testing of various descriptions of an essence until the essential elements and their relationship were differentiated from the unessential and particular (Polkinghorne, 1989). The twelve CEOs in this study each received the textural-structural description, or "essence," of the phenomenon of CEO learning as explicated from the group of twelve CEOs. The comments received from the CEOs supported the textural-structural synthesis of CEO learning developed.

Textural-Structural Synthesis("Essence"): CEO Learning Experiences. Nonprofit association CEOs' learning experiences are shaped by power dynamics that permeate fundamental dimensions of their job environment. These dynamics drive to a large extent both "what" they learn and "how" they learn. CEOs learn that the power they have
over the staff is inescapable. They learn through reflecting on experience the limits in establishing "peer" relationships with staff. Once these limits are learned by the CEOs, the CEOs turn their learning focus to how to manage this power. They learn to be more calculated with their words and actions to minimize being misinterpreted by staff, as well as to create an environment where they are not being told what staff thinks the CEO wants to hear.

Association CEOs learn that the CEO role produces an intense feeling of responsibility and accountability. This personal learning also includes varying levels of vulnerability as CEOs learn that working with, but also "reporting to," a frequently changing board of volunteers is a socio-political challenge beyond what they had anticipated. This learning usually occurs through trial and error experiences with individual board members and the collective board. The CEOs learn that they are the point person responsible for meeting, or at minimum, managing, the multiple self-interests of these many "bosses"—in addition to achieving the stated association interests. The power of the board to remove the CEO is ever present in the mind of these association CEOs. This learning focus on the board is ongoing as positions of power change in the association and new board members are elected. The CEOs' learning becomes focused on achieving desired outcomes while avoiding "excessive vulnerability." This involves learning, primarily through listening and observation, to understand the actual, not prescribed, decision-making process of the board. It also involves learning to understand individual board members' needs and desires and their individual power within the group, as well as learning how to influence both the people and the process to achieve desired outcomes. This learning occurs primarily through trial and error and reflecting on those experiences.

CEOs utilize reflection for learning more than in other positions. Due to the particular power dynamics that exist with the staff and the board, CEOs learn that the CEO role often produces feelings of isolation and loneliness. The absence of "peers" with whom to have candid dialogue makes reflection a more common learning practice. Additionally, CEOs perceive the issues they must address with the staff, the board, and their marketplace to be broader and more complex than other jobs which requires reflection in order to learn. The CEOs with spouses have learned to appreciate and to leverage their spouses as safe and valuable resources for dialogue and reflection.

CEOs view learning as important to success. They view the learning needed to succeed in the CEO role to be much more focused on people than facts. They have learned that this is often harder learning and that they must seek out their own learning. Learning in the CEO role also includes unplanned learning about self, particularly about their personal values. While books, seminars, and networking can occasionally be helpful in the learning process to CEOs, trial and error with real experience is where the learning predominantly occurs.

Implications for HRD Research and Practice

While organizations spend millions of dollars annually on executive development, the focus is almost exclusively on managers and non-CEO executives. The CEO is basically on his/her own in regard to their development (Horton, 1992). This study's focus, specifically on CEOs, helped to inform the field of HRD from both a theoretical and practical perspective about how CEOs learn within the professional context of being their organization's chief executive. Given the study's interest in exploring executive development from an adult learning perspective, employing a comprehensive learning theory such as Mezirow's served this research purpose effectively. Below is a brief discussion of the implications for both HRD research and practice.

Implications for HRD Research. The influence of the CEO context so strongly influences the CEOs' learning experiences that the managerial and executive learning research provides little insight on the learning of CEOs. This conclusion about the profound impact of professional context on learning is consistent with the findings of Clark (1991) who found that context was "more than incidental to the learning process, but was directive and determinative of the learning" (p.98). While this study has helped to address this gap in the literature by exploring the learning experiences of nonprofit association CEOs, additional focused research on CEOs is warranted.

The increased use of reflection and decreased use of discourse provide new insights into how context impacts learning processes in Mezirow's theory. Mezirow (1998) asserts that context is central to learning in his theory, but there is a need to develop more fully the linkage between context and the processes of adult learning. In particular, the reflective learning practices used by the CEOs in this study seem to be less of a critique, less judgmental, than Mezirow suggests. Thus, Mezirow's assertion that vigorous critique is an essential component of reflection is questionable based on this study. Given that reflection was not the focus of this study, this conclusion suggests that further research that focuses on CEOs' reflective practices is warranted. Specifically, it is recommended that the concept of reflection v. critical reflection be explored to better understand the nuances of reflection and their impact on the learning process and outcomes. The research methodology could include asking CEOs to maintain daily or weekly journals so that data on the CEOs' reflective practices might be more closely linked to recent events and/or
actions. Additionally, the discourse that CEOs described as helpful in their learning (often with their spouse) did not appear to be "rational" discourse that Mezirow asserts is necessary for learning to occur. It is recommended that this element of Mezirow's adult learning theory also be explored in more depth by studying CEOs' discourse exclusively. Descriptions of discourse from both the CEOs and those with whom the CEOs spoke could provide data leading to a better understanding of the degree to which the discourses met (or failed to meet) the conditions of "rational" discourse asserted by Mezirow.

This study explored the learning experiences of CEOs with at least two years' experience but no more than seven years' experience as CEO. It would be helpful to compare the findings of this study with the learning experiences of seasoned CEOs. A study of CEOs with, for example, at least fifteen years of CEO experience could provide helpful insights as to whether the political elements of the job are related to length of time as CEO. Additionally, while this study focused on the learning experiences of nonprofit association CEOs, it would be interesting to replicate this study with other types of nonprofit organizations; such as foundations, philanthropic and social welfare organizations and compare the findings.

Implications for HRD Practice. One disturbing conclusion of this study is the tendency for nonprofit association CEOs to become so self-absorbed amid the political intensity of their context that they fail to act on learning that could help their organizations. This conclusion is made based on the fact, that when CEOs were asked to share their significant learning experiences in the CEO role, the stories shared were predominantly about navigating the political process with the board and avoiding political trouble that could put their jobs at risk. HRD must provide mechanisms for CEO development that address the unique pressures of the CEO context.

HRD practitioners can assist CEOs, and aspiring CEOs, in their development by first informing them about the unique aspects of learning in the CEO context and how this will influence, among other things, their access to information, their learning, and ultimately, their capacity to act. Once CEOs become aware of how their context influences what and how they learn, HRD practitioners can focus on development of CEO learning processes and content that address their unique context. It is asserted that CEO development will be most effective if HRD practitioners can develop executive coaching relationships with CEOs or aspiring CEOs. As this study clearly showed, CEOs feel isolated and an effective executive coach could serve as a valuable learning resource to a CEO. Among the areas of focus for the executive coach working with the CEO is development of skills for operating in political environments, development of influencing skills, and development of reflective practice.

Conclusion

The powerful influence of the nonprofit association CEO context on CEO learning was clearly evident in both the phenomenological method of data analysis and the thematic data analysis using Mezirow's theory as framework of inquiry. Both forms of analysis produced important insights into not only what CEOs learn and how they learn, but also the impact of context on CEOs' acting on that learning. This research is significant in that it has addressed an important gap in our understanding of HRD at the CEO level by focusing on the learning experiences of CEOs specifically. It also addressed a gap in the research of Mezirow's adult learning theory by providing new insights on the role of context on key concepts of his theory. Finally, this research began to provide a bridge between the research in adult learning and HRD that benefits both fields of study. As the CEOs' in this study asserted, learning is key to CEOs' leading their organizations, and our better understanding of the phenomenon of CEO learning will ideally translate into increased success for both the CEOs and their organizations.

The Awareness and Utilization of Emotional Intelligence in Leadership Development as Perceived by HRD Practitioners in the Kansas City ASTD Chapter

Joseph Nantawut Leeamornsiri
Robert C. Schwindt
Pittsburg State University

The utilization of emotional intelligence (EI) concepts in the leadership and management development activities of organization in the Kansas City metropolitan area was investigated. Data was gathered and analyzed related to the awareness of EI by HRD practitioners and organizational managers, the perceived benefits of the use of EI competencies, the emphasis put on the core EI competencies in leadership and management development activities, and the perceive emphasis put on the application of EI competencies.

Key words: Emotional Intelligence, Leadership Development

Goleman's book Emotional Intelligence, published in 1995, was widely read. "We are being judged by a new yard stick not just how smart we are, by our training and expertise, but also by how well we handle ourselves and others" (Goleman, 1998, p.1). Mayer and Salovey revised their definition of emotional intelligence in 1997 to include "the ability to perceive oneself and other things accurately, the ability to appraise and express emotions appropriately, the ability to generate and access emotions which facilitate thought, the ability to understand emotion and knowledge, and the ability to regulate emotions to improve emotional and intellectually growth" (Salovey & Mayer, 1998, p.81).

The concept of emotional intelligence has become widely known and accepted in business and industry. Emotional intelligence includes the basic personal qualities of, emotional maturity, self-confidence, self-awareness, personal integrity, and the knowledge of personal strengths and weaknesses. Emotional Intelligence is the capacity for recognizing one's own feelings and those of others, for motivating, managing, and developing (Cherniss, 2000).

Emotional intelligence is very important to HRD practitioners, and it is important for the HRD practitioner to understand the concept, the related values and competencies, and to be aware of the theory and the research on which it is based. This research study describes how HRD leadership development practitioners perceive emotional intelligence, and the perceived benefits related to work environment, performance, and productivity.

Problem Statement

Current literature indicates the success of leaders is related to their emotional intelligence (EI). However there is limited information on the awareness and utilization of EI by HRD practitioners. This study investigated the utilization of emotional intelligence concepts in the leadership/management development activities of organizations in the Kansas City metropolitan area. Five research questions were addressed in order to guide the acquisition of data needed to satisfy the requirements of the statement of the problem.

Theoretical Framework

Emotions influence jobs and lives. Emotion also impacts decisions, questions, instructions, and reactions. Today organization structures and cultures are changing rapidly in most businesses and industries because of the impact of high technology, globalization, political situations, and economic changes. The need for emotional intelligence in leadership development is more important than ever before. Cooper and Sawaf in emphasizing the value of emotional intelligence in leadership and organizations stated: “We are in the beginning stages of what many authorities believe will be the next revolution in business”(1997, p.xi).

The researcher established several parameters for this study, which may affect the application of the findings to other populations. The definition and components of EI under this study, as well as portions of the survey instrument were based on Goleman’s theory of emotional intelligence. Goleman included competencies under two categories of personal competence and social competence. These competencies were self-awareness, self-regulation, self-management(handling emotions), social awareness(handling relationships), empathy, and social skills (Goleman, 1998).
Methodology

This was a descriptive research study where a survey instrument was used to obtain data from HRD practitioners. The population for this study was members of the Kansas City Chapter of the American Society for Training and Development (ASTD) who were listed in the 2000-2001 Kansas City ASTD Membership Directory, and had selected leadership/management development as their specialty. It did not include individuals who joined after the directory was published or members whose address had changed. There were 148 members listed with this specialty. Since this population was small, all were included in this study.

Development of the Instrument

The survey instrument was based upon the review of literature. Each research question was addressed by a specific section of the survey instrument. Likert-type scales were used. A five points scale that ranged from "unaware" to "highly aware" was used to determine the awareness of emotional intelligence. A five point scale that ranged from "strongly disagree" to "strongly agree" was used to determine perceived benefits. A five points scale that ranged from "major emphasis" to "not applicable" was used to measure the emphasis put on emotional intelligence activities in leadership development.

Validation of the Instrument

A sample of HRD practitioners was used to examine the content and face validity of the survey instrument. They were urged to make suggestions to improve the instrument’s format and how the items were written. This was done to enhance the survey instrument and therefore the validity of the study. A panel of experts consisting of the thesis committee also examined the survey instrument for face validity. To determine the reliability of the instrument during the pilot study, the survey instrument was administered to a sample of 22 HRD practitioners who were randomly selected from the Kansas City ASTD Chapter membership directory. Nine survey instruments were returned for a 41 percent return rate. The data from this pilot test were analyzed for the five parts of the survey instrument. Cronbach’s alpha coefficients for reliability for the sections of the survey instrument ranged from 0.8092 to 0.9394. According to these result there were no significant changes needed for reliability.

Survey Times Lines

The survey instrument along with a cover letter and postpaid envelope was sent to each member of the population. A second mailing was sent two weeks after the first mailing to all non-respondents. The researcher started processing the data that had been collected two weeks after the first mailing. The researcher stopped collecting and processing data that came in more than three weeks after the final mailing.

Processing of Data

As the data was gathered, the findings were entered in tables and figures and a narrative was developed to report the findings. The mean and standard deviation were determined for each item for the survey section related to levels of understanding, perceived benefits, and emphasis put on EI.

Limitations

The researcher recognized that there were some factors outside of his control, which may limit the findings of this study. The researcher recognized the following limitations as being viable:

1. This study may be limited by the emphasis put on EI by the organization’s philosophy toward leadership.
2. This study may be limited by the climate in the organization, which may influence the acceptance of EI principles.
3. This study may be limited by the knowledge and understanding of EI by the sample members. There are several different concepts including different competencies related to EI in HRD.

26-2
Results and Findings

A summary of the research study findings follow related to each of this study’s research questions. Conclusions are then given for each research question.

Research Question 1

What is the perceived knowledge level about Emotional Intelligence of members of the Kansas City ASTD Chapter who have a specialty in leadership/management development? Of the 53 respondents, 12 (22.6%) indicated that they did not know the meaning of emotional intelligence. These individuals may have never heard of the concept of emotional intelligence, or they may have heard of EI but did not understand the concept.

<td>4.16</td>
<td>0.777</td>
</tr>
</tbody>
</table>

NOTE: 1= unaware, 5= highly aware

The second section of the survey asked respondents who knew the meaning of emotional intelligence how well they understood the components of emotional intelligence. Data in Table 1 indicates that respondents were the most aware of developing empathy for others (M = 4.33, SD = 0.865) and self-regulation the least (M = 3.95, SD = 1.068). Respondents understood managing emotion (M = 4.26, SD = 0.819) more than self-awareness and handling relationships. The summated mean of 4.16 (SD = 0.777) indicates that overall respondents who were familiar with emotional intelligence clearly understood and tended to be aware to highly aware of the seven components of emotional intelligence as identified by Goleman.

Research Question 2

How aware are managers about Emotional Intelligence, as perceived by HRD practitioners? The third question on the survey asked the respondents how well the manager in their organization understood the components of emotional intelligence. Data indicates that respondents perceived that managers understood motivating oneself best (M = 3.28, SD = 1.031) while developing empathy for others the least (M = 2.72, SD = 1.202).

<tr>
<td>Developing empathy for others</td>
<td>2.72</td>
<td>1.202</td>
</tr>
<tr>
<td>Summated values</td>
<td>3.01</td>
<td>0.901</td>
</tr>
</tbody>
</table>

NOTE: 1= unaware, 5= highly aware

The summated mean of 3.01 (SD = 0.901) indicates that overall respondents perceived that managers in their organizations were only somewhat aware and did not clearly understand the seven components of emotional intelligence.
intelligence. The literature indicated that understanding of emotional intelligence concepts has a major impact on individual performance and organization productivity. Church and Waclawski also stated managerial self-awareness (MSA) is the ability to react and reflects accurately related to one’s own feeling, behaviors, and skills associated with workplace interaction (Church and Waclawski, 1999). Cherniss explains that self-awareness is essential for business and professions success. She pointed out evidence that showed the most successful performers deeply understand and know how to express their feeling when making important decisions (Cherniss, 2000). HRD Practitioners in this study perceived that managers self-awareness was one of the lowest of the EI competencies (M = 2.84, SD = 1.022). If managers are low in self-awareness, the organization may not be receiving the full benefits of emotional intelligence given in the literature.

Research Question 3

What do these HRD practitioners perceive as being the major benefits of the use of EI competencies in their organization? More successful relationships with coworkers (M = 4.49, SD = 0.506) was the highest perceived benefit of EI, while managers with loyalty to their employer (M = 3.17, SD = 0.881) was perceived as the lowest rated benefit. The summated mean of 4.06 (SD = 0.491) indicates that overall respondent’s agreed to strongly agreed with the perceived benefits of emphasizing emotional intelligence, as given in the review of literature by Cherniss, Cooper and Sawaf. Goleman contends that leaders who have control over their emotions are more likely to resolve conflicts.

<tr>
<td>Managers with a high EI are usually more loyal to their employer.</td>
<td>3.17</td>
<td>0.881</td>
</tr>
<tr>
<td>Summated values</td>
<td>4.06</td>
<td>0.491</td>
</tr>
</tbody>
</table>

NOTE: 1 = strongly disagree, 2 = disagree, 3 = uncertain, 4 = agree, 5 = strongly agree

One important finding of this study which conflicted with the literature is the data that showed respondents were uncertain if most managers are able to significantly raise their EI (M = 3.37, SD = 0.829). The literature indicated that emotional intelligence is improved as people age and gain experience and knowledge (Goleman, 1998). Cooper and Sawaf believed people can develop their emotional intelligence. When facing change and challenge, emotional fitness will function and balance the emotional and mental adaptability to handle stress and problems more wisely and more openly (Cooper and Sawaf, 1997). A significant study over developing emotional intelligence in leadership shows that emotional intelligence is developed best at the adult age by focusing on performance, culture diversity and organization change (Hay Group, 1999).
The researcher questioned this perception of the HRD practitioners in this study, whether managers can raise their level of emotional intelligence? What will be the affects in their training programs to improve their people if the HRD practitioners believe that people's EI cannot be improved?

Overall emotional intelligence was perceived to benefit individual performance and organization productivity. These results imply to HRD practitioners how emotional intelligence functions and are correlated to the development of training programs such as management and leadership development, coaching, intervention process, strategic planning, communication, and effective teamwork.

Research Question 4

How much emphasis is put on the core EI competencies by HRD practitioners in leadership/management development activities? Data indicates that respondents put the most emphasis on handling relationships (M = 3.13, SD = 0.812) and put the least emphasized on social skill (M = 2.61, SD = 0.891) in leadership development activities. The summed mean of 2.84 (SD = 0.738) indicates that overall respondents emphasized emotional intelligence in leadership development activities.

Data from Table I indicate that most respondents were very aware of the emotional intelligence concepts but Table IV indicates they did not put a major emphasis on it in their jobs. Emotional intelligence had not been emphasized widely in human resource development before the mid-1990. Earlier work had been more in education. Therefore, the researcher was not able to locate studies that showed were much it has been incorporated into human resource development programs.

<tr>
<td><strong>Summated values</strong></td>
<td>2.84</td>
<td>0.738</td>
</tr>
</tbody>
</table>

NOTE: 4 = Major Emphasis, 3 = Emphasized, 2 = Little Emphasis, 1 = No Emphasis.

In general respondents tended to put more emphasis on those components of EI where they perceived managers having the lowest understanding (Table II). The most emphasis was placed on handling relationships, which has a lower mean rating in Table II. Lower emphasis was reported on social skill, and managing emotions which had higher means in Table II. Respondents reported lower perceived benefits of emphasizing emotional intelligence in leadership development activities as shown in Table III. Most respondents emphasized developing relationships with others rather than on managing and improving their own skill in leadership development activities.

Robert W. Allen, Goleman, and Gerald Grinstein state leadership is the emotionally perception, and source of power in the organization. Goleman also stated that leadership styles are related to emotional intelligence and organizational effectiveness, the visionary leaders are empathetic and have a strong level of self-confidence, important for change (Goleman, 2000). "Covey suggests the way in which leaders conduct themselves in the face of complexity, whether wise of foolishly, is based largely on the leader's knowledge of emotional management and ability of effectively manage him or herself" (Lorie, J, 1997, p.193).

Emotional intelligence is related to managers' personality and leadership style as well as the organization's culture. Therefore, even thought EI is emphasized in leadership and management classes, it may take time to get managers to change their leadership style resulting in a change in the organizational culture. Integrating the concepts of EI into an organization must be thought of as a long term HRD goal. This will include other interventions besides training such as changes in selection, performance appraisal, and rewards that emphasize EI concepts.

Research Question 5

How much emphasis do these practitioners perceive is being put on the application of EI competencies by their organization? Data indicates that respondent's were perceived to put the most emphasis on promoting line
employees to supervisor (M = 2.35, SD = 0.907) and the least emphasis on promoting managers (M = 2.08, SD = 0.870). Overall respondents put more emphasis on emotional intelligence in their organization when promoting line employees to supervisor and selecting new employees than when selecting and promoting managers, professional staff, sales and marketing, management teams, and supervisors.

NOTE: 4 = Major Emphasis, 3 = Emphasized, 2 = Little Emphasis, 1 = No Emphasis.

Respondents perceived that top management in their organization put little emphasis on emotional intelligence (M = 1.98, SD = 0.947). This suggests that top management in most organizations are not using emotional intelligence in their leadership and management. Most of the literature reported that emotional intelligence is one of the most essential factors that predicts success in individual work performance and organization productivity.

The low mean scores for all activities surprised the researcher. This may be related to the perceptions of the manager's understanding of emotional intelligence, as shown in Table II. The respondent's perceived that managers were somewhat aware of the emotional intelligence concepts (M = 3.01, SD = 0.901) while the utilization of the emotional intelligence concepts in their organizations were very limited with little emphasis from managers, executives, and top management in the organization.

According to the literature, emotional intelligence has a major impact on management and leadership development that predicts success and organization’s productivity. Goleman states that emotional intelligence theories can help explain and give a clear reason why so many people who are abrasive, thoughtless, and otherwise interpersonally inept are in so many positions of power in organization (Goleman, 1998). Cooper and Sawaf, in emphasizing the value of emotional intelligence in leadership and organizations, stated, “We are in the beginning stages of what many authorities believe will be the next revolution in business”(Cooper and Sawaf, 1997, p.xi). Dulewicz and Higgs stated that emotional intelligence accounted for 36 percent of the variance in organizational advancement while IQ accounted for only 27 percent and Management Quotient (MQ) account 16 percent of the variance. Their study showed that emotional intelligence was more essential to career advancement then IQ (Dulewicz and Higgs, 1997). A study of managerial success at AT&T Company provides a good example of self-confidence as a major predictor of career success, effective performer, and organization productivity (Boyatzis, 1999, Cherniss, 2000).

Conclusions and Recommendations

Of the 53 respondents, 12(22.6%) indicated they did not know what was meant by emotional intelligence. Data indicated that the other 41 HRD practitioners felt they have a fairly high awareness of emotional intelligence. Respondents perceived the managers in their organizations were only somewhat aware and did not clearly understand the seven components of emotional intelligence. Overall, respondent’s agreed with the perceived benefits of emphasizing emotional intelligence derived from the literature review. Data indicated that overall emotional intelligence was emphasized in leadership development activities and the respondents put the most emphasis on handling relationships in leadership development activities. Respondents indicated little emphasis was placed on emotional intelligence in their organizations and by top management.
Emotional intelligence is reported in the literature as one of the essential ingredients in business, industry and academic work that predicts success in individual work performance and organizational productivity. Goleman stated that emotional intelligence theories can help explain the leadership failures of many people in positions of power in organization who are abrasive, thoughtless, and otherwise interpersonally inept (Goleman, 1998). Integrating the concepts of EI into an organization must be thought of as a long term HRD goal. Limited literature is available over the awareness and the utilization of EI theories among HRD practitioners, so HRD practitioners need to focus on both future EI research and practice. After reviewing the related literature and analyzing the results of this study, the following recommendations for practice were made:

1) Human resources and management professional organizations should emphasize EI more, since over 20 percent of respondents were unaware of the meaning of EI. HRD practitioners need to interact more with other fields related to EI theory and research such as psychology, sociology, and management.

2) HRD practitioners may need more education and research related to the utilization of EI. HRD practitioners first need to believe that people's EI can be improved with effective training programs and organizational and performance development interventions. They must also be highly aware of the impact of EI on their jobs.

3) HRD practitioners may need to focus more on emotional intelligence in leadership development and management development. They should provide education and training in the utilization of knowledge, skill, strategy, and behaviors associated with emotional intelligence concepts. Even though most respondents indicated they emphasized EI, their perceptions are that these concepts are not being utilized strongly by the managers and top management in their organizations.

4) HRD practitioners may need to involve others in human resources in promoting the use of EI in activities such as selection, promotion, and performance appraisals. Respondents perceived that EI received little emphasis in these human resource activities in their organizations.

5) Top management need to promote emotional intelligence so it is implemented in all organizational levels. Respondent's perceptions were that top management put little emphasis on emotional intelligence. More emphasis should help adapt to change, manage conflict and stress, build positive relationships, and allow them to utilize their emotional intelligence to inspire, influence, coach and persuade others.

After reviewing the related literature and research and analyzing the results of this study, the following recommendations were made for future research and study in EI:

1) Future study of emotional intelligence in management and leadership development should involve larger populations so results can be generalized to other populations. It should directly survey managers and leaders.

2) Future study should interview HRD practitioners and managers about their understanding of emotional intelligence and their utilization. This would provide more detailed information than survey perceptions.

3) Future study should identify and measure how using EI affects important business operations and results such as productivity and return on investment. This information should help persuade managers of EI benefits.

4) Future study should put more emphasis on the theory of individual performance and organization productivity by applying the concept of emotional intelligence to jobs and the design of effective training programs.

5) Future study should emphasize how HRD and OD practitioners can design and develop programs for the utilization of emotional intelligence to improve their knowledge, skills, and capacity. Survey data indicated that HRD respondents did not strongly utilize the emotional intelligence in their jobs, and they perceived managers in their organization did not utilize the concepts either.

Contributions to HRD

Findings of this study should be important to the HRD practitioner, manager, and CEO in the organization. Emotional Intelligence is an essential ingredient for business efficiency and success. This study helped identify the EI competencies that help managers and leaders build personal and interpersonal strength and improve skills to balance and manage their emotions appropriately in order to adapt more sustained change throughout the organization. This should help their organizations in the competitive world market place of today and in the future.

This research describes how one sample of HRD practitioners understand, emphasize, and utilizing the concept of emotional intelligence associated with leadership/management development. The benefits of emotional intelligence can have a strong impact when applying the theories of individual performance and organization productivity to jobs and the design of effective training programs. The emotional intelligence concept influence HRD and OD intervention plans and strategies such as selection, promotion, force field analysis, coaching, reengineering, leadership/management development and performance appraisal.
This study adds to the limited emotional intelligence research associated with the awareness and utilization by HRD practitioners. Emotional intelligence theory should be one of the essential considerations for HRD practitioners when designing training programs, developing people's knowledge, skills, and work performance, and when coaching and implementing change.

Moving HRD Beyond “Paint by Numbers”:
Aesthetic Epistemology and Arts-Based Learning in Management Education

Nick Nissley
University of St. Thomas

This manuscript seeks to describe an emerging phenomenon in management education — how aesthetic epistemology (aesthetic ways of knowing), or arts-based learning is informing the practice of management education. It provides a literature review and examples of how arts-based learning is being practiced in management education — framed by the art forms of music (e.g., blues, jazz, and orchestra), drama (e.g., theater and cinema), literature (e.g., novels and poetry), and visual arts.

Keywords: Management Education, Arts-Based Learning, Organizational Aesthetics

This manuscript serves to recognize those management educators who are rethinking the traditional logico-rational paradigm (way of knowing) that presently frames much of management education. It does not seek to suggest that aesthetic epistemology (aesthetic ways of knowing) or arts-based learning can, or should, replace any of the more conventional practices of management education. Mindful of multiple ways of knowing this manuscript seeks to identify arts-based learning as a valuable adjunct to the current dominant pedagogy of management education.

In this manuscript, the term “arts-based learning” is used to broadly refer to ways that “the arts” are being introduced into management education. Elsewhere the term “aesthetic epistemology” (Nissley, 1999a) has been used to refer to aesthetic ways of knowing. And, similarly, others have sought to describe this phenomenon that is here referred to as arts-based learning, calling it: “aesthetic modes of knowing” (Reimer & Smith, 1992, p. 23), “arts based training” (Arts & Business, 2001), “art as a way of knowing” (Greene, 1995), “expressive arts consulting and education” (California Institute of Integral Studies, 2001), or “creative learning” (Vaill, 1996).

Aesthetic Epistemology and Management Education

In the broader context of organizational studies, Barrett (2000, p. 229), recognizing the short comings of the dominant logico-rational paradigm, asks, “If rational ways of knowing are inadequate, are there any alternatives?” Similarly, and more specific to the field of management education, Alvarez & Merchán (1992) assert that the act of management requires the use of several types of knowledge. This manuscript is an examination of one type of “other” knowledge — aesthetic epistemology and its application in management education.

Within the interdisciplinary field of organizational studies, organizational aesthetics is an emerging sub-specialty (e.g., Strati, 1992, 1999; Linstead & Höpfl, 2000). Generally speaking, organizational aesthetics provides us with an aesthetic way of understanding organizational life. This manuscript more specifically discusses arts-based learning in organizations — how artful ways of knowing are being practiced in organizations. While a recent issue of the Society for Organization Learning’s journal, Reflections (2001), was dedicated to “The Arts in Business and Society,” it provided a more limited understanding of arts-based learning in organizations.

Within the discipline of management, there are examples of the use of aesthetic epistemology to frame understanding within the sub-disciplines of: accounting (Chua & Degeling, 1993), business ethics (Brady, 1986; McAdams & Koppensteiner, 1992), marketing (Schmitt & Simonson, 1997), product design (Gelernter, 1999), leadership (Palus & Horth, 1996, 1998, 2001), organization design (Hatch, 1999), organization development (Ramsey, 1996, 1997; De Ciantis, 1995), and career management (Albion, 2001; Whyte, 2001) including management (Vaill, 1989).

Yet, our understanding of aesthetic ways of knowing in the field of management education has been examined only little outside of metaphorical conceptualizations of “the art of good teaching” in management education (Journal of Management Education, Special Issue: The Art of Good Teaching, 1997) and Bilimoria’s (1999) pondering, of what “if management schools focused on helping students gain facility in harnessing aesthetic and evocative aspects to the same degree as developing technical and administrative knowledge and skills” (p. 466).

While the “art of” metaphor can readily be found in the titles of books and articles that seek to educate managers, this manuscript moves beyond the metaphorical conceptualization of “the art of management” to also consider how managers are engaging with the arts, and not just thinking about them. Within this approach, examples...
of both art-perceiving (e.g., watching a play, reading a novel, viewing a corporate art collection) and art-making (company-sponsored and self-initiated) are provided within the practice of management education. This manuscript focuses on the company-sponsored type (e.g., formal management education) versus the self-initiated or self-directed type of arts-based learning noted in Taninecz (1996). Taninecz describes a growing number of “executives who satisfy a need far removed from the mental and physical constraints of corporate corridors,” noting “these whitecollar sculptors, painters, and poets — in addition to satisfying a need to express themselves — believe that creative pursuits can enhance leadership capabilities and management acumen” (p. 111). This manuscript seeks to describe, through a literature review and examples, how aesthetic epistemology (aesthetic ways of knowing), or arts-based learning is informing the theory and practice of management education.

The Art of Management Education

Here we turn our attention to examples of how arts-based learning is being used in the education and development of managers at work. This section provides a literature review and examples of how arts-based learning is being practiced in the management education classroom — framed by the art forms of music (e.g., blues, jazz, and orchestra), drama (e.g., theater and cinema), literature (e.g., novels and poetry), and visual arts. Next, we’ll begin by “tuning-in” to how the musical arts are being engaged in management education.

Musical Arts

There are a growing number of references in the management and organizational studies literature that explore the music-organization relationship, such as Pogacnik’s (1999) connection between music and listening, Hawkins’ (1998) connection between music and dialogue, and Jones & Shibley’s (1999) discussion of the “practice culture” of musicians and the “performance culture” of organizations — asserting that each has a lot to learn from the other. Examples of how the musical arts are being engaged by management education include the musical arts of jazz, orchestra, and blues, as well as other musical forms — including drumming circles.

Jazz. The jazz metaphor has been extensively covered in the organization and management studies literature (e.g., Organization Science (1998) — special issue on jazz improvisation and organizing). Practitioners have joined academic theorists, seeking to make sense of jazz as a metaphor for organizational life. For example, Jazz Impact (2001) engages organizations with jazz music as an arts-based learning approach to management education.

Orchestra. Mintzberg (1998) and Atik (1994), for example, examine the orchestra conductor as a metaphor for organizational leadership. Similar to “Jazz Impact,” mentioned above, practitioners have joined academic theorists, seeking to make sense of the orchestra as a metaphor for organizational life. For example, the musicians of Orpheus (2001), the conductor-less orchestra, have entered conversations with business organizations that seek to learn how the Orpheus orchestra’s way of creating music may serve as a model for their own organization. Harvey Seifter, the Executive Director of the Orpheus Chamber Orchestra, along with Peter Economy (2001) have co-authored a book about the “Orpheus Process” — how the Orpheus model of organizing may help other organizations re-create this model of collaborative leadership. In addition, “The Music Paradigm” (2001) brings business organizations together with orchestra musicians, as the business organization seeks to learn different ways to “look at” organizational life.

Blues. Beyond the orchestra pit, yet similar to “The Music Paradigm,” “Face the Music” (2001), a hybrid of organization development consultants and blues musicians work with organizations — actually creating blues music and exploring the “down-side” of organizational life (Muio, 2000). Mitch Ditkoff (Face the Music, n.d.), founder of “Face the Music,” explains how they use blues music as a means of arts-based learning in organizations:

Most people who work in a corporation are usually experiencing some form of the “blues” — a mixed bag of complaints, gripes, and grumbles that become a kind of low-grade virus on the job ... At the turn of the century, when field workers and share croppers had the blues, their response was basic and soulful. They sang it. And, that quite simply, was the beginning of their change process. In fact, that’s how all change begins. By somebody “telling it like it is” — from the heart — in a way that can be heard. In most corporations, however, there are very few opportunities for people to do this.

“Face the Music” facilitates managers in writing and singing the blues — about workplace life — so, change may be realized.
Percussive. Similar to “Face the Music,” who use blues music as an arts-based learning approach to management education, Fast Company (Pratt, 2000) has noted a growing interest in using drumming and other percussive instruments as another musical approach to arts-based learning in organizations. A number of musicians are bridging the worlds of music and organization, consulting to corporate clients (e.g., One World Music, 2000). These consulting musicians assist organizations with team-building, collaboration, creativity, and diversity training – through making a connection to musical metaphors such as rhythm and tempo.

Drama Arts (Theater and Cinema)

The use of drama, including stage performance (theater) and screen performance (cinema), as a means of management education, is also growing beyond the metaphorical. This is evidenced by the emerging acceptance of drama within the practice of formal management education within academia as well as the growth of consultants engaging in theater-based training within businesses. Similarly, many references exist discussing the use of film as a general resource for management education. Consider the following examples from stage performance (theater) and screen performance (cinema), which show how these two dramatic forms are being engaged as a means of arts-based learning in management education.

Theater. Within the halls of academia, at the 1998 Annual Meeting of the Academy of Management, Steven Taylor (2000) presented straight fiction – a play, Capitalist Pigs. Taylor followed this up with another play, Soft Targets, presented at the 2001 Annual Meeting of the Academy of Management. Similarly, Barry Oshry (2001) has recently written and had performed, a three-act play, that theatrically presents his ideas about power and organizational systems (Power and Systems, 2001). In addition, popular business literature is emerging, such as these books dedicated to what Shakespearean drama may teach us about management: Whitney & Packer (2000), Shafritz (1999), Augustine & Adelman (1999), Corrigan (1999), and Burnham, Augustine, & Adelman (2001). Finally, there is a growing number of consultants engaging in theater-based training (e.g., Harvard Management Update, 1999; Houden, 1997), including scripted stage performances (e.g., Theatre at Work, 2001) as well as unscripted improvisational theater (e.g., Pacific Playback, 2001; Barton, 2000). Within work organizations we are witnessing the development of “organizational theater,” which (Schrey6gg, 2001), defines as tailor-made plays staged for a specific organization, often dramatizing critical problems of work life. He notes that in 1997, over 2000 organizational theater performances were conducted in France, and 200 in German organizations. Even the venerable Globe Theatre has teamed up with Cranfield University’s School of Management (Praxis: The Centre for Developing Personal Effectiveness, 2001), creating an arts-based learning collaboration.

Cinema. Many references exist which discuss the use of film as a general resource for management education (e.g., Carley, 1999; Champoux, 1999a), as well as addressing specific areas, such as organizational behavior and management theories and concepts (Champoux, 2000a; 2000b), business ethics (Gerde, Shepard, & Goldsby, 1996; Giacalone & Jurkiewicz, 2001) and leadership (Wolff & Clemens, 1999). Champoux (1999b) has even considered the specific genre of animated films as a teaching resource for the management educator.

Literary Arts

Beyond the current management education fad of “Shakespeare on ...” (e.g., Whitney & Packer, 2000; Shafritz, 1999; Augustine & Adelman, 1999; Corrigan, 1999; Burnham, Augustine, & Adelman, 2001), there has been a serious growth of fiction as a popular genre of literary art within the organizational studies and management education classroom (e.g., Czarniawska-Joerges & Guillet de Monnoy, 1994; Brawer, 1998; Knights & Wilmott, 1999; Mayer & Clemens, 1999). Some specialized attention has been focused on the use of fiction in teaching ethics in management education (e.g., Kennedy & Lawton, 1992; McAdams & Koppensteiner, 1992). Czarniawska (1999) even proposes the fiction literature genre of the detective story as helpful in understanding management work, and similarly Parker, Higgins, Lightfoot, & Smith (2001) propose that science fiction may enrich our understanding of organizational life. In addition to detective stories and science fiction, the comic genre is also being used in management education (e.g., Telescope Comics, 2001). Poetry has also become a popular genre of literary art in the management education classroom (e.g., Whyte, 1994, 2001; Windle, 1994; Autry, 1994, 1996).
There even exist resources to assist the management educator who wants to integrate literary art (and cinema art) into his/her classroom. For example, The Hartwick Humanities in Management Institute at Hartwick College (USA) provides university faculty with cases (22 film cases and 57 literature cases) to enhance management and leadership education. This aesthetic way of knowing is described by Hartwick as: “Transforming great texts and films into unforgettable management and leadership lessons” (Hartwick Humanities in Management Institute, n.d.).

Visual Arts

This section focuses on the use of visual arts in learning interventions. Consideration of other forums for engaging with visual arts in management education (e.g., corporate art, museums, etc.) is addressed by the author in Rethinking Management Education (Nissley, 2002). The general training and development literature has recently spoken to the potential value of visual art in facilitating learning in organizations (e.g., Simmons, 1999; Cohen & Jurkovic, 1997). Consider the following examples.

First, Marjory Parker (1990) describes an application of arts-based learning intervention in the workplace. She focuses on a process of arts-based learning of the organization’s vision and values, at Europe’s largest producer of aluminum, Norway’s Hydro Aluminium Karmøy Fabrikk. In Creating Shared Vision: The Story of a Pioneer Approach to Organizational Revitalization, Parker, the organizational consultant who helped them through the strategic visioning process, describes why pictures really are worth a thousand words. The final vision statement was co-created by nearly every employee, over a two-year period. It was not a piece of writing at all, but an extraordinary mural of a flourishing garden, in which every plant and element embodied rich metaphorical meaning.

Second, Sims & Doyle (1995) describe an arts-based learning technique, called cognitive sculpting, a “technique for helping managers to talk through and develop their view of difficult and complex issues, which are given expression by arranging a collection of objects, some of them symbolically rich, in an arrangement or sculpture” (Sims & Doyle, 1995, p. 117). And third, Nissley & Jusela (2001b) describe a similar arts-based learning technique and its use by managers in a knowledge creation process. Similar to the cognitive sculpting technique and the process described by Nissley & Jusela, Barry (1996) provides an example of his work with Kinetic Family Drawing technique to better understand management and organizational life.

Fourth, De Ciantis (1995) also describes a training technique (Touchstone), employed at the Center for Creative Leadership (CCL), that uses art to help people develop as leaders. It is designed upon an exploration of artistic modes of inquiry. This learning exercise incorporates visual art, including sculpting, and drama performance. The technique is used by CCL in a program, “Leading Creatively,” that defines a set of “aesthetic competencies” for leadership. Palus & Horth (1998, 2001) note that their work in the “Leading Creatively” program has lead them to find two sets of competencies necessary to lead creatively: rational skills and the often neglected aesthetic competencies.

Fifth, there is an emerging specialty within facilitation, referred to as “visual practitioners” – facilitators who capture ideas and synthesize conversations on large paper, creating a colorful mural from words and images. There are diverse styles, and practitioners have coined many names to identify and differentiate their work: graphic recording, graphic facilitation, reflective graphics, mindscaping, visual thinking, information architects, visual synthesis, graphic translation, group graphics, and ideation specialists (see the International Forum of Visual Practitioners Web Site: http://www.hnl-consulting.com/ifvp.html).

Conclusion

The examples provided in this manuscript suggest that the use of aesthetic ways of knowing or arts-based learning has begun to grow, since Barnard (1940, p. xiv) called for managers to engage the aesthetic dimension of organizational life. Today there exists an emerging theory base within the interdisciplinary field of organizational studies and the growing sub-specialty of organizational aesthetics (e.g., Strati, 1999, 1992; Linstead & Hiipfl, 2000). In addition, there is growing recognition of the practice of arts-based learning in organizations – the actual doing of arts-based learning in management education. Today, there is also a growing recognition for the need to adequately train arts-based learning practitioners. In the US, the California Institute of Integral Studies has recently announced a post-baccalaureate certificate program in “Expressive Arts Consulting and Education” (California Institute of Integral Studies, 2001), and in Europe, Arts & Business’s Creative Forum has been presenting training for the arts-based trainer since 1998 (Arts & Business, 2001).

It should be noted that the growth in arts-based learning in management education is not confined to the United States. Many of the examples noted in this manuscript are from the United Kingdom (e.g., Sims & Doyle, 1994; Praxis:
The Centre for Developing Personal Effectiveness, 2001), as well as Australia (e.g., Brearley, 2000), and New Zealand (e.g., Barry, 1994, 1996). In addition, the heavily European-influenced (e.g., Strati, Linstead, Höpfl) theoretical base of organizational aesthetics continues to inform the practice of arts-based learning. Thus, this does not appear to be a US-centered phenomenon, with examples found throughout Europe and Australia/New Zealand. As sharing and documentation of arts-based learning practices continues, we will likely find that arts-based learning is not the domain of one national culture; but instead, we will find that arts-based learning allows us to cross the boundaries of nations and cultures.

Value Priorities of HRD Scholars and Practitioners

Reid Bates
Louisiana State University

Hsin Chih Chen
Tim Hatcher
University of Louisville

This study identifies, describes and measures a set of six HRD values that reflect two value facets (locus of HRD influence and HRD outcomes) and a seventh value that relates to a perceived normative component inherent in all HRD activity. Results indicated the value scales measured the individual value priorities of HRD scholars and practitioners and that these value priorities varied considerably. Suggestions for future research are offered.

Keywords: HRD Values, HRD Goals

HRD has been characterized as a field in search of itself (Watkins, 1989) and a good deal of literature has been published in the last decade aimed at defining the profession or describing what HRD is or should be. In spite of the fervent discourse, little has been accomplished in terms of generating consensus or moving the field toward an answer to these fundamental questions. It is, as Ruona and Lynham (1999, p. 215) have pointed out,

... a conversation having us — that is, ... a conversation that is ongoing and becomes the prominent focus such that little else actually happens except the having of the conversation. Very few new thoughts are generated, positions are defended, tradition weighs heavy, and very little progress is made in understanding and creating new meaning.

It is noteworthy that, despite this state of affairs, scant research has been done to more fully understand the underlying drivers of the debate. Some valuable work has been done documenting definitions of HRD (Weinberger, 1998; Mclean & Mclean, 2001), articulating different perspectives on the practice of HRD (Dirkx, 1996; Watkins, 1998), and describing the core beliefs of some leading HRD scholars (Ruona, 2000a). However, nothing has been done to uncover and understand the foundation from which these competing definitions, modes of practice, or philosophies emerge. This paper takes the perspective that to fully interpret the discourse surrounding competing definitions, practices, and beliefs about HRD we must first gain some understanding of the values that guide the HRD process. Values are the relatively enduring evaluative criteria or standards that HRD professionals use to make decisions about how the HRD process should happen now or in the future. Values thus represent normative statements describing the ideal state of the HRD process. Discovering and understanding these values is important because they influence the beliefs and attitudes that HRD professionals have about the development of human resources and help form the basis for decision making about individual actions or activities within the HRD process.

The Importance of Values

Values have occupied a central place in the analysis of work systems and have become an increasingly interesting and important area of research in management, organizational behavior, social psychology, ethics and other fields of study (e.g., Argyris & Schon, 1982; Kahle, 1996; Schwartz, 1996). A fundamental rationale for this research is the notion that values can provide potentially powerful explanations of behavior. For example, values have been applied to account for the productivity of nations (Hofstede, 1980), the behavior of organization (Munson & Posner, 1980), and the performance of teams (Maznevski, & Peterson, 1997). In addition, a key to understanding most theories of individual work motivation centers on the goals or desired outcomes around which people organize their actions and cognitions. These theories assert that when goals or outcomes are achieved, they contribute directly to the satisfaction of certain values, values that can and do vary from individual to individual.

Elements can be conceived of as falling within the value domain if they provide a basis for assigning importance to a goal or behavior. In this sense, values represent "a broad tendency to prefer certain states of affairs over others" (Hofstede, 1980, p. 19) and, in effect, describe how an individual feels the world should work or how

Copyright © 2002 Reid Bates, Hsin Chih Chen and Tim Hatcher
he/she would like it to work. Values thus provide standards for conduct and behavioral guides capable of transcending specific situations (Schwartz, 1992).

It is important to note that values are qualitatively different than attitudes. Attitudes address how individuals feel about a specific situation, condition, or event which predisposes them to respond in some manner (Rokeach, 1972). Values on the other hand are abstract preferences that reflect the state of affairs an individual prefers or thinks is more important. In a survey, for example, 'how satisfied are you with your career opportunities?' is an attitude question, but 'how important should it be for you to have career opportunities?' is a value question. Research has empirically shown that attitudes and values are different constructs not only in the mind of researchers, but also in the mind of respondents (Hofstede, 1998).

According to value theory (Rokeach & Balk-Rokeach, 1989; Schwartz & Bilsky, 1990) values are important because they tend to be structured and stable over time. That is, values are acquired and hierarchically organized to become part of a relatively enduring system. The structure of value systems emerges out of the social and psychological conflicts that accompany the expression of values through action (Rokeach, 1973). For example, actions aimed at improving job-specific performance may conflict with the creation of meaningful work: using the HRD process to maximize individual work outcomes may preclude actions aimed at enabling individuals to fulfill important inner needs through work. Thus, the total pattern of conflicts and harmonies among value priorities produces a structure for value systems (Schwartz, 1994). Value structures provide individuals with an ordered framework for resolving conflicts and making decisions. It is through their influence on decision-making that variations in value structures motivate individual behavior and affect specific actions. For example, an HRD professional who values individual learning as a top priority is motivated to be help others learn, derives satisfaction from increasing learning, and fulfills a personal need when being so engaged. The structure of values may therefore be used to understand how potential behaviors may be ordered in a given situation.

Research has in fact linked values to a wide range of individual behavior including participation in civil rights activities (Rokeach, 1973), personal doing (Levy, 1990), job search, safety behavior, and absence (Judge & Bretz, 1992) to name a few. However, the link between values and behavior is dynamic, complex and not fully understood. Value research has tended to take too narrow a view of this link, ignoring antecedent and intervening variables, and generally viewing the relationship between values and behavior as simple and direct. The failure to study values in the context of other variables is seen by some as the primary reason this research has not generally shown a robust effect between values and behavior (Shrum & McCarty, 1997). It is increasingly recognized that to fully understand the values-behavior relationship research must include potentially important antecedents such as age, education, gender, or income (McCarty & Shrum, 1993a), mediators such as attitudes (Homer & Kahle, 1988) or individual differences (Shrum & McCarty, 1992), and moderators including situational factors as well as the relationship among values themselves (McCarty & Shrum, 1993b).

Purpose of Research

This research is exploratory in nature and represents an initial effort to identify the underlying values about the HRD process held by HRD professionals. Our goal was to create a quantifiable description of how HRD scholars (students, academicians and researchers), and practitioners believe the HRD process should be viewed. Rather than investigate values in general, we were interested in specific individual values as they relate to the HRD process in organizations. An explicit focus of this nature has been referred to as a specific frame as opposed to a general frame (Wilkins & Dyer, 1988). It is hoped that this research will provide greater insight into the ongoing debate about what HRD should be and provide a basis for future research aimed at a more complete understanding of both the philosophy and practice of HRD.

Methodology

To analyze the HRD values domain systematically, an attempt was made to define its essential facets. Facet theory defines facets as "characteristic components of relevant variables ... that can be used to formulate a definition of a construct because ... each facet reflects an essential component of a content universe of variable that depicts the construct" (Dancer, 1990, p. 367). Facets are hypothesized elements representing semantic or perceptual properties that distinguish the basic components of variables and provide a frame and approach for measuring a content domain (Edmundson, Koch, & Silverman, 1993). One means of identifying and characterizing value facets is through content analysis of cultural products (Schwartz, 1992). Therefore the identification and classification of HRD values in this study was based on an extensive content analysis of the HRD research and literature representing what is recognized as the three fundamental philosophies about the HRD process (the learning, performance, and
Two basic facets were identified as representing the content domain of HRD values: HRD outcomes and locus of HRD influence. Six values emerged from the matrix of these two facets: creating empowering work (CEW), building caring organizations (BCO), building competence through learning (BCTL), creating learning systems (CLS), improving job-specific performance (IJSP), and meeting organizational goals (MOG). The facets and values are shown in Figure 1 along with sample items for each value scale. A seventh value, macro HRD goal (MG), was also identified. This value was seen as distinct from the two primary facets and is described below.

**Facet A: HRD Outcomes.** A variety of outcomes are attainable from the HRD process. In general, these are reflected in three fundamental outcome domains: meaning of work, learning, and performance. Meaning of work outcomes emphasizes processes that empower and enable individuals to create work that is personally meaningful and that fulfills important emotional and social needs. Learning outcomes emphasize increases in the long-term, work-related learning capacity of individuals, groups and organizations through the development and application of learning-based interventions for purpose of optimizing human and organizational growth and effectiveness (Chalofsky, 1992; Watkins, 1989). Outcomes in the performance domain focus on those elements of work behavior that directly advance the mission of the work system in which those behaviors are embedded. Performance outcomes are work-system specific and although other outcomes can be nurtured and respected these are secondary to a core focus on mission-related performance. A work system is defined as an interdependent, organized architecture of human activity directed toward the accomplishment of a valued goal or outcome. It is a more inclusive construct than organization and is thought to better reflect the range of HRD activity. Conceptually, the HRD process can be exerted at multiple levels in a work system.

**Facet B: Locus of Influence.** The second facet concerns the locus of influence of the HRD process and is seen as cutting across HRD outcomes. Locus of influence refers to the point in work systems that the HRD process is applied. The locus of influence elements that emerged in this analysis reflect two classifications: individual influence and organization influence. Individual influence refers to HRD processes directed at meeting the needs of individuals performing in a work system. Organization influence refers to HRD processes directed at meeting the design, structure, management, and process needs of a work system.
Macro HRD Goal. A seventh value, macro HRD goal, emerged independent of the facets identified above. This value relates to what many see as the normative component that should be explicitly recognized as inherent in all human resource development activity. As a value, the macro HRD goal makes explicit the understanding that the propriety of different HRD objectives must be evaluated against an acknowledged overarching criterion. This criterion extends beyond HRD activities in any specific work system and reinforces the idea that improvement, a core theme in all definitions of HRD, can no longer be equated simply with economic growth, productivity, or shareholder return. It also underscores the necessity of recognizing that there are multiple paths of improvement that ultimately can only be evaluated with reference to larger social, ecological, political, cultural, and economic considerations. Examples of items used to measure this value include "HRD should have a responsibility for human development that goes beyond organizational boundaries" and "HRD should work to build healthy relationships between an organization and the external social, cultural, and ecological environment".

Instrument

Data collection in this study employed the use of a standard paper and pencil survey. Items on the survey were worded in a normative manner (e.g., HRD should support and accelerate individual learning) and designed specifically to tap values. Respondents were asked to rate the extent to which they believed the normative statements should be used to guide practice. A five-point Likert-type scale was used with anchors ranging from 1 (never or almost never) to 5 (always or almost always).

Subjects

The sampling frame of this study consisted of HRD educators, researchers, practitioners, and students in HRD programs of study who are members of AHRD, who attended the 2001 AHRD conference, or who have been invited to participate in this study. Respondents in the data set reported here were provided a paper and pencil survey and asked to return it to the author by mail. Participation in this study was voluntary and as of this writing 84 responses have been collected. Of these, 64% were female and 36% were male. In terms of age, 31% of the respondents were 35 or younger, 64% were between 36 and 55, and five percent were over 56 years of age. Respondents reported an average of 21 years of formal education counting their first year of formal education as a child. About 39% of respondents were classified as HRD scholars (instructors, professors, or researchers in HRD programs in colleges or universities), 53% as HRD practitioners, and eight percent as students in graduate or undergraduate HRD or training and development programs.

Results

Scale reliabilities ranged from .60 to .89 and can be considered in the acceptable range for early scale development. Scale means for the sample range from a high of 4.05 for building competence through learning (BCTL) to a low of 3.02 for the macro HRD goal (MG). When viewed as an aggregate, the scale means appear to fall into three hierarchical value groupings. A high group consisted of two values, BCTL (M = 4.05) and CLS (M = 3.90); a second mid-range constellation that included CEW (M = 3.65), IJSP (M = 3.53), and MOG (M = 3.42); and a third group comprised of BCO (M = 3.21) and MG (M = 3.02). Scale means and reliabilities can be found in Table 1.

Examination of the value scale intercorrelations (see Table 2) yielded several important findings. First, the low to moderate level of intercorrelations between the value scales in this study strongly suggests the scales are measuring qualitatively different values. Second, examination of this data showed several interesting intercorrelations. For example, the significant correlation between MG and CEW (r = .61, p ≤ .05) and BCO (r = .55, p ≤ .05) suggests that individuals who rated meaning-related values (CEW, BCO) highly also believed that HRD should have a overarching normative goal as a guiding value. Examination of the performance outcome value elements (IJSP and MOG) and their relationships with other value scales shows that the MG scale is negatively correlated with both IJSP (r = .29, p ≤ .05) and MOG (r = .23, p ≤ .05) scales. This suggests that individuals who believe performance outcome values are the most important values to guide the HRD process do not give high priority to an overarching normative goal as a guiding value. In addition, BCO and CEW were negatively related to both performance elements (for IJSP r = .28, and r = .28, p ≤ .05; for MOG, r = .24, p ≤ .05 and .13, ns). This indicates individuals who believe that performance outcome-related values should be high priority values to lead the HRD process also give meaning-related values much lower priority.

Multivariate analysis of variance (MANOVA) was used to examine differences in HRD value priorities by gender and job classification. The job classifications of interest in this study included three categories: students (individuals enrolled in graduate or undergraduate HRD or training and development programs); scholars (instructors, professors or researchers working in colleges or universities); and HRD practitioners (those engaged in the full or part time practice of HRD). For analysis purposes, because of the relatively small number of students in the sample this category of respondents was combined with instructors, professors, or researchers to form a single subset titled scholars. Although analysis showed no significant differences in HRD value ratings between genders (Wilks Lambda = .61, F = 10.26), it did indicate some significant differences by job classification (Wilks Lambda = .001, F = .77). The tests of between-subjects effects showed significant differences between scholars and practitioners in ratings of all values except MOG (p-values for CEW, BCO, BCTL, CLS, IJP, and MG were .01, .04, .01, .01, and .01 respectively).

A final analysis examined the relative mean ratings of values by gender, job classification, and across the sample as a whole (see Table 3). Analysis showed that the highest percentage of individuals rated learning-related values (BCTL & CLS) as those most important in guiding the HRD process. Thirty-four percent of the sample ranked BCTL highest and 30% ranked CLS highest in terms of mean rating. On the other hand, it is interesting to note that nine percent of the sample rated the macro HRD goal (MG) highest. In addition, a larger percentage of females than males felt that MG was the most important value that should guide the HRD process (12% versus 4%).

N* = number of individuals who rated a specific value the highest of all values rated
Total** = Individuals with two or more values with equal top ratings are not included in this table

Note that nine percent of the sample rated the macro HRD goal (MG) highest. In addition, a larger percentage of females than males felt that MG was the most important value that should guide the HRD process (12% versus 4%).
Overall MG had the highest mean rating for a larger percentage of individuals than did IJSP (7%), MOG (5%), and BCO (2.86%). This despite the fact that the MG scale received lowest mean rating of all the value scales.

In terms of job classification, the ranking pattern of four of the value scales (BCTL, CLS, CEW, and BCO) is comparable in terms of the percentage of scholars and practitioners ranking each the highest. One of the most striking findings is that although nearly a quarter (23%) of practitioners gave either IJSP or MOG the highest mean ratings, none of the scholars gave either of these performance outcome-related values the highest mean rating. It is also interesting to note that a substantially higher percentage of scholars (10%) rated MG as the value that should always or almost always guide the HRD process while only 3% of practitioners rated it so. These findings are consistent with value theory and strongly suggest that, while the domain of HRD values may be the same for scholars and practitioners, the structure and relative priority of those values may vary based on the differing challenges individuals face in the expression of those values.

Conclusions

At least two important conclusions can be drawn from this research. First, this research demonstrates that HRD professionals operate from a structured set of values that can be described and measured. For example, this study suggests that individuals who place high priority on meaning-related values (CEW, BCO) also tend to give high priority to a normative, macro-level goal (MG) as a guiding value. On the other hand, individuals who place high priority on performance outcome-related values (IJSP, MOG) do not give high priority to a normative, macro-level goal (MG) as a guiding value nor do they tend to rate learning-related values highly. Understanding value structures such as these is important because they represent enduring evaluative standards that individual HRD professionals use to make decisions about how the HRD process should work. Describing and measuring such structures can give insight into both the actions that individuals undertake in the HRD process as well as the beliefs and attitudes that HRD professionals have about the development of human resources.

Second, the data indicate that the measures used in this study tapped individual value priorities rather than a set of normatively approved values of HRD professionals as a group. This is an important conclusion because, to the extent that values represent group ideals, individuals may be inclined to report values that reflect group norms rather than personal priorities. If this were the case, then the values and value priorities identified in this study would better be understood as cultural conventions of the HRD profession rather than reflective of individual motivations and beliefs.

However, our focus and interest in this study was identifying and describing the personal value priorities of HRD professionals. We believe the data provide evidence that we have been successful in this endeavor. For instance, it is clear from this research that the value priorities of individual HRD professionals vary considerably. Not only did each of the seven values measured receive one or more 'top rankings', at most only about one-third of the individuals in this sample were in agreement about any one specific value as that which should be most important in guiding the HRD process. In addition, a number of findings in this study suggest that individual variation in value priorities was associated with individual differences. For example, a higher percentage of women rated MG as a top priority than did men; a substantial percentage of scholars (10%) rated MG as the top priority while only a small proportion of practitioners did (3%); and none of the scholars in this study rated either of the performance-related values (IJSP or MOG) as the top priority whereas nearly a quarter of practitioners gave one of these values the top ranking. If these differences were due to measurement error or error in the respondent's perception of cultural beliefs then it is unlikely that these kinds of systematic differences would have emerged.

Because this study tapped individual value priorities, it would be misleading to draw conclusions from this data about the normative value structure for HRD. Although the descriptive and inferential statistics used in this study were used to characterize the value priorities and differences in this sample, we cannot use this data to conclude that these findings in any way represent the normative value structure of the HRD profession as a whole. In short, the values assessed in this study reflect individual priorities and it is not possible to derive the normative ideals of a larger group or culture from the average of individual responses (Schwartz, 1992).

How This Research Contributes to New Knowledge in HRD

It is perhaps true that "[a]s a profession, we have not done a very good job of working to identify who we are, what we stand for, and what we can [or more importantly should] do for those we serve" (Ruona, 2000b). If HRD is to make headway in determining what the driving goals of our practice should be or how we should define ourselves as a field of research and practice then some understanding of fundamental values driving the HRD process must be...
reached. This research represents perhaps the first empirical attempt to identify a specific set of HRD values and to create a quantifiable description of how individual HRD professionals believe the ideal HRD process should be viewed.

One reason that HRD is viewed as a field in search of itself is that the roles and practices that HRD professionals develop and institutionalize vary widely. The rules that govern individual behavior in these roles and practices reflect an underlying set of core values. Even though espoused values (Hofstede, Neuijen, Ohayv, & Sanders, 1990) can differ from values in use (Posner, Kouzed, & Schmidt, 1985) we believe the identification of values in this study has helped to more fully illuminate the worldview from which individual HRD professionals operate and the standards framing individual research and practice.

This research also lays the foundation for future values-related research that could significantly contribute to the field of HRD. The values assessed in this research can be used to more fully understand individual differences in beliefs, attitudes, and organizational practices of HRD professionals. They also provide a means for investigating how values may affect the actual practice of HRD and how person or system factors might affect the values-behavior link. It may also be fruitful to use these measures to investigate how the individual value priorities of HRD professionals in an organization influence the perceived value of HRD or the expected outcomes from HRD. For example, questions about how other stakeholders in organizations (e.g., top management, line managers and supervisors, individual employees, trade unions, customers, etc.) respond to and interpret these values and how are these perceptions are related to the status and perceived value of HRD represent important future research questions.

Finally, it would be a mistake to accept the current findings as the final word on HRD values. The present data was drawn from a small sample of U.S. professionals, almost exclusively AHRD members. This clearly excluded a potentially large number of other HRD professionals, particularly those from other parts of the world. This is critical since research suggests that the definition of HRD varies “from one country to another, and the national differences are a crucial factor in determining the way in which HRD professional work” (Hillion & Mclean, 1997, p. 695). The clear implication is that the values underlying the role and process of HRD may be related to a country’s cultural or national values, to the level of economic development, or to the point in the life cycle development of the field in any particular country (McLean & Mclean, 2001). Consequently, the cross-national and cross-cultural study of HRD values may lead to the identification of additional values not included here.

The Development of a Research Instrument to Compare Working Values Across Different Cultures—Based on Hofstede’s VSM Questionnaire

Salwa Yousef Al-Sharqawi
Sally Anne Sambrook
University of Wales Bangor

This paper describes the exploratory research approach used to adapt Hofstede’s questionnaire (Value Survey Module, VSM94) for use in a doctoral research project examining work values in public and private banks in Kuwait and replicating Hofstede’s study of cultural dimensions. Drawing upon focus group and interview findings, ‘Kuwaiti’ values were identified and the original VSM questionnaire was adapted for use.

Keywords: Hofstede, Replication, Kuwait

This paper draws upon a doctoral research project, where the final aim is to replicate Hofstede’s study. This suggests the use of Hofstede’s instrument. However, the authors consider that the VSM needs to be looked at from a Kuwaiti perspective, to remove any ‘western’ bias. To address this, the approach followed was similar to that used in the development of the ‘Chinese Value Survey’ (CVS) by Michael Bond (Chinese Culture Connection, 1987). Bond consulted Chinese social scientists for a list of values important to the Chinese, and then developed a questionnaire incorporating these values. Similarly, when consulted about using the VSM to investigate Kuwaiti culture, Hofstede (personal interview 07 May 2000) highlighted the need to incorporate specific values, recommending the use of focus groups. These values could then be incorporated into a contextually adapted questionnaire. Thus the basic research tool had to be evaluated for applicability and suitability to Kuwait. The focus group and interview techniques were used to identify these values. These were incorporated into a new questionnaire. This paper details the process of modifying the VSM94 for Kuwait and presents the results of the focus group and interviews.

The Issue under Study

Beginning in 1966, Geert Hofstede (1980) conducted a research to explore cultural differences. He derived four cultural dimensions: individualism, masculinity, power distance, and uncertainty avoidance. Theoretically, these could explain cross-cultural behavioral differences. The issue is if the questionnaire itself is culture-free, that it does not deal with culture-specific values. Exploring differences and similarities among cultures is problematic, mainly because cross-cultural research can be limited by the ‘made in America’ theories, where there is an indiscriminate export of a theory to a cultural context where its application is inappropriate. To address this, Bond et al (1987) developed the Chinese Value Survey. Turning to the Kuwaiti context, and wary of any cultural bias, the authors of this study examined a Kuwaiti sample to assess if the VSM in its present form could be applied to Kuwait and then be used to replicate Hofstede’s study in Kuwait. However, initial findings suggested that the VSM needed to be adapted to incorporate values identified as being important to Kuwaitis. This paper presents these findings.

The Theoretical Framework of the Study

This paper is an investigation of Kuwaiti work values. Once identified, it is then possible to determine how these score on a series of cultural dimensions. Thus, it is first necessary to consider what we mean by culture. A human society is made of individuals, joined by relationships and codes of conduct that dictate actions and behaviors. These behaviors are commonly referred to as the social or national ‘culture’. Schein describes culture as ‘a pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think and feel in relation to those problems,’ (1997, p. 12). Hofstede defines culture as the "collective programming of the mind that distinguishes the members of one group of people from another" (2001, p. 9). To study and compare cultures, researchers need conceptual frameworks to understand patterns and practices. Hofstede says that such frameworks must ‘consist of empirically verifiable, more or less independent dimensions on

Copyright © 2002 Salwa Al Sharqawi and Sally Anne Sambrook
which cultures can be meaningfully ordered' (1980, p. 36), such as 'values' and 'culture'.

At the center of any society is the 'value system' (Hofstede, 2001, p. 11) adopted by the majority of the population, originating in social institutions like family, education, politics, history, etc. Cultural changes come from forces of nature and forces of human beings. Hofstede (2001) points out that individual differences within the same culture may be due to age (values shift with age), generation (values in young people of a certain period and continuing over the lifetime) and / or zeitgeist (drastic system changes that cause total value shifts). The following model shows the formation of culture. The central proposition is that socio-political environment is responsible for shaping the culture. Any environmental modifications reflect in the culture and individual behaviour.

Interested in identifying possible cultural differences, Hofstede administered the VSM in 20 languages to 116,000 IBM employees in 50 countries. He analyzed the data such that he could compare results across countries. From a factor analysis of cultural averages, his study proposed four cultural dimensions each located on a 'continuum ranging from high to low, along which nations could be also placed' (Tayeb, 2001, p. 92). A fifth dimension was added later. Following are the definitions of the five dimensions of national culture:

- **Power Distance** – The extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally (Hofstede, 2001, p. 98).
- **Individualism** – This stands for a society in which the ties between individuals are loose. Everyone is expected to look after him/herself and her/his immediate family only. Collectivism stands for a society in which people from birth onwards are integrated into strong, cohesive in-groups, which throughout people’s lifetimes continue to protect them in exchange for unquestioning loyalty (Hofstede, 2001, p. 225).
- **Masculinity** – This stands for a society in which social gender roles are clearly distinct. Men are supposed to be assertive, tough, and focused on material success; women are supposed to be more modest, tender, and concerned with the quality of life. Femininity stands for a society in which social gender roles overlap. Both men and women are supposed to be modest, tender, and concerned with the quality of life (Hofstede, 2001, p. 297).
- **Uncertainty Avoidance** – The extent to which the members of a culture feel threatened by uncertain or unknown situations (Hofstede, 2001, p. 161).
- **Long Term Orientation** – This stands for the fostering of virtues oriented towards future rewards, in particular, perseverance and thrift. Its opposite pole, Short Term Orientation, stands for the fostering of virtues related to the past and present, in particular, respect for tradition, preservation of 'face' and fulfilling social obligations (Hofstede, 2001, p. 359). Initially identified as Confucian Work Dynamism, this dimension was added after the 'Chinese Value Survey' (CVS) by Michael Bond (Chinese Culture Connection, 1987).

To validate his findings, Hofstede (2001) later used nine geographic, demographic, and economic indicators: national wealth, past and present economic growth, geographic latitude, population size, population growth, population density, organizational size and relative organizational size (to the total inhabitants of the country). This correlation lead to a suggested causal chain for the origin of national differences. Further cross-cultural research has been conducted based on Hofstede’s methods. Three main studies are briefly reviewed below.

**Michael Bond and the Chinese Culture Connection (1987):** Bond constructed a Sinocentric version of Hofstede’s study and demonstrated a Western bias in the VSM. Introducing a deliberate eastern bias in the Chinese Value Survey (CVS) questionnaire, Bond studied values of students in 23 countries. Bond’s results replicated Power distance, Individualism, and Masculinity, but failed to find Uncertainty Avoidance, and instead discovered a fifth dimension: Confucian Dynamism (now called Long-term Orientation), that was rooted in Confucian teachings.

**Shalom Schwartz’s country level analysis (1987, 1990, 1992, 1994):** Schwartz et al. (Schwartz, 1992, 1994; Schwartz & Bilsky, 1987, 1990) proposed the universal structure of value theory that clusters cultures into groups and explains differences and similarities. Schwartz first identified mankind’s fundamental issues, and then found value dimensions. He identified 3 fundamental biological, social and survival needs. Then 56 values were identified and students and schoolteachers in 50 countries indicated the extent to which these values had guided them.
Though more numerous, Schwartz's work is a refinement of Hofstede's research. There are values like stimulation and hedonism (similar to Individualism) and opposites like security, tradition, and conformity (similar to Collectivism).

Charles Hampden-Turner & Fons Trompenaars (1993, 1994): Trompenaars and Hampden-Turner identified five value orientations: universalism/particularism, individualism/collectivism, neutral/emotional (replaced with equality/hierarchy, 1994), specific/diffuse and value achievement/ascription. Additionally there are attitudes to time and attitudes to the environment. The universalism/particularism orientation (preference for rules rather than relationships) can be interpreted as part of both Uncertainty Avoidance and Individualism. The individualism/collectivism orientation is identical to Hofstede's individualism. The neutral/emotional orientation (range of feelings expressed) appears to be part of Masculinity. The achievement/ascription orientation (how status is accorded) is linked to Power Distance. The specific/diffuse orientation (range of involvement) cannot be directly linked.

Research Questions or Propositions

Having reviewed these studies, it can be suggested that simply 'applying' research instruments developed in one cultural context to another will fail to address cultural bias. This highlights the inadequacy of Western frameworks to analyze non-Western cultures. Thus, the authors had to establish a research instrument that would 'fit' the Kuwaiti context. It was considered necessary to introduce a 'Kuwaiti' bias to the VSM, by adding questions based on values that are important to the Kuwaitis, and shifting the focus of the VSM to Kuwait. This raises methodological and research questions. Can an instrument designed in one cultural context be applied to another? Would the results be the same, different or altogether incorrect as the measures are wrong? Would it be possible to identify a new set of values specific for Kuwait, by modifying VSM94?

Methodology

Kuwait provides a unique context in which to examine work values. Kuwait, within the Arab world and Asia, is far from the European and North American base from where most of the commonly held theories arise.

- **Geographical and eco-political aspects:** Kuwait is located in the Middle East, bordering the Persian Gulf, between Iraq and Saudi Arabia, occupying 17,820 sq. km, at 29° 30' N, 45° 45' E latitude (CIA, 2001). The terrain is flat to slightly undulating desert plain with intensely hot summers and short, cool winters. Kuwait was a fishing, pearling and trading community on the Europe - India trade route, before oil was discovered in 1938. The 1960-70s saw rapid development. Kuwait has about 10% of the world’s oil reserves. Kuwait is a quasi-hereditary emirate. The ruler, the Amir, is chosen by the members of the ruling family from amongst themselves. Islam is the state religion. Arabic is the state language, but English is widely spoken.

- **Demographic structure:** Kuwait’s population is about 2,041,961 (CIA, 2001. July 2001 est.), of which 1,159,913 are non-nationals, mainly Egyptians and Indians. The population growth rate is about 3.38% (CIA, 2001. 2001 est.). The population density (per sq. km) is 107.4 (Hutchinson Family Encyclopedia, 2000. 1998 est.). Of the labor force only 16% is Kuwaiti, of which 92% works in the public sector. 32% of the Kuwaiti labor force works in the public and private banks (Institute of Banking Studies, 1994).

- **Role of the family:** In Kuwait, the family is an important cultural influence. Traditionally, families were a single, large, extended economic unit. Often male children would continue to live in the family home, with their own families. The Oil Era and urbanization lead to nuclear, double income families. This resulted in dependence on domestic help. This, though not unique in itself, had peculiar effects on Kuwait.

- **Effects of the dependence on domestic help:** In 1997, 62% of all Kuwaiti households had at least one South East Asian female domestic worker (Central Statistics Office, 1998). This greatly altered the values and behaviors of young Kuwaitis. They grew accustomed to having someone providing services to them. ‘Work’ and the ‘need to work’ became synonymous with these workers. Young Kuwaitis feel no need to work for a living since their family and the government is obliged to provide for them. (Higher Planning Council, 1991)

- **Welfare System and Social Security Scheme:** The government’s cradle-to-grave welfare system provides Kuwaitis with free housing, health, and education. This has created a group of individuals who rely on social aid and feel no need to earn a living. A divorced woman, for example, who can work, may choose not to work as she gets social aid. Additionally under the Social Security Scheme, male Kuwaitis can retire after 20 years of service (15 years for females) (Public Authority for Social Security, 1995). Many choose this option.

- **Work Ethics:** The private sector is not appealing as most Kuwaitis prefer the relaxed and guaranteed employment of the public sector. Many in Kuwait’s post-Oil generation grew up perceiving work as a form of social gatherings.
There is apathy to work, low productivity, lack of commitment, and a resistance to discipline.

- Emphasis on Status and Hierarchy: In Kuwaiti society status distinctions play a vital role in public and private life. Birth and clan are determinants of the status and prestige of a particular person. Very often, hierarchy or legalities are over ridden by family connections or clan affiliations (wasta = Arabic for 'reference' – literally).

Selection of Survey Content and Subject

It was important to identify and isolate these 'Kuwaiti' values, to modify the VSM94. As a first step, the research process included a focus group. This method was chosen as it allows maximum interaction and cross-questioning and it is possible to explore opinions, attitudes, and beliefs. To support this, interviews were conducted with job applicants. In addition, to augment the findings of the focus group and interviews, human resource managers were interviewed as well. The questions for the focus group and the interviews were based on a consultation that the Kuwaiti author had had with Kuwaiti colleagues, from various functional areas such as marketing, finance, and human resources. These individuals first listed values that they felt were important for Kuwaitis. In this way, the Kuwaiti author collected a set of 'Kuwait values'. Based on this she prepared a set of questions that when asked to a sample of Kuwaitis would hopefully yield the same answers as in the list. The questions were first developed in English and translated independently by two bilingual persons. An acquaintance of the Kuwaiti author, Essa Al-Jassem, former Research and Development Director, Ministry of Education, guided in re-writing the questions. He also circulated the questions to his 'bilingual' acquaintances for back-translation and content equivalence.

The Focus Group Session – Sampling and Data Collection

A focus group of 33 participants was convened on July 23, 2001. To assemble the participants, the snowballing technique used. The Kuwaiti author asked friends and acquaintances to invite their friends and acquaintances to invite their friends and acquaintances and so forth. The main criterion was that the participants had to be employed, retired or looking for a job. Students and housewives were not included. Before the session began, the participants were briefed about the project. Flipcharts
were used during the interactive session to ensure the clarity of the questions. Notes were taken, and the session was audio-recorded and later transcribed. In the focus group, four main questions were asked.
1. What does work mean to you? What are you trying to achieve through work?
2. What were you trying to achieve in the beginning of your career and has it changed now? If so, how?
3. What are your expectations from your organization, colleagues, and superiors?
4. What are the factors that can make you change your job for another?

To validate these answers, twelve job applicants were later interviewed separately, with the same questions.

The Interviews

Four human resources managers were interviewed (3 - private banks and 1 - public bank). They were asked similar questions as the focus group to help confirm the former answers. Specific questions about the private and public sector were asked as this issue is peculiar to Kuwait.
1. Why Kuwaitis prefer the public sector over the private sector?
2. Why staff turnover rates are much higher in the private sector than the public sector?
3. What a job really meant for Kuwaitis?
4. What are Kuwaitis expectations from a job and the organization?

Key Findings

Focus Group Findings

1. What does work mean to you? What are you trying to achieve through work? Majority mentioned income as the reason for work. Others said that they worked to augment family income. Some worked to provide for material possessions like cars, etc and to meet community expectations. Socializing, networking, and building relationships through the job were specific purposes. Doing favors and obliging others, achieving 'power' by working in prestigious organizations and influencing decisions was another reason. 'Self satisfaction' came in much later.
2. What were you trying to achieve in the beginning of your career and has it changed now? If so, how? Older participants said that they had been looking for 'achievement' while younger participants mentioned income.
3. What are your expectations from your organization, colleagues, and superiors? Most participants said that they wanted to work with very little pressure. For organizational expectations, some said that they expect jobs that allow adequate personal time. Flexible working hours were also welcome. Other expectations were getting long and frequent leaves. Some expected their company to follow Islamic percepts (mostly banks employees - Islam forbids interest/usury - and law firm employees -distortion of facts to plead a case is seen as deceit). Some wanted comfortable physical working conditions. Opportunity for on-job training or education with full scholarship had medium importance. Noticeably, very few mentioned what they would do or contribute to the organization or the country. Many said that they look for informal terms with their colleagues, after working hours as well. As for superiors many participants said that they did not welcome any criticism of their performance. It was seen that males did not mind working for a female boss, while females preferred a male superior.
4. What are the factors that can make you change your job for another? Majority said that the main factor would be the level of 'appreciation' given, most wanted to be pampered. Additionally, being consulted for day-to-day decisions was very important. Many said that the job title was important. A person is willing to work as a 'secretary' but wants the title of 'office manager'. The job is not important, the social acceptance of the job designation is. Career advancement came much later, although, this must be accompanied by an increase in income as well. Few mentioned that they would switch for jobs that offered new and international experiences.

Specific Demographic Correlations: Participants who were better educated, older and held higher managerial positions mentioned that 'achievement' was important for them. More older and experienced participants said that in the beginning of their career they were looking for 'achievement' and not money. On the other hand, younger participants said that they are trying to achieve a high level of income. It was also noticed that participants who were educated outside Kuwait were more focused on issues like training opportunities and self-satisfaction.

Interviews Findings

Job applicants were asked questions similar to the focus group. The outcomes were comparable.
From the interviews of the Human Resources managers, these observations were noted:

1) **Reasons for Kuwaitis' preference for the public sector over the private sector**: The main reasons were job security (no one can be 'fired'), high salaries, less work pressure, less demand for productivity, flexibility to leave the workplace for personal reasons (relaxed attendance rules), long annual leaves and generous retirement schemes.

2) **Reasons for high staff turnover rates for Kuwaitis in the private sector**: Services can be terminated for non-performance, there is demand for productivity with longer working hours and attendance regulations. These observations are supported by the results of a study by the Institute of Banking Studies (1994).

3) **What a job really meant for Kuwaitis**: In order of importance: Income, authority, networking and satisfaction.

4) **Kuwaitis' expectations from a job and the organization**: Kuwaitis give little and expect more. 'Expectations' include that the company must accept social and personal obligations. Kuwaitis expect much appreciation for doing their job and expect to be promoted faster. Kuwaitis are difficult to manage, as they resist authority and corrective criticism. Any coaching or remedial measures are unacceptable (Item responses available by contacting authors.)

**Conclusions**

From the focus group and interviews, it can be concluded that there appear to be distinct work values among Kuwaitis. The foremost observation is that there are cultural factors that the VSM is not equipped for. In principle, the VSM94 is transferable in totality. However, the question is how to address the cultural issues whose measurement is not provided for in the VSM. Many Kuwaiti values do not have equivalents in the VSM. This has implications for any research intended to replicate Hofstede's study. For example, the addition of questions to fine-tune the VSM to the sample under study has been done by Micheal Hoppe (1990). He used a questionnaire that had the IBM questions plus a section on organizational learning, and approached the alumni of the Salzburg Seminar, Austria, a cross section of international leaders from politics, business, art, and education. Out of the four dimensions, masculinity required different questions and computations (1998), implying that there was no single set of questions. Hofstede (2001) says that the ideal questions must be nationality dependent and mean the same to all society members. The VSM was developed for IBM in the 70s, meaning that questions have to be adapted to the intended respondents, situation, and period. For this purpose, 29 additional questions are proposed.

**Translation and Content Equivalence.** Having identified these additional work values, the new contextualised questionnaire was finalized in English to maintain closeness to the VSM and then it was translated into Arabic. Mr. Essa Al-Jassem assisted once again with the back-translation and content equivalence. The questionnaire was then pilot tested with 12 respondents to check the continuity and flow of questions. The questionnaire has been used in the main data collection phase with employees of public and private banks in Kuwait. The data analysis is in process.

**Further Course of Action**

Once the data is collected from this modified questionnaire the findings will be analyzed and used to modify Hofstede’s value system to reflect Kuwaiti values. This next course of action is the aim of the thesis. Both the original VSM questions and the added questions will be treated according to Hofstede’s methodology. It is only after the factor analysis that it will be clear which dimension the new questions align with, or if there is a new alignment. Reliability and validity analyses will be done later. This stage is the preliminary one.

**How this knowledge contributes to new knowledge in HRD**

Bond (1987) demonstrated the need to be cautious in generalizations. The key (methodological) conclusion from this study is that any research instrument has to be adapted for the local culture before application. This study reinforces the need to adapt ‘generic’ research instruments so that they are culturally relevant to investigate values within a specific context. Kuwait, excluded from Hofstede’s research on account of small sample size, presents unique geographic, economic, demographic and political indicators for a study of cultural variations. This study contributes to existing knowledge of cross-cultural analysis by identifying work values in a previously unresearched context. The completion of this thesis will add to the countries already studied by Hofstede and others, and will serve as the benchmark and prepare ground for repeat surveys. This is mainly because a limited number of such studies have been done for Kuwait. A study by the Institute of Banking Studies (1994) on the high turnover among Kuwaitis in the private banking sector is worth reviewing. Among other issues, the study analyzed the social and educational characteristics of the sample, the reasons for resignation and the extent of satisfaction with the current job. It also
analyzed the extent to which the respondents said that they were able to achieve their goals through the new job.

Empirical findings from this thesis will also contribute to new knowledge in HRD by providing understanding of Kuwaiti work values. This can assist human resource practitioners in developing more culturally relevant HR practices, for instance, designing relevant interventions to change Kuwaiti orientations to work. The knowledge of the Kuwaiti culture and the dominant work values can be applied to training programs to increase motivation, and Kuwaiti policy makers can draft better methods to remedy the problems of low productivity in the native workforce. This thesis will also provide a platform for further research. Kuwait is a multi-ethnic, multi-cultural society. The current sample is the Kuwaitis in Kuwait. Similar studies can be conducted for the different residents of Kuwait, giving an insight into the work values of expatriates. Another question that can be answered is that would the Kuwaitis demonstrate similar values if they were an expatriate group working in the USA, UK or India.

All this will proceed to contribute categorically to new understandings of cultural work values and thus contribute to international developments in Human Resources Development.

An Examination of the Viability of the Work Ethic Construct

Sharon S. Naquin  
Elwood F. Holton III  
Louisiana State University

This paper discusses the Protestant Work Ethic (PWE) literature and conducts exploratory and confirmatory factor analysis on leading composite measures of PWE constructs. Exploratory factor analysis results replicated those found in previous literature. However, confirmatory factor analysis, which had never been done in the literature, showed that the scales did not load on the PWE latent construct. Thus, it is recommended that PWE not be used in HRD research.

Keywords: Work Ethic, Dispositional Effects, Values

Employers frequently mention work ethic (also termed Protestant Work ethic or PWE) as a desirable characteristic of employees (Hill, 1992). HRD research has paid little attention to the work ethic construct. Thus, there are three primary purposes of this paper— to review the PWE literature as it relates to HRD; to use confirmatory factor analysis to test the dimensions of the work ethic construct, and to discuss the viability of this construct in future HRD related research. The work ethic construct has not been tested using Confirmatory Factor Analysis (CFA) techniques. Previous work ethic exploratory factor analysis (EFA) techniques only serve to determine whether the data have separate common factors underlying the item responses. EFA does not establish whether those separate constructs load on a single, higher order construct. This requires either a CFA or a second order EFA.

Review of Related Literature

Countless researchers have offered definitions of the work ethic construct. Greenberg (1977), for instance, identifies work ethic as a personality construct, and Morrow (1983) defines the term as the extent to which a person believes in the importance of work itself. Depending on the specific conceptualization and measure chosen, ideas related to the importance of independence, self-sufficiency, frugality, paid employment, and explicit rejection of leisure are also part of the definition” (Morrow, 1993, p. 1). Other researchers extend their conceptualizations of the work ethic past the notion of intrinsic value and introduce personal accountability and responsibility for the work that an individual performs into the definition of work ethic (Cherrington, 1980; Colson and Eckerd, 1991; Yankelovich and Immerwahr, 1984).

There are other characteristics attributed to individuals with high levels of work ethic. As defined by Weber (1958), these principle aspects of PWE include: individualism (the assertion of one’s uniqueness), asceticism (the renunciation of the comforts of societal in favor of an austere, self-disciplined lifestyle), and industriousness (assiduous work or study, diligently active). Of these, industriousness probably represents the most critical aspect of PWE (Wollack, Goodale, Witjing, and Smith, 1971). Furnham (1990b) provides more detailed descriptions of the characteristics associated with the construct. Some of these characteristics are a high internal locus of control (Furnham, 1987; Lied and Pritchard, 1976; Waters, Bathis, and Waters, 1975); conservative attitudes and beliefs (Furnham and Bland, 1982; Joe, 1974; MacDonald, 1971), individualistic attribution styles (Furnham, 1982b; Feather, 1984); and a high need for achievement (McClelland, 1961; Furnham, 1987). Furnham (1990a) also contends that high PWE scorers are independent-minded, competitive, and hard working.

Representing a set of values related to work, work ethic generally seems to refer to a commitment to work that is stronger than just providing a living (Barbash, 1983, Lenski, 1961). Thus, the PWE, according to Aldag and Brief (1975), Rim (1977), and Wannous (1974), also serves other functions – patterning and regularity of working hours, intrinsic work satisfaction, and role-identity with the task.

The concept of work ethic has also been defined for “an individual (or for a more or less homogeneous group of individuals) as a value or belief (or a set of values or beliefs) concerning the place of work in one’s life that either (a) serves as a conscious guide to conduct or (b) or is simply implied in manifested attitudes and behavior” (Siegel, 1983, p. 28). This definition is an important one because it applies to a wide variety of groups: it is culture-free, neutral to a historical context, to location, and to nonwork interests. It is also "positive" as opposed to being "normative," and allows room “for all the composite work ethics that have been described or sponsored in a vast corpus of sociological, political, and religious literature – Protestant, Calvinistic, Puritan, Primitive, Christian,

Copyright © 2002 Sharon S. Naquin and Elwood F. Holton
monastic, feudal, Talmudic, Buddhist, utopian, communist, etc” (Siegel, 1983, p. 28).

As the above definitions illustrate, there is no fixed definition of the construct. One of the primary reasons for this is the fact that work ethic is multidimensional and is associated with aspects of economic, political and social life. In this study, work ethic is considered to be a personal value. Regardless of the definition adopted, however, researchers generally agree that work as the core of a moral life is the central premise of the work ethic concept (McCracken and Falcon-Emmanuelli, 1994, p. 5). “Work makes people useful in a world of economic scarcity: It staves off the doubts and temptations that preyed on idleness; it opened the way to deserved wealth and status; it allowed one to put the impress of mind and skill on the material world” (Rodgers, 1978, p. 14).

**Theoretical Foundations Of PWE.** Regardless of the definition used to describe the term, researchers attribute the origin of the construct to sociologist Max Weber’s (1958) PWE theory (i.e., Barbash, 1983). Weber’s treatise maintained that the work ethic involved an entire philosophy of life (Cherrington, 1980), related business success to religious beliefs, and first introduced the concept of the Protestant Work Ethic. Weber wrote, “Labour must be performed as if it were an absolute end in itself, a calling” (1958, p. 62). According to Weber (1947), “the holder of the Protestant Ethic is committed to the values of hard work, to the work itself as an objective, and the work organization as the inevitable structure which those internalized values can be satisfied” (Kidron, 1978, p. 240).

The PWE construct emerged from Calvinistic and Quaker individualism and asceticism (Maccoby, 1983). Weber recognized this, and described the Calvinist tradition of frugality, hard work, conservatism, success and its contribution to capitalism (1904-1905, 1958). “Unlike the Lutheran view of a calling as one’s fate that should be accepted with good grace, the Calvinistic-Puritan view demanded constant work at one’s ‘calling’ as proof of one’s faith and membership in God’s elect. Citing the parable of the talents (Matthew 25), the Puritan was urged to prosper: ‘You may labor to be rich for God, though not for the flesh or sin’” (Maccoby, 1983, p. 183).

Though the origin of the concept had religious affiliations, the current conceptualization is much more a secularized construct (Hill and Petty, 1995). The underlying attitudes and beliefs that have contributed to and supported hard work have been incorporated into Western cultural mores and are no longer solely connected with a particular religious sect (Hill and Petty, 1995; Rodgers, 1978; Rose, 1985a). However, many of the characteristics associated with the construct are still applicable today.

**Studies Relating To Work Ethic.** Much of the research effort relating to work ethic have been focused on devising psychometrically sound measures of the PWE; examining the relationship between PWE beliefs and other work and non-work behavior; and investigating the relationship between the PWE beliefs and other individual difference measures of personality, values and social attitudes (Furnham, 1982b, 1983, 1984b, 1985, 1986, 1990). Furnham (1990a), for instance, content analyzed seven work ethic scales. He found that items from PWE fit into six possible categories: 1) work as an end in itself, 2) hard work and success, 3) leisure, 4) money/efficiency, 5) spiritual/religious, and 6) morals.

In a study designed to examine the relationship between work behavior and the PWE, Merrens and Garrett (1975) found that individuals with high PWE scores performed better and longer on tasks designed to provide low motivation and interest levels. Also, Greenberg (1977) found that negative performance evaluations resulted in performance improvement among individuals with high PWE scores and a decrease in performance levels among individuals with low PWE scores. Greenberg (1979) also found that high PWE scorers had a tendency to take both productivity levels and duration of work into consideration when making decisions regarding the allocation of money to hypothetical workers. In contrast, individuals with low PWE scores used the duration as the only criterion in deciding how to distribute funds.

Other correlates of PWE include higher order strength needs, authoritarianism, and internal locus of control (Morrow, 1983). The construct has also been studied with regard to job design variables (Ganster, 1980; Sekaran, 1989), psychological distress (Jackson et al., 1983; Stafford et al., 1980), days off (Koslowsky et al., 1990), sick days (Koslowsky et al., 1990), employment status (Stafford et al., 1980), mental health (Stafford et al., 1980), occupational rank (Dickson and Buchholz, 1977), religion (Buchholz, 1977) and job satisfaction (Morrow and McElroy, 1987). Morrow (1993) also reported:

- A composite measure of professionalism and five constituent subscales . . . demonstrated correlations with PWE ranging between nonsignificant and r = .34 (Morrow and Goetz, 1988) while job involvement . . . and PWE correlations ranged between r = .24 (Sekaran, 1989) and r = .41 (Morrow and McElroy, 1986). Organizational commitment . . . and PWE correlations were between r = .28 (Morrow and Goetz, 1988) and r = .42 (Morrow and McElroy, 1986) (Morrow, 1993).

PWE has also been investigated in several different cultures (Tang, 1993). Tang (1993) lists these as Great Britain (Furnham, 1984a, 1984b, 1989; Furnham and Muhiodeen, 1984), Malaysia (Furnham and Muhiodeen,
1984), Taiwan (Ma, 1986; Ma and Smith, 1985; Tang, 1990; Tang and Bumister, 1984), Hong Kong (Ma, 1987); New Zealand (Poulton and Ng, 1988), the Caribbean islands (Gonsalves and Bernard, 1983), East Africa (Munroe and Munroe, 1986), and South Africa (Bluen and Barling, 1983). This diversity in foci of studies gives testimony to the fact that researchers generally attribute great significance to the strength of the work ethic to pervade many aspects of life.

McClelland (1961) drew heavily upon Murray's work and became a pioneer in the attempt to conduct a psychological analysis of PWE (Furnham, 1990a). Their efforts were primarily directed at examining the relationships between an individual's need for achievement (n Ach) -- which is considered a dispositional or psychological individual difference variable-- and economic growth. Based on McClelland’s studies, Furnham (1990b) concluded that n Ach “is clearly a major component of the PWE though these overlapping concepts are not identical. The latter is multi-dimensional, while the former unidimensional” (p. 29).

Method

Sample. Data for this study were obtained from a nonrandom sample of 245 subjects from a single private sector health insurance organization. Respondents were participants of in-house training programs, and ranged from clerical employees to mid- to upper-level managers. Training topics included computer training, team building skills, new employee training, technical training, and leadership training sessions.

This sample size is well within the recommended range for structural equation modeling research studies (Hair et al., 1998; Kelloway, 1995). Generally, a minimum of 200 subjects is recommended (Hair et al., 1998), and a respondent to parameter estimated ratio of 5:1 is considered adequate. In this model, the ratio falls within the acceptable range.

The average age of the respondents was 35.5 years (min. = 19 years, max. = 68 years, sd = 10.516); 28.4% or 68 of the respondents were male and 71.6% or 171 of the respondents were female. Five of the respondents (2.0%) had less than 1 year work experience; 16 respondents (6.7%) had 1-3 years work experience; 30 respondents (12.6%) had 3-5 years work experience; 101 respondents (25.1%) had 15-25 years work experience; and 27 respondents (11.3%) had more than 25 years work experience. Fifty-five respondents (22.7%) reported 1-3 years with the company; 36 respondents (15.0%) reported 3-5 years with the company; 48 respondents (20.0%) reported 5-15 years experience with the company; 39 respondents (16.3%) reported 15-25 years with the company; and 6 respondents (2.5%) reported more than 25 years with the company.

Procedure. Surveys were administered to respondents prior to their participation in an organizational training program. All participants were required to attend these classes as part of their job responsibilities. In each case, the trainer read a description of the research project with instructions for participation from a prepared script. Questionnaires were presented to participants as part of the training program. Instructs were told to allow the participants to withdraw if they had any objections to the study: none objected, however.

Measuring Work Ethic. Furnham (1990a, 1990b) conducted a comprehensive review of the work ethic literature (Blau & Ryan, 1997). He cited seven measures of the construct: Protestant Ethic (Goldstein & Eichorn, 1961); pro-Protestant Ethic and non-Protestant Ethic (Blood, 1969); Spirit of Capitalism (Hammond & Williams, 1976); Protestant Work Ethic (Mirels & Garrett, 1971); Leisure Ethic and Work Ethic (Buchholz, 1977); Eclectic Protestant Ethic (Ray, 1982); and Australian Work Ethic (Ho, 1984). Furnham a priori content analyzed and then empirically factor analyzed these measures. His content analysis indicated that there are seven dimensions of PWE: hard work, nonleisure, independence, asceticism, separate morals and spiritual/religious factors. His subsequent factor analysis with varimax rotation found empirical evidence for five factors: belief in hard work; leisure avoidance; religious and moral beliefs, independence from others and asceticism. The multidimensionality of this construct (e.g., multiple eigenvalues greater than unity) is also supported by factor analyses by Heaven (1989), Tang (1993), and Mirels and Garrett (1971).

Building on the work of Furnham (1990a, 1990b), Blau and Ryan (1997) conducted exploratory factor analyses to identify dimensions of the work ethic construct. Their study revealed a four-dimensional construct: hard work, nonleisure, asceticism, and independence. Coefficient alpha reliabilities were .85 for hard work; .80 of nonleisure; .75 for independence; and .70 for asceticism. Their findings were supported in various sub-sample analyses. Also emerging from the Blau and Ryan (1997) study was an 18-item secular work ethic instrument (see Table 1). The items were selected from high loading items drawn from the seven instruments used in Furnham's work. This instrument consists of 6 hard work items, 5 non-leisure items, 3 asceticism items, and 4 independence items. Even though Blau & Ryan (1997) contended that a shorter (12-item) instrument could be formed by choosing the 3
highest loading items for each factor, this study will utilize the longer 18-item factors that emerged from their study. This instrument appears to contain the most valid items empirically derived from the seven different instruments.

**Analysis.** This study's analysis was a two-step process. First, the factor structure of the 18 items used to measure PWE (Blau & Ryan, 1998) was evaluated through exploratory factor analysis to replicate their procedures. This initial analysis evaluated the initial loading of the individual items on the scales. The next step was to conduct a separate confirmatory factor analysis of the work ethic instrument. A second analysis was conducted to evaluate the fit of the measurement model comprised of the scale scores and latent constructs. Input for estimation of the measurement and the structural model was provided by a covariance matrix prepared with PRELIS 2.2.

**Results**

**Step 1: Exploratory Factor Analysis.** These results indicated that the scales of hard work, asceticism, independence and non-leisure were present in the data as separate constructs. The initial exploratory factory analysis suggested five factors. However, the fifth factor was only a two-item factor representing two items that were expected to be part of the first factor. A second EFA constraining the number of factors extracted to four resulted in those items loading at acceptable levels on factor one. In this case the factor structure was identical to that found by Blau and Ryan (1987). The minor variation found in the initial EFA is within the scope of that expected by normal sample specific variations (see Table 2).

**Step 2: Confirmatory Factor Analysis.** Using the procedures and guidelines described above, the complete measurement model was examined. Results of the analysis of the complete measurement model indicated that all paths were significant (t-values ranged from 2.77 to 12.88). Following the Hair et al. (1998) criteria for factor loadings, this factor analysis confirmed the four hypothesized factors. Factor loadings ranged from .44 to .91, and all items loaded on the appropriate factor. The fit was considered adequate ($\chi^2$=295.88(113), p=.001; GFI = .87; AGFI = .83; RMSEA=.082; SRMR=.082; NNFI = .85; CFI = .88) and superior to that of the single factor baseline model ($\chi^2$=1166.76(113), p=.001; GFI = .64; AGFI = .53; RMSEA=.19; SRMR=.16; NNFI = .41; CFI = .48).

A second confirmatory factor analysis was subsequently conducted to evaluate the fit of the four first-order factors on the latent construct work ethic. As shown in figure 1 below, the paths to the higher order factor should be significant provided the four scales do, in fact, represent one underlying work ethic construct. However, all of the paths to work ethic were non-significant and there was a negative error variance for non-leisure. This was an early indication that the work ethic construct had measurement problems. Thus, nonleisure was eliminated from the model to determine if a plausible higher order model existed for the other three components of work ethic.

Following the recommendations of Rindskopf (1984), models with this situation should be re-examined for signs of factors with either no or only large loading, or two large loadings if the factor had low correlations with other factors. Work ethic fit one of Rinskopf's categories with low loadings on all factors (hardwork = .27; independence = .18; and asceticism = .21). Based on Rindskopf's recommended strategy, work ethic would be combined with another latent construct.
Eliminating non-leisure from the model did resolve the negative error variance problem. However, it also revealed more significant problems. Specifically, none of the paths from work ethic to the first order latent variables were significant and there was a near zero squared multiple correlations for two factors (hard work, $r^2=0.05$; asceticism, $r^2=0.001$) indicating that almost no variance in them was explained by work ethic. Only independence had a substantial portion of variance explained by work ethic ($r^2=0.65$) but the path was non-significant.

**Discussion**

Blau and Ryan (1997) extended Furnham's (1990a, 1990b) initial work on the work ethic construct and, through exploratory factor analysis, identified a four-factor structure of the construct. These four dimensions were hard work, nonleisure, independence, and asceticism. Blau and Ryan (1997) also advocated the use of an 18-item secular work ethic instrument. However, when subjected to confirmatory factor analysis, severe instability of the construct was detected. The scales for asceticism, independence, and nonleisure did not load on the work ethic latent construct. These findings suggest that work ethic is not a single latent construct with these four dimensions.

One possible explanation for the failure of these scales to load on the work ethic construct stems from the changing values in contemporary society. This construct, which originated with the work of Max Weber (1958), may have provided a more adequate representation of work values during earlier times. According to Weber's conceptualization of work ethic, which stemmed from Calvinistic and Quaker individualism and asceticism (Macoby, 1983), work is "performed as if it were an end in itself, a calling" (Weber, 1958, p. 62). Individuals with a strong work ethic are committed to the values of hard work and embrace the Calvinistic tradition of frugality, hard work, conservatism, and success (Weber, 1958).

Today's culture, however, does not necessarily support the same conventions and values as the culture of previous times. The history of work values is constantly changing and evolving, so the notion that the work values of 1958 would not be applicable today is consistent with historical trends. A redefinition of work values has occurred. Bernstein (1997) describes contemporary employees as "inner-directed employees who clearly place their personal wants and aspirations above those of their employers" (p. 221). Work schedules and business priorities are secondary to self-fulfillment (Sinetar, 1980). For instance, there is an increased emphasis on stress management and wellness initiatives that frequently involve leisure activities (e.g., walking, fishing, golfing, jogging, etc.). In fact, entire industries are built around filling our leisure time and, as a society, we are inundated with advertising campaigns enticing us into leisurely living. So, while the values of previous generations may have been deeply rooted in nonleisure as the norm, such is not the case in contemporary society.

Asceticism, like nonleisure, may not be representative of today's values. The term is defined as "rigorous abstention from self-indulgence" (Webster, 1986, p. 126). In the 21st century, the current emphasis is not on minimalism, but rather on materialism. Certainly, the wants and needs experienced during post-depression/post-war times differed greatly from what many of us currently express as "wants" and "needs" (e.g., motor homes,
swimming pools, luxury automobiles, etc.). Thus, the concept of asceticism may no longer be a component of the work ethic construct.

A closer examination of the concept of independence also challenges its place within the construct. Many organizations (including the one used in this study) stress teamwork as a desirable work behavior. In fact, team-building training courses are offered in countless organizations, and staff meetings consume a large percentage of many employees' workdays. Thus, independence is not necessarily the most desirable employee behavior. Therefore, its failure to load on the work ethic construct is understandable.

In light of the prevailing values, cultures and mores, it is possible for an individual to score high on the hard work scale, but low on asceticism, nonleisure, and/or independence. Compliance with the norms and values of today's society would lead an individual to respond to the instrument in a manner that would be contrary to the protestant work ethic construct which requires high scores on all four facets of the construct — hard work, nonleisure, asceticism, and independence.

While the work ethic scale items emerged from previous first order exploratory factor analysis studies, no other known study has attempted to analyzed the construct using confirmatory factor analysis of the latent work ethic construct. First order exploratory factor analysis only identifies whether the four scales are separate factors, not whether they represent one higher order construct. In this data, an exploratory factor analysis did, in fact, replicate the Blau and Ryan (1997) structure. However, this study went further by evaluating not only whether the items loaded on the respective scales, but whether the four scales represented one latent construct of work ethic.

This findings of this study suggest that the secular work ethic scale (Blau and Ryan, 1997) may no longer be an appropriate instrument to assess work in contemporary society. Despite the fact that the individual scales appear acceptable, these findings do not support the premise that these scales are representative of a single underlying work ethic construct.

Cost Analysis of E-Learning: A Case Study of a University Program

Tim L. Wentling
Ji-Hye Park
University of Illinois at Urbana-Champaign

Due to the advantages of e-learning, more and more schools and companies are adopting e-learning and increasing their investment in it. The increased investment has brought the need to demonstrate the cost-efficiency of the investments. This study reviewed the literature related cost drivers of e-learning programs and analyzed the cost-efficiency of the HRE Online program at the University of Illinois. Breakeven analysis revealed that the minimum enrollment should be twenty-three to attain the cost-efficiency.

Key words: Cost Analysis, Cost-efficiency, E-learning

In an age of severe competition and turbulent change, survival is a pivotal problem which organizations confront. Organizations have tried to find ways improving employees' performance, and training has been regarded as one of the most important strategies to solve the problem.

In addition to the accelerated importance of training, rapid development of technologies and computers has changed methods of education and training and caused the blossom of e-learning programs. The use of technology-based training and electronic training (e-learning) is one of major trends in the field of HRD (Bassi, Benson, & Cheney, 1996; Bassi & Van Buren, 1998). Various terms are being used to name these emerging training methods, i.e., asynchronous learning, distributed learning, online learning, web-based learning, computer-based training, e-learning and distance learning. Asynchronous learning focuses on the difference of time when learning occurs; online learning, web-based learning, e-learning and computer-based learning emphasize the learning technology and tools used; distance learning concentrates on the difference of places where a learner and a teacher exist. Regarding the interrelation among those terms, Urdan and Weggen (2000) identifies e-learning as a subset of distance learning, online learning as a subset of e-learning, and computer-based learning as a subset of online learning. Among those terms, e-learning is the most increasingly used concept especially in corporate setting. E-learning is defined as "the acquisition and use of knowledge distributed and facilitated primarily by electronic means (Wentling, Waight, Gallaher, Fleur, Wang, & Kanfer, 2000, p.5)." Based on this definition, e-learning would be evolved to systems consisting of a variety of channels and technologies and can take the form of courses as well as modules and smaller learning objects and may incorporate synchronous or asynchronous access and be distributed without geographical limits (Wentling, et al., 2000).

E-learning using technologies and computers to improve learner's skill and knowledge has the following advantages (Schrader & Giles, 1999; Au & Chong, 1993): space is not needed; learners do not need to wait until a class is available; learners can complete training when it is least disruptive to their schedule; and the methods can increase learner's interesting, deliver contents clearly, and feedback students easily.

Due to these advantages of e-learning, the popularity of e-learning has dramatically increased over the past few years. According to the National Center of Education Statistics, the number of enrollments in all distance education courses approximately tripled from the 1994-1995 school year to the 1997-1998 school year. About one third of all are two-year and four-year postsecondary institutions offered distance education in 1997-1998 in the U.S., and an additional twenty percent planned to start it within three years (Morgan, 2000).

The increased investment in e-learning has led companies to be concerned with the performance and efficiency of the method. That is to say, organizations are eager to know how effective e-learning is. Accordingly, organizations have increased efforts to prove whether the training intervention was successful or not, especially e-learning (Phillips, 1997).

Based on the literature related to evaluation of e-learning programs, three major factors were identified as the focus of e-learning program evaluation: cost efficiency, learner satisfaction, and learning resources. Among these issues, cost-efficiency of e-learning programs has been increasingly important because some institutions have failed due to the lack of well-thought out financial plans (Morgan, 2000). Further, chief executives are increasingly
concerned with the impact of training on "the bottom line" (Phillips, 1997). In addition, it was revealed that trainers perceived that cost is a key barrier for successful implementation of e-learning (Xebec McGraw-Hill, 2000).

Cost-efficiency of E-learning Programs

Cost-efficiency and cost-effectiveness are two similar terms related to financial performance. Even though they have slightly differentiated meanings, they have been used without clarification. Efficiency means the ratio of output to input and effectiveness is concerned with only output. Stated differently, efficiency focuses on "how much output was obtained from the input," that is, the quantity and effectiveness focuses on "how relevant the output is," that is, the quality. A learning method is relatively cost-efficient in the case that its outputs cost less per unit of input and it is cost-effective if its outputs not only spend less cost than others but also are relevant to learner' needs (Rumble, 1997). Hence, a learning method can be effective but not necessarily efficient and vice versa. Accordingly, two terms should be used cautiously and be well-defined.

From the perspective of education, when relating the financial performance of education and training, it does not mean just program costs but costs related to educational value and learner's needs. Therefore, the cost-effectiveness rather than the cost-efficiency is more apt to mention the financial performance of education and training. However, many educators and decision-makers believe that the fact that e-learning can save costs is the major advantage of an e-learning program, because it is assumed that enhanced student enrollment would result in increased revenue and lower cost. Most decisions related to training, especially in private organizations, are based on cost-efficiency. Even though this fact does not mean that cost should be the most critical information for educational decisions, it is certain that cost efficiency is one of the crucial types of information.

The analysis of cost-efficiency of e-learning programs has three benefits (Parsons, 1995). First of all, the analysis might help trainers look at the program through the customer's perspective. Secondly, it provides a guide to discuss the program with major stakeholders of them. Lastly, it is helpful to make a decision related to the program.

There are various methods to measure and analyze the cost-efficiency. Mostly used methods to analyze cost-efficiency are cost-to-benefit ratio (CBR), return-on-investment (ROI) (Phillips, 1994) and breakeven point analysis (Whalen & Wright, 1999).

The cost-to-benefit ratio is simply the program benefits divided by program costs. The formula is as follows:

\[ \text{CBR} = \frac{\text{Program benefits}}{\text{Program costs}} \]

Return on investment utilizes the percentage of the net program benefits over program costs. The net benefits are the program benefits minus the costs. The formula is as follows:

\[ \text{ROI (\%) = \frac{\text{Net program benefits}}{\text{Program costs}} \times 100} \]

When calculating the program benefits, it is crucial to convert various data to monetary value in order to get an accurate and credible result. Phillips (1997) suggested ten major strategies to convert data to monetary value: output data is converted to profit contribution or cost savings; cost of quality is calculated; wages and benefits are used for the value for time; historical costs; internal and external experts; external database; participants estimates; senior management provides estimates; and HRD staff estimates.

Breakeven analysis means the number of students that offset the fixed cost of the e-learning program. E-learning programs need enormous investment at the start-up stage of developing and delivering a program. Because of the high start-up and fixed costs, e-learning programs are more expensive than traditional classroom learning in the case of small enrollment (Jewett, 1998). Young (1998) summarized and synthesized eight case studies evaluating the benefits and costs of mediated instruction and distributed learning. Four out of eight studies included breakeven analysis.

There is no firm formula for determining the optimum number of students for e-learning programs (Bates, 2000; Morgan, 2000). Bates (2000) mentioned that the appropriate number of students should be determined by educational philosophy, course design, and the number of students who can be handled by the technology. Despite this difficulty, Bishop (2000) tried to determine optimum cohort size based on the cost analysis. According to the result, a cohort consisting of 25 students appeared both fiscally viable and pedagogically sound, even though the result showed a small profit with the 20 student cohort. In the case of courseware for remedial mathematics which utilizes an interactive (Cates, 1998), multimedia learning system developed by Academic Systems Corporation in order to improve the success rate of students, sufficient levels of annual enrollment that the costs of mediated learning system can be less than those of classroom course were 1,000 students per year. Another study compared the cost-efficiency of on-campus programs and multiple receive sites programs via an integrated satellite and
videoconferencing system of the Human Computer Certificate Program at Rensselaer Polytechnic Institute (Bray, 1998). Consequently, the course had a break-even enrollment of about 15 receive-site students. Whalen and Wright's study (1999), which hypothesized that there are several key design elements that should be identified as costs in the web-based training programs and analyzed a break-even point and return-on-investment, revealed that the program had a break-even number of 112 students and a ROI of 228% through 3283%. Even though a break-even point of each program is totally different, the common fact is that an e-learning program is more expensive than traditional instruction makes it important to compute. Therefore, the decision about how many students would be admitted to one cohort is important educationally as well as economically.

As stated above, break-even point analysis provides crucial information for deciding class size. Deciding online class size is balancing between quality and budget and one of the crucial issues course designers should consider (Distance Education Report, 2000). Accordingly, this study focused on measuring the breakeven point and further suggesting an appropriate cohort size of a course in HRE Online program at the University of Illinois at Urbana-Champaign.

Questions

As indicated above, the importance of cost analysis of e-learning program is getting more important. So is that of HRE Online program at the University of Illinois at Urbana-Champaign. Accordingly, this study addressed the following questions:

1. How cost-effective is the HRE Online program?
2. What is the appropriate cohort size for HRE Online in terms of cost?

Background of the HRE Online Program

The University of Illinois at Urbana-Champaign has a rich history of technology leadership and was the home of the first web browser development that has resulted in the major growth and access of the Internet. In the mid-nineties, the University of Illinois saw an emergence of professors using the Internet within their instructional efforts. These efforts were pedestrian to today's use but they represented the growth of ideas and use. By 1997 several campus leaders decided that the university should invest in the design and delivery of online courses and programs. The HRE Online program is entitled “Global Human Resource Development” was proposed in the Spring of 1998. The HRE department initiated this effort for several reasons. The department has a fairly sophisticated faculty in terms of technology use, with faculty using web support for most on-campus courses. The department also has several faculty who teach courses related to instructional technology and they also conduct research in this area. Consequently, there was a built-in interest in online instruction. Additionally, the HRD emphasis of the department puts faculty in contact with practitioners in the private sector who are involved with e-learning projects (the author has major research funding from the industrial partners of the National Center for Supercomputing Applications, the Office of Naval research, and the National Science Foundation). This provided for increased levels of faculty expertise as well as awareness of trends in the field.

The Department was also experiencing a growth spurt in terms of adding faculty. Consequently, capacity for new ventures was present. This increased capacity allowed for released time for development and the adding of additional online course offerings. The department had experience in delivering a master's degree in off-site locations that included Chicago, Peoria, Rockford, and Nairobi Kenya, even though these early programs were delivered face to face. Consequently, the move to an online program was attempted to meet an existing demand for a master's degree in HRD. The online approach allowed for the identification of a broader audience than ever before for off-campus programs because of the "anywhere" feature of online learning. The first cohort of fourteen students graduated in May and August of 2001. The department recruits students on an annual basis and simultaneously enrolls three cohorts of students.

This program is a degree program resulting in a Master of Education degree. The program includes nine courses. These courses are similar in content to courses taught on-campus as part of the masters program. A cohort of students is recruited every year. Students take one course per term that includes Fall, Spring, and Summer. The course length was adjusted to twelve weeks after experience with the first cohort. Campus based courses are sixteen weeks long, however, the same amount of subject matter is included in both length courses.

The department achieved a high level of support and involvement of the faculty - with nine different faculty members being involved in the masters program. The faculty were provide released time from the teaching of one
course to compensate them for the extra time involved in transforming a course to the online form. Consequently this was a cost to the department - the loss in teaching capacity for one term. However, since development/transformation was spread over a two-year period of time, it did not place an extreme strain on the department. In addition to release time, faculty were provided "development assistance" for the technical parts of course transformation. This assistance was provided by a team of graduate research assistants, who had technology experience. It is estimated that fifteen hours per week for sixteen weeks in development assistance was provided for each course. During the term that faculty actually teach or deliver a course, they are provided teaching assistant ten hours per week.

The nine courses are delivered in a combined synchronous and asynchronous form. The asynchronous delivery occurs through students receiving a streamed PowerPoint supported lecture. These lectures are usually fifteen to twenty-five minutes in length. Additionally, students are provided by learning activities that they complete either independently or as a team activity, depending on what the professor requires. Students submit their work electronically in a variety of forms and ways, according to professor's preferences. Synchronous instruction is provided through once per week session that lasts approximately one hour. This session involves all students logging onto a text chat system with each other and the professor. The professor uses live, streamed audio to talk to the students and to lead discussions.

Data Collection

This study collected cost information about cohort 2 among three cohorts who are enrolling in HRE Online program at the University of Illinois at Urbana-Champaign at present and conducted the breakeven point analysis. The reason why this study focused on the cohort 2 instead of the cohort 1 which already graduated in May 2001 is that tuition of the first cohort had been underestimated and it was adjusted for the second cohort. In addition, because the second cohort will graduate in next summer, the remaining cost for this cohort can be projected accurately and easily.

As stated above, e-learning programs need enormous investment at the start-up stage of developing and delivering a program unlike a traditional program. Because of the high start-up and fixed costs, e-learning program is more expensive than traditional classroom learning in case of small enrollment below the breakeven number of learners (Jewett, 1998). Even though the start-up cost of e-learning programs has a great impact on the breakeven point, start-up costs for this program have not been considered in this study. Since funding was received from the central administration for the support of start-up and because the department contribution was in released time, it was not necessary to recover these costs and thus this information was not collected. Accordingly, the cost analysis result of this study may be shown to be more cost-efficient than that of others.

The Results of Cost Analysis of HRE Online Program

Cost-effectiveness of the HRE Online Program

Cost drivers of the HRE Online program consists of two elements - fixed costs and variable costs. Fixed costs include tech coordination salary, administrative time, secretarial support, equipment, facility, contracted server support, network support, and office communication cost. Variable costs depending on the number of courses are faculty salary, technology support staff, teaching assistance salary, course materials, and mailing costs.

In strict cost analysis using a business model it would be expected to include all costs, that is, fixed costs, variable costs, direct costs, and even indirect costs. In the university setting, however, it is typically not required to include some of the fixed costs of a program such as office rental, secretarial support, network administration and so on. This analysis included only direct costs related to operating the program such as faculty salary, TA and tech support, coordination, software and equipment updates, and office supplies. Some of fixed and indirect costs are shared with on-campus program and it is hard to exactly differentiate the portion of the on-campus program and the portion of the online program.

The program start-up was funded through a cost sharing approach between the HRE department and the University Vice President for Academic Affairs' office (VPAA). The VPAA provided a sum of $156,000 to be spread over a two-year period. These funds were used for hiring graduate assistants for development and teaching assistance, for equipment, and for design and programming on a work for hire basis.
The department invested both direct and indirect resources in the program. The major direct cost was in the form of faculty release time. This amounted to approximately twenty-five percent of nine faculty member's time for one semester. The teaching load at HRE/UIUC is two courses per term, which accounts for 50% of one's load (50% teaching, 35% research, and 15% service). Therefore, approximately fifty-five thousand dollars in faculty time was devoted to start-up. Additionally, indirect expenses in the form of space, utilities, and some equipment were costs born by the department.

Operating or recurring costs for the program included primarily the fixed costs of faculty salary and development and teaching assistants. This accounts for three faculty per year at twenty-five percent of their salary for one term each. Graduate assistants were funded at the level of .25 FTE for technical support and .25 FTE for teaching support for each of the three courses offered per year. A .25 FTE appointment for graduate students is ten hours per week. The current salary for .25 FTE Graduate Assistants is $687 per month. Also, a full-time coordinator is employed to oversee and support the program. This person's salary is split among the three cohorts in the HRD program and another online program offered by the department. Revenue for the program is based on tuition from enrolled students. More specific information regarding revenue and income statement for one cohort was presented in Table 1 and Table 2 respectively.

The third cohort was admitted in August of 2000 and the first cohort started the program in 1998. The fourth cohort will begin in the Spring of 2002. The expectation of the Department is to run three cohorts simultaneously at all times. The first cohort paid the standard tuition rate charged to all off-campus students at the in-state rate. This amounted to $640 per four-semester hour course. The cohort had paid the same rate through the duration of their cohort program. Before the second cohort was recruited and admitted, the department obtained approval to increase
the rate of tuition to $848 for each four-hour course. It has been increased to $936 to the present. Because the tuition rate for the first cohort was underestimated, this study focused on the cost-analysis for cohort 2. For cohort 2, the total revenue based on students’ tuition was $145,162 and the total costs were $194,296. Specific costs spent were presented in Table 3.

This result shows that total cost of this program exceeds total revenue. Thus this program is hardly said to be cost-efficient at present. Revenue for the program is based on tuition from enrolled students. On the contrary, most of costs are fixed and not affected by the number of students enrolled. As more students enroll in the program, revenue increases, but total costs do not fluctuate. Making profits from this program, therefore, depends on the number of students enrolled. As seen from Table 4, the number of enrolled students has gradually dropped out and it caused this negative result of cost-efficiency. To make this program cost-efficient, therefore, it is important to maintain the number of enrolled students over the breakeven point. The following section is focused on analyzing the optimal number of students for each course.

Table 3. Expenses for Cohort 2

Optimal Cohort Size

Based on the current amount of expenses, total costs for one cohort course are $20,523. Based on the current tuition rate, the program begins to make profits from the point that 22 students enroll one cohort (Revenue: 22 x $939 = $20,592). Consequently, the cohort size should be kept at or above 22 who pay tuition. Since it is impossible to predict the number that will receive tuition waivers, it is important to enroll more. It is also expected that attrition will occur and this should be estimated and considered in recruiting.

This study assumed that the start-up costs would be prorated over the first five years of the program. During that period of time, the number of courses offered would be 50.

As indicated above, the start-up costs $156,000 were funded from the University Vice President for Academic Affairs’ office (VPAA) through a grant and the HRE department invested approximately fifty-five thousand dollars in faculty released time. Since a grant supported part of development, there is no need to recover that cost. However, the departments investment is of interest. When the start-up costs are divided by the average number of courses offered over the first five years (ten), the amount of money which each course should cover is about $1,100. To earn...
$1,100 from students’ tuition, approximately 1 more student needs to enroll in each course in addition to 22 paying students for breakeven. Accordingly, the optimal cohort size is 23 students with waivered students above this number. The result of this study was consistent with the result of Bishop’s (2000), which was concluded that the 25 students cohort option seemed to be proper in terms of both finance and education.

Discussion

When all expenses are included, the HRE Online program has not broken even since the program was launched. However, in the case of e-learning programs provided by a university, the cost-analysis does not always require faculty salaries to be included. This is especially true when existing faculty capacity is being used to cover the expenses of the program. If this analysis excludes the faculty cost, HRE Online is definitely cost-effective.

When considering the financial performance of education and training, it is to focus not on just costs but on non-costs related educational value and learner’s needs. The basic question determining the financial performance is not “Does distance education cost more or less than traditional education?” but rather “Are the educational outcomes worth the cost” (Thompson, 2000). Hence, other factors are critical to the success of the program - student learning, student satisfaction, retention, and faculty satisfaction. Especially student retention is crucial factor to determine the success of e-learning program. As the number of students enrolled in the cohort 2 show, students’ retention directly affects the cost-efficiency of the program and furthermore indirectly demonstrates the degree of students’ satisfaction with the program. Therefore, special concern should be given to issues in relation to retention, e.g., how the program retains students and why students leave the program in addition to the cost-analysis. Related, it is important to estimate attrition when setting an enrollment goal for a program to ensure cost efficiency of the last course as well as the first. Historical retention data can provide predictive information for planning.

Additionally, a philosophy of the department which offered this e-learning program is not to view program cost information in isolation from other data. One major benefit of the e-learning program to the department is the establishment of a pipeline for its doctoral program. It is expected that some of the best e-learning students will be recruited into the on-campus Ph.D. program. Additionally, the e-learning efforts of the department generate almost $60,000 in graduate student support for technical assistance and teaching assistance. The consequence is the ability of the department to recruit and support at least four half time assistants each year.

Examining the cost-effectiveness of e-learning programs is complicated, because the constantly emerging nature of technology makes it complex to assess accurate costs (Bishop, 2000). Also, it is difficult to analyze the cost-effectiveness across institutions because different institutions have unique background of the program development and analyze it based on different definitions of cost-effectiveness (Picciano, 2000).

How This Research Contributes to New Knowledge in HRD

Cost analysis is one of the major concerns that HRD practitioners need to consider. According to Middleton (1997), different educational sectors have different concern about the effectiveness of training and development. For instance, administrators and managers have a concern about why a given program or course is undertaken in the first place and whether or not it has been successfully accomplished. That is, overall evaluation, instructors or designers focus on teaching methods and contents, and students consider broader base of not only the test results but also their learning satisfaction. Among various concerns, the ultimate criterion the business sector uses to judge the financial performance of training is cost (Middleton, 1997). Whether a program is cost-efficient or not is crucial information for further decisions about expansion or contraction of the program. It is hard to expect the increased investment to HRD without demonstrating the financial effectiveness.

This study is meaningful in that it reminds HRD practitioners or scholars of the importance of cost analysis of e-learning programs which became a major educational form of the HRD field. This study, however, is not limited to emphasizing the importance of cost analysis of an e-learning program. This emphasized equally how unique a cost-analysis of an educational programs is. In other words, it is needless to say that cost-analysis in a business setting should include all expenses, but it is not always true in cost-analysis in educational settings. Some costs do not need to be included in the model, for instance, faculty salary. This case study provided information about which costs should be included in cost analysis of e-learning programs especially in university settings and which ones should not, how to get the breakeven point and optimal cohort size and so on. This result may influence further
decisions regarding the number of students admitted or issues related costs for this program as well as for other universities which are planning to operate e-learning programs. Furthermore, other factors should be considered to ensure the effectiveness of the program - student learning, student satisfaction, retention, and faculty satisfaction in addition to costs. These variables are being monitored in relation to financial efficiency by the e-learning evaluation system. HRD practitioners should be able to understand distinctions of cost analysis of training programs and analyze the cost in an appropriate way.

The Complex Roots of Human Resource Development.

Monica Lee
Lancaster University, UK

This paper uses notions of complexity in which to frame the case for the existence of processes that underlie the ‘human condition’ and that colour our existence and our understanding, theorising, and depiction of that existence. I use a Jungian typology to reinforce the parameters of four paradigms by which management and HRD have been interpreted, and locate this within some findings from evolutionary psychology. This analysis suggests that HRD is located at the dynamic and co-creative interface between individuals and organisations. The language of complexity is used to articulate implications this view holds for our understanding and practice of ‘HRD’.

Keywords: Complexity, Evolutionary Psychology, Meta-typology

As the various branches of social science have developed the way in which they build accounts for the world and our existence within it they have moved away from each other and from the natural sciences. Barklow, Cosmides and Tooby (1992) note that the natural sciences have retained a common root in their development, such that any move forward needs to fit with both its ‘home’ discipline, and also be concurrent with all others in order to be accepted. This has not happened in a consistent way within the social sciences. In adopting a post-scientific perspective postmodernism has challenged many of the contradictory yet self-sustaining frameworks that have developed. Yet in creating a world that is devoid of structure other than our own unique and individual structuring of it, postmodernism is actively engaged in preventing constructive (or ‘with structure’) dialogue between the various disciplines of the social science (though see Cilliers, 1998). In contrast to this, the notions of complexity provide the ideal vehicle by which a meta-view of human existence can be established within which apparently contradictory world views can be accommodated.

Central to complexity theory is the idea that a complex system is more than ‘just’ a complicated system. A complicated system or a problem might be very complicated indeed, but with time and effort all its parts, and its whole can be measured and understood. In contrast, a complex system might be quite simple, yet its parameters cannot be measured or quantified (in the normal sense) and the whole is more than the sum of the parts. However much we atomise the different parts we can never get to the essence of the whole. In this there is similarity between postmodernism and complexity theory, however, unlike postmodernism, complexity theory suggests that whilst aspects of complex systems cannot be measured in the normal sense, we can infer relationships between the constituent parts and sub-systems, and we can deduce global underlying principles. Put another way, however we chose to view the world, there exist processes that underlie all of humanity, and the principles of complexity theory might provide a language by which we can get closer to an appreciation of them. (Tsoukas & Hatch, 2001)

There is no requirement that a complex system be uniform in nature. It may have sub-systems that appear in structure and function to be significantly different to each other and to the whole yet each is in relationship to the others and to the ‘environment’ of the whole, and the whole is in relation to the wider environment. This relationship might be one that is in a state of ‘far from equilibrium’ (Stacey, 1993) yet the system maintains dynamic coherence through autopiotic processes, and adheres to its global underlying principles. The following sections of this paper suggest that there exist processes that underlie ‘the human condition’ and mechanisms by which these are transferred across generations. Further, the diversity apparent between individuals and nations is indicative of self generating and autopiotic sub-systems that might be complex in their own right, but which are still parts of the whole, as each derives its identity or being from its opposite (as perceived from the whole) and ‘development’ in any of these sub-systems is synonymous with interaction with the whole.

Underlying Processes

In this section I shall explore what these processes might be through illustration. I do this to emphasis their metaphorical or representational nature. The words employed are used to represent concepts which are themselves socially constructed representations – in other words – whilst there might be some commonality of language between the various constructions discussed here it must be remembered that the meanings behind the words are dynamic, situated and ephemeral. One word may mean different things in different contexts and different things to different
people (Jankowicz, 1994). I am therefore trying to explore the parameters of the concepts or meanings behind the words, whilst acknowledging that these concepts are also socially constructed and essentially undefinable.

Four main views of 'management' can be identified: the classical, scientific, processual and phenomenological. (Lee 1997a). Managers, within the classical view, must be able to create appropriate rules and procedures for others to follow, they must be good judges of people and able to take independent action as and when required. Good managers are assumed to be 'born' rather than 'made' – and so Management Development is a matter of selecting the 'right' people with leadership potential. The scientific view assumes that human behaviour is rational, and that people are motivated by economic criteria (Taylor, 1947). Within this view 'correct' decisions can be identified and implemented appropriately through scientific analysis, and thus good management techniques can be acquired by anyone with the right training and 'training departments' systematically identify and fill the 'training gap'. Both of these approaches assume a structured and known world based upon rational principles and in which rationality leads to success. The other two approaches to management assume a world in which agency (rather than structure) is the predominant force. The processual view of management assumes that economic advantage will come to those who are best able to spot opportunities, to learn rapidly, and to create appropriate advantage amongst colleagues. Human resource development is seen to help managers develop leadership and interpersonal skills, creativity, self reliance and the ability to work in different cultures. Although the individual is the main stakeholder in his or her own development, the direction of the organisation (and thus of an individual’s development) remains at the behest of senior management who, through initiatives such as Business Process Re-engineering (BPR), aspire to mould the organisation and the people within it. Phenomenological management, differs from processual management by the way in which the activities drive the functions, strategies and even leadership of the organisation. For many, management is about 'purpose' and 'doing' whilst phenomenology is about the 'study' of 'being'. All individuals are seen to collude with their situation and, through that collusion, are ‘together’ responsible for the running and development of the organisation (despite some being 'senior management' and others from the shop floor). ‘Management’ is about being part of a system whose activities change as a function of the system and of its relationship to its environment.

These four approaches link quite closely to the four ways in which the word 'development' is used in the literature, as delineated through an entirely different line of research (Lee 1997b). Development was used to indicate a form of maturation – the (inevitable or natural) progression through series of stages of life cycle. When used to indicate shaping it similarly implied a known endpoint to which the individual or organisation was steered by the application of various tools, within a known, quantifiable and manageable environment. In contrast, the other two uses of the word 'development' that were identified did not have a known endpoint. Development as a voyage was evident in literature about personal development – in which the self was the agent and the object, and development as emergent was evident in social science literature particularly, in which the lines between the individual and the organisation became blurred and the focus was upon co-development and co-regulation.

Figure 1 shows a representation of these four forms of development, presented as a typology (in which the lines of the figure indicate the strength of spheres of influence, and not delineations or divisive categories) and maps on to these the four views of management discussed earlier. This latter point is important and worth emphasising. I am NOT here discussing 'real' differences and saying that there exist four ways of 'doing' management or development – or that management or development are 'things' that can be done, or can be done to. In contrast, I am saying that there appear to be differences in the way that people talk about, or enact, whatever it is that constitutes 'development' or 'management' in their
There is strong evidence of individual variation in preferred perceptual and judgemental styles (see, for example, Mitroff and Kilmann, 1978, and Reason, 1981). Such variation forms the basic premise of the Myers Briggs Type Indicator (MBTI), a management assessment and development tool for individuals and organisations that is being increasingly used worldwide. It is beyond the remit of this chapter to go into the MBTI based literature in any depth, though see Briggs Myers and McCaulley (1985), Krebs Hirsh and Kummerow (1987) for more detail. I raise the issue here to record general acceptance of the MBTI tool, and thus (by implication) the assumptions on which the tool is based. Other researchers have used Jungian dimensions as a basis upon which to build an analysis of their work, such as that of Hofstede (1991), can also be mapped onto these dimensions. Similarly, as can be seen in Figure 2, the work of other researchers who make no claim to root their work in Jungian typology, such as that of Tufts-Richardson (1996), links Jungian typology to individual spirituality by mapping four types of spiritual path, whilst McWhinney (1992) maps four paths of change, or choice, for organisations and society. There is strong evidence of individual variation in preferred perceptual and judgemental styles (see, for example, Mitroff and Kilmann, 1978, and Reason, 1981). An Evolutionary Basis?

Research into evolutionary psychology and psychiatry (Barklow, Cosmides and Tooby, 1992; Bradshaw, 1997) suggests that human (and primate) affectional development progresses through the maturation of specific affectional systems, and that ‘All major psychiatric syndromes may thus be conceived as inappropriate expressions of evolved propensities concerned with adaptive behaviour in the domains of group membership (…), group exclusion (…), and mating (…).’ (Stevens and Price, 1996:29). They argue that there exist two ‘great archetypal systems’. The first formative experience faced by our proto-human ancestors would be that of parenting and family. As our ancestors developed the pattern of bearing live young that needed parental care for survival they also developed the pattern of behaviours and emotions that bonded parent and child in
a dependant relationship. Thus their first great archetypal system has to do with attachment, affiliation, care giving, care receiving, and altruism. As the child grew, was replaced by other children, and eventually became a parent themselves, so 'self' — and as a necessary and integral part of that process, 'not-self', or the 'other', emerged. Therefore, that the first fundamental dynamic played out in each person's life is that of self and other. This pervades the whole of our existence and is the core of self-development literature.

The second formative experience was that of collectivity. For 99 percent of its existence, humanity has lived in 'extended organic kinship groups' of about forty to fifty individuals, comprising six to ten adult males, twelve to twenty child bearing females, and about twenty juveniles and infants. (Fox, 1989). As predators, they were sufficiently effective not to need to develop large aggregations, flocking behaviour and high sensitivity to others in the group in order to survive, but they were sufficiently weak that they could only exceptionally survive as solitary individuals. We are therefore left with an awareness of society and its necessary structures and hierarchy, and also of individual agency. This equates to Steven and Price's second great archetypal system, that concerned with rank, status, discipline, law and order, territory and possessions. Stevens and Price posit that the search for achievement of archetypal goals occurs throughout the whole of the life-cycle, though the presenting face of the goals we seek changes as our circumstances change with age. These dual aspects of our collective psyche (self and other, and the structured law and the anarchic body (Hopf, 1995)) can be seen mirrored in the tensions between sociology and psychology, or between structure and agency, as elucidated by Giddeons (1976). .

In other words, we can identify two fundamental processes derived from our evolutionary history that continue to effect our humanity and our enactment of our existence. I want to make a clear distinction between the discussion here about the existence of fundamental or underlying processes and our day-to-day appreciation of them. Our daily lives and ways of seeing them are framed by our sense making of our past and by our anticipation of the future — we each live in our own self-constructed worlds. The surface diversity of our own worlds does not, however, detract from the existence of underlying processes. Our existence is interpreted differently across the spread of our civilisations, but that is a matter of the ways in which we choose to make sense of our existence.

**Autopiotic Mechanism for Promulgation of the Sub-sets.**

Socialisation can be seen as a mechanism by which the tensions and their resolution between self and other, and between structure and agency, are promulgated and emphasised through succeeding generations. I base my argument on the view that social development is a process of creative interaction in which 'individuals dynamically alter their actions with respect to the ongoing and anticipated actions of their partners.' (Fogel, 1993:34; Smith, 1992; McWinney, 1992; Lee, 1994). Relationships exist within mutually constructed conventions or frames of reference (Kelly 1955; Duncan 1991:345; Moreland & Levine, 1989), and a dynamic view of culture is facilitated (Hatch, 1993). 'Society' exists in so far as people agree to its existence - and could be a family unit or a nation. In some way (whether by being born into and thus socialised within it - as in a family or nation; through meeting 'like minded people and thus forming friendship groups; or formally through induction into an organisation) individuals come to identify (and be identified by others) as part of a community. In doing so they help create and collude with underlying values and norms. This process starts at birth and is a basal acculturation mechanism in which the underlying processes are the same whether the focus is upon family and friendship groupings, temporary 'micro-cultures', small or large organisations, or national culture (Burns, 1977).

There is empirical evidence of correlation between form of parenting and the child's life stance (Baumrind, 1973; Bee, 1985), and between career and family history (Cromie, Callaghan & Jansen, 1992). Similarly, there is evidence that choice of curricula, methodological approach and course design are partially governed by the value base of the providers, and thus perpetuate that value base (Ashton, 1988; Boyacigiller and Adler, 1991). Thus the approach to learning adopted by each society has a fundamental effect upon the continuation of the parameters of that particular society (Lee 1996). In Figure 1 different forms of learning were mapped against the archetypal parameters of self and other, and of structure and agency. In practical terms, the 'cognitive' environment carries with it group norms about received wisdom and the value of qualifications. Power is vested in those who have achieved qualifications and those who can give them. Cogent argument carries more importance than does applicability or individual difference. The 'problem' student (or heretic, Harshbarger, 1973) would be someone who lacked sufficient intelligence to master the required concepts. The 'behavioural' environment focuses upon activity, functionalism, and the importance of the end result. Norms are about identifying competence, and filling the 'training gap' to achieve appropriate levels of competence. The heretic is someone unable to demonstrate the required competence. The 'humanistic' environment focuses upon difference and equality. Received wisdom (in so far as it epitomises a particular view of reality) is inappropriate, as are identifiable and assessable 'competencies' (in so far as they epitomise a 'right' way of doing things). The problem participant is unwilling to explore and share
their affective and attitudinal aspects. In the 'experiential' environment the focus is on actionable outcomes - the end justifies the means. The heretic is someone who questions the route, or prefers inactivity. ('The confidence to act is a prerequisite for learning', Blackler, 1993)

It is rare, in 'real life', that 'learning' only occurs within one approach. Instead, it is much more likely that in any situation one learns more 'holistically' (Lee 1996). Honey and Mumford (1989) suggest that 'experience' plays a part in any learning, regardless of whether or not it is acknowledged or focused upon within the educational process. One of the best known models of experiential learning is that of Kolb (1974, 1984) who suggests that the process of learning is cyclical, revolving through experience, reflection, theorising and planning. In Figure 3 this is represented by the large (arrowed) circle. From this perspective, we only really learn by engaging in all aspects of the activity.

Figure 3. Movement through typologies. (after Lee 1996)

Transformative experiences, therefore, appear to be those that force us to (re)examine our world-view... (Emery & Trist, 1965, Pascale 1990). Any 'experience' is an opportunity for learning, however, as Dewey (1938) pointed out, 'It is not enough to insist upon the necessity of experience, nor even of activity in experience. Everything depends upon the quality of experience which is had... every experience lives in further experiences.' Vasilyuk (1984) takes it further, building the case that all learning that has a transformative effect upon us is derived from a clash between our understanding of the world and our experience, such that learning and change are painful processes of redefinition and Romanelli & Tushman (1994) offer empirical support for rapid, discontinuous change in organisations being driven by major environmental changes. Similarly, Stevens and Price argue that our changing lives necessitate re-negotiating our position with respect to the great archetypal systems, and that 'Psychopathology results when the environment fails, either partially or totally, to meet one (or more) archetypal need(s) in the developing individual.' (1966:34). In the terms of complexity theory, transformative experiences occur at bifurcation points, when the system and the environment impact in such a way that the system can either continue in its current, well travelled pattern, or shift to some way of being that is new and unpredicted (though not necessarily unpredictable). Indeed, the current analysis would suggest that the system is likely to shift to incorporate qualia of a different world view.

I have argued that there exist two main bi-polar underlying processes by which the human condition is structured, and that these give rise to four main archetypes. The processes of socialisation, or learning, emphasise particular aspects of our world view, such that the various systems or sub-systems, be they individuals, organisations or nations, have a tendency to enact the qualia of a single archetype. However, although I have talked of the qualia of the archetypes, I have deliberately failed to define them other than by example. Archetypes, by their nature, are undefinable in the scientific sense, and also, as discussed above, the qualia are unmeasurable other than dialectically (Pascale 1990) by reference to their 'opposite'. Furthermore, that 'opposite' might be different under different occasions or interpretations. For example, in one situation it was found that the word 'conflict' was interpreted by some people to be 'contested negotiation' whilst others saw it as 'a fight to the death', and acted accordingly with misunderstanding on both sides (Lee 1998). We could extrapolate that for these people the opposite to their views of conflict would be the similar but subtly different qualities of 'easy negotiation' and 'peaceful life'. We live within our own world view yet in order to understand or even describe it we need to compare it with that of others in a dialectic manner. In other words - to know what we are, we also have to know what we are not. We can't categorise the human condition in a positivistic mutually exclusive sense, but we can use the arguments above to develop a dialectically based typology.

A metatypology has been developed, but eight pages of text are too limiting to explore it. The benefit of a metatypology based upon notions of complexity is that it helps model the variability of social form. Different parts of the system might well adopt different configurations, and configurations might change as 'needed'. The activities of the system are emergent and feed back into it (Weick, 1977), they can influence all other aspects of the system, and the system itself can be 'far-from-equilibrium' (Stacey, 1993). This approach, therefore, denies the ability to 'plan' or 'control' organisational development - it argues for a resource-based view of the organisation in which the
role of ‘managing’ is fragmentary (i.e. Mintzberg, 1979) and offers a valuable critique of the established ‘discipline’ of strategy. In addition, because this view eschews ideas of (real) control by a hierarchy, as well as questioning the ability of the organisation to (really) predict or plan, it is more in tune with work that questions the serial and causal nature of our existence (Author & Flatau, 1996).

From Hereclites onwards (circa 500 BC) it has been suggested that humanity is in a state of always ‘becoming’ despite the appearance of structured categorisation and ‘being’ fostered by Western scientism (Lee 2001; Stacey, Griffin and Shaw, 2000). In other words, our lives are dynamic, and in a state of constant change. Fixed goals, known end points and clear delineations are tools that we use to provide a sense of stability, but that sense merely a mechanism and is false with respect to the wider reality of existence. The meta-typology, presented here with lines and detail, is merely an attempt to indicate underlying structures, those structures exist, however, not as things in themselves but are presented as a possible pattern of relationships: a representation of the relationships between other representations. As noted above, even the terminology used is just a representation. For example, Campbell and Muncer (1994) show that both occupational role and gender are indicative of whether a person views ‘aggression’ as a functional act aimed at imposing control over other people, or in expressive terms as a breakdown of self control over anger. Thus understanding of the word ‘aggression’, co-varies with the axes and will be interpreted by different readers in different ways.

HRD as the Relationship Between Representations.

As illustrated in Figures 1 and 2 above, one’s view of the nature and role of HRD is dependant upon one’s world view. This paper, however, suggests that, regardless of one’s ‘understanding’, or the terminology used, that which might be called the development of human resources is actually located at the dynamic and co-creative interface between the elements of the system, and between sub-systems, such that interacting, they become more than the sum of the parts. Thus the business of HRD, in so far as it exists as a concept and a practice, is concerned with the relationship between the representations. Research into HRD is, in effect, research into the processes that underlie the human condition, and the practice of HRD is about influencing the relationships that comprise the glue of the human condition.

As we research into HRD it means that we need to be aware that we are researching the intangible and un-measurable. We can catch glimpses of what we are looking for and we can try to represent or model it – but we need to avoid the temptation to overly objectify or embody that which we research. The ‘individual’ and the ‘organisation’ are not unitary bounded concepts – they are part of a whole and are identifiable by their relationship to the whole. It is the interactions that are of importance, rather than descriptions of ‘purpose’. Similarly, a change in approach requires a change in the language and meaning that is used. For example, would be inappropriate to talk of ‘organisations’ as if they had a body and could be anthropomorphised, or of ‘people’ as if they were machine cogs within ‘the organisation’ whose function was to ‘operate’ if we were to adopt a loosely bounded or relativistic view of these elements of the system.

As practitioners of HRD we intervene in the human condition with some aim in mind, yet both the ‘outcomes’ and the ‘value’ of them are subject to interpretation. There is no longer necessarily a clear and obvious route between cause and effect - and one person’s preferred ‘outcome’ might be someone else’s feared possibility / cause. In both theorising about HRD and in the practice of HRD we can no longer assume that a particular intervention at a particular time will produce a known effect. We lose the gloss of certainty that many HRD professionals feel is necessary for their work as academics, consultants, trainers etc. HRD and learning are becoming more central to the needs of the nation (as in Watson, 1994) and this shift in provision further increases the complexity and uncertainty of inquiry into the nature (and practice) of HRD.

In Conclusion

I have suggested that there exist ‘great archetypal structure’ that underlie the human condition, and that these can be identified by their effect upon it, such that human society and thought clusters into four main archetypal world views, termed here, for the sake of convenience and baring in mind the fragility of language, hierarchical, normative, entrepreneurial and facilitative. The axes by which these are located are bi-polar and termed, again, for convenience, self and other, and structure and agency. I suggest that these great systems and their products are most fruitfully discussed using the language (and thus concepts) of complexity. This recognises that whilst the whole system cannot be pulled apart and understood, it can be accessed by examining the relationships between the multiplicity of representations that are located within it. Thus the study of the system is the study of the relationships within it, and that study is that which we might commonly call HRD. It follows from this that the practice of HRD is about agency...
in a pluralistic, relativistic and interpretative world. This involves the search for the patterning of the whole, for
dynamic structures, an understanding of the possibilities and their links - a holistic approach. Holistic agency (Lee
1996) is therefore about individual action (or non-action) within a relativistic yet structured world, and thus is about
the 'doing' and 'becoming' of HRD.

HRD Literature: Where is it Published?

Larry M. Dooley  
Texas A&M University

In the chapter, "Finding and Using HRD Research", Sleezer & Sleezer found five journals containing the majority of all manuscripts published. As our field has grown since the mid 1990's, has the source of our publications changed as well? This study continued on the work of Sleezer & Sleezer to discover if HRD professionals are publishing in the same journals as they found in 1994, or if new avenues are now being pursued, such as international journals.

Key Words: Definition of HRD, HRD Literature, Publication in HRD

The theoretical bases of HRD research are multidisciplinary and disciplines such as psychology, philosophy, economics, and sociology are commonly accepted as roots of our field. This multi-disciplinary nature of HRD suggests that there is no discrete set of journals where HRD professionals publish. Bradford's Law, on the other hand, suggests that there is an essential core of journals that serves as the literature base for any given field of study and that, within that core, the most important papers are published in relatively few journals (Testa, 1997). So where does Human Resource Development fit? What are the core journals for our field and which of those journals might be considered the most important for our field? Should there be a core set of journals? Moreover, what journals publish the most papers? Prior to examining these questions, we must first discover where the majority of papers in the field of human resource development are indeed published.

A study by Sleezer, Sleezer and Pace (1996) identified 1,290 refereed HRD articles published in 258 distinct journals from 1980 to 1994 (Sleezer & Sleezer, 1997). In the chapter, "Finding and Using HRD Research", published in the Human Resource Development Research Handbook, Catherine and James Sleezer found five journals containing the majority of all manuscripts. These were, Human Resource Development Quarterly, Public Personnel Management, Performance Improvement Quarterly, Journal of Organizational Behavior, and Personnel Psychology. As our field has grown dramatically since the mid 1990's, has the source of our publications changed as well? This study continued on the work of Sleezer & Sleezer to discover if HRD professionals are publishing in the same journals as they found in 1994, or if new avenues are now being pursued, such as international journals.

Research Questions

Human resource development (HRD) is a profession of scholarship and practice that has continued to grow since the 1930's. As the discipline continues to accelerate, individuals in professional practice as well as academics increasingly need a literature base to support the ever-changing environment. The following questions serve as the basis for the task of this paper.

1. What is human resource development?
2. What is the literature base for the field of human resource development?
3. For individuals in professional practice, to what core journals should they have access if they want to stay on the cutting edge in the field?

Before one begins to search the applicable journals for HRD related manuscripts, it is important to offer a clarifying definition of human resource development. As there are many in the literature, this paper will operationally define HRD in the next section.

Definitions of HRD

There are almost as many definitions of human resource development (HRD) as there are individuals writing about the subject. Moreover, as the field matures, these definitions will more than likely gravitate towards a common set of constructs. In order to conduct this literature review, we must establish on e definition for HRD. One of the earlier noted definitions by Nadler in 1970, HRD is a series of organized activities conducted within a specified time and designed to produce behavioral change. The definition has evolved over time to include, for example, the components of training and development, organization development, and career development (McLagan, 1989).

Copyright © 2002 Larry M. Dooley
Training and development was integrated into the definition in 1983 by Pat McLagan: Training and development is identifying, assessing and through planned learning – helping develop the key competencies which enable individuals to perform current or future jobs. Chalofsky and Lincoln in 1983 added a collective learning component when they defined HRD as the study of how individuals and groups in organizations change through learning. Swanson in 1987 added the performance dimension when he defined HRD as the process of improving an organization's performance through the capabilities of its personnel. HRD includes activities dealing with work design, aptitude, expertise and motivation. McLagan added another definition in 1989 which included career development when she defined HRD as the integrated use of training and development, career development and organization development to improve individual and organizational effectiveness (McLagan, 1989).

As the profession moves more to an international perspective, Gary and Laird McLean introduced a definition in 2001 that was of a more global perspective, namely, that human resource development is any process or activity that, either initially or over the long term, has the potential to develop adults' work-based knowledge, expertise, productivity, and satisfaction, whether for personal or group/team gain, or for the benefit of an organization, community, nation, or, ultimately, the whole of humanity (McLean & McLean, 2001).

For the purpose of this study, the authors will use the definition adopted by the HRD faculty at Texas A&M University in 2001: Human resource development is the process of improving learning and performance in individual, group, and organizational contexts through domains of expertise such as lifelong learning, career development, training and development, and organization development (Texas A&M University, 2001). This definition encompasses the major theme areas captured in the literature of training & development, organization development and career development, while also recognizing the evolving foci of both learning and performance. See Table 1 for a listing of these definitions. The theoretical bases of HRD research can be found in areas such as psychology, philosophy, economics, and systems. From the definition above, one can see there is no discrete journal or sets of journals where HRD professionals publish.

Adapted from Swanson & Holton, 2001

Methodology

The initial intent of this study was to replicate the Sleezer and Sleezer study to determine if the outlets for HRD research have changed since 1994. Sleezer & Sleezer, in their study, searched three databases, namely, Educational Resources Information Center (ERIC), Abstracted Business Inform (ABI/nform), and Psychlit. The keywords used to search these databases were identified as human resource development, organization development, and career development. In their study, they found 1,290 refereed HRD articles published in 258 distinct journals from 1980 to 1994. Moreover, although the raw data were not available, it appears from the rankings that they published, that only one journal was either published outside the United States or contained an international focus in the title.

This study replicates the original study in several ways. We used the databases of Educational Resources Information Center (ERIC), Abstracted Business Inform (ABI/nform), and an analog of Psychlit, PsychINFO, in the search. Furthermore, this study used the same key terms as those employed by Sleezer and Sleezer, namely, human resource development, organization development, and career development.
Using the above approach, our initial search yielded an unwieldy number of 38,634 references! Keep in mind, the number of findings does not necessarily translate into articles. Another influencing factor in the conduct of this search was the need to cover international journals. Since the term human resource development is not common in all countries we chose to use search terms that described the components most commonly found in the definitions of human resource development in the literature. We therefore identified the keyword/terms for international journals to be: organizational learning, organization development, training & development, lifelong learning, career development, organizational performance, individual performance and individual learning. Although this international search still yielded a very large number of citations, the results included only 20 distinct journals (this does not count the journals with international in the title as some of these are published in the United States), and most of these journals yielded only one article germane to human resource development.

Our next step was to examine the articles concerned. This task was accomplished by reviewing either the published abstract or the article itself, which enabled us to determine if the article was in fact one concerning HRD. Of the 3,776 manuscripts reviewed, 540 were specific to HRD. This final number of articles, if averaged per year, exceeds the number in the Sleezer and Sleezer study. The Sleezer and Sleezer study found 1,290 articles from 1980 to 1994, which is an average of 92 per year. This study found 540 articles from 1995 to 2000, which is an average of 108 per year. (This amounts to roughly an 18% increase in total number of HRD manuscripts published over this time period.)

Results and Findings

It is interesting to note that we used the same key terms that Sleezer and Sleezer used in 1994 and included some international journals in languages other than English, we found slightly more individual journal articles per year, but a lesser number of total journals than were identified in the 1994 study. By way of example, the Sleezer and Sleezer study found 258 different journals while our study identified 149 different journals. Table 2 displays the number of citations obtained by key term search and the databases searched. Each database searched is cited below independent of the others (in other words there could be duplicate citations) however the final results are not duplicated.

Table 2 detailed the citations from the databases using the key terms noted above. These citations were used to inform the number of articles and the respective place of publication. Table 3 lists these publications by journal title.

The Sleezer and Sleezer study noted five journals that published the most manuscripts: Human Resource Development Quarterly, Public Personnel Management, Performance Improvement Quarterly, Journal of Organizational Behavior, and Personnel Psychology. Of these five journals, three remained in the top five of this study.

Discussion

An interesting finding of this study is that the only journal sponsored by the Academy of Human Resource Development appearing in any of the databases was Human Resource Development Quarterly. Not appearing in any of the databases searched were Human Resource Development International or Advances in Developing Human Resources. The reason these journals did not appear in our study is because they are not indexed in the three databases we used. Perhaps our field should take the necessary steps to have our journals included in this indexing process.

The increase in journal articles and decrease in the number of journals suggests that HRD professionals are becoming more targeted in outlets that they perceive as “HRD-friendly”. Unfortunately, also noted was that many of the represented journals are relatively obscure without wide readership. One reason they do not have wide readership is the subscription numbers. Some of these journals are included in membership to professional organizations where the membership is quiet low in comparison to other organizations. Indeed one of the journals recognized by the Social Science Citations Index as an outstanding publication is no longer even on the list of sources for recent HRD research, the Journal of Organizational Behavior.

Implications

There is a need in our field to cluster or have some sort of formal ‘ranking’ of journals; as well as highlighting a wider array of journals eligible for publication in by HRD scholars. As professions grow in the academics, questions are continually asked by administrators and others as to the ranking of individual programs. The answer, programs are not ranked in our field is generally not accepted by the more established fields of study. One of the very important criteria for ranking is the number of articles published in the top journals. While there are a number of journal ranking systems that are commonly accepted, most of the journals in which HRD research appears are not ranked. Not being ranked does not necessarily imply that their quality or impact is suspect. It is incumbent upon our field to identify what ‘quality’ or ‘impact’ means. Typical criteria for inclusion in the SSCI includes peer review, inclusion of international reviewers/board members, rate of journal citation, readership, and satisfactory reviews by scholars (Testa, 1997). While we do not suggest implementing an independent ranking system, we do believe that identifying and tracking what constitutes quality and impact for journals in our field would be useful for both academics and practitioners.
We also need to know why some journals are being published in more than others. Is the audience appeal greater for researchers for journal X and more a practitioners in journal Y? We should not code journals as research vs. practitioners; to do so would assume that practitioners do not need to read research journals and vice versa.

If HRD researchers are to make a significant impact on the organizational world, they must expand their circle of publication outlets to those that are more widely read. Having said this, however, we also recognize that some limitations in our study may have contributed to this seemingly limited circle of publication outlets.

First, the keywords we used to identify HRD publications may not have adequately captured those articles whose authors believed represented HRD research. As we noted earlier, there are multiple definitions and perspectives of HRD; although we tried to be as inclusive as possible, some research that is clearly related to HRD may not have included the specific keywords we selected. Second, the very indexes that we used to search for HRD research do not comprehensively capture all the available journals that might include HRD work. With all the indexes available, it is difficult for individuals to determine which index might have relevant articles.

Our findings caused us to realize that significant work must be done before we can more clearly answer the questions we posed about publication outlets. First, we must better understand how authors apply keywords to identify their work. We used keywords derived from a variety of definitions of HRD. But, what if authors tailored their keywords to a publication outlet that was not necessarily HRD specific? What if authors were attempting to reach an audience outside of HRD, believing that those within HRD might find their research because of name recognition in our relatively small field? This leads to another area that requires close attention.

Second, we must consider modifying our approach to uncovering HRD research outlets. We recognized that our keywords might be limiting; indeed, we recognize that there are as many definitions of HRD as there are authors. If this is the case, it is very possible that searching for research based on our a priori definitions will not yield accurate results. However, those who are members of the Academy of Human Resource Development identify themselves with the field of HRD. Perhaps another approach to uncovering HRD research is to begin with the names of those AHRD members who are publishing. From there we can identify the keywords they use, the outlets they selected, and expand our list of authors as well.

Third, we must look at other possible outlets for HRD research that are appropriate for our field. In other words, rather than search for existing research, we should consider looking for journals that seem to be relevant for HRD research. For example, Management Learning, a European journal, seeks articles that explore issues associated with learning and organizations. The Journal of Organizational Behavior seeks articles associated with organizational behavior, including topics such as motivation, work performance, training, job design, and career processes. There are a host of other journals that would likely be relevant for HRD research (e.g., Human Relations, Work & Occupations, Evaluation, Organization Studies, American Journal of Evaluation, Group and Organization Management, and more).

Finally, we should explore in more depth how we choose to define what constitutes ‘high impact’ for publications in our field. Many of the journals we discovered in our present study are not ranked in the Social Science Citations Index (SSCI). Because SSCI is a commonly accepted ranking system for scholarly publications, we need to decide whether or not we choose to select outlets according to these ratings. If we choose to select outlets based on other criteria that denote high impact for our field, we need to identify what constitutes high impact. Tenured and tenure-track faculty are being asked to demonstrate that they have published in high impact journals; the profession should adopt this criteria for use across the academic programs in our field.

How This Research Contributes to New Knowledge in HRD

Although this study does contribute ‘new’ knowledge to HRD, it provides a current pulse on some of the publication outlets for our field. Perhaps more importantly, our study shows us some key limitations to finding outlets for our work. The literature base for human resource development is limited somewhat in comparison to other more established fields, however for a growing and emerging field, it is quiet good. We found eleven referred journals that are currently publishing HRD related work. For new scholar in the field, these are the publication outlets that should be pursued.

Our third research question asked, for those in professional practice, what journals should they consider important to stay current and to allow the most current research inform their practice. This study identified two journals in particular: Human Resource Development Quarterly and the Journal of European Industrial Training.

We do believe that the questions raised by this study offer new knowledge in HRD. However other questions have been raised that are not answered: Why do we seem to publish in these journals and not more widely read and
cited journals? What other outlets could we seek for publication? How do we judge what constitutes a quality outlet for our work?

Post-Millenial Discourses of Organizational Spirituality: The Critical Role of HRD.

Sharon Turnbull
Lancaster University, UK.

This paper analyses the growing interest in spirituality inside organizations through a textual analysis of a number of recent publications, many of which draw connections between spirituality to organizational performance. The paper discusses how the HRD community might respond to this trend, and concludes that in colluding with the desire to colonise spirituality as a new management fashion, we may inadvertently destroy the very meaning that the spirituality movement sets out to pursue.

Keywords: Organizational Spirituality, Organizational Discourse, Meaning of Work

Over the past few years there has been an increase in talk of spirituality in the workplace. A proliferation of literature has started to appear on the subject, ranging from self-help books sold in airport bookshops through to academic reports. In the field of HRD, some interest has also been displayed. Indeed, the Academy of Human Resource Development devoted a pre-conference to the subject in 2000, the same year as a special interest group was set up at the Academy of Management. It is perhaps no surprise that these developments should have accelerated around the time of the millennial year. Indeed, Neal (1997) has suggested that it is this landmark event that has provoked the desire for renewal and a turn to the soul. Others connect the interest with other significant current sociological and economic trends. These include a turn away from religion as a source of meaning (Novak, 1982), and a mourning of the loss of traditional communities (Heelas and Morris, 1992). Furthermore, the increasing emphasis on consumption in today's society, and the constant media-led call for us to re-invent, re-construct and re-shape our identities is thought by some to represent an assault on the conventional western, holistic view of a whole and authentic self which has for so long remained unchallenged at the heart of the modernist western belief system. (Du Gay, 1996; Mestrovic, 1997) All of these trends, felt to be the result of globalisation, technologization (Fairclough, 1992), and the fragmentation of post-modern society (Bauman, 2001) can be seen to be destabilising and a direct challenge to the values that have hitherto provided a sense of certainty and security in Anglo-American society.

Despite these convincing reasons for the growing interest in spirituality, however, a first glance at the prolific literature devoted to the subject suggests that interpretations vary widely, even to the extent that they are apparently being premised on some fundamentally different assumptions.

Problem Statement

The purpose of this paper is to consider the meaning and sources of this post-millennial quest for the spiritual, its significance for the future of work and work relationships, and how this potentially important trend might be theorised and acted upon in the context of HRD. It will ask whether this growing interest can be described as a short-term management fashion designed by leaders and consultants to enhance performance, or alternatively as a more fundamental shift in thinking driven by disillusionment at the loss of meaning in today's society and work (Casey, 2000). Furthermore, this paper will demonstrate that the HRD community needs to be increasingly cognizant of trends which affect the cognitions, emotions and behaviours of the workforce, in order to plan appropriate responses and thus to play a critical role in today's organizations.

The paper will report on desk-based research into the way that spirituality is articulated and described by a range of sources: firstly by academics who have conducted empirical research into spirituality in organizations and secondly by practitioners and consultants engaged with the day to day challenges of running businesses. It will then examine the implications of these trends for the HRD community as a whole, paying particular attention to the varying ideological positions of those researching and performing HRD work, and attempting to take these differences into account. (Kuchinke, 2000a; 2000b).

Theoretical Framework and Methodology

The paper engages with two significant bodies of theory. The first is the literature concerned with spirituality, soul, meaning at work, and self-identity. The second is literature concerned with the purpose, function, and values of HRD. The aim of the analysis is to ask how the former should be interpreted by the HRD community in the light of the different perspectives about the role and focus of HRD. Each will be developed in more depth in the findings and interpretation section below.

A literature review was conducted using ABI/Inform and BIDS of the most recently articles written about spirituality in organizations, using the keywords: spirituality, organizations, managers, management, meaning, soul, and work. The intention was to focus the research on literature published over the millennium period, therefore most of the literature examined was published between 1999 and 2001. Relevant articles in business and management journals aimed at the practitioner audience, as well as those written for the academic community interested in organizations, management and organization theory were sought. Focussing on a similar time period, the body of knowledge concerned with the role of HRD in our organizations was then explored, seeking particularly, but not exclusively, those which contained messages about spirituality, meaning and purpose.

Having identified a large number of relevant articles, an analysis of these texts was conducted, with a view to identifying the key discursive themes embedded in the papers, many of which were reporting on empirical research. A qualitative study of each text was carried out, identifying and coding the key narratives, assumptions and messages in each. Having identified some wide differences between the texts, as well as some recurring themes that emerged from them, the research explored the implications of these findings for HRD.

Findings and Interpretation

Despite the many articles published over the last three years devoted to spirituality, few make much headway in their attempts to theorise the concept, despite evidence of its growing importance for numerous organizational employees. The reason for this gap, and for the tendency in the literature for authors to make their own assumptions about the meaning of spirituality is undoubtedly because it is a construct that is soft, difficult to define and certainly not measurable in a scientific sense. Furthermore it has long been associated with the private domain, a taboo or personal subject (Braham, 1999) making empirical studies difficult to conduct. The analysis below attempts to interpret the meaning(s) of spirituality as it has been constructed by scholars engaging with the topic, as well as by addressing the implications of this interest for HRD theory and practice.

Attributes of the Spiritual Organization

What constitutes spirituality was found to be a highly disputed territory. Wager-Marsh and Conley's (1999) research, for example, which is based on a literature review, professional observations, and "in-depth personal interviews with leaders of spiritually-based firms" reveals three types of attributes which lead to spirituality in the workplace. Many of these are concerned with the behavioural characteristics of the organization's leaders e.g. honesty with self, articulation of the corporation's spiritually based philosophy, commitment to employees, others appear to reflect the wider cultural norms in the organization e.g. mutual trust and honesty with others, commitment to quality and service, and finally a small number of attributes relate to organizational processes e.g. selection of personnel to match the corporation's spiritually based philosophy.

A focus on Values. Kriger and Hanson (1999) focus on values as being the key to spirituality, arguing that when the values at the heart of the world's major religions are found to be present in organizations this will form the basis for "healthy organizations" as they will enable both "economic and spiritual ideals to thrive". The values they select are truthfulness, trust, humility, forgiveness, compassion, thankfulness, service, and peace. These are more wide-ranging than those suggested by Wager-Marsh and Conley, yet overlap with their core themes of honesty and service. They suggest a number of steps that leaders need to go through in creating a spiritual culture: behaviour consistent with values; creating a climate where morality and ethics are truly important; legitimising different viewpoints, values and beliefs; developing imagination, inspiration and mindfulness; letting go of expectations that are unrealistic; acknowledgement of the efforts and accomplishments of others; and creating organizational processes that develop the whole person - not just exploiting current talents and strengths.

Arguably this list exhibits little difference from that of Wager-Marsh and Conley, consisting of the desired behaviours of leaders, cultural values and processes. The language of imagination, inspiration and mindfulness, however, is new in this paper, appearing to reflect the post-bureaucratic turn, which has led some scholars to identify a new organizational form that they have labelled the "enterprising" organization (Du Gay, 1996; Legge, 1999).
"Letting go of unrealistic expectations" is an interesting entreaty, which at first glance appears to contradict the requirement for increased imagination and inspiration. The authors base this idea on Christian parables in which Jesus called people to the kingdom of God "as little children". Paradoxically, this image suggests a relinquishing of control appearing to contradict the taking up of responsibility conveyed by the last point. It might also point to a view that in today’s turbulent world, controlling events both inside and outside the organization is no longer a realistic expectation, and spirituality is more likely to be achieved if leaders accept this as inevitable.

**The development of the Whole Person.** The development of the whole person posited by Kriger and Hanson (1999) as an important dimension of spirituality is a discourse that reflects the modernist view of a "whole self", a self that is dissatisfied when it cannot be freely expressed. This view can be found at the heart of a number of world religions, including Christianity, and was also found strongly in research conducted by Chalofsky (forthcoming) who concluded that bringing one’s whole self to the workplace (mind, body, emotion, spirit) is one of the core tenets of spirituality as defined by a number of writers. Whilst this image may suggest a sense of balance between the work, personal, and spiritual self (Chalofsky, ibid), the blurring of boundaries between work and home by corporations has also been shown to be on the increase by a number of commentators (Hochschild, 1990; Scase and Goffee, 1989; Willmott, 1993; Rose, 1989) and is often described as leading to confused identity and "stress" (Newton, 1995) as employees are asked to give up the previously long-held calculative psychological contract which dominated organizational relationships until the late eighties in favour of a moral psychological contract. Etzioni (1961) had previously ascribed the moral psychological contract only to religious, charitable, and voluntary organizations, but the new moral psychological contract has now become embedded into the ideology of many post-millenial global businesses, and appears to ask employees also to contract their "souls" (or hearts) to the organization (which many appear to relish, but others reject as intrusive).

**Ethics and Morality.** Kriger and Hanson’s (1999) inclusion of morality and ethics as important attributes of the spiritual organization was, surprisingly, rarely found in the other literature on spirituality analysed for this study. Cavanagh (1999) proffers an explanation for this, noting that despite their parallel interest in personal integrity and moral growth, religion has not been a significant theoretical resource for business ethics.

A small number of writers, however, do concur with Kriger and Hanson and Cavanagh that ethics is an essential component of spirituality. Bierly et al (2000) for example, define spirituality as being essentially moral and emotional in nature, and Walsh and Vaughan (1993) cited in Butts (1999) focus on the development of the individual through six essential elements "that constitute the heart and art of transcendence". These traits, "ethical training; development of concentration; emotional transformation; a redirection of motivation from egocentric, deficiency based needs to higher motives, such as transcendence; refinement of awareness; and the cultivation of wisdom." are reminiscent of eastern religions, in particular Buddhist practices.

**Emotions: Passion, Love and Enthusiasm.** Whilst emotions are implicit in most of the papers on spirituality analysed for this study, with a few exceptions (eg. Butts, 2000; and Chalofsky, forthcoming) these are rarely made explicit. Bierly et al, however, do move into the affective domain in suggesting that it is passion that lies at the heart of spirituality:

"Spirituality promotes passion...Along with passion comes pride, commitment, empowerment, and energy". (p. 608.)

Other recurrent emotions associated with spirituality are love (eg. Burack, 1999; and Delbecq, 1999) and enthusiasm (Milliman et.al., 1999). They also point to humour as an important aspect of spirituality, which is unusual as most treat the construct with considerable gravitas as has been indicated above.

**Leadership.** The role of leadership features strongly in the spirituality literature. Like Wager-Marsh and Conley, Kriger and Hanson (1999) associate their "spiritual" values with the leadership role, arguing that possessing these values is not enough; leaders must support them with activities consistent with them. This warning is echoed by Konz and Ryan (1999) and Delbecq (1999), who both stress the importance of leadership in maintaining organizational spirituality. The forms of leadership that encourage spirituality vary, however, as we have seen above. Moxley (2000), for example focuses his discussion almost entirely on leadership as partnership and shared power.

**The Religious and Secular Roots of Organizational Spirituality**

Many of the articles on organizational spirituality have their roots in the Christian tradition. In their study of 28 Jesuit universities, Konz and Ryan (1999) are surprised that despite being an explicitly religious institution with a
spiritual tradition of over 500 years, and the commitment to promoting spirituality "the development and maintenance of an organizational spirituality is no easy task". (p. 209)

Delbecq (1999) takes a more positive, but also explicitly Christian view of the expression of spirituality:

"The unique and personal inner experience of and search for the fullest personal development through participation into the transcendent mystery. It always involves a sense of belonging to a greater whole, and a sense of longing for a more complete fulfillment through touching the great mystery." (p. 345)

In this definition we see a move away from the quest for the whole self, into self which finds union with a greater Being, in this case a deity. An emphasis on Christian theology, however, is not the only form in which spirituality is found in the literature. Braham's (1999) study, for example, features a number of CEOs, all of whom selected as being spiritual leaders. Amongst his sample (along with a number of Christians) is a Hindu leader of a major corporation in silicone valley. Butts (1999) has identified a growing interest in Asian religions (see also Millar, 2000) in organizational practice, and others have identified a growing interest in New Age spiritual practices (Casey, 2000; Bell and Taylor, 2001; Heelas, 1996) as well as in humanist ideologies (Kahnweiler and Otte, 1997).

Spirituality as an Individual or a Communal Pursuit?

Despite the broad and varied conceptions of organizational spirituality which attribute both religious and secular meanings to the concept almost interchangeably (see for example Bell and Taylor, 2001), few studies have attempted to differentiate between the concepts of spirituality which have arisen from these very different roots, nor indeed to ask how the concept of spirituality might differ from that of religion. One exception is Mitroff and Denton's (1999) empirical study which found a societal shift away from valuing community in favour of valuing autonomy (also echoed by the work of Bauman, 2000):

"religion is organised and communal, contrasting with spirituality which is highly individual and highly personal" (Mitroff and Denton, p. 87).

These findings are supported by much of the literature on spirituality analysed in this research. Indeed, Cavanagh (1999) criticises the literature for this emphasis on the individual, which he attributes as much to evangelical Christianity as to the New Age movement, both of which emphasise the relationship between the self and God (or gods), paying little attention to the importance of organizations or the common good. Freshman (1999) supports Cavanagh's findings. Her own thematic analysis of survey responses found that spirituality is seen as uniquely individual, with the word "personal" occurring several times in the words of her respondents.

The literature on spirituality in organizations tends to oscillate between an emphasis on the individual and an emphasis on the whole community, with some papers stressing one or the other, and others mixing both perspectives. Whilst an emphasis on the individual is most commonplace, this is not exclusive, and as has been demonstrated, there are many instances in the literature of attention to communal and organizational activity under the banner of spirituality.

Why is the Spirituality Discourse Becoming Increasingly Popular in Organizations?

It appears to offer meaning in work. Casey (2000) has sought to explain this trend. Pointing to the influence of the New Age movement, she finds this interest manifested particularly amongst professionals whom she sees as being disaffected by "modern economic hegemony" (p. 6). The quest for spirituality is, she suggests, a way that corporate employees are finding "to resist, counter, or escape the self-identity erosion composite of intensified corporatization".

Cash et al (2000) also focus on explanation rather than prescription, finding like Casey that "many employees appear to be searching for greater meaning in their workplaces". They attribute this quest to a range of causes from the impact of technologies and workplace restructuring to the hypothesis that the "baby boomers who came of age during the idealistic 1960s and 1970s are now a large part of the workforce". (a proposition also suggested by Neal, 1997 in Cavanagh, 1999)

Chalofsky (2000) believes this is only part of the picture:

"The baby boomers are going through mid-life questioning the meaning and purpose of the work and their lives. The twenty somethings are questioning whether they even want to start down the path their parents took, career-wise, and are making different choices about the role of work in their lives".

Like Casey (op. cit.), both Cash and Chalofsky also attribute the spiritual turn to feelings of disillusionment. Casey attributes this to the "totalizing organizational rationalities and concommitant configuration of self-identity". Cash et al (2000) as a result of widespread and pervasive feelings of distrust of business "many fear losing their jobs, getting cancer, being victims of violence and dying alone. They hunger for a deeper meaning to life". (p. 125)

Cash et al, conclude by arguing for the encouragement of a spiritually and religiously expressive society.
It Appears to Provide Identity. The eclectic mix of religious and secular roots of the spirituality discourse in organizations has been described by Bell and Taylor as a "21st century spiritual supermarket". This consumption-based imagery portrays spirituality and the forms in which it appears in organizations as an example of the post-modern consumer choice which, as Du Gay (1996) has persuasively argued, pervades every aspect of our organizational life today. His research on identity at work found that the desire to possess and consume is highly influential in shaping identity in today's society and that this is reflected in organizational life. This reading of spirituality suggests that even such an aspirational concept may be simply a short term fad which reflects the latest social aspirations, in danger of being in vogue for a short while, but then dropped and replaced by a new, more exciting concept.

Vaill admonishes the academic community for a preoccupation with "behaviours and attitudes we can measure" which has meant that "we have missed the spiritual need and spiritual feeling". This, he says is systemic; it is part of what it means to be human and doesn't differentiate itself as an attribute or a competency. He goes on: "Reductionism has pushed Spirit out of our inquiry although-Deo gratia-it cannot push it out of the phenomenon!" (p. 115)

It Facilitates the Development of the Whole Person. Cavanagh (1999) notes the separation that business people often feel in their lives as a result of feelings of separation from other people, alienation from their work, and lack of meaning in their lives. This he attributes partly to the compartmentalisation of work, family life and faith, with the large part of time available being given to work often with an hour at weekends for worship.

Chalofsky argues that spirituality can help to overcome this tension: "The integration of the total self means that there is an alignment between the person's beliefs, values, and competencies, and the purpose for the work (and hopefully the mission of the organization). This alignment translates into an inner feeling that this is the work I was meant to do and this is how I was meant to live my life." (2000, 4-3)

This emphasis on the quest for self-understanding is identified by Butts (1999) in his editorial comments for the special issue of Journal of Organizational Change Management: "Business owners, managers, policymakers, and academic researchers all need to remember, as many surveys indicate, that tens of millions of world citizens are hungering for transmaterial, mind-expanding, soul-enriching, and heart-centred (spiritual) values" (p. 328).

However, he goes on to see the performative potential of such "hunger" in the workplace, suggesting that this can be harnessed to maximise human capital through cultivating these values in a learning organization (Senge, 1990) or through developing emotional intelligence (Goleman, 1995).

Spirituality as Enhancer of Performance?

One of the most recurrent themes to appear in the literature on spirituality is that of organizational performance. Spirituality in many of the articles studied was presented as "the holy grail", the solution to all organizational problems, and a catch-all replacement for previous management fads, many of which are considered to have failed due lack of commitment or consistent behaviour. These performative articles, apparently written with the explicit intention of assisting leaders of organizations to become more spiritual and therefore, it is assumed, more successful contain various prescriptions for the workplace. Wager-March and Conley (1999), for example, typify this genre in their article "The fourth wave: the spiritually-based firm". They seek, as shown earlier, to provide a formula for success in this quest. Milliman et al (1999) clearly state in their Abstract that they are looking at how spirituality in the workplace can be "used" and "developed to the advantage of organizations". (p.221) They go on:

"We believe that the issue of whether spirituality can have a positive impact on both employees and organizations is particularly important because many chief executive officers (CEOs) will not justify a practice unless it favourably impacts on the bottom line." (p.222)

They then suggest a direct and pragmatic correlation between spirituality, emotionality and performance in the following proposition:

"Company spiritual values that tap both the mental and emotional aspects of employees will be more positively related to employees' work and spiritual attitudes and organizational performance than company values which only tap the mental aspects of employees" (p. 230)

There is little in any of the articles cited above, however, nor indeed in any of the other articles analysed, to suggest that there is evidence that a company that becomes more spiritual will necessarily "thrive" (Kriger and Hanson, 1999) and become healthier. Whilst the claim linking spirituality with economic prosperity is common (see
also Neal et al, 1999) it is often glossed over and its positive associations taken on trust, largely based on the
authors' claims that these tenets are common across all world religions and must therefore have substance.
Bell and Taylor (2001) also note the performative intentions of much of the literature on spirituality. They are
critical of this, however, suggesting that the current interest in workplace spirituality is "an extension of the
corporate culture movement" since it too appears to be attempting to "engineer the soul" and thereby secure
employees' emotional as well as mental and physical participation.

Conclusions and Implications for HRD

The concept of spirituality has been shown to have proliferated in its appeal to both scholars and practitioners over
the years at the turn of the millennium. This analysis has demonstrated that the meaning given by scholars to this
construct varies widely both in its origins and in what it encompasses, and that the origins of the concept can be
traced back to a number of roots, including a number of religious and neo-religious sources. Its appeal to individuals
has been shown to lie in the possibilities that it offers to create personal identity and social meaning in an otherwise
increasingly secularized, instrumental and post modern world. However, it has also been demonstrated that the
concept has already been colonized by those for whom the performance motive overrides all others.

The connection between spirituality and performance remains unclear. It is taken as a given by many, and
sought after by others. However, none of the research analysed was able to offer any convincing evidence to
demonstrate this proposed relationship. The desire by organizations to capitalise on the human need for meaning has
been shown to be paradoxical, particularly as Casey has suggested that one explanation for its current popularity lies
in the loss of meaning inside today's corporations. Certainly, Casey has identified a backlash to the totalising effects of
"rational instrumentality and secularisation" which led organizations to consider people simply as "human
resources" who are "assumed to learn at work for the good of the organization and its production imperatives and for
the advancement of their skills for careers in such organizational activities".

As Casey's findings have suggested, it is senior management's need to control the workforce by whatever means
available that appears to have initiated the quest for spirituality by those seeking to loosen the hold of the
corporation and to find meaning beyond it. Indeed, this reading of spirituality's current popularity suggests that such
instrumentalism may be seen to be creating the very hegemony that has itself spawned its own opposition in the
 guise of the quest for spirituality.

It is clear that such attempts to instrumentalise spirituality for performative intent are in danger of destroying
the very meaning they set out to commodify. Not only does this colonizing of the spirituality discourse for purposes
of control clearly diminish its potential to bring joy to organization life, it is also likely to accelerate the
dissillusionment and cynicism found inside many organizations, as a result of the constantly changing management
fads and fashions.

This paradox is a central finding of this paper, and presents a major challenge for HRD, both in terms of theory
and in the practices that we espouse. Similar to the rhetorics that associate culture with performance, we in the HRD
community need to beware of blindly pursuing the latest "holy grail" to performance enhancement, only to create
more disaffected employees in the longer term.

If HRD undertakes to re-focus its interest in spirituality on enhancing the quality of individuals' organizational
lives and the meaning they find in their work, and to safeguard the authenticity of this quest by refusing to support
the cynical colonizing of the rhetoric of spirituality, we can make some significant strides forward in our
understanding of the social processes that affect today's organizations. Such attempts to colonize would lead the
HRD community into an empty and meaningless pursuit of a new management fad which, like many of those now
past, would quickly be identified by recipients in organizations as inauthentic and a clandestine attempt to control.

We must, however, also challenge the potentially false dualism of spirituality as either focusing on performance
or on individual meaning. This will clearly lead to polarized positions that arguably need not be inevitable. These
perspectival differences in the literature on spirituality are clearly mirroring current debates over the nature and
beliefs in HRD (Ruona and Roth, 2000). The human quest to find meaning in work, and the parallel desire to
capitalise on this quest and harness it for performative gain parallels the ongoing debates on the role of HRD as
developers of individuals on the one hand and organizations on the other and raises important issues for HRD's
response to the growing interest in organizational spirituality.

Kahnweiler and Otte (1997), for example, take a strongly humanistic view on the value of spirituality for HRD
practice, focusing almost entirely on the transcendence of the individual:

"If we want to discover the myths capable of energizing and directing the field of HRD for the good of
humanity and the earth, it seems prudent not to sit down and work at it. Rather it may be best to relax into it,
opening ourselves to images and ideas of the future that emerge from the unknown sources of creativity. Then we can discuss what has bubbled up with colleagues in the field." (p. 173).

They do, however, also attempt to connect this project with organization goals:

"The theory is that by helping individuals, the work groups they are part of will perform better, and their whole organization will perform better"

Although this rationale is never further developed in their paper, it is persuasively championed by Chalofsky (forthcoming) who shares the same starting point as Kahnweiler and Otte (1997), but makes a strong case for the connection between the growth of the individual and the flourishing of the work organization:

"In this age of the "new employee contract" we need to pay attention to... our whole selves at work, to admit that some work has no meaning to us and offers no possibility of joy, to examine what work will have meaning to us and seek such work, to meet our co-workers self-to-self, center-to-center, and to stop pretending that our interior lives don’t matter. (Only then) will our work become more joyful (and) our organizations will flourish with commitment, passion, imagination, spirit, and soul (Richards, 1995, p.94)

When the emphasis on performance is paramount over all else, employees gradually lose the meaning of their work. Such loss of meaning affects attitudes, behavior, and overall mental health. Our profession needs to search for and implement new workplace models that address work as both a vehicle for production and individual and social development and satisfaction.(Svendsen, 1997)."

This is clearly a very different message from those criticised by Casey (2000) and Bell and Taylor (2000) for harnessing the rhetoric of spirituality simply for instrumental purposes. Indeed Holton (2000), who has long stressed the importance of linking employee expertise with the strategic goals of the organization (1999) has also argued that there is much common ground between the learning school of HRD and those pursuing organizational performance. Both Chalofsky and Holton have concluded that this common dualism is unhelpful for HRD, and consequently for individuals in organizations.

This paper has demonstrated that if HRD is to demonstrate its authenticity and its vital role in supporting theory and practice, it will need to reject all forms of meaningless instrumentalism. Instead, a focus on finding more effective models for enabling fulfilment at work for the individuals in organizations must be our prime goal, whilst recognising that this pursuit need not interfere with, and assist in the production of effective work organizations.

Despite the profusion of literature on the topic, further research is clearly needed into the meaning of spirituality for both individuals in organizations, as well as its impact on the well-being and functioning of organizations. We also need a means for critically analyzing and understanding the discourses that relate spirituality to performance, in order to make transparent those inauthentic attempts to colonise spirituality and the soul solely for instrumental gain, as well as to better understand how meaning and performance may be more successfully interwoven.

Professional Crisis Workers: 
Impact of Repeated Exposure to Human Pain and Destructiveness

Lynn Atkinson-Tovar 
Northern Illinois University

This paper discusses some of the issues related to the impact on professional crisis workers when exposed to repeated human pain and destructiveness in the course of their work lives. It is a brief summary of the limited literature on the two prevailing effects of repeated exposure predominately gathered through studies on therapists, however the author identifies other crisis workers who's effect of repeated exposure to trauma needs to be researched further.

Key words: Repeat Exposure, Crisis Workers, Affect of Trauma

The United States and the world changed forever Tuesday September 11, 2001. Today, more than ever HRD must acknowledge the area of trauma and how it effects crisis workers who are repeatedly exposed to human pain and destructiveness. These are the people who have chosen a career in helping others deal with pain and trauma but do not realize or recognize how what they see, hear, smell, taste and feel affects them on a daily basis. Their responses to human pain and destructiveness are so subtle and long-term that they do not realize what is happening to them until they begin to lose what is most important in their lives: their families, friends, health, spirituality, honor, commitment, and sense of self-worth. Life experience(s) have always been an important component of adult learning theories (Dewey, 1983; Knowles, 1970, Kolb, 1984). A number of studies have also identified job experience as a powerful stimulus for organizational and managerial development (Morrison, 1986). Morrison (1986) posed that on the job work experiences, rather than formal training events, were the main source of development for individuals in organizations. Contextual features of this type of development, such as the presence of organizational support, appear to be critical. It is incumbent upon HRD practitioners to help these organizations, which are comprised of crisis workers who devote their careers to helping others. HRD must have an understanding of what these men and women are doing on a daily basis and how it affects their lives and those around them. The acknowledgement of the organization to provide resources and direction through HRD is critical in the well being of their employees who deal with crisis daily. The development and continued education through employee assistance programs or peer counseling is a beginning, however HRD has the responsibility to the crisis workers as well as the organization to strive for personal acceptance and organizational development. They need to recognize how trauma affects them, both in their professional and personal lives (Kates, 2001).

Looking at the Literature: Daily Trauma in the Workplace

Stress is an always-present component of our lives. Factors such as the pace of current technology, economic instability, complexity of interpersonal relations, and the ever-growing crime rate have produced a society that must respond to a barrage of problems and changes in a timely manner. Constantly, individuals are asked to take on more and more responsibilities and become increasingly more efficient at the performance of their job (Senkor, 1995). The increased complication comes with the factor of exposure to traumatic events during the course of a day. However, HRD has the role of a change agent in the development and well being of the employee. HRD practitioners have the responsibility for the induction of interventions designed to bring about organizational change through people. Every organization today is seeking ways to address problems that affect performance. Ovaece (2000) stressed the importance of considering human factors when discussing organizational performance. All organizations possess cultural norms that frame expectations and influences strategic support and perceptions of effectiveness. With crisis workers and their ever changing professional life of trauma exposure requires the HRD practitioner to be an aggressive change agent to maximize the effectiveness of interventions as well as improve communications and relationships.

This paper will examine secondary and vicarious traumatic stress disorder and the role HRD professionals can influence through their understanding and effectiveness in program development. There has been sporadic attention given to the caring professionals; medical, social sciences, family therapy, law

Copyright © 2002 Lynn Atkinson-Tovar
enforcement, and psychological literature to the phenomenon referred to as secondary/vicarious traumatic stress disorder. So it is prudent that HRD take a closer examination into the development of strategic assistance mechanisms for professional organizations that can be affected by stress related performances from their employees. Helping organizations offer a greater challenge to HRD professionals in that they are so resistant to accept assistance from those who they believe do not understand their unique culture. There is a vast amount of literature, which describes a variety of stress related areas, however the literature is limited in the area of those crisis workers who are repeatedly exposed to human pain and destructiveness. In this review of contemporary literature the author will cite and describe specific impacts to professional workers and their organization when exposed to human pain and destructiveness in the course of their work lives. The paper provides a look into the two potential stress related outcomes for crisis workers exposed to repeated trauma that HRD practitioners might be able to influence through program design and alternative thinking. Further research is required in examining the outcomes of active HRD program development to demonstrate employee change and effectiveness. After reviewing the literature on the effects of trauma to crisis workers, it appears there is no set course or path a professional might follow; however, the dilating factor is the severity of the symptoms and treatment. Researchers (Matthews, 1987) agree, generally, that people-oriented occupations are more stressful than occupations which require persons to work alone or in small groups with data because they are more predictable rather than people who are unpredictable (Farber, 1983: Gherman, 1981; Maslash, 1982: Pines & Kafry, 1978). Matterson and Ivancevich (1982) reported a study, which showed that individuals having responsibility for other people suffered from more heart disease than individuals who had responsibility of objects. Stressors affect workers differently because of a number of genetic and environmental factors, such as personality type; metabolism rate; physical condition of the body as a result of exercise, rest, and disease; and the use of self-regulation techniques; however, stress has been associated with a number of practices, which occur within the organization itself. Because people-oriented occupations are in a variety of work settings and involved numerous types of interactions, it seems plausible that different work environments impose more or less of the practice associated with stress. Matthews & Casteel (1987) did a study on stress and the workplace; a comparison of occupational fields. The study examined if persons in different people-oriented occupational fields would have significantly different scores by comparing crisis workers such as the health and social services fields with banking and industry. They found that most people believe their jobs are stressful, however the study showed especially those who work with children, the needy, and physically ill, feel their environment is more stressful, and they have a higher burnout rate.

Secondary Traumatic Stress Disorder (STSD)

Secondary traumatic stress disorder can be defined as "the natural consequent behavior and emotions resulting from knowing about a traumatizing event experienced by a significant other--the stress resulting from helping or wanting to help a traumatized or suffering person" (Figley, 1995, p.7). Therefore, STSD has symptoms nearly identical to post traumatic-stress disorder (PTSD), except that exposure to knowledge about a traumatizing event experienced by a person is associated with the set of STSD symptoms, and PTSD symptoms are directly connected to the sufferer, the person experiencing primary traumatic stress. Symptoms under one month duration are considered normal, acute, crisis-related reactions. Secondary traumatic stress disorder is a natural consequence of caring between two people, one of who has been initially traumatized and the other of whom is affected by the first's traumatic experiences. These effects are not necessarily a problem but a natural by-product of caring for traumatized people (Figley, 1995). There as been a side range of STSD symptoms documented in crisis workers. The literature exemplifies diverse occupational samples, differences in measurements, differing traumatic event factors, and degree of proximity to harm, as well as mediating contextual variables and workers characteristic (Beaton & Murphy, 1995). Crisis workers perceive a role conflict when they themselves must seek help. They feel out of control, weak, and vulnerable, and their self-worth may be in question. Furthermore, most crisis workers consciously and unconsciously use defense mechanisms such as denial, repression, black humor, and suppression, to deceive themselves, as well as others (Beaton & Murphy, 1995). A second barrier is that often times family members, and co-workers cannot detect symptoms as secondary trauma because they are subjective in nature. Family and friends find it difficult to understand because they believe that the crisis worker must have known what they were getting themselves into. Crisis workers often will second guess their decisions, engage in self-blame, and become depressed. "Finally, traumatized crisis workers are subjected to more stigma than most victims. Their traumatization is troubling to their supervisors and co-workers since it reminds them it could also happen to them" (Beaton & Murphy, 1995 p.75).
Vicarious Traumatization

The concept of vicarious traumatization, introduced by McCann and Pearlman (1989) provides a theoretical framework for understanding the complicated and often painful effects of trauma work on therapist, however the theory can apply to crisis workers in general. Previously stated, secondary traumatic stress disorder was described as the responses of individuals to hearing about other peoples' traumatic experiences. Vicarious traumatization includes the symptoms of STSD in the context of profound changes in the crisis workers sense of meaning, identity, world-view, and beliefs about self and others. However, even though there is some overlapping between STSD and vicarious traumatization the differ lies in the focus and emphasis. Vicarious traumatization, (Pearlman & Saakvitne, 1995) refers to transformation in the crisis workers inner experience resulting from empathic engagement with clients' trauma material. Through exposure to graphic accounts such as child sexual abuse experiences and to the realities of peoples' intentional cruelty to one another, and through the inevitable participation in traumatic reenactments, the crisis worker is vulnerable through their empathic openness to the emotional and spiritual effects of vicarious traumatization. These effects are cumulative and can be permanent, evident in both crisis workers' professional and personal life. Crisis workers acknowledge they entered this type of work by choice, and continue because of their commitment to others and the tremendous rewards of helping others, recognize that it affects them personally. It is an occupational hazard that must be acknowledged and addressed.

McCann & Pearlman's (1989) recent research in vicarious traumatization focuses primarily on the portion of the theory that describes psychological needs and cognitive schemas. The cognitive portion of the theory is based upon a constructivist foundation. The underlying premise is that human beings construct their own personal realities through the development of complex cognitive structures, which are used to interpret events (Mahoney, 1981). Piaget (1971) describes these cognitive structures as schemas. These schemas or metal frameworks include beliefs, assumptions, and expectations about self and world that enables individuals to make sense of their experiences. These cognitive structures evolve and become increasing more complex throughout your life span. McCann & Pearlman's major hypothesis in their research is that trauma can disrupt these schemas and that the unique way that particular trauma is experienced depends in part, upon which schemas are central or salient for the individual (1989). Vicarious traumatization is unique to trauma or crisis workers, because first, traumatic events such as child sexual abuse are painfully real and part of our larger world and society. If crisis workers are to help, they cannot protect themselves from acknowledging this reality as they listen to the victim's stories. Crisis workers are left with the powerful affects stirred as they face this reality on a daily basis. Secondly, trauma or crisis workers inevitably become aware of the potential for trauma in their own lives. Traumatic events can happen to anyone, at any time; it is almost intolerable however to accept the fact that lives can be permanently changed in a moment when a traumatic event occurs. And, thirdly often times crisis workers have gone into the profession because they were victims of trauma, such as childhood sexual abuse, and it is reminder of their own painful experience(s). Crisis workers are often helpless witnesses to current reenactments of traumatic memories, which can be an excruciating experience. These reenactments can be expressed at many levels: behavioral, emotional, and physiological (van der Kolk, 1989).

Assessing Vicarious Traumatization

Trauma disrupts the self in specific ways, disrupting the frame of reference, which is an individual's sense of identity, central beliefs in the world, and spirituality. The loss of a familiar sense of identity is disturbing and often times a by-product of a crisis workers profession. Often the crisis worker will question who they are as a professional, a man or women, husband or wife, parent or child. They can also lose their central belief in the world, the way they understand the world, including, life philosophy, and moral principles. For example, world views can be challenged including the beliefs that people behave according to a set of values, that the world is fundamentally just, that people can influence outcomes in their lives, that the future is bright, and so forth (Pearlman & Saakvitne, 1995). Being that crisis workers are exposed to prevalence and acceptance of violence, cruelty, and bigotry, the emergence of cynical beliefs about the world, such as the idea that life events are random or that people are basically malevolent or selfish, is not uncommon (Janoff-Bulman, 1985) which is the central symptom of vicarious traumatization. The worst symptom however of vicarious traumatization is the loss of a sense of meaning for one's life, a loss of hope and idealism, a loss of connection with others, and a devaluing of awareness of one's experience...spirituality. Pearlman and Saakvitne (1995) believe the larger sense of meaning and connection is crucial psychological well being in general and disruption in this realm may be the most troubling, and perhaps the least explored. Crisis workers who work with victims are exposed to the many cruel ways that people deceive, betray, or violate the trust of other human beings. They become suspicious of other peoples' motives, more cynical, or distrustful, sometimes expecting the worst from people. Personal safety becomes an issue especially those crisis
workers who work with victims of crime, might experience increased thoughts and images associated with personal vulnerability, such as a love one being killed in a car accident, or over time may experience an enhanced awareness of the fragility of life. There can be a disruption in psychological needs, safety, trust, esteem, control, and intimacy, which motivates behavior which are particularly susceptible to change through traumatic experiences (Pearlman & Saakvitne, 1995). Understanding that adults learn primarily through the acquisition of knowledge by study and/or experiences the HRD expert must foster improved performance so that the organization can function efficiently in the personal growth and development of employees. Applying the Humanistic approach to crisis workers and their unique work environment maintains that all people are unique and possess individual potential. "It also maintains that all people have the natural capacity to learn; thus, the purpose of learning is to encourage individual to develop to his or her full unique potential (Gilley, 1989 pp121)" "Based on life experiences, people develop beliefs founded in these needs and their ability to meet them, which, in turn, shape their perceptions of new life experiences. When, as a result of trauma, an individual believes certain basic needs cannot and will not ever be met (e.g., "I am never safe," "People are not trustworthy," "I am not worthy of being loved"), these beliefs shape relationships, identity, and access to hope or despair" (Pearlman & Saakvitne, 1995, p. 162). Vicarious traumatization has a profound effect on a crisis worker's interpersonal relationships; if they believe that others are not trustworthy or valuable for example, it is difficult to have a rewarding relationship. Similarly, one's belief about oneself can also lead to interpersonal disruptions; social withdrawal, inability to tolerate the wide range of feelings necessary to maintain intimate relationships, feeling alienated from intimate friends and sexual partners because of their unique work, inability to enjoy common forms of entertainment, or one can become less available to others because of the demands of work (Pearlman & Saakvitne, 1995). This area of understanding is critical for the HRD change agent; the lack of trustworthiness and relationship development complicates the program design potential learning experience.

Future Research Questions

There is a cost to those who are in the caring and crisis profession. "Professional who listen to clients' stories of fear, pain, and suffering may feel similar fear, pain, and suffering because they care" (Figley, 1995, p.1). There as been sporadic attention given to the caring professionals even though there is clear identification of the phenomenon of secondary traumatic stress disorder in the DSM-III and DSM-IV, however nearly all the attention has been directed to those people in harm’s way rather then those who care for and worry about them. Research questions that need to be addressed.

- How can HRD practitioners make a contribution to change within the crisis worker and his/her personal and professional development?
- How can learned experiences from trauma exposure be affected through program development and design?
- How can HRD and management build a working relationship of trust to assist their employees through difficult times of stress?

Discussion and Implications to HRD

HRD practitioners must perform several different activities and duties, such as design, develop, and implement learning programs and training activities within an organization. Without the understanding of what crisis workers are exposed to and the effect the trauma causes in their professional and personal lives HRD cannot and will not make an impact to the organization. They need to understand in order to make a needs assessment as well as an evaluation of programs involving the crisis worker learner. Human resource development implies the development of people in an organization as well as financial and capital resources. Since HRD is the development of people within the organization, it is critical for the well being of the organization for HRD practitioners to face the day-to-day events of the crisis worker and their lives. "The development of the people refers to the advanced knowledge, skills, and competencies, and the improved behavior of people within the organization for their personal and professional use (Gilley, 1989, pp5)." The role for the HRD practitioner is their commitment to the professional advancement of people within the organization through career development and understanding to bring about change within the crisis worker.

Embarrassment and fear may prevent crisis workers from seeking support from family, friends, or outsiders (Kates, 2001). The idea of asking for help from anyone let alone an outsider is unsettling for several reasons, first usually the "masculo" value of their occupations. There is a kind of natural personification, which makes many crisis workers resistant to seeking help. Men and women who gravitate to specific crisis occupations, such as police
Stressful traumatic events or repeated exposure to traumatic incidents can be described as unusual occurrences involving exposure to events that are sudden, overwhelming and emotionally challenging. The past decade has witnessed a growing recognition that the professionals who are called upon to assist those affected by traumatic events can themselves become secondary victims. Occupations such as police work, fire fighting, emergency services, hospital, health and social services, mental health professions, and rescue workers may be more susceptible to traumatic aftereffects as a result of either primary or secondary involvement with trauma. Perhaps the most important dimension of this exposure to traumatic event(s), whether direct or secondary, is that a consequence is usually atypical in nature, its intensity and duration may cause the crisis worker to be unable to draw upon previous learning, training, or experience to help them understand the event or their reaction to it (Paton, 1996). Exposure to such an event can trigger feelings and emotions which, are normal in the context of the traumatic experience, can be
difficult to understand and manage. If these feelings continue over time, dysfunctional reactions can occur and affect their well-being, their families, and their organizational performance.

Preparation for potential critical occupation workers makes good sense. As a result of the horrific terrorist act committed against our nation, the trauma crisis workers are being exposed to have been forced to the front pages of many newspapers. HRD experts in many of the crisis workers organizations are being catapulted to action with little knowledge of how to help. HRD practitioners cannot wait for a tragic act to propel them toward program design; employees are being exposed on a day basis. While members of these high-risk occupations may possess the technical skills required to meet the needs presented by victims, their own training may not provide them with the psychological and self-maintenance skills required to readily comprehend their traumatic experience or to understand and deal effectively with the aftereffects. Many of these crisis workers are unprepared for their own feelings about the incident. They have been trained to help others but not to help themselves. If help is not sought, or if their organizations fail to recognize and respond to the ensuing traumatic reaction, their well-being can be threatened. The cost not only to the worker but also to the organization if they fail to recognize the potential effect on workers can be substantial. Projections indicate that hundreds of crisis workers from the New York area will leave their jobs due to their recent trauma exposure. They may experience long term personal stress related damage, however their departures will also ultimately effect the organizations; many such as the New York Fire Department can not afford to have further lose of employees. Trauma can generate contagious effects. This ripple effect extends the circle of impact into the whole organization and the surrounding community. The potential impact on the crisis worker, staff, and others and the cost and performance problems generated within critical occupations signals the importance of recognizing the existing and implications of psychological trauma. Organizations and their HRD professionals must acknowledge that education, prevention, intervention, support and additional research is required to deal with the problems that crisis workers exposed to traumatic events pose for the worker, the organization and the community as a whole. Recognition, preparation and treatment for those affected will help to alleviate this hidden problem and ensure, that, in the course of extending professional assistance to others, the members of these crisis occupations do not suffer unnecessarily. It is the role of the HRD professional to have an understanding of the unique culture of the very self-protecting crisis worker. The HRD professional must re-enforce the effects of repeated exposure to traumatic events not only to the crisis worker but also to the organization itself through education. Education brings about better understanding, which results in alternative solutions to problems.

The Transfer of Technology of Highly Skilled Foreign Workers for Thai Workers in Thailand

Boon-Anan Phinairrup
National Institute Development Administration

Few studies have examined technology transfer among Thai skilled-workers. Some studies had reported that Thai people have relatively low technological abilities and skills. This paper reports on research utilizing quantitative and qualitative methods including interviews, observations, and surveys. The study demonstrates the manner in which information and education are transferred between Thai employees and foreign workers.

Keywords: Transfer of Technology, Technology-Based Training, Thailand

Since the industries in Thailand are growing, the need to face the transfer of the technology and the capabilities to sustain is more. Thailand likes to approach industrialization with open-economy and promote the export goods. In this connection, many researchers have recognized the importance of the transfer of technology. Chantrammonklasi (1994) had stated that the transfer of technology could assist the country achieve economic and provide convenient life. The government has also strongly promoted the foreign investment in the industry. For instance, the government has provided some training program, industrial promotion, reduce tax, establish the government unit such as Board of Investment (BOI) to look after the foreign investment, and promote exports. In addition, the government has encouraged some high technology small business, which need the most modern technology in order to complete effectively manufacturing or providing service. These situations mean that the investment policy of the government is increasingly concerned with the entry of domestic firms into industrial market. The country needs to have the investment policy to innovate Thai industries in the world competition and encourage more transferred technology.

The investment policy is very essential to convince foreigners to invest in Thailand. Since the investment policy of the Thai government allows foreign labors to work here, it has created some concerns. For example, there are more and more foreign workers brought in and caused Thai workers have less opportunity to get a job. The second concern is that the transfer of technology has not been accrued including the limited transfer of technology for local staff. The scarcity of skilled local labor and the restriction found in technology transfer agreements, which were imposed by technology suppliers is another concern.

Unfortunately however, few studies have looked specifically on how technology has been transferred for Thai skilled-workers. Some studies had reported that Thai people had been trained with the poor communication of technology information. Within the immediate locality, the manufacturer may be aware of the technology requirements for established products and it is still difficult to obtain or develop new product design. In addition, some studies have shown that even where information on technology is available, lack of relevant skills with low level of education make difficult to achieve with unfamiliar or new technology. Infrastructure development needs to be a step ahead of the industrial development. It should be a forerunner before technology transfer.

The project purposes thus rest on how technology has been transferred in the manufactures. The project will apply quantitative approach and documentation approach including interview, observation, and survey. Moreover, data collected for the project will be analyzed and provided the broader pictures in term how one relates to transfer the technology and how to develop Thai workers.

Objectives

To study how technology has been transferred from foreign workers to Thai workers.

Literature Review

Thailand's economic growth since the late 1980s has been increased. Then, it makes technology become more important element for the national development. The current industrial policies in Thailand are designed to promote manufactured exports, labor-intensive industries and agriculture-based industries. The BOI is responsible for these activities. The organization is empowered to offer incentives, guarantees, and measures to protect industries against competition, and special exemptions from various laws. Then, many manufactures have imported the technology from abroad in order to assist them in the production and management. For instance, there are many manufactures in Thailand which are Thai-Japanese joint-ventures such as Toyota.
about the costs of alternative sources has resulted in unreasonably high profits for the owners of technology. The disadvantaged position of the buyer and his ignorance evaluate alternative sources of technology and to negotiate effectively with suppliers. As a result, contracts are perceived, however, is that the strategy of building capacities in local institutions has not met with much success, in part because of the absence of effective linkages between the public and private sectors, as well as the lack of explicit measures and schemes to promote technological literacy.

These situations have created some concerns about the transfer of technology included the limited transfer of technology to local staff, the restrictions found in technology transfer agreements which were imposed by technology suppliers, the stated and hidden costs of technology agreement, the inappropriateness of the technology introduced, and the scarcity of skilled local labor. For instance, the Thai-Japan joint ventures have failed to transfer the know-how technology to Thai local partners. (Chantramonklasri, 1994)

Other concern is that the report traces the vicious circle within which many local companies are caught. It begins with a market for technology in which a small number of suppliers face a large number of buyers, with whom costs, terms and conditions are determined individually on the basis of crude bargaining power rather than competition. Moreover, the buyers are usually uninformed and lack the technical and legal expertise to evaluate alternative sources of technology and to negotiate effectively with suppliers. As a result, contracts are concluded to the advantage of the supplier and the buyers accept restrictions, which have the effect of increasing their dependence on the technology suppliers.

Although the transfer of technology is usually identified with the inflow of foreign capital, there have been questions raised about the prices paid for technology. The disadvantaged position of the buyer and his ignorance about the costs of alternative sources has resulted in unreasonably high profits for the owners of technology (Cooper, 1994). The government study reports that the evaluation of an offer to supply technology grows in complexity when the technology is offered in packaged form, with technical assistance and management provided (Kanthachai, 1987). The offer may contain many hidden costs. In addition, some reports provide information to support the contention that the outflows of funds (foreign remittances and expenses for import receipts) have exceeded fund inflows (foreign capital infusions and export receipts) among Thai joint ventures that have been paying copyright fees and royalties (Ng, 1986). The technologies that foreign firms have introduced are generally inappropriate or excessively capital-intensive, given the labor surplus conditions in these countries as mentioned earlier. Moreover, these technologies are seldom adapted to make better use of local factor endowments. Some foreign companies had introduced second-hand equipment and passes it off as “labor-intensive, appropriate technology” (Chantramonklasri, 1994). These are usually machines that had become less efficient and had to be replaced in the originating country. The unfortunate impact on the host country or on the technology buyer is usually high maintenance costs, which offset the benefits from increased employment, and cheaper equipment costs.

The shortage of skilled labor is regarded as the another major problem to the effective transfer and absorption of technology. The various skills training programs are unable to cope with the needs of the extremely large labor pool and the requirement of industrial firms (McLeod, 1988). Moreover, the educational system has thus far failed to keep up with the demands for more science-based technically grounded and relevant educational programs. The potential for technological absorption and control is related to the availability of qualified and experienced technical personnel. Although such individuals were to be found in most Thai research institutions, the report showed that such institutions have been unable to adequately supply the requirements of private industry (Kanthachai, 1987).

The limited utilization of R&D capability is isolated and disconnected in the real world. The researchers carry out technology activity in an improper manner. Even though there is an attempt to commerce R&D programs and it is often unable to have an impact on the industry. A well-known argument often used to explain this ineffectiveness is that industrial firms have a tendency to utilize proven technologies from foreign sources, thus limiting the demand for local scientific and technological capabilities (Ng, 1986). This argument remains highly questionable because it presumes that those “centers of excellence” have available the kinds of products which are relevant to the needs of their potential clients. As noted by an empirical study, “industrial firms tend to doubt the ability and effectiveness of universities and public technical institutes to solve practical industrial problems” (TDRI, 1992a, p. 85).
According to some statistics in the country report, advanced countries have a higher level of national investment in R&D. For example, Japan spent about 3 percent of its GNP and newly-industrialized countries like Korea, Taiwan and Singapore spent about 1 to 2 percent of their GNP in R&D (TDRI, 1992). The R&D investment in Thailand in recent years was less than 0.2 percent of GNP. It shows that Thailand is less interested in R&D investment which causes to develop the country slowly.

Other problem is that many firms can draw sources of technology from foreign sources and that lead the firms to feel that there is no need to invest in R&D. Since the firms receive efficient technology, they then assume that everything will be fine. They would take a passive action until the new production system has arrived. Therefore, they can simply engage limited technological learning such as only at the minimum level needed to operate the systems. Indeed, it is less awareness of the industrial firms to develop the in-house technology.

Many reasons mentioned above have caused Thailand to hardly ready for the transfer of technology and have the limitation of competitiveness. Moreover, there are many new market economy with lower wages and more sufficient sources. Many developed countries have become more modern and research new production and make many new products which make Thailand will become less competitive and could become at risk in the future. It is thus highly possible that without substantial efforts to develop better capability in science and technology to support industrial development. Thailand may face a major economic and social crisis in the near future.

Furthermore, transfer capabilities and motivation of the enterprise supplying the industrial technology each have an important bearing upon the effectiveness and efficiency of technology transfers. The competence of the transfer agents, including their ability to design an easily transferable technology package, is an important factor. The supplier enterprise and its transfer package report a combination of documentation, training and technical assistance. Motivation of the technology supplier depends in large part on the transfer mode and the potential return the supplier hopes to realize an effective and efficient transplant.

Many problems mentioned above show the technology gap. It represents the differences in the levels of technical competence of the supplier and the absorptive capabilities of the recipient enterprise. The extent of this gap and the time and resources will take to effectively implant a technology package that will depend on enterprise differences in terms of likeness, scale, and sophistical of product line, quality of metallurgy, quality control standards, and relative levels of general, "system-specific", "firm-specific" technical knowledge.

Conceptual Framework

The transfer of technology gap between developing and developed countries is happening for long time. It causes the technology gap wider and wider. There are a few countries in Asia, which have crossed the gap and developed a national technology of their own. The essential question is why. Why has so little worthwhile know-how flowed to developing countries? It is the believe that there is no one answer to the question. There are some studies to learn the success and failures of some factories. Some failure stories in the transfer of technology are because of poor negotiating technique and poor contract drafting, poor English language, and poor skilled-labor. Some success stories occurred because the negotiation knew what they wanted, knew how to bargain for it, and knows how to draft the necessary contract.

This paper is to study how technology has been transferred from foreign labs to Thai labs under the concept of the transfer of technology that defines as the act of sharing know-how by such devices as constancy, joint ventures, gifts, licenses, franchises, and patents. In this case, it focuses on the transfer of technology in the manufactures because the industry in Thailand is more promoted and more buying - selling technology in this area than other area.

The project took into account the aboved definition as an assist to determine of how-to transfer the technology. The technology can be transferred and adapted by demonstrations, dissemination, training, constancy and management assistance. Some of the questions for investigation are: to find out which technology do you think that Thai workers' skills are not as good as they should, Does the manufacture provide training to Thai workers? How does the manufacture develop Thai workers after they have the transfer of technology? What are the advantage and disadvantage for hiring foreign workers? How can the government assist you with the transfer of technology? This, in turn, will assist Thai manufactures to know their problems, and to learn about the transfer of technology.

Research Methodology

1. Research Limitation
   The research is to study a model and technique how to transfer technology to Thai workers.
2. Sampling Population
   Sampling population focused into four groups:
1. Foreign workers are from Japan, China, India, Taiwan Australia, German, South Korea, France, and America.
2. Thai workers that work as labor force in the manufactures.
3. Senior administrators in the institutions.
4. Entrepreneur or human resource managers.

Research Questions/Propositions

How can the transfer of technology from foreign workers to Thai workers?

Random Sampling Technique

The size of sample is 350. It consists of:
1. Foreign workers: 150 persons
2. Thai workers: 100 persons
3. Entrepreneur or HR manager: 50 persons
4. Institutions: 50 persons

Data Collection

Data collection is to:
1. Collect information from the secondary source by collect data through statistics, type of business, type of technology, labor workforce, labor demand.
2. Collect information from the primary source by interview with Thai and foreign workers, entrepreneur, or human resource managers.

Words of Definition

The transfer of technology defines as a knowledge transfer from supplier (usually a developed country) to the receiver (a developing country).

Foreign workers define as foreigners who are granted the work permit to work in Thailand by the BOI.
Thai workers define as Thai workers who work in the manufactures.
Human resource manager defines as the manager who is responsible for personnel management.
Institution defines as Thai higher education institution.
Entrepreneurs define as one who organizes a business/manufacture.

Result and Findings

The questionnaires were provided for four groups. They were 50 HR managers/entrepreneur, 100 Thai labors, 150 foreign labors and 50 institution administrators. The research took about one and a half months in the field. The study included twenty four manufactures from four regions of Thailand and ten institutions. The section will discuss some important issues on how foreign workers transfer the technology to Thai workers.

The first set of questionnaire was distributed to the HR manager/entrepreneur. The result displays that every factory has hired foreign workers with the working permit to work in Thailand. Most of them came from Japan, Korea, China, Taiwan, Philippines, Malaysia, Singapore, Pakistan, and India. A few of them came from the United States, Canada, the Britain, France, Italian, and Australia. These people hold the positions of senior and middle manager and technician. Examples of positions are mechanical manager, marketing manager, managing director, quality audit manager, shift supervisor, maintenance supervisor, R&D manager, production manager, tooling design specialist, process development manager, and information system manager. Many responses have stated that some positions have transferred the technology in order to increase the experience and specialist for Thai workers to work efficiently. They also mention that there is an organizational policy reinforced the transfer of technology more than 76% in the manufactures. The reasons are that Thai workers cost cheaper and have ability to do the job. In order to transfer the technology in the manufactures, the result displays the four type of the transfer of technology in Table 1 and the method of the transfer of technology in Table 2 as shown below.
Since the transfer of technology has occurred, the responses (76.6%) are willing to replace foreign workers in the middle management such positions as plant manager, control manager, mechanical technician, safety and environment manager, production technician. The factory also has the plan to continuous the development of Thai labors in order to keep up the new technology. They will provide coaching, in-house training, simulator, require the self-evaluation, and do the portfolio.

The responses also state the advantage and disadvantage for hiring foreign workers as shown below:

<table>
<thead>
<tr>
<th>Advantage</th>
<th>Disadvantage</th>
</tr>
</thead>
<tbody>
<tr>
<td>- transfer the technology for Thais</td>
<td>- highly cost</td>
</tr>
<tr>
<td>- exchange of culture</td>
<td>- conflict culture</td>
</tr>
<tr>
<td>- easily to communicate with mother company</td>
<td>- language barrier</td>
</tr>
<tr>
<td>- highly experience and specialist</td>
<td>- hardly transfer the technology</td>
</tr>
<tr>
<td>- provide new technology and knowledge</td>
<td>- difficult to apply for Thai visa</td>
</tr>
<tr>
<td>- provide suggestion and recommendation</td>
<td>- look down Thai people</td>
</tr>
</tbody>
</table>

On the government side, the responses indicate the need of some assistance from the Thai government as follows:

- encourage Thai people to learn foreign language
- train Thai people for foreign culture
- improve the school curriculum including teaching and learning
- send students for training
- reinforce the law for foreign labors to do something for Thai society
- coordinate between the government and industry
- provide the training package
- establish the center of consultation about the expert in the technology for Thailand and abroad

The second set of questionnaires was distributed to foreign workers. The response from the survey show that the average age of the foreign workers is 41 years old, the average years of experience are 14 years and earn the average salary is 80,080 baht ($1,777 per month). The responses are male (98%) and female (2%). Their education in details is shown in Table 3:

<table>
<thead>
<tr>
<th>Table 3. Level of Education of Foreign Workers in Thailand</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level of Education</td>

<tr>
<td>Lower secondary school</td>
</tr>
<tr>
<td>Upper secondary school</td>
</tr>
<tr>
<td>2 years college</td>
</tr>
<tr>
<td>Bachelor Degree</td>
</tr>
<tr>
<td>No answer</td>
</tr>
</tbody>
</table>

The foreign workers are Asia (79.9%), European (11.4%), and America (6.7%). Most Asian came from Japan and followed by Taiwan, China, Korea, Malaysia, Singapore, and India. Their positions are president, vice president, manager, assistant manager, and technician. Their main jobs include quality control, quality audit, organizational management, safety, production design, contact customers, supervise workers, marketing product, investment planning, coordinate, and maintenance. These people came to Thailand because their mother companies sent them to help Thai team members improve their skill, learning, and development. This has created an opportunity to train and transfer the technology to Thai workers. However, there are some difficulty for the transfer of technology to Thai workers in several reasons. For example, language barrier,
communication gap, and conflict culture. Others include Thai staff will quit the job after training in order to get a better job, some Thai labors don’t pay attention to what had been taught, and both foreign and Thai workers sometimes misunderstanding.

The third set of questionnaire was distributed to Thai workers. The survey shows that the average age of Thai workers is 31 years old, the average years of experience are 5 years, and earn average salary about 20,262 baht ($406 per month). The responses are male (83%) and female (17%). Their education in detail is shown in Table 4.

<table>
<thead>
<tr>
<th>Level of Education</th>
<th>Percent</th>

<tr>
<td>Bachelor degree</td>
<td>49%</td>
</tr>
<tr>
<td>Master degree</td>
<td>6%</td>
</tr>
<tr>
<td>No answer</td>
<td>3%</td>
</tr>
</tbody>
</table>

The responses are holding the positions in the middle manager, for instance, head of the technician, and director of production. The responses show that these positions can be replaced by Thai people for several reasons. Thai people have more experience, work hard, responsibility, willing to do the job, like challenge job, and always develop themselves. In addition, many responses stated that Thai workers have equal opportunity to progress their job like foreign workers, they work and coordinate with foreign staff and learn the technique from them. The question asked the responses whether they attended the training courses. They all attended the training courses in a variety of areas. The training courses are the industrial orientation, professional manager, internal audit, foreign language, manufacturing, ISO 9000, ISO 14000, safety and save energy, and time management both in Thailand and abroad. The technique for the transfer of technology is to work closely with foreign labors, practice by yourself, testing, coordinate in the project, train on the actual job, and send them for training abroad and other professional conference.

The fourth set of questionnaire was distributed to the institutional administrators. The responses are the public institutions (95%). Their curriculum are in the fields of engineering, technology food, industrial technology, ceramic, business-computer, business-economic, science food, accounting, marketing, hotel, and tourism.

The institution’s policy to produce the graduates for the market labor is to produce graduates who can think, work, be responsible, and communicate including foreign language. The question also asked whether the institutions knew about the need for the number of Thai workers in the manufactures. Many of them don’t know (52%) while some institutions have known (48%). The question asked further how they know about the need of factories. The result shows that the institutions knew about the need from province labor council (5.45), announcement of the factories (13.5%), BOI (5.4%), and no answer (75.7%).

In order to help the manufactures find the qualified labors, all institutions have the counseling unit under the different name such as the counseling department, counseling unit, career and development section, career information section where they work closely with students and the manufactures. Their jobs are to provide counseling, finding job for students, coordinate with the Ministry of Education, service on career information.

The responses also display that students in the institutions have an opportunity to learn and practice their skills in the manufactures in order to increase the experience, sometimes attend training short course for 2 months or 23 years in the manufactures. The techniques to train students is implemented in Thailand are shown in Table 5.

<table>

<td>35%</td>
</tr>
<tr>
<td>Learning through a documentation</td>
<td>15%</td>
</tr>
</tbody>
</table>

Some problems in the Thai institutions regarding the production of graduates for market labor are:
- unclear the national policy for the higher educational level
- a lack of personnel and equipments - less experience teachers to teach
- a lack of budget - a lack of private coordination
- a lack of language and culture - old curriculum including teaching and learning
- less activities for students to participate in the field
The final question was to ask whether the government can help to improve the transfer of technology for Thai workers:
- determine how to transfer the technology
- provide training and more education
- coaching and mentoring
- determine the policy on the transfer of technology
- coordinate with the foreign investment
- encourage the exchange of technology among the industries
- set up the transfer of technology center
- open new curriculum with the emphasis on the foreign language
- encourage more foreign investor to invest in Thailand
- conduct more seminars, workshop, conferences, and other activities that involve the transfer of technology among labors

Conclusion and Recommendation

In this paper, we analyze how technology has been transferred from foreign workers to Thai workers. The finding shows that the majority of foreign and Thai workers are male and holding the position of middle and senior managers in the manufactures. Foreign workers have average experience about 14 years while Thai workers have average experience about 5 years. It could be that the average age of foreign workers are much higher up to 41 years old with more skills while the Thai workers are 31 years old with less skills. It results for the foreign workers to be able to distribute their new and advanced knowledge for Thai workers who have less experience. The foreign workers train Thai workers through the on-the-job-training as the primary vehicle for building the capacity to work efficiently.

The method of the transfer of technology range from on the job training, in-house training, training abroad, and training in Thailand in the areas of mechanism, production, management, and marketing. It shows that there are four main methods for the transfer of technology that most manufactures in Thailand implemented and work well. The manufactures still feel that it is necessary to hire the foreign workers because they would like to hire their own people to do their job. They feel that their people can do better job and trust them more. In addition, there is the recognition that the Thai government and the manufactures have play major roles to facilitate and support the process of technology transfer. The government is encouraged to support the process through the provision of required incentives, educational infrastructure and support institutions. It must be a strong collaboration between the manufactures and the government for the transfer of technology.

The educational curriculum has offered the courses that are not quite modern and not geared to keep up with the changes in technology. The responses from the manufactures had stated that the graduates can’t do the work. However, the institutions have tried to help by providing practicum and have students do the actual work while in school. The equipments in schools are not new for students to practice. It also a lack of qualified teachers resulted in the incomplete or improper transfer of technology. It is also a high turnover among skilled workers resulted in the lack of continuity in technology transfer to the local manufactures. Consequently, the ability of Thai workers to absorb and adapt technology is weak.

New Knowledge to HRD

This research can contribute to the new knowledge in HRD that there is a growing awareness between the manufactures and the transfer of skills available to increase the productivity and growth in industrial production. It displays the important for Thai workers to be better educational and training opportunity in order to do a better job and compete in the world manufactures. Therefore, the education and training has played the essential role to develop the workers’ skills. In addition, the government must be a strong support for the process of technology transfer.

Revisiting the New Deal: A Longitudinal Case Study

Judy Pate
Graeme Martin
Jim McGoldrick
University of Abertay Dundee

This paper examines the new psychological contract in the light of changing economic circumstances by examining evidence from a longitudinal case study of the links between job security and HRD. The case study draws on data from surveys and interviews. Our conclusions support the hypotheses that it is employee demand, driven by a fear of job insecurity, which underlies much of the recent upsurge of interest in HRD rather than the more optimistic employability thesis.

Key Words: New Deal, Psychological Contract, Case Study

Throughout the 1990s there was a plethora of mainly US literature that made much of the impact of changing market conditions and changing psychological contracts on careers and career development. At root, the general tone of this writing was optimistic in nature. Much political capital was made of the increased expenditure and efforts made by employers on HRD in the US (Marquardt, 2000) and in the UK (Milward, Bryson & Forth, 2000). At the same time the new career literature focused on the positive benefits of the breakdown of the old psychological contract or old deal. This resulted in employees no longer being offered job security but instead being offered employability (opportunities for continuous learning and enhanced future marketability) in return for their willingness to commit themselves to work flexibly for their present employers. This new psychological contract or new deal and new career literature became associated with concepts such as “boundaryless” (Arthur, 1994) and “protean” or variable careers (Hall & Moss, 1998), both of which connoted individuals largely seeking psychological growth moving along career paths that were discontinuous and often outside the boundaries of single firms.

In much of the writing on new patterns of employment, the benefits to individuals are stressed in the form of increased opportunities for learning and for balancing work and life style issues. However, the evidence and discussion largely focused on the new economy and on employees of new organizational forms such as networked and cellular structures, with much of the data drawn from employees in Silicon Valley and others parts of the golden triangle in the US. Because of this rather restricted empirical base, this literature was criticised for its apocalyptic tone and lack of transferability to other, more traditional parts of the US economy, for example, the considerable US public sector and the burgeoning, largely low-skilled, service economy (Thurow, 1999). Such criticisms were even more widely voiced in countries that had not experienced the levels of continuous growth which characterised the US economy for nearly all of the 1990s, such as most of those in Europe, including the UK, France and Germany (Eire was a notable but limited exception). In essence, it was argued that the new deal and new careers were limited to small(ish) pockets of the US economy and high growth regions in Europe with the benefits only likely to be felt during periods of sustained economic growth.

This is not to say that academics in Europe failed to observe changes in employment relationships, careers and in the relative importance that individuals were placing on their own career development. Rather it shows that they were less likely to see these changes in wholly positive terms, believing that these concepts were heavily tied to the features of particular labour market conditions. Thus, given the US/new economy focus of the literature, it comes as no surprise as Sullivan (1999) has pointed out, that there were few studies that examined the negative changes in employment relationships associated with new psychological contracts. She noted three such US studies (Tsui, Pearce, Porter and Tripoli, 1997) that highlighted the negative outcomes of changed. In contrast, there were a much greater number of studies in the UK that gave the new career literature a more critical treatment (see, for example, Kessler and Undy, 1996; Thomson and Dunkerly, 1999).

Theoretical Framework

The concept of the psychological contract has also been embraced by the academic community from a number of disciplines including psychology (Mansour-Cole and Scott, 1998; Deluga, 1994), sociology (Fincham and Rhodes, 1988; Delbridge and Lowe, 1997) and human resource management (Sims, 1994; Rousseau and Greller, 1994). Academics have firstly aimed to establish the prevalence of changes in the psychological contract.
and secondly offered models and theories to advance understanding of the factors that shape the psychological contract (Guest et al., 1996; Rousseau, 1995).

Our study is rooted in this framework and explores the relationship between career development, the demand for training and job security. This study examines what we referred to as the optimistic and pessimistic versions of the new deal and its relationship to the demand for training. The optimistic version of the increased interest in HRD by organizations and employees was linked to the employability thesis, which can be stated in the following terms. The new, transactional psychological contract, established by employers to deal with fluctuating demand conditions associated with global competition, has provided employees with a flexible process of training and (essentially) self-development to ensure that they become more employable internally if circumstances permit but externally if the firm experiences a downturn. Indeed, the Silicon Valley version is premised on the assumption that constant change of employees among employers in that region is one of the reasons underlying its success and that boundarylessness is a positive virtue. Consequently, it is this new and enlightened employer position that has led to an increasing interest by employees in training and development to cope with the new rules of the game. It is also argued that such boundarylessness suits the changing aspirations of new economy employees who value change and learning more than their old economy colleagues do. Such transitions have come to be associated with cosmopolitan personalities who were more likely to change jobs and employers and view HRD in terms of psychological growth (Larwood, Wright, Desrochers and Dahir, 1998).

The more pessimistic position, which we label the employee-driven demand thesis, makes much of how employees adjust to the reality of downsizing and to perceptions of job insecurity and feelings of powerlessness by engaging in a transactional form of employment relationship. Through this they seek to acquire more skills to make themselves more employable internally and by increasing their expectations of what they are owed by their employers from training and development. Such reactions to HRD are associated with local personalities (Larwood, Wright, Desrochers and Dahir, 1998) who are more likely to engage in HRD for political reasons and have a narrower interest in HRD. Consequently, from this perspective it is employee politically driven demand rather than employer initiatives or psychological growth that have been the primary influence on training and development moving up the agenda for both parties.

Our main conclusion, drawn from our single case study of mainly lower level employees working in a traditional industry and with relatively limited opportunities to move jobs, provided much more support for the pessimistic version of why HRD had moved up the agenda. This finding contradicts employer claims that they were behind the increased emphasis on training and development because of uncertain market conditions and their desire to make employees more employable.

Our study has the benefit of a degree of longitudinality in being able to relate changes in employee aspirations, expectations and satisfaction to changes in context, an advantage rarely enjoyed by the cross-sectional survey research which have underpinned much of the US based career literature. And it is precisely the importance of relating changing career orientations, patterns of HRD and context that are likely to loom large in the coming years, given the recessionary pressures in the world economy. It is interesting to note how the literature on careers and boundarylessness changed as the US economy began to decline during 2000. With the events following September, 11th and the possibility of much more restricted growth in the world economy, studies which focus on changing contexts and HRD are more likely to be of use to academics and practitioners than those which were built on "years of feast". For this reason, we have revisited our original study and use new data to examine how employees' demand and satisfaction with training and development is influenced by the local economic and organizational context in which they find themselves and to further test the employee-driven demand thesis.

Research Questions and Propositions

To test our two propositions, we have attempted to answer the following questions:
First, to what extent had training and development become more important to employees over the four years of research? Second, was there a mismatch between employees' expectations and desires on training and development and what the company provided? In other words had the employer violated psychological contracts in this area (Rousseau, 1995)? Third, if any violation was experienced, what impact did this have on employee perceptions or behaviour? Finally, how did attitudes to HRD change over time and context?

Methodology

Many of the psychological contract studies have drawn conclusions from national surveys (see Guest and Conway, 1997; Kessler and Undy, 1996) or from questioning postgraduate students (for example see Rousseau.
and Parks, 1993). As a result these studies have ignored the importance of context or have used a small and unrepresentative sample. The strength of this research lies in the narrative accounts of 'real' experiences within a case study organisation and highlights the influence of contextual issues in the analysis of psychological contracts (Yin, 1994; Eisenhardt, 1989).

The research is based on a single case study, a medium-sized industrial textile company employing approximately 600 people in 2000. The company was based in a small rural town in Scotland. The company has four separate sites in the locality specialising in various aspects of the product range (Figure 1, below, outlines the characteristics of two contrasting sites). Four lines of commodities were produced in the year 2000: industrial yarns, floor-coverings, industrial textiles and geo-textiles.

Between 1986 and 1999 the company was a wholly-owned subsidiary of a multinational holding organisation producing polypropylene products. The period 1996 - 2000 was characterised by ongoing change due to pressures from the shareholders and the market. As a result the company reduced the workforce from 660 in 1996 to 600 in 1999 with further redundancies expected in 2001. This action had a predictable "knock on" effect on employee perceptions of job security. At the same time the company's directors had attempted to create a new organisational culture based on customer service, flexibility and good human resource management. These changes were accompanied by the directors "talking up" training and development and in increasing effort and expenditure in specific areas of training such as continuous improvement, healthcare and team working.

In November 1996 employees were told of new plans to reorganise its productions facilities by locating two of the older sites close by the two newer sites. This relocation of facilities would create one large "greenfield" site that would allow the company to rationalise its organisational structure and to "downsize" its employment levels. In this connection, although training had been primarily focused on business needs, the outgoing human resources director claimed that such training had also been undertaken with a view to helping secure employment for those who would need to be "let go".

The period 1997 - 1999 witnessed a difficult time for the company due to the strength of the pound and operating in a mature global market. This was coupled to problems with quality and the loss of major customers. The company responded to this problem in two ways, development activities and employee training. In 1998 the overall holding organisation put the company on the market and it was bought by a family-owned Greek company. The uncertainty associated with the sale of the company had implications for perceptions of job security and morale.

Data Collection

The research occurred during the period 1996-2000, though we have drawn on a consultancy survey conducted in 1994. The research design has adopted a mixed methodology approach (Cresswell, 1994). The purpose of the quantitative aspect of the research was to use repeated cross-sectional data from employee surveys (conducted in 1994, 1996 and in 2000) to provide a longitudinal test of our key research questions. A consultancy firm undertook the first survey in 1994 and the following surveys, undertaken by the researchers, retained the key questions from the first survey for comparison. The 1996 survey was distributed to the whole workforce with an 80% response rate (from a total population of approximately 660). In the year 2000, due to pressures of work, the company was not prepared to allow all members of the organisation to complete the survey in worktime as they had in 1996. As a result a stratified sample (structured to reflect the proportion within each site) of employees was identified, the response rate was again high at 52%.

In the second phase of the research focus groups and in-depth individual. The organisation was made up of five distinct sites and a stratified random sample was selected to gain a representative group from each site. During 1997 one hundred and five interviews were conducted in total. In 1999 the company agreed to follow up interviews with employees but felt unable to allow us to interview the same 105 employees as in 1997. Consequently 50 employees were re-interviewed; involving 10 randomly selected from each site, due to the confines of this paper the findings of only 2 sites were reported.

The purpose of the qualitative dimension of the study was to determine whether, how and why different groups of employees come to hold varied perspectives on training and development during the six-year period between the surveys and to ground these perceptions in a specific context (Basznger and Dodier, 1997). Specifically we were interested in how an explicit and implicit employer position to renegotiate the psychological contract by offering more training for greater employee flexibility in a context of declining security in employment had influenced employee perceptions of the contract. This attempted renegotiation of the contract was revealed to us through interviews with some of the key directors and human resource staff, who recognised that the lifetime employment contract for some employees was not possible under current and forecast market circumstances.
Results and findings

Ranking Of Employee Expectations on Training and Development

In all three surveys employees were asked about how important certain aspects of the employment contract were to. In absolute terms the data appeared to show that all aspects of what employees valued had become more important during 1994-6 and 1996-2000.

</tbody>
</table>

The important point to note about the data in tables one and two is the relative ranking of training and development, which, according to the data, has consistently moved upwards in employees' preference schedules. This greater priority accorded by employees to HRD was further supported by the qualitative data as employees felt that training gave them more strings to their bow. The organisation had also emphasised the importance of training and development but employees were sceptical of the employability rhetoric of the company. A typical comment was “they are not going to spend all that money so we can go somewhere else. They'll spend money so they can get more out of us!”

Violation of the Psychological Contract

Employees (in the 1996 and 2000 surveys only) rated different aspects of the company mission statement according to (a) how important they personally regarded them and (b) how they saw them being put into practice by the company. Table three and four show that in both 1996 and 2000 employees perceived the largest, statistically significant gaps between what they valued about the mission statement and what they saw the company putting into practice were: providing a fair system of financial and non-financial reward; providing open communications, and providing opportunities for personal development.

</table>

(Scale: 1 is important, 4 is not at all important).

The gap between policy and practice was corroborated by the qualitative data. One employee summed up the feelings of many: "If someone says to me 'we'll give you training' then they should do it. But nothing happened! If it doesn't mean anything, there's no point saying it!"

Consequences of Employer Violation

The quantitative and qualitative data also showed that there were significant negative associations between: being given adequate skills to do their jobs and enjoying their jobs and being given plenty of opportunity for career development and enjoying their jobs. These findings were in line with Robinson and Rousseau's (1994) research on the association between employer violations of psychological contracts and the lower levels of job satisfaction of those employees who continued to work for their employers.

Variation amongst Sites Levels of Jobs

Although the data for the company has shown some general trends, employee expectations varied amongst sites during the period covered by the 1996 and 2000 survey. Two sites in particular referred to as Site A and Site B (see Figure 1) exhibited markedly different attitudes towards training and development. A comparison of these two sites showed that Site A agreed more strongly than Site B that it was important to receive suitable training (1996: two sample t-test t (224) = 2.58; p < 0.05 and 2000: t (30) = 2.54; p < 0.05). The data also showed that workers at Site felt that there were fewer opportunities to acquire relevant skills. A typical comment was "I would take the opportunity if I was given the chance, but we haven't been given the chance!" It was also suggested that that there was less scope for career development than in site B as "there is no place to go" with a flat organisational structure.
Our data showed that there was a significant difference between 'blue collar' and 'white collar' employees. White-collar employees expected to have a long term 'career' whereas blue-collar employees tended to accept the realities of their market position and limited prospects for promotion are expressing satisfied with a 'job'.

Our general conclusions from the data for the company as a whole were (a) that employees had come to value training and development significantly more highly throughout the period and (b) that they also saw training and development as one of the key areas of the psychological contract that had been most violated during the period covered by the surveys. Moreover, this violation seemed to be associated with lower levels of job satisfaction. However, employees' perceptions and expectations concerning training and development varied amongst sites. The qualitative data showed two sites, in particular, to hold markedly different attitudes towards training and development. These sites operated in quite distinctive product and labour markets and employed different types of people, which, we believe, have a major influence on how they responded to questions on HRD.

The survey data appears to provide some support for the second hypothesis that the demand for training and development was primarily employee-driven and was associated with heightened expectations and perceived violation of the psychological contract in this area. These data also suggested the importance of key contexts in shaping variations in employees' perceptions. As we indicated, to explore these issues further we undertook focus groups in all sites and individual interviews with employees in the various sites. We expected that such data might not only provide a degree of triangulation for the research programme but also give a dialogical and contextual account(s) of the variety in employee perceptions found in the surveys (Keenoy, Oswick and Grant, 1997). For reasons of time and space we cannot discuss these data but only allude to them in the comments below.

Contribution to the Development of HRD

The purpose of this study was to explore two hypotheses concerning changes in the psychological contract and the so-called "new deal", with a view to revisiting this concept in the light of changed economic circumstances in the world in general.

Our storyline is that, despite the directors claiming that employability had been a key feature of their thinking and practice, few employees saw their employer as particularly enlightened; nor did they see employability as the main reason underlying the increased emphasis of the company or its employees on training and development. Instead all of our data provide support for the employee-driven demand thesis, which implicates political behaviour by employees in placing increased value on training and development. Such political behaviour is associated with employees trying to adjust to a climate of increasing job insecurity by making themselves more employable inside the company. The increased expectations of training and development that accompany this enhanced valuation of training and development are clearly linked to employees' perceptions that the company had failed to deliver on the promises made in this area. In this case, although the company may have "talked up" training and development (in the mission statement and policy documents) and in actually delivering training in areas such as safety, they did little to honour their "side of the bargain" by giving employees the kind of skills that they regarded as necessary to secure their future. This was seen to be a violation of the contract even in circumstances where employees had low-discretion jobs and low expectations of training.
Though we can only allude to the interview data, the stories told by employees, in particular, show that training and development have become a more valued part of the psychological contract of employees. They also show that employees view this as one of the key aspects of the contract where employer rhetoric did not match reality. Moreover, as Robinson and Rousseau (1994) found, there is also evidence to suggest that the more employees perceive the company to violate their obligations with regard to providing skills and career development, the less satisfied they are with their jobs.

Leaving aside the question of variation among sites for the moment, the data from the survey, the focus groups accounts and the text of the interviews in both sites generally corroborated each other on the increasing expectations of employees for more relevant training and development and the failure of the company to deliver in these aspects of employment. These perceptions are particularly evident in Site A, which employ a younger workforce, many of whom - at the time of the survey - felt more worried about job security than in Site B. Inevitably, such feelings of insecurity in Site A are linked to their lack of power to influence their employment prospects, given the location of the company and the lack of suitable alternative employment in the area. Thus, worries about job security, perceptions of contract violation have led employees to a more transactional or exchange-based view of their psychological contracts rather than the old-style relational contracts, which involved a guarantee of job security in return for commitment.

However, these data and accounts also show that production workers and white-collar workers see things differently. The horizons of production workers, particularly in Site B, tend to be local (Gouldner, 1957), consistent with the lack of discretion in their work, their expectations of alternative employment and their lack of ambition. Thus, their expectations of training and their views on careers were shaped by their desire to remain employable. Consistent with the work of Larwood, Wright, Desrochers and Dahir (1998) these employees are more likely to engage in HRD for political reasons and have a narrower interest in HRD. On the other hand, white collar workers, whilst influenced by the lack of alternatives, have broader cosmopolitan orientations (Gouldner, 1957; Larwood, Wright, Desrochers and Dahir, 1998) and see training and development as a means of making themselves more marketable outside of the company and as part of a natural process of life-long learning.

In summary, within this one company there were sufficient similarities between sites and groups of workers to support the employee-driven demand thesis concerning the psychological contract and HRD. However, it is also true that there are important differences between sites and between categories of employees. These differences have allowed us explore the importance of contextual factors such as historical, organisational and product market influences and to examine the importance of the "causes" of the psychological contract such as site culture, human resource practices, alternative opportunities for work and some key demographic variables.

For practitioners, the implications of these findings are three-fold. First, when employers' rhetoric on human resource development is not matched by practice it can sometimes rebound on them to produce paradoxical and counter-intentional effects (Dahler-Larsen, 1997). Thus, for example, Maitland (1994; 1996) argues that employees have come to learn the lessons of market economics only too well and, like pay and communications, training and development may have become something of a "moving target" for organisations. So, instead of being satisfied with what employers are delivering under this new deal, a dynamic is set in progress where employee expectations with regard to training and career development increases rapidly and, consequently, lead to constant and increasing frustrations as employers are seen to fail to meet their side of the bargain.

Second, job security remains, and will continue to be in the near future, a key source of worry for many employees who work in downsized organisations. In a study that is surely one of the most important antecedents of the psychological contract literature, Alan Fox (1974) criticised the assumption of a natural consensus underlying much management practice and pointed out when workers perceive low trust initiatives on the part of management, these will be met by low trust responses. This low trust dynamic in the employment relationship is often masked by outcomes such low labour turnover and absenteeism. However, such apparent behavioural commitment should not be taken as evidence of attitudinal commitment or employee satisfaction with their "lot". Instead, it should be read as evidence of an asymmetrical power relationship in which workers are fully aware that no real alternative employment exists for them.

Finally, what employers sometimes regard as providing suitable training and development for employability is often at odds with what employees perceive as career-enhancing, even in relatively low discretion jobs. Thus employers' concerns with firm-specific training needs to be matched with individual needs for external employability if the revised new deal is to be seen as fair by employees. However, such a match can only be brought about when there are open and realistic discussions by both parties concerning their mutual expectations, perceptions and obligations with respect to training and career development.

R. Wayne Pace, First President of the Academy of Human Resource Development:
An Historical Perspective

Heather Hanson
Gary N. McLean
University of Minnesota

As a step in collecting living histories of HRD leaders, this paper provides a brief history of R. Wayne Pace, first President, and arguably (as many were involved) the founder, of the Academy of HRD. Original documents, an historical video, and electronic conversations with him and six colleagues were used. Pace has been a leader in school, church, professional, and personal lives. Pace exhibits a common characteristic of HRD leaders—an eclectic background in Organizational Communication and HRD.

Key Words: History of HRD, Academy of HRD, Wayne Pace

Over the years, and from its multiple roots, Human Resource Development (HRD) has produced many leaders who have made significant contributions to the field. The Academy of Human Resource Development (AHRD, the Academy) has recognized some of these leaders in its HRD Scholars' Hall of Fame. Most of those currently recognized are no longer alive. However, there are many leaders who are still alive and whose histories have not yet been adequately captured. One of these individuals is R. Wayne Pace, the first President and arguably the founder of the AHRD. In this paper we will present a brief history of Dr. Pace, highlighting his contributions to the field of HRD with specific emphasis on his contributions to the founding of the Academy. We see this effort as a first step in beginning to capture the histories of significant leaders in HRD while they are still alive to assist in the writing of those histories.

Research Problem

Often, histories are not written until the people involved are no longer alive to participate in the writing of those histories. While there is some benefit in writing a history from the perspective of hindsight (including the greater willingness of participants to offer negative observations or criticisms), there are also benefits in writing such a history while those involved are still able to participate. This is not an either/or question; present histories can always be revisited in the context of new insights that might come to light after the person involved is no longer alive. In this paper, we intend to provide a brief history (limited by the page limitations of the paper) of Dr. R. Wayne Pace, with some information on his personal life, but concentrating on his professional life and, specifically, his involvement in the founding of the Academy of Human Resource Development.

Significance of the Problem

The field of Human Resource Development has not done a very good job of capturing its own history. In another paper (Azevedo & McLean, in process), several texts in Human Resource Development were reviewed to determine their perspectives regarding the history of HRD. Many of the texts were silent about its history, while the others included only a very short history of the field. Few articles were found about its history, either, and few articles were found that provided a detailed history of the individuals who have been influential in the development of the field. This is a deficiency that needs to be remedied. An ancient Chinese proverb says that one should "...foresee the future by reviewing the past" (Kuo, 2001). By looking to our former leaders, we can better prepare our leaders for the future.

In contrast, the 1982 Yearbook of the American Home Economics Association provided a history of 70 of the leaders in Home Economics Teacher Education (Bailey & Davis, 1982). What a wonderful contribution such a book could make for HRD! We hope that this paper will serve as a catalyst to encourage researchers in the field to continue this beginning step, ultimately resulting in a book of such biographies, or, perhaps, an issue of Advances in Developing Human Resources.

Historical Research Methodology

Gottschalk (1969) identified four essentials in writing the history of any particular place, period, set of events, institutions, or persons:

- the collection of surviving objects of the printed, written, and oral, of any materials that may be relevant
- the exclusion of those materials (or parts thereof) that are unauthentic
- the extraction from the authentic material of testimony that is credible
- the organization of that reliable testimony into a meaningful narrative or exposition (p. 28)

For this paper, we first contacted Dr. Pace and obtained from him his curriculum vita, a personally developed history, a videotape of him sharing his history in an interview (Baldrige, 1989), a list of eight colleagues whom Pace was willing to contact to give his personal permission for us to seek additional information about him via e-mail, and the documents generated in the development of the AHRD. In addition, we were given permission to contact Dr. Richard Swanson, one of the key players in the founding of the AHRD. From the vita, we identified articles, textbooks, and other publications. All of the suggested colleagues were contacted, as was Dr. Swanson. Six of the nine colleagues contacted participated in providing information based on a set of questions sent to them (see Appendix). Dr. Pace also interacted with us via email throughout the process of writing this paper to provide additional information (at one point he indicated that we were being "very curious," but he generously responded to all questions posed).

There is one major problem in doing a history of a living person. For many reasons, not the least of which is continued friendship, in a living history it is very difficult, if not impossible, to be critical. None of the respondents provided any information that one might consider critical. Likewise, it would be an unusual person who would provide critical information about himself. Thus, there is nothing in this history that one would consider critical. No one, however, is perfect, and there are clearly areas of weakness or criticism that should be included in this history if it is to be truly authentic. Perhaps that aspect of the history will need to wait until after Pace's death.

Wayne's World

A colleague, Ken Baldrige, said of Dr. R. Wayne Pace, "His interests are varied; his sense of humor is infectious; he is constantly involved in a writing or consulting project—his energy seems boundless." This is a common perspective of those invited to comment on the work and personality of R. Wayne Pace. He has influenced many aspects of the education community, and in this paper we will examine many aspects of his life.

Wayne's Pre-professional Life

Pace grew up in a small community in Summit County, Utah. He attended North Summit High School. In high school, he was already exhibiting leadership abilities, serving as class secretary in each of the upper three years. He was also very active in athletics, lettering in four sports—basketball, football, baseball, and track. In his senior year, he captained both the basketball and football teams. Pace also participated in the school's debate team and his 9th grade class play.

He graduated in 1949 and decided to attend the University of Utah in the College of Education, on a scholarship based on his high school achievements. While he did not feel a strong pull toward education as a major, he declared that as his major as a way of retaining his scholarship. He majored in secondary education with a focus on Language Arts. This program was an experimental interdisciplinary program consisting of a combination of courses in English, journalism, and speech. Pace was one of the first students admitted to this program. In 1953 he graduated with a teaching certificate and his B.S. in Language Arts.

Pace claimed that he was a late starter in the dating game, but, as a popular athlete, he quickly caught up. His first steady girlfriend was his wife-to-be, Gae, whom he met in 1952. They were introduced in the driveway to his apartment, as his neighbor was giving her and her friends a ride home from a social activity at church. Gae was a bookkeeper at an insurance company in Salt Lake City at the time and dated Pace until March 19, 1953, when they were married in Salt Lake City.

After receiving his bachelors degree, he spent some time in the service. On July 28, 1953, he was inducted into the Army and stationed in Monterey, CA. Assigned to the Sixth Division of the Army, his duties included issuing military ID cards and Privilege Cards for dependents of military personnel. During his time with the Army, he participated in the All-Church basketball tournament and also formed a theater group and produced the operetta,
HMS Pinafore. The theater group performed for the soldiers in the area and also went on tour to Utah and performed at Salt Lake City and Ogden.

Pace’s teaching career started at Box Elder County High School in 1955. Here, he taught speech, drama, and English; he was the coach of the debate team, director of two major theatre productions, and teacher in at least four courses. After a year at Box Elder High School, he decided to continue his college education on the GI Bill. After looking around at his options, he was offered an assistantship at Brigham Young University. In this position he was responsible for teaching an Introduction to Public Speaking class. Along with this job, Pace assisted with the debate team and other activities in the Speech and Drama Department. In 1957 Pace received his masters degree in Public Address and Rhetoric; his thesis topic was “A Study of the Speaking of B.H. Roberts—The Blacksmith Orator.”

His time at Brigham Young led him further into his collegiate career. While traveling with the debate team, he met a man who would have a large influence throughout his life. W. Charles Redding was a speaker at one of the debate meets that Pace attended. He introduced himself to Charles and realized during his presentation to the debate team that Redding had taken a position at Purdue University. Pace followed his intuition and decided to go to Purdue and pursue his doctoral degree under the direction of Charles Redding. In 1960, Pace received his Ph.D. from Purdue University in Industrial Communication. He was one of the first doctoral students under Charles Redding. His doctoral dissertation was, “An Analysis of Select Oral Communication Attributes of Direct-Selling Representatives as Related to Their Sales Effectiveness.” The subjects for this dissertation were Avon sales people who bought copies of his completed dissertation to have at the company headquarters. That was a minor landmark around the school; not too many people sell copies of their dissertations. He then worked for a year at Purdue University as an instructor in the Department of Communications.

University Career

Pace then was offered (and accepted) a position as Associate Professor at Parsons College in Fairfield, Iowa, in the Speech and Drama Department. The Chair for the Speech and Theatre Department at Parsons College was the individual who invited Pace in for the interview; he also was familiar with the work of Charles Redding. The Chair had told Pace that the reason he was invited in for the interview was because he listed organizational communication as his specialty, and he had been unable to find any other candidates who admitted to having a background in communications. The quality of his work led to his being selected as Department Chair in 1962. He described his work at Parsons as a fantastic experience, where the college was rapidly developing with enthusiastic faculty and some national publicity. One advantage of being at Parsons was its compensation that was quite a bit more than what others were offering for similar positions. Also, the President of the College was very insistent that Pace join them by giving him a local country club membership, a $5,000 interest free loan to buy a house, and the rank of Associate Professor. On top of all this, he got an additional $5,000 and a guaranteed $500 raise each semester he was employed there.

While at Parsons College, he had a chance to explore another opportunity as they were on the trimester system. Under this system, faculty taught for two trimesters and then took one off. In 1961, he took his trimester off to serve as a visiting professor at Bowdoin College in Brunswick, Maine. Pace stated that his experiences there in the Department of English were very valuable, and he has fond memories of his time there. After this trimester, he returned to Parsons College to finish the year.

Pace was climbing through the ranks in the education field very rapidly and was greatly enjoying the work he was doing. His next move was to Fresno, CA, to California State University in the Speech Arts Division in 1962. He spent four years there as Assistant Professor and Head, Public Address and Communication Area. He also had the opportunity to work as the debate coach and enjoyed that work and travel tremendously. At Fresno, Pace hired new faculty members for the Speech Communications Area.

One of the most exciting and fulfilling career moves for him was to the University of Montana. He spent six years there as Professor and Chair in the Speech Communication Department. Here he was able to influence the program greatly and actually built the Speech Communication program, which was later renamed, Interpersonal Communication. As chair of the Department, he had a chance to hire many new faculty members. He called upon many past friends and colleagues to join him to build a strong foundation of highly talented professors to work in the field of communication. Pace was also the creator of one of the first courses in organizational communication, which was very cutting edge for that time.

From the University of Montana, he was hired away to the University of New Mexico as Chair of the Communication Department. In New Mexico, Estelle Zannes, a colleague of Pace’s, said, “The best years were when Wayne was the chair. He brought his energy, enthusiasm, and good sense to the department.” One of his major accomplishments here was the development of one of the first undergraduate programs in Organization
Development. This was seen also as very much on the cutting edge as far as curriculum development went at New Mexico. At this institution, he introduced a relatively new approach to the basic course in communication. It was handled more like a physics class, in which the faculty illustrated principles by conducting experiments and "interviewing students in the audience like Johnny Carson and talk-show hosts." Here, they also designed courses that could be taught using the large "kiva" or auditoriums to teach 300 students per section. This style was much more interactive and included a lot more student participation than similar courses in Montana.

Move to HRD

Pace's next move was to Brigham Young University in 1978. Here he established a program in Organization Communication that had significant national publicity. At this time, his career started to take a change in direction. In 1987 he took an exchange position at Brigham Young University in Hawaii (BYU-Provo and BYU-Hawaii had a common administration at that time) in Human Resource Development. This was a change from his strong background in communication and speech departments. Pace stated, "As I studied careers in organizational communication, I concluded that communication was the theory base for all programs that involved learning, that learning was simply a sub-division of communication." From this he wrote his first papers on "organizational communication as the theory base of training and development." From here he was invited to participate in the first conference on the academic preparation of practitioners in training and development sponsored by ASTD. At this conference he argued that "communication, not education, was the appropriate theory on which to base an academic program."

From here, he took a different position within Brigham Young University, transferring back to Utah in the Organizational Behavior Department in the Marriott School of Management. The management school in Utah resisted the addition of a human resource development department and eventually worked out a way to phase it out as it was seen as overlapping with much of the material that other management classes covered. The HRD program was disassembled by 1990, and there are no remaining elements of the program at BYU. (The same outcome has also occurred at BYU-Hawaii.) At this time, many communication departments were being torn apart and installed in different programs, while others were growing stronger. Pace stated his belief that the outcome depended on how well the department was established and also the image it was trying to hold up. Also, he stated, "HRD will never flourish in schools of management because they have incompatible driving forces."

There are many other significant contributions that Pace has made to the field of HRD. He attended and delivered papers at, and participated in, all three or four of ASTD's conferences on the Academic Preparation of Practitioners of HRD; and he established and advised the first official student chapter of ASTD at BYU-Utah and helped the chapter receive various national awards. He also helped create the Professor's Network of ASTD and served as founding co-chair; he served on ASTD's Professional Development Committee during the Standards or Competencies studies, participated in the design and implementation of the first competency study, and served as a role expert in both studies. Pace published three books on HRD, Analysis in Human Resource Development and Organization Development (1989), Human Resource Development: The Field (1991), and three editions of Organizational Communication: Foundations for Human Resource Development (1983, 1989, 1994). Finally, he served on the Executive Committee of the Management Development Professional Practice Area of ASTD and received an award for a Bibliography of Literature on Management Development (1987), and he presented numerous papers on the theory and practice of HRD at professional meetings in the field of communication, broadening the understanding of HRD in other areas.

Personal Characteristics

This research has identified a number of personal characteristics possessed by R. Wayne Pace that have contributed to his success. Pace identified three such characteristics about himself: the tendency to initiate action, persistence in goal achievement, and the ability to make friends. Pace said that he has "a tendency to want to move things forward," resulting in action taken more frequently and quickly than may be the case with others. With goal achievement, Pace stated that he has the "tendency to pursue a goal with dedicated tenacity." Last, in Pace's mind, "he has been able to make and maintain friendships with a wide range of individuals who both agree and disagree with his own philosophy, but who are willing to continue to be friends."

His colleagues and friends also attributed much of his success to his personal characteristics. According to Baldridge (2001), "He has an enormous capacity for work, his determination to keep busy doing worthwhile things, his insistence upon sound scholarship, and his refusal to be thwarted by temporary obstacles." Pace was described by Eric Stephan (2001), a professor at BYU, as an "empire builder." His colleague described this concept as
meaning that, "when he comes into a situation, he immediately thinks about a way it is organized and how to make it better. Few people see how to improve something as quickly as Pace, and, therefore, they usually end up in his dust trying to figure out where he is taking things." Stephan also stated that Pace has a great philosophy on education: "Make knowledge useful."

There are many people on whom Pace has had a large impact or influence. The phrases that were heard most often in this research were that he was very supportive and encouraging of his co-workers, he was a joy to be around, and he was a "professor's professor." While he had fun, he always exemplified what a professor is supposed to do: explore new ideas, present papers, do research, and write books, but most of all help students to succeed. Pace made a big impact on Baldridge (2001), who stated, "Wayne's personality has had a decided effect upon me as it is nearly impossible to be anything but upbeat whenever he is around." Another quote from a colleague of his states, "If it hadn't been for Wayne's influence, I never would have seen the fun of writing articles and books." Pace has left a major impact on the people with whom he has worked.

Influencers

Not only did Pace influence many, but also there were many people who influenced Pace. In an interview, Pace listed three main influences on his life. The first of these is his spouse, Gae Tueller Pace. According to Pace, "she has been supportive through numerous major moves, cared for six children, and ensures some continuity in their lives as they entered and exited different cultures and crossed numerous time zones." Also, "her psychological, physical, and spiritual stability have sustained them through a vast number of dramatic changes."

The second most influential people in Pace's life have been his parents, Ralph and Elda Fernelius Pace. They were owners of a rural small business that dealt in general merchandise for farmers, ranchers, and miners. Pace, being the oldest, had the chance to participate in the business through various jobs, such as pumping gas, mixing milk shakes, and delivering bags of cement. Pace stated that his parents instilled in him the strong desire to perform well and to pursue higher education.

The person who influenced his professional career the most was Dr. W. Charles Redding, his major professor at Purdue University. Redding was the first person who served as an instructor, advisor, and friend to Pace, all three, and who also provided mentoring. He spent countless hours with Pace—redirecting his energies, taking him out on consulting jobs, and providing professional support, both in school and afterwards. Pace stated that even today he has a picture of Charles prominently displayed on a shelf in his office, just to make sure that his standards at least reach towards his.

Academy of HRD

One of the major contributions Pace has made to the field of human resource development has been the creation of the Academy of Human Resource Development. Richard Swanson (2001), a former President of the Academy, stated, "Wayne has expended a great deal of energy for the Human Resource Development profession during his distinguished career and was a perfect founding president of the Academy of Human Resource Development."

The vision of this entity evolved out of a proposal Pace prepared around 1983 for the establishment of an Academy of HRD at Brigham Young University. The original proposal was "designed to advance the academic program there and to establish a way to accept financial donations for support of faculty chairs and the academic program." This original proposal, however, never got underway. In 1992, Pace prepared and distributed a paper at a meeting of the Professor's Network of the American Society for Training and Development (ASTD) urging that an Academy of HRD be organized separate from ASTD. According to Swanson, "Wayne was positioned perfectly between the unwieldy Professors' Network of the ASTD that was represented by Karen E. Watkins and the elitist University Council for Research on HRD that was represented by Richard A. Swanson." He had three main reasons for making this proposal: HRD faculty could associate and fellowship with one another in a separate organization; HRD faculty could be stronger advocates for academic programs within an organization created to support academic programs; and HRD faculty would receive stronger support for their research efforts in a separate organization.

There were many goals and expectations that Pace had for this Academy of HRD. To be successful, Academy members would have to have a great dream, in which true success would come only from taking some very practical actions. The Academy must raise its own expectations by setting demanding goals and expressing high aspirations for the field. Pace raised three issues at the start of this organization: the members of the Academy must share specific research designs to advance the body of research; the Academy must become a powerful vehicle for supporting faculty who are attempting to establish and strengthen academic programs in colleges and universities;
and the Academy should provide information about HRD, academic programs, and graduates of those programs to employers to convince them to look for HRD graduates when they have openings.

The Academy has made many amazing advances throughout the years. However, according to Pace, the goals and expectations Pace held for the Academy have not all been met. Pace has expressed the wish that the Academy would do more in assisting faculty in establishing new academic programs and advancing the status of current programs. Another aspiration for the Academy was to function independently with a full-fledged international office. For some time, it had an executive director on loan from the University of Texas while attempts were made to raise funds to hire a permanent director. Unfortunately, they were unable to raise enough funds from training and development and consulting organizations to hire a full-time director, and this has resulted in great regret for Pace.

There was much effort and time involved in founding the Academy. Through some key contacts, he was able to organize an office and get it up and running. Robert Cox arranged for the Academy offices to be in the same building in Austin, TX, as the International Communication Association and agreed to serve as interim executive director until the Academy could make other arrangements. Tom Schindel, a graduate student at the University of Texas-Austin, agreed to serve as Office Manager. In spite of this help, "simply put, it is unlikely that there would be an Academy of Human Resource Development without Wayne," stated Swanson (2001).

Actual work on organizing the Academy began after the 1992 meeting of ASTD in late May or early June. Because of Pace's involvement in many organizations, he was well acquainted with the effort it would take to organize a group this size. Pace spent a lot of time on the phone and writing letters to enlist the support of faculty for the Academy. Starting with the roster from ASTD's Professors' Network, Pace selected fifty or sixty people who he thought would support the formation of this Academy and assigned each of them to a committee. These committees were all very much standalone as Pace did little consulting with them. He appointed chairs for each committee and asked them to contact their committee members and work from there. He gave each chair a detailed description of what he thought the committees should do but left most of it up to the individuals involved.

Pace wanted to make participating in the Academy a memorable occasion. His plan for this was to provide some mementos to those who attended the first meeting and made a contribution to the organization. Through making contact with several publishers, he managed to gather from $500 to $1,000 from each in donations to pay for these items. The mementos included pens with the Academy of Human Resource Development on them, post-it note holders with the name on them, charter member certificates, and certificates for Fellows of the Academy (a concept that has not continued).

A meeting was arranged at Georgia State University to review and edit the by-laws. A small group of three respected members were asked to review and make any editing changes to motions coming from the group. Everyone who attended the subsequent chartering meeting held just before the ASTD Conference in San Antonio, TX, was put into a self-selected group with the responsibility to review the proposed by-laws and motions for approval. Throughout the meeting there were obvious differences of opinion among the groups that resulted in heated discussions, but, nevertheless, by 4:00 p.m. on May 7, 1993, all provisions of the by-laws had been edited, moved, and approved. After this task was completed, papers were submitted to the U. S. Internal Revenue Service to establish the Academy as a not-for-profit corporation. Within the next few weeks, the charter membership list included approximately one hundred individuals. Pace was subsequently elected President of the Academy, an office in which he served for one year, followed by two years as Immediate Past President.

Wayne's Life Outside of HRD

Pace's professional career has made an impact on his family. Not one of his children went into the education field. One of his younger brothers ventured into teaching but retired early and is no longer teaching. His mother, Elda, is very proud of his accomplishments, and his spouse, Gae, and children are all very supportive.

Pace has also achieved major accomplishments outside of his career in Communication and HRD. As Pace stated, "Raising a family of six very self-sustaining children, who are all married, and by the year 2001 have provided me and my spouse with twenty grandchildren, is a major accomplishment."

He has had continuous activity in the Church of Jesus Christ of Latter-day Saints ("the Mormons") where the callings were often very demanding of his time and talent. He recently served as President of the Sunday School of a local unit of the Church in which he managed instructional programs for almost 200 members. There is a long history of involvement in the church that streams way back into his family's history. The long and powerful tradition has had a significant though subtle influence on his professional career. He has striven to live by two major tenets of the LDS church: experiences in this life are simply preparation for the next life, so how people develop their minds and bodies and carry out responsibilities here contribute to what they will be able to achieve later; and people should
be honest, chaste, benevolent, and virtuous, and that they should obey, honor, and sustain the law. Pace has tried to live by these tenets and to allow these goals to affect his professional relationships.

Also, he was constantly involved in community-based organizations that were both a pleasure and a burden. Pace served in elected positions on the Board of Trustees of the Pace Society of America, "which is an association of people whose last names are Pace or who are descendants of Paces." The Board of Trustees is a group of thirty elected positions that publish the "Bulletin of the Pace Society of America" and holds an annual conference. He also served as President of a large chapter of the Sons of Utah Pioneers, and on the Board of local chapters of both Rotary International and Kiwanis International.

The Future

Pace's views on the future of academic programs in HRD are very enlightening. He thinks that most current academic programs will continue to be strengthened with the gradual addition of new faculty and an increase in students who select HRD as a major field of study. The resistance he has seen to HRD, he believes, will continue, but new academic programs in colleges may increase. The programs that seek to make knowledge useful so that students can compete with allied majors in the job market are most likely to succeed. Also, the elements of philosophy and practice of both organizational performance and organizational learning must be introduced into HRD academic programs in order for them to prepare students to compete successfully for jobs.

Pace is still active in this field of work. Presently he is a Professor Emeritus at Brigham Young University in the Marriott School of Management in the Department of Organizational Leadership and Strategy, from which he retired in 1996. Also, he is currently an Adjunct Professor at Southern Cross University in the School of Social and Workplace Development in Lismore, Australia, and will continue in this role until 2003.

Conclusion

R. Wayne Pace has had a prominent career, first in fields related to Communication and then in Human Resource Development. His many experiences have left a path for us to follow. He has been influenced by many successful figures, and, in turn, he continues to influence those around him. The career and life of this outstanding professional will always challenge those of us who follow to emulate his excellence.

Implications for HRD

First, it is critical that the field know and understand its pioneers and celebrate the contributions that they have made to the field. R. Wayne Pace is clearly one of those people whom the field needs to celebrate. Second, it is important for those who are entering the HRD field to know and understand its pioneers. Especially as the field matures, our pioneers who are aging will not be with us forever. It is important that we gather their information while they are still able to participate in developing this history. Third, Pace's life reveals the eclectic nature of the field, consistent with the findings of Worley and Feyerherm (2000) who found, in interviews with the early thought leaders in Organization Development, that their success was largely attributed to their "broad exposure and experiences to areas outside of the field of OD," with "almost half of the sample attributed their success to eclectic backgrounds, broad study curriculums, readings outside the field, and so on" (p. 10). We must resist the temptation of over-specialization in HRD. Finally, those who are in leadership roles in the Academy must continue to work to see that the founding vision of the Academy is fulfilled and that continuing efforts are made to expand that vision.

**Personal**
What are the personal characteristics you possess that you consider most important to your success? Why?
How has your personal connection with the Mormon Church affected your professional career?
Who has influenced you the most along your career path?
Outside of your career, what do you think have been your major accomplishments?

**Family**
How has your family affected your professional career? How did your career affect them?

**Professional**
When founding the Academy for Human Resource Development, what were your expectations or goals for the organization, and have they been achieved?
Please share with us some of the processes that were involved in the establishment of the AHRD.
Briefly, what have been the major influences in your career?
What have been the major obstacles for you to overcome in regards to your professional career?
What do you think your major contributions have been to the field of HRD?
What are your thoughts for the future of the field of HRD? Where do you see it going?
Where did your career start? Looking back at this, are you satisfied at how it progressed?
Who do you think have been the major contributors to the field of HRD?

**Questions for Wayne Pace’s Colleagues**
(Please share stories with us, as well as answering the questions.)

How did you know Wayne? What were your connections?
How has Wayne influenced your career?
Besides your career, how has Wayne influenced you?
What do you feel are Wayne’s major professional contributions?
To what do you attribute Wayne’s success?
What do you admire most about Wayne?
HRD: A Perspective on the Search for New Paradigms in a Time of Crisis

Ross E. Azevedo
Gary N. McLean
University of Minnesota

Human Resource Development (HRD) has emerged as a field from a wide variety of root disciplines. Using Kuhn's and Nagel's frameworks, this paper explores the death of the mixed paradigm for HRD and the need to find a birthing process for the field, even though this birthing process may result in a diversity of new paradigms. In this essay, readers are challenged to enter into a dialogue regarding this birthing process.

Keywords: Theory, History

Human Resource Development (HRD), as a field of intellectual inquiry, has evolved as a mix of theory and practice, coming a long way since the term was first introduced (by Nadler in 1969?) (Nadler, 1970). An outgrowth, in part, of the vocational education tradition, HRD was intended to encompass more than vocational education, to be seen and applied more broadly to workplace performance and learning, and to give more to practitioners. What follows is what we believe to be a challenging inquiry into the mix of theory and practice as they have evolved in HRD. We base our exploration on two classics from the philosophy of science--The Structure of Scientific Revolutions (Kuhn, 1970), and The Structure of Science: Problems in the Logic of Scientific Explanations (Nagel, 1961). We invite the readers to accompany us on this journey into the world of theoretical development in HRD and the creation of a structural process for theory advancement.

The Research Problem

The purpose of this paper, then, is to set the stage for a new dialogue on theory and its development in HRD. Historically, the field has been marked more by practice than theory. Thus, we intend to challenge the existing practical orientation of HRD as it is currently viewed and support the need for other paradigms as a perspective for further development of theory in the field of HRD.

Kuhn (1970) used paradigm to describe theories and other phenomena (p. 11), leading to some confusion with the way in which paradigm is popularly used today. He viewed the relationship as follows: "To be accepted as a paradigm, a theory must seem better than its competitors, but it need not, and in fact never does, explain all of the facts with which it is confronted" (pp. 17-18). This relationship is further explained as Kuhn stated: "A theory accounts for the effects seen/perceived and provides scientists with a common paradigm for their research" (p. 15). A theory is described by Kuhn as being "used to predict factual information of intrinsic value" (p. 30), with "the emergence of new theories" being "generally preceded by a period of pronounced professional insecurity" (pp. 67-68).

This paper, thus, explores the interface of theory and practice as it has influenced past paradigms impacting HRD, is influencing theories in HRD currently, and will influence the emergence of new paradigms of HRD in the future.

The Historical Setting

The evolution from vocational education was complicated and could be characterized as more heavily focused on practice than theory. The evolution probably began as a result of the Industrial Revolution. According to Gilley and Eggland (1989),

the earliest forms of training, often referred to as vocational education, was (sic.) provided by the apprenticeship system in colonial America. Apprenticeships were designed principally for the education of the poor. During this period, the workplace was not seen as a primary environment for human learning. (p. 8)

HRD's early focus in practice are further exemplified by DeSimone, Werner, and Harris (2002), who argued that the early roots of HRD included three: apprenticeship programs, vocational education, and factory schools. Nadler and Nadler (1990) argued that the earliest form of HRD goes back to the beginning of time and is focused almost
exclusively on on-the-job training. They claimed that the primary users of HRD were the military, religious groups, and governments, though others (such as seamen) were also included. According to Gilley and Eggland (1989), other roots of modern-day HRD, all with a practice or practitioner orientation, include Taylorism, the organizational implications of the famous Western Electric research, the human relations school of management during the 1950s, the behavioral science movement of the 1960s, the influence of the American Society for Training and Development (ASTD), and, finally, the influence of international competition. Swanson and Holton (2001) provided a complete chapter in their text, which provides coverage from the early Greeks and Romans up to the present day. Blake's (1995) history of HRD focuses almost exclusively on anecdotes related to the field of Organization Development. The Lee and Stead (1998) article focused on the last half of the last century in the UK, beginning with the Second World War, an important point in the development of HRD in the U.S., as well. Henschke (1999) traced the literature related to the history of HRD, providing a very useful bibliography. In addition, he recounted the development of HRD during the last decade of the last century, focusing on the performance-learning debate. Shaw and Craig (1994) provided a visual time line of the history of the field, though it is heavily biased toward a history of ASTD and its influence on the field. Interestingly, Rothwell and Kazanas (1989) did not include any reference to the roots of HRD nor to the process of evolution. Neither is this question addressed in a more recent book published in the UK (Walton, 1999).

While there has been considerable interest in HRD about the definition of the field, with emphasis on HRD as a field of practice (see McLean & McLean, 2001, and Weinberger, 1998, for a review of international and U.S. definitions of HRD), it appears that very little attention has been paid to the history of the field, particularly from a theoretical perspective. In spite of the numerous references above, all of the coverage is superficial with no in-depth analysis. In contrast, Kuo (2001) has completed a very detailed history of HRD in Taiwan. There, it is very clear that HRD, which is seen primarily as training, developed from a strong vocational education background that emerged from the birth of the country in 1949, along with considerable input from consultants from the U.S.

From the perspective of vocational education, a classic textbook in the field (Evans & Herr, 1978) made no reference to HRD, but the index has numerous entries under "Training." That is not too surprising as the term, HRD, was still emerging. Today, the former University Council on Vocational Teacher Education has been renamed (University Council on Workforce and Human Resource Education) and fully includes HRD. In fact, it sponsored a book entitled Beyond Tradition: Preparing HRD Educators for Tomorrow's Workforce (Stewart & Hall, 1998).

Moreover, with the change in name came profound changes in focus and orientation. In addition to the almost sole root of training, today, we look to apply the skills of the academic and practitioner researcher to questions of organizational performance and effectiveness, organizational change, knowledge management, continuous process improvement, career development, employee retention, organizational culture, globalization, and more.

Equally challenging is the fact that these changes have not been viewed in the same way, theoretically or practically, worldwide. McLean and McLean (2001) found, for example, that there is a strong emphasis on community development through HRD in Thailand, that HRD is used almost synonymously with Human Resources in China and France, that HRD refers almost solely to training in Taiwan, and so on. Thus, great caution must be exercised in assuming what is meant when someone uses the term, Human Resource Development, and what one is referring to in discussions of the concomitant theories of HRD.

This litany of invaluable developments on the technical and practice sides of HRD has not been fully matched on the theoretical front. It is the authors' perspective that the amalgam of ideas, concepts, practices, and perspectives which has been drawn together as HRD has not yet benefited from the richest possibilities of developments on the theoretical side, which is consistent with HRD being a normal science.

HRD as a Normal Science

While some may look at these varied developments and see them as disturbing or threatening, Kuhn (1970) would have proffered a different notion, advanced because of what he identified as the progress of a normal science. In the interest of brevity, only those items of particular interest will be referenced explicitly, though this whole section evolves from Kuhn. For Kuhn (1970), a normal science advances through three stages of paradigm development—birth, life, and death—in response to the need to solve problems for the field of inquiry. Paradigms succeed and take over from their predecessors or competitors because they provide richer answers to the questions of import and do a better job of predicting the results of empirical research investigations. Kuhn did not argue that any "dominant" paradigm answers all questions better than its competitors/predecessors, only that it does better in the preponderance of cases. Equally important for Kuhn is the idea that this evolution of a paradigm is not planned in the sense that researchers start out by calling for the replacement of one paradigm with another. We agree with this perspective. The process is developmental in that research, which reveals a developing inability to explain, makes it abundantly
clear that the existing paradigms are falling short, creating a crisis, and leading ultimately to the specification of new paradigms.

It is in the process of investigating the empirical phenomena of the field that the paradigm has meaningful existence—and in some sense lives and dies for Kuhn (1970). The paradigm first has value by revealing the underlying nature of things in solving problems through the provision of explanations of precision in a broader variety of circumstances, in a sense defining the significant facts of the field, and doing so better than its rivals do. But, Kuhn pointed out. initially, it likely might do so on a rather limited basis by solving only a few problems (p. 23). It then takes on value because of the predictions it can make about what is presently unknown but is revealed by further scientific investigation, here matching facts with theory. The third and subsequent stage of a normal science involves attempting to reach out to a far wider array of problems than is initially addressed, producing predictions over a vast assemblage of phenomena.

The varied intellectual threads that have come together as HRD could lead to a perspective somewhat different from that offered by Kuhn (1970)—a view that, rather than moving through the three stages, we are now facing the task of creating an entirely new paradigm woven from the whole cloth provided by the varied theoretical threads of the present disciplines suggested earlier. Such a position follows from the contention that, since HRD is but forty years old, its paradigm structure has not had the opportunity to evolve through the cycle of birth, life, and death spoken of by Kuhn (1970). Rather than a single-track evolution of intellectual inquiry, with one paradigm that is dying and others being birthed, HRD may be facing the potential demise of several paradigms as the field ultimately coalesces around those standards of scientific practice that allow furtherance of the tradition of scientific research. What this likely means is that HRD is facing the birth of paradigms of its own while working through the death of those paradigms that have supported the diverse fields that have been incorporated into the science that is HRD. This speaks to a greater burden upon the field than would be the case with a singular paradigm model proposed by Kuhn (1970).

Thus, it is here, in the third stage, death, where, we would contend, HRD as an amalgam of many fields now is—which it is apparent that the paradigm is falling short. As the acceptance of a paradigm grows, it becomes evident that it is not meeting the needs of the field. While it may provide predictions for a long list of phenomena, it also becomes evident that it is failing to be predictive of much of the richer array of empirical questions to which it is now being applied. While it may have been unable to address a few phenomena all along (which may have been acceptable because of its other successes), the paradigm now reveals its inability to be fully responsive to more and more of the empirical assessments to which it is put, creating a list of anomalies that grows. A major one, perhaps, is the ongoing concern of the field to determine ways to evaluate adequately its contributions to an organization. Other problems facing the field are significant questions about how adults who are fully developed can be changed; how to respond to a rapidly changing environment; how to deal with some of the most significant human issues of poverty, inequity, diversity, discrimination, and the like; determining individual learning styles and responding to them; and the inability of most people to deal with the ambiguities of life. It is this failure that now moves the field on to a new first phase of birth of new paradigms that will address these questions that are unanswered by existing paradigms.

Thus, what is particularly important at this juncture is that Kuhn would categorize these tumultuous experiences described above and expanded upon below as manifestations of a crisis within this field of intellectual inquiry. Kuhn (p. 67) called this awareness of crisis and theoretical anomaly the necessary precursors to acceptable changes (i.e., developments) in theory. What this involves, according to Kuhn, is wholesale destruction of existing paradigms and major shifts in the problems addressed and the techniques used in their investigation. We offer the following few examples as indicators of these shifts and changes in problems studied and techniques used as evidenced in HRD:

- Inability to provide an appropriate and practical model of evaluation. The complexity of the variables involved have made it impossible, to date, to provide evidence that HRD contributes to an organization's bottom line.
- Movement to qualitative paradigms rather than positivistic is requiring us to surrender the ability to predict.
- Difficulty in taking complex concepts and translating them into practical applications (e.g., through the use of Chaos Theory) brings charges from practitioners that research, and even the field, are irrelevant.
- Rampant tendency of practitioners to accept fads, without any evidence of successful application or sound theoretical constructs, has led many businesspeople and employees to see HRD as irrelevant and incompetent.
- Failure of HRD to impact the field; few practitioners are interested in, or aware of research, and so they do not refer to the research to find answers to business problems (McLean, 1998).

A recently convened Future Search Conference, co-sponsored by the American Society for Training and Development and the Academy of Human Resource Development (in June, 2001, in Orlando, FL), was intended to construct a future vision for the field. Over sixty participants represented most of the stakeholders in HRD. While it did have scholars and academics represented, practitioners were far more widely represented. From the authors' perspective, in spite of three days attempting to do so, the meeting was successful only in identifying 11 common
ground statements about the field. Most of these points were conceptual rather than applied, and they did not push us into the future. A subgroup is continuing to work on conceptualizing a vision of the future; many emails and subsequent meetings have occurred in these efforts, but, to date, there is no indication that progress is being made. Why did the meeting fail to produce such a vision? Perhaps it was because of the methodology used. Perhaps it was a factor of those in attendance. But both of these factors are indicators of the current state of HRD.

If one still questions whether HRD is a field in crisis, one needs only to have attended the 8th annual conference of the Academy of Human Resource Development held in the Spring of 2001 in Tulsa, Oklahoma, for evidence. Our perception is that many of the sessions ended up in matches of vigorous (and healthy) debate with contrary positions taken and steadfastly defended, suggesting the search for a new body of theory. As Kuhn would have said, ... the emergence of new theories is generally preceded by a period of pronounced professional insecurity... generated by the persistent failure of the puzzles of science to come out as they should. Failure of existing rules is prelude to a search for new ones. (pp. 68-69)

That insecurity is marked by debate, disagreement, and competition as the old and the new (or the developing) contend for primacy in explaining a field's world of inquiry. This issue also may be considered in light of some of the topics explored in theoretical presentations at the 2001 Academy of Human Resource Development conference:

- "Indigenizing Knowledge Transfer" (McLean, 2001)
- "Using a Human Capital Framework to Inform Human Capital Investment Decisions" (Provo, 2001)
- "Theorizing Human Resource Development" (McGoldrick, Stewart, & Watson, 2001)
- "A Multilevel Theory of Organization Performance: Seeing the Forest and the Trees" (Fisher, 2001)
- "A Performance Perspective Synthesizing Intellectual Capital, Knowledge Management and Organizational Learning" (Arnett, 2001)
- "Is Knowledge in the Head or in the World?" (Torraco, 2001) and
- "The Theory Challenge Facing Human Resource Development" (Swanson, 2001).

It is clear that the conceptual questions and concerns illustrated here, while regarded as positively expansive in the eyes of some, also would be described as chaotic by those who are looking for a unifying theoretical framework upon which to focus the intellectual inquiry of HRD. Such a situation is indicative of the nature of a crisis, according to Kuhn (1970). As argued above, this is a crisis born out of an inability to explain rather than cries to reject any existing paradigms.

What is interesting about this chaotic state of affairs, and what we must remember, is that it is not unusual but rather self-generated in the progress of a normal science, contributed to by each of us as a result of our research efforts. That is, many of the problems noted above are truly the result of our attempts to understand more deeply and broadly as the field has evolved from its predecessor fields, leading to new challenges and attempts to address them. In some sense, the nature of a science sets the stage for its own destruction--at least in terms of its paradigm base--as it evolves in the nature of its inquiry. Indeed, just as we would contend that the physics of Maxwell (1878) is not the physics of Einstein (1945) and the physics of Hawking (1988) is like neither of these predecessors, we must face the fact that HRD in the 21st Century is like none of its predecessors, either. In fact, the Academy of HRD's "Scholar Hall of Fame" members (Channing Dooley, Malcolm Knowles, Lilian Gilbreth, Kurt Lewin, B. F. Skinner, Donald Super, Robert Gagne, Gary Becker, Leonard Nadler) (HRD Scholar Hall-of-Fame, 2001), given this reality, consists of people who no longer speak today to the world of the 21st Century. This is true even though the phenomena being assessed and measured often are the same across paradigms. Thus, while a physicist in the 18th, 19th, and 20th Centuries may have been trying to explain gravity and planetary movement with the paradigm of the day, there are now black holes to complicate that analysis.

The resolution of this intellectual crisis, and the movement to a new paradigm, is not without considerable work and substantial resistance (Kuhn, 1970, p. 74). The emergence of new theories that are able to unify the field will come only after there is general acceptance within the academic and professional communities of the failure of the field, such as those referenced earlier, to solve the new questions to which its attention is directed and a recognition of the need for something different. Indeed, Kuhn argued that this might take decades.

Part of what slows the advancement of a field of inquiry is the tenacious resistance of many in the science to give up what they have accepted as fact and accepted theoretical foundations. The field abounds with such examples: Knowles' (1984) andragogy, Kirkpatrick's (1959) 4-levels of evaluation, Swanson's (1995) 3-legged stool, McLean and Sullivan's (1995) Action Research Model for OD, Cooperrider's (1986) concept of OD as Appreciative Inquiry, and Dannemiller's (2000) Large Scale Intervention Event. Such a list of such concepts is almost endless. In large part this stems from the fact that the traditional does work in dealing with some problems, creating a tendency to cleave to it in spite of evidence that it is no longer providing the comfortable answers it once did. Thus, Kuhn
(1970) pointed to the strong resistance to the "new" ideas of Copernicus (p. 67), Newton (p. 12), Priestley (p. 54), and others as evidence of how clinging to the traditional theoretical foundation slowed substantially the progress of science. Such resistance certainly exists in the field of HRD as well.

Proposals for New Directions

Readers may feel that they are alone in the academic wilderness among social scientists, treading on new ground in trying to deal with crisis in their discipline. But such is not the case. For example, T. W. Hutchinson directed an essay in *Knowledge and Ignorance in Economics* (1977) to "'Crisis' in the Seventies: The Crisis of Abstraction." The problems were raised by much of the research activity of the economists of the day failing to address real-world problems, the work published was based on an extreme of abstraction, and economics was failing to account for the role of history in its work (Hutchinson, 1977). Indeed, there is no evidence that this crisis has been resolved through a movement to a new paradigm some three decades later. One has only to look to the annual presidential addresses of the leader of the American Economic Association for confirmation of this. See, for example, Eisner (1988), Debreu (1990), and Harberger (1998) for continuing discussion of particular aspects of this "crisis."

Recognizing that we are not alone in HRD as a discipline in crisis should be the first step in convincing us that we are on the first steps of a great journey—a difficult, challenging, and ultimately rewarding one. It seems appropriate to offer some road maps and guideposts that will assist us in our search. We do not offer all of the answers, for we do not know them yet. What follows is our perspective only; we recognize that other perspectives exist, and we ask those who understand and support them to join us in the journey. Our objective is to initiate and facilitate a dialogue in order to obtain new answers and insights, while having no preordained specifications as to what they should be. We seek broad participation and involvement, not limited and rigidly focused discussion.

Perhaps the first point we need to recognize clearly is that our discipline falls within the realm of "social science" as classified by Nagel (1961) in his work on scientific explanation. In no way meant to diminish this work, Nagel was offering a framework for our research approach, consistent with the tradition of scientific inquiry, while encompassing the methods and methodologies we use to address the particular nature of social science problems. In this recognition, Nagel focused on the uniqueness of research in fields like HRD and suggested direction for the pursuit of our work.

Foremost in Nagel's (1961) classification of social science, and what is dealt with explicitly in his book, is that we must not—and indeed cannot—do our research and theory building in precisely the same way the chemist, physicist, or botanist does. This does not mean we do not do scientific experiments; rather, the nature of those experiments is different. Nagel pointed to the "controlled experiment" or the "controlled investigation" as the indispensable approaches we social scientists must use in our inquiries. We do not generally utilize the rigidly controlled laboratory environment or research regimen/controls the hard sciences offer, but, instead, we must use different approaches and techniques that are customized to our ends in our quest for answers.

Nagel, in analyzing our work as social scientists, might be described as pointing out that ours is a far more difficult field of research inquiry than is found in the hard sciences. First, the variables we investigate are far more complex in many situations. Thus, while it may at first blush appear easier to assess training effort than it is to measure gravity, the reality is that "effort," and its various dimensions, is a far more complex variable than is gravity and that puts us to the test as researchers. Similarly, an intervention to improve productivity is a far more difficult enterprise than the attempt to obtain a better estimate of the speed of light. Here, the basic meaning of productivity is a question of enormous weight, and individual definitions will yield different levels of success; speed, or more precisely velocity, suffers from no such definitional questions (although the measurement questions may be profound).

A second clear difficulty we face in the social sciences is that our research methods may interfere with or in some way alter what it is we are trying to measure. In the first instance, what this means is that, by deciding what we study and then by doing the inquiry, we may actually affect the results of our efforts. The idea of a self-fulfilling prophecy comes to mind here, where sufficient concern about the existence of a particular phenomenon may lead to its occurrence.

Nagel (1961) pointed to a third challenge we face as social scientists trying to answer questions of scientific import, a difficulty that may substantially slow our efforts to find theories appropriate for HRD. It is easy, and quite natural, for us to ask questions of "Why...?" as it is often important to us to find out why certain designs, efforts, programs, and projects do or do not work. Such an approach to intellectual inquiry is something we are always quite comfortable with because our efforts to improve always press us to identify the limitations in what we have done and eliminate them as we move forward. Nagel, however, pointed out that for theorizing in the social sciences we need to focus on the "how's" of the phenomena we are trying to explain. The problem of how versus why surfaces
frequently because of improvements in our ability to analyze and quantify empirical results. As our tools—particularly the quantitative/statistical ones—become more sophisticated and applicable to a wider range of problems and questions, meaning they are or appear to be more useful, it is easier for the focus to be on them and their explanation of “why” things happen than on the crucial theoretical interest of “how” things happen.

We now turn to the final consideration that makes the task of theory construction in HRD so very challenging—the value-oriented biases that we bring to our inquiry (Nagel, 1961). We can bring a sense of right and wrong, individual perspectives on what the social order should be, personal standards of what is socially significant to the research we conduct—and cloud our research in the process. Here, Nagel pointed out that our knowledge of this difficulty allows us to separate our values from the theory, to be honest to our results and to those who read them, and—more importantly—to isolate the conceptual framework we wish to identify. Put differently, we are charged with recognizing our value systems as generating a caveat to our work but not as applying a brake to it; our challenge is to provide the clarity and separation to make this distinction a valid one, apparent to all who follow and work with our efforts.

A major shift in research paradigm has occurred and is continuing within HRD. While many of those who earned their doctorates prior to 1970 were steeped in positivistic approaches to research as the sole research paradigm, the field has moved rapidly in other directions, including, today, interpretive, critical science, ethnographic, phenomenological, case studies, action research, and many other paradigms, and there is no longer the illusion that there is "one answer" to find.

Where Do We Go from Here?

What must we do as we attempt to find the new paradigms for the field of Human Resource Development. While not an exclusive list, we propose the following.

1. Continue the search for theories at all levels of analysis; to seek the one grand theory for HRD at this point would seem to be of little value in our quest.
2. In all of our work, ask the question, "how?"
3. Begin a search of alternative fields of inquiry which may—or may not—appear to be related to HRD.
4. On an international basis, obtain/create a taxonomy of what is believed to be important HRD outcomes in different countries and cultures.
5. Despite what has been said herein, seek to identify the international differences that make HRD inquiry varied across national/regional boundaries.
6. Explore more deeply what paradigms for HRD might best enable the field to contribute to the eradication of human rights violations across the globe.
7. Expand rather than contract our thinking—it is far too easy to keep our inquiry consistent with what we already know or desire to cling to from the existing paradigm rather than moving forward.
8. Ask basic questions, more basic than we typically have the courage to do:
   Why are we here?
   What are we trying to accomplish?
   Are we making a difference? If so, how?
9. Raise and discuss the issue of whether, given a particular national/cultural milieu, one, two, three, or more theories is/are appropriate.
10. Look to this inquiry as a challenge rather than a threat.
11. Expect the answers to come slowly—not quickly—as the search is likely to be a lengthy one.
12. Set up a "theory" chat room on the World Wide Web where theories/ideas/concepts can be put forth, explored, and argued. (This is something that the Academy could facilitate.)
13. Focus and refocus our thoughts at every opportunity to ask repeatedly the question, "How?" even as we ask the question, "Why?"
14. Recognize the existence of theoretical bases from economics, systems, psychology, and other disciplines that we have built upon in the past but also recognize that they are likely ultimately to prove deficient for HRD in the future.
15. Organize a theory-wide search effort, attempting to pull together those theories and elements of theories from any source that might play a role in explicating HRD activities.
16. Recognize that it may not be possible for HRD theory to be based on existing theory, particularly theoretical models from other fields of intellectual inquiry.
17. Organize theory sessions at the AHRD conferences where individuals concerned about theory can submit a brief list of concerns/ideas/structures/issues/suggestions in advance that could then be distributed in advance to those interested for discussion and analysis by the group in a working session environment.

18. Seek to identify the differences between causality and the underlying mechanisms of any processes we are investigating.

Conclusion

Obviously, one major conclusion to be drawn from the above analysis is that the theoretical crisis in HRD will be difficult to solve, perhaps taking the decades noted by Kuhn (1970). But that should not discourage us as the journey promises to be a valuable one that adds valuable insight to the field.

Training Evaluation With 360-Degree Feedback

Froukje A. Jellema
University of Twente, The Netherlands

Training evaluation is an important issue in many organizations. Even though organizations are becoming more interested to measure the effects of their training investments, organizations often lack the tools for the measurement of training effects, especially at the level of changed behavior. This paper will focus on the use of 360-degree feedback for evaluation of changed behavior as a result of training. The results of an experimental study in a large Dutch hospital will be described and discussed.

Keywords: Training Evaluation, 360-degree Feedback, Behavioral Change

Human resource development (HRD) is a process of developing and unleashing human expertise through organization development and personnel training and development, for the purpose of improving performance (Swanson, 2000 AHRD). Training evaluation can be useful to find out whether investments in training are contributing to performance improvement. One evaluation focus is changed behavior as a result of training (Kirkpatrick, 1994). Though change in behavior is in most cases not an end in itself, it is a necessary intermediary step to evaluate whether the training contributes to performance improvement. That is why in this paper the focus is on the evaluation of behavioral change.

Evaluation of changed behavior is done for only 11 percent of the training programs, though companies expect to increase this proportion in the future (1999 ASTD report). A main reason why training evaluation is not often focused on behavioral change of trainees, is the lack of appropriate methods. The specific aim of this paper is to examine one particular method that may be useful in this context. This method is 360-degree feedback, where employees receive feedback about behavior from a 'full circle' of co-workers such as the supervisor, peers, subordinates and clients. 360-degree feedback may be used to determine whether co-workers have experienced a difference in the behavior of the trainee. The main research question of this paper is whether 360-degree feedback is indeed useful for training evaluation.

Theoretical Framework

Though the use of 360-degree feedback for training evaluation is often mentioned in evaluation handbooks (see for example Brown and Seidner, 1998; Kirkpatrick, 1994; Robinson and Robinson, 1989), this method has rarely been studied in an evaluation context, though often in an employee developmental context.

One study in which 360-degree feedback is used to evaluate a training program, is the study by McLean, Sytsma, and Kerwin-Ryberg (1995). This study included 73 ratees, who received 360-degree feedback both before and two years after a training program. Though participants' skills increased during these two years, it was difficult to attribute this behavioral change to the training program, due to the long period between pre- and posttest and the fact that a control group was not included. The authors concluded that 360-degree feedback should be applied very cautiously as a tool to evaluate training.

Another study, in which 360-degree feedback is used for training evaluation, and in which a design with a control group was used, is the study of Van Sandick and Schaap-Neuteboom (1993). This study was situated in a large Dutch supermarket chain and focused on a training program for department-managers. This study included 162 ratees, distributed over two training groups and one control group. In this study a training effect was measured (i.e. 0.2 on a 5-point scale). However, this study was limited by the fact that only one supervisor and one peer were involved in the feedback.

Another example is the study of Rosti and Shipper (1998), where 360-degree feedback is used to study the impact of training in a management development program based on 360-degree feedback. Feedback was collected both before and after the program to enhance learning and evaluate training. Results, when analyzed by means of a series of four matched-pairs tests, were supportive that the change in the experimental group was significantly different than the change for the control group, and in the expected direction.

Since organizations are becoming more interested in measuring behavioral change as a result of training, it is interesting to study the usefulness of 360-degree feedback for this purpose. Since previous studies in this area are rare and often limited, it was decided to use as strict an experimental design as possible to again look at the usefulness of 360-degree feedback for training evaluation.

Research Questions

The main research question of this paper is whether 360-degree feedback can be useful for training evaluation. More specifically, the questions are:

1. Is training evaluation by means of 360-degree feedback reliable?
2. Is training evaluation by means of 360-degree feedback valid?
3. What training effects are found with 360-degree feedback?

Methodology and/or Research Design with Limitations

The methodology that is used to answer the questions, is a quasi-experimental study. This study is situated in a large Dutch hospital. Recently, this hospital has created a new professional job for nurses, the senior nurse, hierarchically situated below the head nurse. All senior nurses have to attend the course, that has been specifically developed for this function. This is an extensive course, consisting of 18 outdoor training days during a nine-month period. Coaching skills are an important part of the program.

At the time of this study, about 40 senior nurses were working at the hospital. Though all senior nurses have to participate in the program, only 14 nurses could attend at the same time. That is why it was possible to study three conditions. Group 1 had already started with the program at the beginning of this study and received only a 360-degree feedback post-test. Group 2 received a pretest with 360-degree feedback before attending the program, and afterwards a posttest with 360-degree feedback. Group 3 received the feedback at the same time as group 2, but did not attend the program. All post-tests took place after ten training days, about seven months after the pretest. It would have been preferred if the post-measurement had taken place at the close of the training program, but that excluded the use of a control group, since group 3 would have started with the training by then.

The Dutch 360-degree feedback instrument Reflector was used in this study, consisting of eight behavioral competencies: dealing with stress, integrity, active listening, creating partnership, diagnostic skills, stimulation, giving feedback, and adapting. Each behavioral competency consists of five items, so the questionnaire included 40 items. The response scales that are used in Reflector are 5-point scales were raters select a position between opposite statements of behavior. The reliability and validity of Reflector has been examined in previous studies (see Jellema, Visscher and Mulder, 2000) and was found to be satisfactory.

Each senior nurse was allowed to select his or her own raters, but preferably their supervisor, two peers and four subordinates. Clients (in this case: patients) were not included. The ratees were encouraged to ask the same raters to provide feedback at the pre- and posttest, for as far as this was possible. All ratings could by given anonymously. After the results were analyzed, the results were summarized in reports and send to the home addresses of the ratees. All ratees were invited to join in a follow-up session.

The post-tests included a retrospective self-test and a questionnaire with questions regarding background, motivation for the training program, perceived support on-the-job, etc. Out of group 2 and 3, eight senior nurses were found willing to participate in a coaching simulation, that took place at the time of the post-test. Main purpose was to study correlation between 360-degree feedback (post-test) scores and scores of the simulation and thus to gain insight into the validity of 360-degree feedback. The research design is summarized in Table 1.

<td>360° &amp; retrospective self &amp; background &amp; coaching simulation</td>
</tr>
</tbody>
</table>

Response

At the start of the study each group consisted of 14 senior nurses. However, several senior nurses could not partake because they were ill (especially in group 3, the group that was on the waiting list for the program), left the organization or did not want to cooperate. At the posttest, again several nurses were ill and could not participate. Table 2 summarizes the response.

In this paper, the focus will be on group 2 and 3, since these groups received a pre- as well as a posttest. The pretest included 21 senior nurses, 12 in the experimental group and nine in the control group. A total of 155 raters were involved, an average of 7.4 raters for each ratee. Raters were divided as follows: self (21), supervisors (20), peers (62) and subordinates (52). At the posttest, a total of 18 senior nurses again participated in the 360-degree feedback. One senior (in group 2) participated in the posttest but had not participated in the pretest. A total of 126 raters were involved, an average of 6.6 raters for each ratee. Raters were divided as follows: self (19), supervisors (17), peers (50) and subordinates (40). About 35% of the seniors had asked exactly the same raters as at the pretest. In the other cases, one or more of the raters at the posttest had not been included in the pretest. All senior nurses filled in the questionnaire with background questions and the retrospective questionnaire.

Since this study was a quasi-experimental study, and the groups were not selected at random, they were compared on several variables to find out if they were different (see Table 3).

Table 3. The two groups compared on several variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Group 2 (n=12)</th>
<th>Group 3 (n=9)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gender</td>
<td>53.8% female; 46.2% male</td>
<td>77.8% female; 22.2% male</td>
</tr>
<tr>
<td>Age</td>
<td>36 (4.6)</td>
<td>34 (8.1)</td>
</tr>
<tr>
<td>Working experience</td>
<td>12.2 (5.4)</td>
<td>12.7 (9.6)</td>
</tr>
<tr>
<td>Experience senior nurse</td>
<td>.8 (1.3)</td>
<td>2 (1.8)</td>
</tr>
<tr>
<td>Experience coaching</td>
<td>66.7%</td>
<td>88.9%</td>
</tr>
<tr>
<td>Perceived need to develop coaching skills</td>

<td>11.1% very high; 66.7% high</td>
</tr>
<tr>
<td>Motivation for program</td>
<td>25% very high; 66.7% high</td>
<td>22.2% very high; 66.7% high</td>
</tr>
</tbody>
</table>

As can be seen in Table 3, the groups are different on many of these variables. However, differences between groups were tested by means of chi-square (gender and experience with coaching), ANOVA (age and need to develop coaching skills) and Kruskal Wallis (experience and motivation), and none of the differences are significant. This is probably due to the limited number of respondents that was involved in this study.

This limited number of respondents and the fact that respondents were not selected at random for each training group, is the main limitation of this study. Interpretation of results may be difficult due to this limitation. In addition, the rates that were included at the pretest are not always (though often) the same individuals as the rates at the posttest. In addition to this, it is a limitation of this study that it was not possible to train the raters in advance.

Results

In this section the following results will be presented: the psychometric properties of the 360-degree feedback instrument and the measurement of behavioral change as a result of the training.

Psychometric Properties of the 360-degree Feedback Instrument

In this section the focus will be on the internal consistency and inter-rater reliability and validity of the instrument.

Internal Consistency. Internal consistency is measured by means of reliability analysis of the scales. The analysis is done on the complete data set (pre- and posttest, including group 1). Table 4 summarizes the alpha coefficients.
Table 4. Internal consistency of the scales

<table>
<thead>
<tr>
<th>Competency</th>
<th>Alpha</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active listening</td>
<td>.60 (n=357), .68 after deleting item 2</td>
</tr>
<tr>
<td>Creating partnership</td>
<td>.66 (n=341)</td>
</tr>
<tr>
<td>Diagnostic skills</td>
<td>.76 (n=333)</td>

<td>.72 (n=356)</td>
</tr>
<tr>
<td>Dealing with stress (control competency)</td>
<td>.78 (n=349)</td>
</tr>
</tbody>
</table>

Two scales are below .7, i.e. active listening and creating partnership. The alpha of active listening can be increased to .68 by removing one item. The alpha of creating partnership and the other behavioral competencies cannot be increased by removing items. When all items are considered as one scale ('coaching skills'), the alpha is .94 (n=272)

Inter-rater Reliability

Since most of the senior nurses have received feedback from more than one peer and/or subordinate, it is interesting to see if scores within each rater-source are more or less the same. Since many ratees have feedback from three or more peers and/or subordinates, it was not possible to use a correlation coefficient. That is why the standard deviation is used as a measure for within-source agreement. The data was first analyzed separately for each ratee after which an average score for all ratees was computed. The standard deviation is computed for all competencies and for an overall score of all competencies. Table 5 shows the average standard deviation for peers and subordinates.

Table 5. Within-source standard deviation for peers and subordinates

<table>
<thead>

<tr>
<td>Giving feedback</td>
<td>0.43  (n=44)</td>
<td>0.44 (n=39)</td>
</tr>
<tr>
<td>Overall score</td>
<td>0.45  (n=44)</td>
<td>0.46 (n=40)</td>
</tr>
</tbody>
</table>

The average overall standard deviation for peers is .45. This differs slightly for each behavioral competency, with most agreement between peers on integrity and less agreement on diagnostic skills. The average overall standard deviation for subordinates is .46, which again differs slightly for each behavioral competency. Most agreement between subordinates is on integrity and less agreement on adapting.

Since the main characteristic of 360-degree feedback is that several different rater sources are included, it is interesting to study agreement between rater-sources. Whenever a ratee has two or more peers and/or subordinates, an average score for these raters is computed. This average peer-score and average subordinate-score is used in the analysis. The analysis is based on the complete data set (both pre- and posttest, including group 1). For each ratee, a score was computed for self, supervisor, peer and subordinate. These scores were averaged for all ratees. In Table 6, the average scores are summarized.

SV=supervisor; P=peers; SO = subordinates

31-1
As can be seen, the overall scores of all rater-sources are very similar. The standard deviation in Table 6 indicates the differences between rates. When the assumption is that rates have different levels of performance, this coefficient should be large; it is, however, rather low.

Correlation between these sources was studied by means of T tests, since the scores appear to be normally distributed. In Table 7 the coefficients are summarized. The marked coefficients are significant (at .95 level).

</table>

SV = supervisor; P = peers; SO = subordinates

The fact that correlation appears to be moderate for most competencies and rater-sources, implicates that scores should be presented for each rater-source separately. This is in accordance with what you might expect for 360-degree feedback. Correlation between peers-subordinates, peers-self and self-subordinates, is in some cases even negative. When the correlation of the overall score is used as a measure of rater-correlation, the correlation between supervisor-self, supervisor-peer, and supervisor-subordinates is significant. These correlation coefficients are in agreement with the low correlation that is often found in other studies (see for example Harris and Schaubroeck, 1988). However, correlation between self-peer, self-subordinate and peer-subordinate are much lower than have been found in previous studies. Interesting to note is that the correlation between the supervisor and any of the other rater sources is significant, while correlation between the other sources is not significant.

Validity

To study the validity, the 360-degree feedback scores were compared to another, more objective, measure of the same behavior. Eight senior nurses were found willing to participate in a coaching simulation that consisted of a coaching conversation that the senior nurse had with an employee, played by an actress. The simulation focused on some of the competencies that had been included in the 360-degree feedback, i.e. active listening, creating partnership, diagnostic skills and stimulation. The eight conversations were recorded on videotape and two masters students evaluated the videotapes by means of the same questionnaire that was used for the 360-degree feedback. The students were trained in advance (with an extra videotape) to use the instrument and assess the coaching behavior. Each student rated each ratee, after which they discussed the results and tried to come to agreement. Since each student-score correlated significantly with the agreement-score, this agreement-score is used in the analysis. Because the simulation was in the same period as the 360-degree feedback posttest, the posttest scores are used. Table 8 shows the correlation that was found.

Table 8. Correlation between 360-degree feedback and coaching simulation

<table>
<thead>
<tr>
<th></th>
<th>Sim-360 Self (n=8)</th>
<th>Sim-360 SV (n=8)</th>
<th>Sim-360 peers (n=8)</th>
<th>Sim-360 SO (n=8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active listening</td>
<td>.16</td>
<td>-.58</td>
<td>.31</td>
<td>-.70</td>
</tr>

<td>-.44</td>
</tr>
<tr>
<td>Stimulation</td>
<td>-.44</td>
<td>-.60</td>
<td>.29</td>
<td>-.58</td>
</tr>
</tbody>
</table>

SV = supervisor; SO = subordinates

As can be seen, the correlation between the 360-degree feedback and simulation is in most cases negative. Only peers have a positive (though not significant) correlation with the simulation-score.

Measuring Behavioral Change as a Result of Training

In this section the focus is on the gain scores between pre- and posttest. First, it is important to focus more specifically on the self-scores, since these may be sensitive to 'response-shift bias': because rates in group 2
receive intensive training of coaching skills, their ideas about coaching may change. This may result in the fact that self-scores at the posttest are based on another perspective of coaching, which makes them difficult to compare with the pretest scores. Self-scores could be lower at the posttest, even though performance has improved, because trainees have learned how difficult coaching actually is and are more demanding of their own performance. The same process may happen for ratees in group 3, who received no training but who did receive a feedback-report after the pretest, joined in a follow-up meeting and were encouraged to make a personal development plan. These individuals may also have changed their ideas about coaching. That is why a retrospective self-test was included with the posttest, where ratees were asked to again rate their coaching skills at the time of the pretest. Correlation between pretest self-scores and retrospective scores was studied by means of a T-test (see Table 9).

Table 9. Correlation between 360-degree pre self-score and retrospective self-score

<table>
<thead>
<tr>
<th>Competency</th>
<th>Pretest self-score</th>
<th>Retrospective self-score</th>
<th>Correlation</th>
</tr>
</thead>

<td>.53*</td>
</tr>
<tr>
<td>Giving feedback(n=31)</td>
<td>3.93</td>
<td>3.78</td>
<td>.43*</td>
</tr>
</tbody>
</table>

Though the retrospective self-scores are indeed lower than the pretest self-scores, this is for most competencies not significant. That is why the pretest scores will be used in the further analysis.

In Table 10, the pre- and posttest scores are summarized. Again, the score for peers and subordinates is based on the average score. A paired samples T-test analysis was executed, to see if differences between pretest and posttest are significant (the significant differences are again marked in Table 10). Whenever there is a (-) in the table, this indicates that the posttest scores are lower.

SV=supervisor; P=peers; SO = subordinates; (-) = the posttest lower than the pretest

As can be seen, both group 2 and 3 have higher posttest scores than pretest scores for most behavioral competencies. Supervisors of both groups, have often significantly higher scores at the posttest, as well as the raters of group 3 themselves. Peers in group 2, are also significantly more positive at the posttest than at the pretest for two competencies (active listening and diagnostic skills). However, subordinates of both groups are more negative (though not significantly) at the posttest.
Next, group 2 and 3 were compared to see if the gain scores between these two groups are different from each other. Since group 2 is the training-group, it was expected that the gain scores of this group are higher than the scores of group 3. The results are summarized in Table 11 (marked coefficient is significant).

SV = supervisor; P = peers; SO = subordinates

As can be seen in Table 11, most rater sources indicate positive gain scores, with an exception for subordinates and for peers (regarding some competencies). A first quick look seems to indicate that the gain scores in group 3 are, contrarily to what might be expected, higher than those of group 2. However, in only one case is this difference significant, and more positive, for group 3.

### Discussion

This study focused on the use of 360-degree feedback in a training evaluation context. First the focus was on the psychometrical properties of 360-degree feedback. Results indicate that the psychometrical properties with regard to internal consistency of the scales and inter-rater reliability are more or less in accordance with previous research. Alphas of most scales are sufficient (.70 or higher). Within-source agreement, measured by means of the standard deviation, was found to be high (.45 for peers and .46 for subordinates). However, this may be caused by the fact that the scores of most raters are very positive, as can be seen in the overall scores for each rater source (ranging from 4.04 to 4.09 on a 5-point scale). Subordinates appear to be slightly more positive than the rates themselves, who are in their turn slightly more positive than peers are. Supervisors are of all rater-sources the least positive. However, note that this is still a very positive score. Interesting is also the fact that supervisors are the only rater-source that significantly correlate with the other rater sources. All other combinations have extremely low correlation.

Next, the 360-degree feedback scores were compared with scores of a 'more objective' method, i.e. a coaching simulation. The 360-degree feedback scores were negatively correlated, though except for one case not significant, with the coaching simulation. Only peers have a positive, though not significant, correlation with the simulation score. This is interesting since subordinates were expected to have the most relevant view in this case, since they are the individuals that are being coached by the senior nurse. However, the peers in this case are other senior nurses, who work closely with the ratee so they may also be a relevant rater-source. Nevertheless, these results do not support 360-degree feedback as a valid method.

Next, the focus was on the ability of 360-degree feedback to measure behavioral changes. First, pretest self-scores were compared with retrospective self-scores, to study response-shift bias. It appeared that retrospective self-scores are lower than pretest self-scores, for all competencies. The fact that retrospective scores are lower, though except for creating partnership and stimulation not significantly lower, may imply that response-shift bias actually took place. However, lower retrospective scores may also have different reasons, such as the fact that rates lower their scores after they have seen the pretest feedback report, for example because they were 'over-raters' at the pretest.

Gain scores for the experimental group and the control group were compared to see if, according to what was expected, the experimental group improved more than the control group. However, the opposite seemed to be the case. Though ratees in both groups have higher posttest scores than pretest score from themselves, their supervisors, and their peers (except for some competencies), it is striking that the subordinates' gain scores of both groups are negative. This is interesting, since subordinates are expected to have the most relevant view in this case because they are the ones that are being coached by the senior nurse. An explanation could be that the pretest has raised the consciousness of subordinates of what to expect from a coach. A similar process as the 'response-shift bias' of trainees, could also have happened to subordinates, resulting in different expectations of their coach at the time of
the posttest. In a follow-up study interviews with participants will be used to answer the question why subordinates have lower posttest scores. Interesting is also that the supervisors have the highest gain scores. Though supervisors of both ratees in group 2 and group 3, have the lowest pretest scores for almost all competencies, they have the highest posttest scores for almost all competencies. Again, interviews will be used to try to explain this result.

The results further seem to indicate that the gain scores in group 3 are, contrarily to what might be expected, higher than those of group 2. This is especially the case for self-scores and supervisor-scores. For peers, the results are more mixed, with sometimes higher scores for group 2 (dealing with stress, active listening, and diagnostic skills and overall score) and sometimes higher scores for group 3 (integrity, creating partnership, stimulation, adapting and giving feedback). For subordinates the results are also mixed, sometimes higher (or better to say: less negative) for group 2 (integrity, active listening, adapting, giving feedback and overall score) and sometimes for group 3 (dealing with stress, creating partnership, and diagnostic skills). However, in only one case is this difference in gain scores significant, and more positive, for group 3.

As table 3 has shown, the groups were different on several variables. Respondents in group 2 are more often male and on average two year older than respondents in group 3. In addition, respondents in group 3 indicate that they have more experience as a senior nurse and more experience with coaching. It may be the case that senior nurses must have some experience in their new job as a senior, and especially with coaching, before they are able to develop their coaching skills. Another explanation may be that the nurses that have been to the training need more time before they are able to change their coaching behavior. Note again that at the time of the posttest, the training program was not yet concluded. Further analysis of the data, especially combination of the gain scores with background variables, as well as interviews with some of the participants, may clarify this interesting result.

Conclusions, Recommendations and How This Research Contributes to New Knowledge in HRD

Organizations are becoming more and more interested in evaluating their training programs at the level of behavioral change, for which 360-degree feedback is often suggested as a possible method. However, critical reflections on this purpose of 360-degree feedback can also be found in literature (see for example McLean et al, 1993). In this paper the possibility of 360-degree feedback to measure behavioral change was the object of study. Contrarily to what was expected, this study indicated more behavioral change for the control group than for the experimental group. Still, this study has provided more insight in the psychometrical properties and the usefulness of 360-degree feedback. However, further experimental research is necessary, especially with a larger number of respondents than was the case in this study and with the possibility to randomly select ratees, to answer the question whether 360-degree feedback is indeed useful for training evaluation.

Theory-driven Evaluation: An Alternative

Katie Robertson
University of Georgia

While researchers have advanced our ability to understand the effectiveness of Human Resource Development (HRD) interventions, practitioners are still in search of an evaluation model capable of accounting for the complex relationship that exists between HRD interventions and intended outcomes. The purpose of this article is to offer theory-driven evaluation as an alternative to existing HRD evaluation models.

In order to overcome the problems faced by the existing models, this alternative not only establishes a casual link between HRD interventions and outcomes, but also goes further to address contextual factors affecting the intervention (Chen & Rossi, 1989).

Keywords: HRD Evaluation, Theory-driven Evaluation, Review

The field of Human Resource Development (HRD) has faced the issue of demonstrating that HRD interventions are directly contributing to organizational functioning. Therefore, evaluation of HRD interventions has become a critical issue in the field (Holton, 1995). It is imperative that HRD evaluators have the tools available to demonstrate the utility of HRD efforts. A review of the evaluations models available to HRD practitioners and academicians revealed that few models were available. And while recent evaluation strategies have expanded our ability to explain the effectiveness of HRD interventions, there still exists a need for an evaluation model capable of accounting for the complex relationship that exists between HRD interventions and intended outcomes. To examine the common evaluation models and strategies used within the field of HRD, a literature review was conducted. Based on the review, theory-driven evaluation is presented as an alternative evaluation approach.

Evaluation Models in HRD: A Review

To better understand the problem facing evaluators, a literature review was conducted to explore common models used in HRD evaluation. The review focused on the Academy of Human Resource Development (AHRD) conference proceedings for the years 1995-2001. The review revealed that the most common evaluation strategies in HRD include: Kirkpatrick’s four level typology (Kirkpatrick, 1976), Holton’s integrated model (Holton, 1995), the Performance-Learning-Satisfaction evaluation approach (Swanson & McClernon, 1996), Critical Outcome Technique (Swanson & Mattson, 1997), and various financial benefit assessments (Brauchle & Koenecke, 1999; Jacobs & Hruby, 1996; Swanson, 1998).

The most salient result of the review of the literature was the reliance on Kirkpatrick’s four level evaluation model. Briefly defined, Kirkpatrick’s hierarchical model has four levels: reaction, learning, behavior, and results. Reaction is what the trainee thought of the training intervention. Learning is the quantifiable indication that learning has taken place. Behavior is the assessment of the transfer of what is learned in the training intervention into practice. In other words, are the skills learned in training being used on the job? Results indicate the impact of the training on the desired objectives (Kirkpatrick, 1976). While the methodologies for the evaluation varied, Kirkpatrick was the guiding model in many cases (Hastings & Nichols, 1995; Moore, 1999; Nurmi, 1999; Ravishankar & Miller, 1997). In a broader literature review, Preskill (1997) found that 77% of journal articles pertaining to evaluation models contained Kirkpatrick’s model.

While Kirkpatrick’s four level model is a popular basis for research, the model does not go uncriticized. The model is often sighted as a mere taxonomy of possible intervention outcomes in need of further research to fully develop the theory (Holton, 1995). Furthermore, in practice the taxonomy is rarely fully implemented (Rothwell, 1996). A survey of evaluation practitioners revealed a narrow range of practices, indicating that the method most commonly used to evaluate interventions was class evaluations or “smile sheets” (Rothwell, 1996). Similarly, Dixon (1987) reports that when conducted at all, evaluation usually takes the form of participant reaction.

While criticism for Kirkpatrick’s model was abundant, alternative evaluation models were scarce. In an attempt to strengthen Kirkpatrick’s model beyond a simple taxonomy of results, into one that is able to account for causal relationships, Holton (1995) presented an integrated evaluation model. The integrated model adds intervening
variables that influence the learning and transfer process that have been identified as affecting HRD interventions. This model is a step in the right direction, in that it moves away from a simple input/output model. While the integrated model presented by Holton is much more inclusive than the simple four level approach that preceded it, several questions are left unanswered. First, this integrated model does not address characteristics of the intervention. Cervero (1985) suggests that processes in the design and implementation of the intervention should be related to the outcomes. In other words, this model does not account for the type or length of the intervention. Second, there is little room in the model for intervening variables other than those specified. The model does allow for unnamed external events to be added, otherwise, the model is a fixed set of relationships that does not allow situationally specific variables to be added.

A third model identified in the literature review was the Performance-Learning-Satisfaction (PLS) evaluation system (Swanson & McCleron, 1996). The PLS system identifies five major elements, one of which is an evaluation model. The model specifies the three domains (performance, learning and satisfaction), and then further breaks them down. For example, learning is broken down into knowledge and expertise, performance is divided into business results and financial results, and satisfaction is divided in to participant’s satisfaction and sponsor’s satisfaction. The PLS system also contains an evaluation plan, evaluation tools, an evaluation schedule and an evaluation report (Swanson & McCleron, 1996). While this model offers a comprehensive system for approaching an evaluation, it is based on the simple input/output concept, which has been criticized in Kirkpatrick’s evaluation typology.

A fourth model that has been presented as an alternative to Kirkpatrick’s four level taxonomy is the Critical Outcome Technique (COT) (Swanson & Mattson, 1997). The post-hoc evaluation technique is designed to systematically investigate performance outcomes. The purpose of COT is the investigation of intervention outcomes through definition, inquiry, verification and valuation of outcomes. This model has the potential to be a practical alternative for practitioners who need simple evaluation results, after the intervention has been conducted. A pilot test of the COT model revealed that the model resulted in information that was useful to intervention stakeholders (Mattson, Quaranta, & Swanson, 1998). Additional results provided possible refinements to the original model.

Other evaluation methods identified in the literature review focused on demonstrating the financial benefits of HRD (Brauchle & Koenecke, 1999; Jacobs & Hruby 1996; Swanson, 1998). This information is needed to change the notions that HRD is simply an optional activity and the cost of such interventions is greater than the resulting benefits (Swanson, 1998). Brauchle and Koenecke (1999) present an overview of contemporary Return-On-Investment (ROI) approaches. The list of possible approaches includes a basic model, a cost/benefit ratio model, and benefit-forecasting model.

While this literature review has focused on evaluation models or strategies appearing in the AHRD conference proceedings, other evaluation models must also be considered. In a recent publication, Russ-Eft and Preskill (2001) comprehensively review eleven evaluation models and approaches. Furthermore, Hilbert, Preskill, and Russ-Eft (1997) present a comprehensive review of evaluation models proposed in the last four decades. Included in this review are Kirkpatrick’s four level model and Holton’s HRD integrated evaluation model, which are models also appearing in the conference proceedings review. However, several other models not found in the proceedings were included in the Hilbert, Preskill, and Russ-Eft review including: Hamblin’s five level model, Training effectiveness evaluation system, Binkerhoff six stage model, Input, process, output model, Richey model, Kaufman, Kellor, Watkin’s five level model, and the Training efficiency and effectiveness model. This review concludes that evaluation has “focused on a limited number of questions, using only a few tools and methods” (p. 145).

This literature review reveals that evaluators have few alternatives to Kirkpatrick’s simple taxonomy of outcomes. Furthermore, the available models do not account for the complex relationship that exists between HRD interventions and intended outcomes. While Holton’s (1995) integrated model is moving in the right direction, even more is needed to fully account for the complex evaluation context. Preskill (1997) reiterates the concern about the few evaluation approaches available by noting how rarely “HRD professionals and scholars have tapped other disciplines such as public education and the government or military in their development of evaluation theories, models and approaches” (p.51). The problem then, is that evaluators have few models to choose from and the available models do not fully account for the complex HRD intervention context.

Purpose

The purpose of this paper is examine the evaluations models available to HRD practitioners. This review revealed the dominance of simplistic evaluation models. More specifically, the models identified in the review can be classified as “black box” evaluation models, which focus primarily on input/output relationships, leaving out variables of context. The one-variable black box evaluation may be able to establish a connection between the HRD
intervention and outcomes, but it fails to explain the relationship. In order to build causal explanation, causal moderators or intervening variables need to be defined. Including such moderators results in a more complete understanding of the organizational conditions, individuals, and characteristics of programs that are the most likely to produce the desired outcomes (Cervero, 1985). The channels through which the program achieves (or fails to achieve) the desired results can then be mapped. By answering the "why" question evaluators will be able to contribute to our understanding of how to plan effective HRD interventions (Cervero, Rottet, & Dimmock, 1986). The problem is that HRD evaluators need evaluation models that open up the black box, resulting in information that can contribute to better program design.

Theoretical Framework

To address the problem identified above, theory-driven evaluation is presented as an alternative theoretical framework. In order to overcome the problems faced by the existing models, this alternative not only establishes a casual link between HRD interventions and outcomes, but also goes further to address contextual factors affecting the intervention (Chen & Rossi, 1989). Theory-driven evaluation is a significant contribution to the evaluation practitioner because it attempts to move evaluation away from the black box evaluation, and answers questions about why the program worked. The remainder of this paper takes an in-depth look at theory-driven evaluation.

Theory-Driven Evaluation: An Alternative

Chen and Rossi (1983) developed the concept of theory-driven evaluation as a process capable of incorporating existing theoretical knowledge into the evaluation process. Theory-driven evaluation has been a movement of critical importance in the last two decades, in that it is a broader perspective of evaluation that has been conceptualized in the past (Chen, 1994). Central to theory-driven evaluation is the use of an intervention theory to examine the expectations of the intervention (Reynolds, 1998). Intervention theory is essentially a blueprint of how the HRD intervention is supposed to work. In other words, it is a "plausible and sensible model" of the intervention (Bickman, 1987, p.5). This model outlines the relationships between the treatment and outcomes. Additionally, other factors such as intervening and contextual variables are included (Chen & Rossi, 1989). The complete model should be a broad view of the channels through which the intervention will achieve the desired results. Theory-driven evaluation will be further explained in terms of the components of the intervention theory and the process involved in conducting the evaluation.

Components of an Intervention Theory

The intervention theory is a complex model that has several key components. These include: the problem, intervention strategies, and expected outcomes (Mohr, 1995). In addition to the three main elements of the model, other variables, intervening and exogenous, must also be specified (Chen & Rossi, 1983). A more detailed discussion of the each of these components follows.

Three Main Components. When the development process is complete, the intervention theory must include specification of three main elements, the problem, intervention strategies, and the expected results (Mohr, 1995). First, the problem should be defined including behavior to be addressed, where appropriate, and the population for whom the intervention is targeted. In addition to the “what and who” of the problem, the context in which the problem is located must also be considered. The description of problem context will be useful in explaining or interpreting the empirical findings of the evaluation study (Chen & Rossi, 1989). Second, the intervention content, or the elements of the intervention that will produce the effect must be outlined. It is important to identify the intervention as planned (Chen & Rossi, 1989). It will be shown later that the planned intervention can be very different from the implemented intervention. Finally, the intended or expected effects of the intervention must be clearly defined (Reynolds, 1998). The specification of outcomes deserves special attention. Mohr (1995) names the comprehensiveness of outcomes identified, as a factor that could increase utilization of evaluation results. It is well known that intervention outcomes are not always easy to identify, and the possible outcomes could be numerous. The process whereby the multiple intervention outcomes are specified should be a joint effort between stakeholders and the evaluators (Chen & Rossi, 1989). The evaluator has a special role in this process, and that is the consideration of unexpected and potentially negative effects of the intervention that stakeholders may overlook.
Other Variables in the Model. In addition to the three main elements, intermediate or intervening events must also be well specified (Mohr, 1995). Intermediate or intervening variables are factors that link the activities of the intervention with the intended outcomes (Mohr, 1995). For example, if an HRD intervention is designed to reduce absenteeism through increased work motivation, both the intervening variable (increased motivation) and the outcome variable (decreased absenteeism) must be included in the model, as well as the proposed relationship between the two. Not all models will have intervening variables as a part of the intervention theory. However, when intervening variables are present they should definitely be included in the model. The specification of intervening variables is beneficial in that a model that is well specified is more sensitive when tested (Chen & Rossi, 1983). That is, a model that includes each of the intervening steps can be used to determine exactly how an intervention worked or did not work. The intervention theory can then be used to track success, or for revision of the intervention as needed.

There should also be consideration given to what Chen and Rossi (1983) term “exogenous variables” (p.286). Exogenous variables are factors correlated with treatment variables that could also have an impact on the outcome variable. These variables are included because the outcomes of the complex social interventions are rarely the result of the treatment and intervening variables alone (Chen & Rossi, 1983). The effect of the correlation between these variables and the treatment can be eliminated by the use of a classical randomized experiment. However, randomization is often not possible in applied settings, and the inclusion of the variables in the intervention theory can further explain the intervention contexts and outcomes.

The Process of Theory-Driven Evaluation

Now that the concept of intervention theory has been explored, it is important to understand the process involved in conducting the evaluation. The process of conducting a theory-driven evaluation can be broken down into four steps, including the development of the intervention theory, implementation analysis, selection of relevant outcomes, and use of appropriate methodology. It is important to remember that each of the steps in the process is linear. In other words, each step relies on the successful completion of the previous step.

Development of Intervention Theory. The formulation of the intervention theory is an important first step, creating the foundation of the evaluation. The theory should be constructed with input from a variety of sources. First, the evaluator should look to existing literature for research findings that address similar problems, treatments or outcomes as the evaluation in question (Chen & Rossi, 1989). Also useful are pre-existing social science theories that pertain to the intervention theory being developed. Finally, the evaluator must seek input from intervention stakeholders and intervention designers. Often these individuals can provide unique insight into how the intervention was designed to address the problem (Chen & Rossi, 1989). During this process each of the intervention theory components should be defined. The resulting theory should outline the conceptual framework that is guiding the intervention and subsequently will guide the evaluation.

Implementation Analysis. The implementation of the intervention must also be carefully reviewed (Mohr, 1995). Implementation analysis is used to insure that the intervention activities are in place to bring about the desired outcomes (Mohr, 1995). In other words, it is a procedure used to determine if the HRD intervention is actually being conducted as specified during the development of the intervention theory. Chen & Rossi (1983) note that an intervention can look very different in theory than it does in practice. To illustrate, the authors cite instances in which "evaluators have found that some programs were never implemented, others were placed in the hands of inappropriate personnel, and in others implementation effectively negated the program process" (p.303).

The implementation system must be evaluated because it is a component that necessarily precedes all other components of the intervention theory. If the implementation analysis reveals that the intervention is not being conducted, or that major discrepancies exist between the intervention theory and the actual intervention, the evaluation process should be halted and the intervention theory developed should be revisited and revised. There is no need to continue to explain relationships between components in the model if the model is known to be incorrect.

These discrepancies in intervention implementation happen because of the complex implementation system that support the intervention. These systems consist of administrative rules and regulations, bureaucratic structures, and personnel who are responsible for intervention delivery (Chen & Rossi, 1983). Fortunately, the intervention activities tend to be open and easy to observe. This allows the implementation analysis to be a relatively simple process, requiring few of the evaluation resources (Mohr, 1995). Scott and Sechrest (1989) have further specified
that the treatment strength should be considered including, intervention specificity, intensity, and duration among other factors.

**Determining Relevant Outcomes.** As noted earlier, when the intervention theory is being developed, all possible outcomes should be identified. This list should include both positive and negative potential outcomes (Chen & Rossi, 1989). However, it will not be possible to submit all outcomes identified to actual research (Mohr, 1995). Instead, the evaluator and stakeholders must collaborate to choose from among all outcomes identified, selecting only those most relevant. This is a decision that should be made with input from stakeholders so that the most relevant outcomes are selected. Careful selection of outcomes to be tested has the potential to increase utilization of evaluation results (Mohr, 1995).

**Selecting Appropriate Methodology.** Once established, the intervention theory can be confirmed or denied by investigating the linkages between the elements of the theory. Theory-driven evaluation is unique in that it does not rely on one type of research methodology (Chen & Rossi, 1989). Instead, a variety of research methods can be used to develop and test the intervention theory. In fact, because of the comprehensive nature of theory-driven evaluation, multiple methods are often needed to complete the entire process. Quantitative methodologies have dominated the discussion of appropriate methodology and will be discussed here. However, it should be noted that qualitative methods hold great promise in the future of theory-driven evaluation.

There are several techniques that have proven useful for theory verification. Causal modeling is one technique used to verify the intervention theory. Causal models can take several forms including, linear structural relations (LISREL), confirmatory factor analysis, latent variable structural models, and path analysis (Lipsey & Pollard, 1989). The use of causal modeling techniques requires that each of the components in the model be a variable. In other words, the components must vary in such a way that different levels have different values for each component (Lipsey & Pollard, 1989). This leads directly to the second requirement, which is that variables must be quantifiable, so that the differing levels or values for each component can be identified (Chen & Rossi, 1989). The advantage of using causal modeling is that it forces evaluators to get specific on the intervention theory components and the relationship between those components. Furthermore, advanced computer programs are available to assist the evaluator when testing the model. Lipsey and Pollard (1989) also present a simpler form of causal modeling called the “basic two-step” (p.320). The basic two-step narrows the focus of the evaluation to include the first intervening variable in the intervention theory, that is, the variable that is expected to change as a direct result of the treatment. The second “step” is the more distant variable that is expected to be impacted as a direct result of the changes in the first intervening variable. This technique broadens the range of a simple “black box” evaluation considerably by considering major mediating variables, but is not as likely to explain complex intervention contexts (Lipsey & Pollard, 1998).

A second methodological approach used in conducting theory-driven evaluation is known as Confirmatory Program Evaluation (Reynolds, 1998). This approach is also used to establish causal relationships between program, intervening variables, and identified outcomes proposed in the program theory, specifically in the post-program stage and periods of follow-up. While the exact process for conducting a confirmatory program evaluation is beyond the scope of this paper, the process is very similar to the causal modeling techniques described previously (the interested reader is referred to Reynolds, 1998). The process may be applied to experimental, quasi-experimental, or non-experimental data. One benefit of this approach is the ability to strengthen causal inferences “in most quasi-experimental and non experimental designs” (Reynolds, 1998, p.207).

Third, Mohr (1995) presents methodology designed to generate measures of effectiveness or adequacy. These two measures are based on a comparison between actual results and the counterfactual, the state of the world without the intervention. For this comparison to be complete Mohr advocates the use of a control group. While the identification of this control group is often a difficult task, and by far the strongest limitation of this evaluation strategy, Mohr does offer many strategies for working with quasi-experimental designs. In addition, regression-discontinuity designs, and time series designs have been offered as strategies for evaluation when no control group is available. The benefit of this rigorous process is the ability to attribute causality to findings, if and only if designs are meticulously executed.

**Conclusions**

Introducing theory-driven evaluation as an alternative to available HRD evaluation models holds great promise. Like the Holton (1995) integrated model, theory-driven evaluation goes beyond a simple input/output model to consider important contextual factors affecting the intervention. The unique contribution of theory-driven

Note: The text above is a continuation of the previous one, ensuring a seamless and coherent flow of information. The page number "31-2" at the bottom indicates that this is a continuation of the previous page. The content is extracted and structured in a natural language format, adhering to the guidelines provided.
evaluation is the ability to consider a broader range of influences on intervention success in a situationally specific way. Theory-driven evaluation has many advantages, however, it will not be appropriate for every evaluation situation. Considering the advantages and disadvantages of the model can help determine when it is an appropriate evaluation strategy.

Advantages

The advantages of using theory-driven evaluation are numerous. First, the process of developing an intervention theory allows for detailed specification of the problem and the target groups. This process may assist intervention developers with specifying the reasons for the intervention in question. Furthermore, the intervening or causal mechanisms that are designed to address the problem also must be specified. So the way in which the intervention leads to expected outcomes must be clearly defined. This approach allows for the success or failure of the theory to be established, and also answers the question of why a theory did or did not work. Included in this is the distinction between the failure of the intervention to have a causal impact and the failure of the theory to operate in the way specified.

However, as Finney and Moos (1989) point out, “the greatest benefit of a theoretical foundation for evaluation research is a very practical one - the enhanced usefulness of findings” (p.314). More specifically, findings can help make instrumental changes to improve and develop the intervention and also influence the way intervention stakeholders conceptualize the problem and the intervention.

Limitations

Of course theory-driven evaluation is not appropriate in every evaluation context. The barriers to the use of this type of evaluation are quite serious. Bickman (1989) identified multiple barriers to use. First, increased costs can be incurred from activities such as, a lengthy planning session, the development of measurement tools and the collection of data on the various components of the model. Second, the evaluator must be technically competent in the strategies used to implement a theory-driven evaluation approach. In addition, the evaluator is expected to be knowledgeable in the problem and treatment literature. This creates the need for evaluators who are technically competent in evaluation research techniques as well as HRD. In this situation it is possible for the evaluator to be more knowledgeable about the intervention and its content than the intervention developer. This could lead to role confusion as there are not yet clearly defined role specifications (or limitations) for the theory-driven evaluator. Patton (1989) stresses that theory-driven evaluation, which results in generalizations about causal linkages are very applicable in some situations, but not all situations. He points out that simpler evaluation models are sometimes more appropriate.

Implications for HRD

Theory-driven evaluation can contribute to new knowledge in the field of HRD in two ways. First, it may be possible to generalize the results of the evaluation to other situations (Chen & Rossi, 1989). In other words, if desired outcomes were produced through specified intervening variables, it may be possible to replicate the findings in similar intervention situations. Second, knowledge can be generated which contributes to the broader body of evaluation knowledge (Chen, 1994). This generation of new knowledge is crucial to the development of program evaluation as a field, and in turn to the field of HRD.

Future Research. The most obvious next step in the incorporation of theory-driven evaluation into the field of HRD is the use of the theory in an applied setting. Chen (1994) reiterates this need, calling for more research examples in various evaluation situations. The application of this model can be used to test the utility of the various methodologies presented. It must be noted however that the possible methods mentioned here are by no means a comprehensive set. The list of possible methodologies should be expanded to include qualitative and mixed-method designs. A second line of future research is also needed to identify intervening variables common to HRD interventions. This list may include known organizational and individual factors that could have an influence on the desired outcomes.

Implications for Practitioners. Theory-driven evaluation has the potential to change to practitioner’s role in evaluation quite a bit. There is need for highly trained evaluation practitioners with the skills to carry out the rigorous evaluation designs. This involves qualitative skills needed for the development of the intervention theory,
as well as, quantitative skills to test the intervention theory. While the theory-driven evaluation process maybe more demanding on practitioners, the result is a comprehensive understanding of the problem, the intervention and the outcomes produced.

Creation and Utilization of Evaluative Information for Organizational Learning

Youngsook Song
University of Illinois at Urbana-Champaign

From the literature review on organizational learning and evaluation, this paper defines the meaning of organizational learning and examines organizational conditions enabling the organization to promote learning at different levels and in various ways. This paper attempts to explain the linkage between organizational learning and evaluation by emphasizing the function of evaluation as a process of creating, distributing, and utilizing evaluative information. In addition, the conditions that influence evaluation to better function for organizational learning are investigated.

Keywords: Organizational Learning, Evaluative Information, Evaluation Use.

Today’s organizations have been experiencing dramatic changes (Marquardt & Berger, 2001). Diverse forces, such as rapid development of technology, a more comparative and globalized market, and increased workforce diversity influence organizations internally and externally for changes (Dixon, 1992; Schwandt & Marquardt, 2000). To survive in this ever-changing society, organizations should be able to adapt and respond to changing conditions and learn and transform continuously.

Learning in the organization becomes more critical with increased complexity of internal and external environments (Sullivan, 1999). Organizations are not any more entities simply controlled and managed depending on a linear system model (Hudson, 2000). Inside and outside of the organization, many influences are interacting each other and all influences are changing dynamically. It becomes much less predictable to determine organizational situations, for instance economic trends, global markets, and internal/external customer needs. Today’s organizations coping with escalating changes and complexity cannot help but have a focus on continuous organizational learning and development.

In order for the organization to learn, each organizational member should learn first. Although organizational learning is more than accumulation of all individual learning, it calls for individual changes in thinking and behavioral ways. With respect to the notion of lifelong learning, it is important that every person should be in a position to keep learning and need to have continuous learning opportunities throughout his or her life (Maehl, 2000). People accustomed to stability and permanence in the workplace may be more likely to face unanticipated problems and increasing demands for changes. They could lose even their jobs unless they deal with these unexpected problems and demands effectively. Over the past decade, many organizations have undertaken numerous kinds of layoffs in scale with various names of organizational interventions, such as reengineering, merger and acquisition, and downsizing, etc. It is essential for the organization as well as for him and her to determine whether he or she, as a member of the organization, can learn effectively and efficiently.

From the viewpoint of strategic alliance and management, all functions of the organization ought to be integrated with each other to achieve organizational goals, and its system and culture should be able to maximize all employees’ capabilities to contribute to the organization’s success (Gilley & Maycunich, 1998). Since organizational learning is a critically emerging organizational goal, organizations need to consider the extent to which all functions and people in their organizations are ready to complete the goal and enhance it. In this sense, evaluation also should be a part of strategic organizational process. Preskill and Toress (1999b) propose that evaluation should and can be a means for enhancing learning in organizations. They believe that organizational learning will occur when organization members are involved in collaborative, communicative, and reflective evaluation processes (Preskill & Toress, 2000).

Evaluation has been performed in numerous ways and on different purposes. In general, it is believed that there are mainly three different types of evaluation use based on the purposes they serve, which are instrumental use (decision support and problem solving function), conceptual use (educative function), and symbolic use (political function)(see Leviton & Houghes, 1981 for details; Weiss, 1998b). However, as Shulha and Cousins (1997) indicate in their literature study on evaluation use, there is the emergence of a conception of evaluation as a continuous information dialogue. They discover that there are more frequent occurrences of evaluators and
stakeholders sharing responsibility for generating, transmitting, and consuming evaluation information. This supports the aspect that there is a growing need to reconsider the roles of evaluation with regard to organizational learning and improve the ways in which evaluative information should be created, communicated, and utilized.

**Purpose of the Paper**

Because evaluation is a critical component for organizational learning, it should gain more attention as an effective way of creating and sharing information/knowledge and promoting learning. In this regard, the purpose of this paper was to examine how evaluation can play a pivotal role to enhance organizational learning by reviewing the related literature. More specifically, this review was guided by the following questions: 1) What are important organizational conditions to enhance organizational learning? 2) What is the main function of evaluation to enhance organizational learning? 3) Under which conditions can evaluation better function to enhance organizational learning?

**Organizational Learning**

There have been variations and even confusion in defining organizational learning. Before detecting the meaning of organizational learning from the literature, it might be worth mentioning a difference between organizational learning and learning organization. Although organizational learning and learning organization are used interchangeably in many forms of literature, they are different concepts. Preskill and Torres (1998) describe the difference as following.

> When we talk about learning organizations, we focus on the what, and describe systems, principles, and characteristics of organization that learn as collective entities. Organizational learning, however, refers to how organizational learning occurs, that is, the skills and processes of building and utilizing knowledge. It is particularly concerned with the ways in which learning is created and shared. (p. 42)

Organizational learning has a focus on a process of how organizational members learn at various levels and in different ways, whereas learning organization refers to a product as a representation of a desired end of organizational learning (Shwandt & Marquardt, 2000).

**Definitions of Organizational Learning**

Over time various definitions of organizational learning have been offered that help to better understand the process of learning in the organization (Jenlink, 1994). As pioneers in the organizational learning field, Argyris and Schon introduce the concepts of single, double, and deutero-learning (1996; Argyris, 1998). The organization able to do deutro-learning considers as a learning organization, since deutro-learning means comprehensive, systematic, and continuous learning. This type of learning may often occur every place in the learning organization ideally. Argyris and Schon explain the composite process through which and how the organization responds to external and internal influences and develops its own learning system.

Huber (1990) articulate four constructs related to organizational learning -- knowledge acquisition, information distribution, information interpretation, and organizational memory (p. 88). He views organizational learning as processes of creating, distributing, interpreting, and databasing information/knowledge in multifaceted ways. Although he spends much room to explain the elements of “know acquisition”, his main point is to declare how effectively the information mechanism within the organization can be developed and work for learning.

Nonaka and Takeuchi (1995) propose a conceptual framework for managing dynamic aspects of organizational knowledge creation processes. They argue that organizational knowledge results from a continuous dialogue between tacit and explicit knowledge. According to Nonaka (1994), existing organizational learning theories are just related to “internalization”, which is a process of transforming explicit knowledge into tacit knowledge. In other words, most organizational learning theories mainly focus on explaining how to obtain information/knowledge and why people take actions in certain ways. However, Nonaka and Takeuchi (1995) attempt to expand the notion of organizational learning by suggesting a holistic approach that describes a continuous and intensified interaction between different types of knowledge at individual, group and organization levels.

Schwandt and Marquardt (2000) suggest an organizational learning model based on Parsons (1960)'s general theory of action. Schwandt (1993) define organizational learning as “a system of actions, actors, symbols, and
processes that enables an organization to transform information into valued knowledge which increases its long run adaptive capacity” (p. 8). They emphasize the organization system’s ability enabling adapt to its internal and external conditions. The system’s ability includes a creative learning capacity through the transformation of information into knowledge and a performance-orientation.

Although the organizational learning theories reviewed here have different focuses and perspectives in explaining the concept of organizational learning, three central points can be derived. First, as a major learning source, information and knowledge should be generated, distributed, and utilized at various levels in the organization. Next, it is critical to develop comprehensive and systematic understanding of interrelations between different types of information/knowledge. Lastly, the organizational capacity or ability for learning plays an important role to manage and facilitate the organizational learning function and system.

**Conditions for Organizational Learning**

It is significant to identify under which conditions information and knowledge can be better created, distributed, and utilized at various levels, and to know what factors need to be considered to promote organizational learning. According to Senge (1990), in order to be a learning organization, the organization should embrace and implement five disciplines. They are systems thinking, personal master, mental models, building shared vision, and team learning. “Systems thinking” refers to a concept for understanding patterns of events and behaviors to know how to improve them. This discipline is the most emphasized one among the five disciplines, since he believes that this is an essential to integrate all disciplines into each other and to fuse them into a coherent theory and practice of the organization. Without systematic understanding, it is evident that there is no motivation as well as channel to see how the disciplines interrelate to enhance each other and to lead to organizational learning.

Watkins (1996) emphasizes organization capacity, motivation, and slack as three triggers for organizational learning. According to her, learning occurs when the organization is able to learn (capacity). Learning is critically influenced by organizational motivation at various levels (motivation). And, organizational learning takes place when financial, technological, or human reserves have spare resources to learn (slack). The organization able to learn may be externally and internally well motivated and have abundant learning resources at various levels.

Marsick and Watkins (1999) address various ways to achieve organizational learning. For instance, work redesign, change of reward systems, flatter structure, and team work, etc. are suggested as means of enhancing organizational learning. Watkins (1996) emphasizes organization capacity, motivation, and slack as three triggers for organizational learning. It is significant to identify under which conditions information and knowledge can be better created, distributed, and utilized at various levels, and to know what factors need to be considered to promote organizational learning. Without systematic understanding, it is evident that there is no motivation as well as channel to see how the disciplines interrelate to enhance each other and to lead to organizational learning.

**Evaluation**

In order for evaluation to enhance organizational learning, evaluation itself needs to be learning oriented and thus effectively create evaluative information. Moreover, information and knowledge generated through evaluation should be disseminated at various levels and be used for organizational learning.
Evaluative Information for Organizational Learning

Evaluation is a process of systematically assessing the operation and/or the outcomes of evaluend (a person, a thing, an idea) against a set of explicit or implicit criterions (Weiss, 1998a). Through evaluation, evaluators generate mainly evaluative information and knowledge of evaluend. Evaluative information means information and knowledge with amount of valuing and judging. In effect, evaluation does not intend only to generate evaluative information. Like Chen (1989)'s claim, in some cases, it should be a critical part of evaluation to understand a nature of a program and develop a theory of the program. Patton (1997) asserts that the most important element for the success of evaluation is to identify and meet major evaluation clients' needs. In addition, evaluative information can be generated without borrowing a form of evaluation. For instance, critical inquiries, reflection processes, and communications with other organizational members help to estimate a phenomenon and result in creating and distributing evaluative information or develop an evaluative consensus of the phenomenon (Torress, 1994; Preskill, 1994, 1999b).

However, evaluation is the most formal, systematic, comprehensive, and professional way to generate, distribute, and utilize evaluative information. As already mentioned in the previous section, without a process of acquiring or producing information and knowledge, organizational learning cannot take place. In terms of organizational knowledge construction and intellectual growth, evaluation can play a significant role by creating and consuming evaluative information. Evaluative information and knowledge generated and shared through evaluation should lead to program development and organizational change (Cronbach and Associates, 1980). It is obvious that evaluative information ought to be a critical learning source to foster diverse types and levels of learning and help to apply them to visible actions. Furthermore, evaluation should embrace ample opportunities of creation, distribution, and utilization of evaluative information for evaluators and stakeholders. Preskill and Torres (2000) suggest that when organization members are involved in the evaluation process that is collaborative and guided by dialogue and reflection, learning occurs not only at the individual level but also at the team and organization level. This suggestion means in order that evaluative information can be effective within and outside of the evaluation boundary for organizational learning, the evaluation process should be learning-centered by offering diverse chances to share and develop evaluation participants' knowledge, skills, and attitudes on evaluend collectively as well as individually.

Conditions to Generate and Utilize Evaluative Information for Organizational Learning

In this section, the author discusses that under what conditions evaluative information and knowledge can be better created, distributed, and utilized to enhance organizational learning. Rogers and Hough (1995) argue that evaluation focus, methods, and management should reflect realistic assumptions about how organizations work. In a similar viewpoint to Rogers and Hough, Jenlink (1994) claims that evaluation needs to take place based on understanding how the organization learns and it should function to transform the organization to be a learning organization. Rogers and Hough (1995), and Jenlink (1994) stress that it is crucial to take into account the organization' context in terms of its learning infrastructure or "architecture", so that evaluation functions for organizational learning in considering the organization's nature and being integrated with the place where it is implemented.

The organization capacity for learning through evaluation is also critical to produce and use evaluative information as the organization learning ability is essential when organizational learning occurs (Torress, Preskill & Pionek, 1996). It is not productive and effective to engage in evaluation processes unless the organization is ready to use evaluation results and learn from evaluation practice. In this sense, evaluators and stakeholders need to determine the extent to which the organization has the readiness for learning through evaluation.

Moreover, Preskill and Torres (1999b) investigate in which ways evaluative inquiry can contribute to the maintenance and development of organization (see also Shulha, 2000; Rossman & Rallis, 2000). They focus on the four elements of organizational infrastructure, which are leadership, forms of communication, systems and structures, and culture (1999a, 1999b, 2000). According to them, when evaluation is employed as a means of accumulation of information for organizational learning and development, these four organizational elements are essential to implement evaluation effectively and change the organization to be learning-focused.

Several other researchers study the factors that influence the evaluation process for organizational learning. As highlighting enlightenment of stakeholders and formative evaluation process, Owen and Lambert (1995) claim that negotiation of an evaluation plan, heightening awareness, synergetic techniques of reporting, and guidelines and ongoing personal level support are important conditions to assist with strategic decision-making committed to organizational learning and change. Shulha and Cousins (1997) also provide their insights on what affect creation as
well as utilization of evaluation information and findings. They identify predictors for evaluation use and cluster the predictors into ten categories such as: quality of evaluation implementation, credibility, relevance, communication, user involvement, potential for information processing, clients’ need of information, anticipated degree of program change, perceived value of evaluation as a management tool, and contextual characteristics of the decision or policy setting (p. 196). Evaluation is required to consider more and more complicated situations and conditions to promote learning rather than simply match evaluation clients’ questions with a particular method and approach. And, several articles show the ways in which evaluation can bring out successful creation and utilization of evaluative information as involving participants in the evaluation process and creating information with collaborative team working (Cousins, Donohue, & Bloom, 1996; Fetterman, 1994; Scriven, 1997).

The organizational conditions that the author mentioned in the previous organizational learning section can be applied to enhance organizational learning through evaluation. In other words, well-customized applications of systematic support, empowering, collaboration, and communication to evaluation processes help to better generate, distribute, and utilize evaluative information for organizational learning. With a broader and comprehensive concern, contextual understanding of the organization and organizational readiness for learning through evaluation are considerable elements to maximize creation, distribution, and utilization of evaluative information to lead to numerous types and levels of learning across the organization.

Contribution to HRD Research and Practice

There have been academic efforts that suggest alternative views to expand the HRD evaluation field (Holton, 1996; Kaufman & Keller, 1994), since HRD evaluation theories and practice have been pretty much dominated by Kirkpatrick (1998)’s well known four level evaluation model. In this sense, the attempt to link evaluation and organizational learning can bring out beneficial possibilities to develop the existing HRD evaluation theories and practices. As a more systematic and comprehensive evaluation, learning oriented evaluation approaches give critical insights to consider evaluation as a continuous information creation and utilization process for organizational learning and development. However, there are not many practical applications and experimental evidences of how this discussion can influence action and performance improvement and make actual changes in the organization. These approaches seem to be even idealistic or conceptual (Shulha, 2000).

For further research, it is necessary to know how evaluative information should interrelate and interact with different types of information and knowledge to promote organizational learning. More empirical evidences supporting the power of evaluation to foster organizational learning need to be mixed with concrete concepts and sound principles. Additionally, the linkage between information/knowledge and action/performance through evaluation should be more defined and developed.

The Effects of Performance Feedback upon Small Businesses: A Literature Review

Sonji Lee
Karen K. Yarrish
Patricia Bederman Miller
Keystone College

This review explores literature related to performance feedback in small businesses. It investigates the relationships and significance of performance feedback to the theory and practice of Human Resource Development (HRD). It studies research of performance feedback in larger organizations, and it identifies concerns about the lack of such research specific to small businesses. This review also exposes the need for further study of performance feedback in small businesses and the implications for HRD.

Keywords: Performance Feedback, Small Businesses, Employee Development

Businesses, regardless of size, location, or type, strive to be successful. This success depends, to a very large part, upon the degree of employee performance. Practitioners in the field of Human Resource Development (HRD) recognize the importance of employees and promote many techniques and methodologies to help assure enhanced performance by them. HRD professionals constantly study business environments in their seeking of improvements in the performance of personnel. One area of study that is of particular importance in the business arena involves the feedback of performance data between employees and their supervisors.

Problem Statement

Much research has demonstrated that there is a positive link between improved productivity and the provision of effective feedback processes. There are substantial amounts of empirical research regarding the relationship between employee feedback and performance in larger organizations, but more research should be conducted in small businesses (Westhead & Storey, 1996).

It is generally accepted that the performance feedback process and the method of communicating performance feedback are key components to effectively develop human resources. However, one of the key issues in HRD is the identification of the specific factors that influence the performance of employees. These factors include, but are not limited to, communicating; coaching; conducting career workshops and supervisory training; developing and implementing effective feedback systems, critical incident programs, and goal setting processes; and increasing personal motivation at all levels of an organization. This review explores some of these factors that affect employee performance.

Theoretical Framework

Various theories support the concepts that feedback to employees provides many benefits, including the improvement of their job performances.

Goal Setting

The establishment of performance goals is one tool in the process of effective employee performance feedback. Setting goals and tracking accomplishments towards these goals are especially effective when mutually developed and when the feedback is ongoing and it involves all parties.

Research has demonstrated that the setting of sensible, clear, short- and long-term goals is a trait or habit of successful people and organizations. These people recognize that goals are not easy to achieve and that they can fail to reach them. They also know that goals require taking risks. Seldom does anything positive occur without the taking of intelligent, well-conceived risks. Further, the risks demand sacrifices, such as time, money, reputation, or other resources. But, reaping rewards in the future typically demands making careful investments today. The fruits of setting goals and of making changes go to those who prudently take the risks and make the wise investments (Wax, 1997).

Copyright © 2002 Sonji Lee, Karen K. Yarrish and Patricia Bederman Miller
The theory of goal setting proposes that motivation can be affected positively by utilizing goals. Employees' efforts and their focusing of attention, persistence, and selection of work strategies are all improved when well-conceived goals are properly presented and acted upon.

Locke and Latham (1984) state that goal setting is a theory "that helps to explain why other motivational techniques or approaches... work" (Locke & Latham, 1984, p. 107). According to them, goal setting is pivotal for the success of other motivational approaches, including job enrichment, organizational behavior modification, participation, and monetary incentives. These approaches are contingent upon the inclusion of goal setting for their successes (Locke & Latham, 1984).

As an example, in endeavoring to modify employee behavior, the recognition of the presence of goals helps direct employee behavior until either the goal is accomplished or else it is rejected or modified. Other researchers of motivation agree that goal setting is a well-supported theory of motivation in the workplace (Harris & DeSimone, 1994).

As a motivational tool, goal setting is extremely valuable. It achieves results, but the results are not automatic. As any tool, goal setting must be utilized properly. To be successful, goals must be set systematically and used effectively. If done so, goal setting can improve productivity, stimulate creative problem solving, and increase satisfaction, confidence, and pride (Locke & Latham, 1984).

Organizational Development

Providing feedback to employees is often prompted by the need to initiate and manage change.

Ivancevich and Matteson (1997) employ the term "organizational development" (OD) to refer to "the process of preparing for and managing change" (Ivancevich & Matteson, 1997, p.614). They further refine their definition by including long-range planning for improved operations through better utilization of the resources of the organization. They list three sub-objectives of OD: changing values or attitudes, modifying behavior, and inducing change in the structure and policy of the organization (Ivancevich & Matteson, 1997).

Organizational development has been defined by Harris and associates "as a process used to enhance the effectiveness of an organization and the well-being of its members through planned interventions" (Harris & DeSimone, 1994, p. 414). The latter part of this definition deals with intentional and planned interventions, such as introducing and implementing employee feedback mechanisms. In some instances, these are called intervention strategies. Regardless of terminology, these represent a task or a series of tasks undertaken by an organization (or a segment of an organization) where the goals are related to the improvement of the organization. Accordingly, planned intervention or intervention strategy is the primary method by which changes are made and improvements occur to the organization (Harris & DeSimone, 1994). These changes and improvements are critical components of any successful employee performance feedback system.

Beckhard offers his definition of organizational development as “…an effort [that is] planned, organization-wide, and managed from the top to increase organization effectiveness and health through planned interventions in the organization’s ‘processes,’ using behavioral-science knowledge” (Beckhard, 1969, p. 9). His definition mandates planned change through systematic diagnoses, the development of strategic plans aimed at improvements, and the mobilization of resources to implement the plan. In addition, it involves the total system. Even though a change may focus upon a subpart of an organization, the system to be changed is the total, autonomous entity that is essentially free to determine its own plans and future (Beckhard, 1969).

Leadership

Successful performance feedback is unlikely to occur without effective leadership from within the organization.

From Jack Welch, the highly respected and successful former Chairman and Chief Executive of General Electric Corporation: "I simply dislike the traits that have come to be associated with 'managing'.... The word manager has too often come to be synonymous with control — cold, uncaring, button-down, passionless. I never associate passion with the word manager, and I've never seen a leader without it" (Lowe, 1998, p. 72). "I don't run G.E. I lead G.E. (Lowe, 1998, p.74)."

In the Wall Street Journal, Welch is described as "a combination of charismatic preacher, all-knowing judge, internal ombudsman and hard driving coach" (Murray, 2000, p. A8). Welch, himself, describes a CEO as being equivalent to an orchestra leader. He continues with his principles: "Always meet targets, don't accept mediocrity, embrace change, [and] don't cling to tradition" (Murray, 2000, p. A8). His dedication to leading and to accepting change at General Electric is echoed throughout the article.
The first step in changing an organization is to scrutinize every product, service, process, market, customer, personnel training and development program, the use of all information, and every other component of the organization for the end of its useful life. (Cendron, 1999).

Culture

The culture within an organization must accept and actively endorse performance feedback as positive, enriching experiences. The alternative is resistance and ineffective change.

Culture, as found in business organizations, is established during many years and is founded upon many different stories and interpretations. As such, it is difficult to change. This resistance to change is, in fact, one of the strengths of a business culture. But, correspondingly, it also is a weakness. Culture within a business organization can be changed, but doing so demands much time and extensive, careful leadership. The people at the top of the organization must be intimately involved and must be seen as being truly committed and involved in the change. But the leadership cannot rest solely at the top; it must permeate down through all levels of the organization. Unless everyone actively advocates for a particular change, it will be ignored as a passing executive fancy (Nadler et al., 1995). In business, nothing replaces solid leadership.

Motivation

The appropriate use of feedback can yield substantially improved employee attitudes and motivation.

In studying motivation, Abraham Maslow’s hierarchy of needs (Maslow, 1970), ranked the needs of people into a hierarchy, each level having to be satisfied before motivation will advance to the next level. Maslow ranked the needs in his hierarchy according to their apparent importance, placing the most important ones, the physiological needs, at the bottom. His theory holds that until these needs are satisfied, the other needs do not play a significant role in motivation. Maslow’s hierarchy of needs is relevant to the study of performance feedback, because feedback from others effects the highest levels of the hierarchy of attainment satisfaction.

Hackman and Lawler (1971) found that every higher-order need they studied was positively and significantly related to the satisfaction of feedback. However, they found little agreement in the area of which jobs provided the highest level of feedback.

Frederick Herzberg (1959) developed the two-factor theory of motivation where hygiene factors were found to have little influence on motivation and motivation factors were found to provide motivation. Hygiene factors include such things as supervision, working conditions, interpersonal relationships, pay, security, and company policies. His motivation factors include achievement, recognition, the work itself, responsibility, advancement, and growth. Although the results of the study remain controversial, they are important to consider when examining performance feedback systems, because they relate directly to recognition, to the possibility for increased responsibility, and to advancement and growth.

Science-Based

Rensis Likert’s (1967) work centered on science-based organizational theory emerging from the research findings on management and organizational performance and the implications for labor/management relationships. Likert’s theories are important to evaluate, because his research considers areas of employee involvement in business decisions and the relationship of organizations’ success based on management styles.

Research Questions, Purpose, Design, and Data Collection

The purpose of this literature review is to explore the research related to performance feedback in small businesses and to consider the implications of performance feedback to HRD theory and practice. The following questions were determined:

1) What is the theoretical framework for researching performance feedback?
2) How do employees and employers benefit from performance feedback?
3) What research findings can help the HRD practitioner develop methods and programs to improve relationships using performance feedback in small businesses?

ABI Inform, Psyc Info, ERIC, and EBSCO Host were used to review the scholarly literature. The terms used to conduct the searches included Performance Feedback, Performance Evaluation, Employee Development, and Small Businesses.
Methodology

This literature review was conducted using a meta-analysis of the current research pertaining to performance feedback in small businesses.

Literature Review

Job Performance

According to a study by Minter and Thomas (2000), communication and job performance improves when employees are provided with immediate feedback and consultation. Job performance tends to be directly related to the quality of relationships between the individuals involved. Providing feedback has been identified as being essential for the success of positive working relationships among workers and managers (Deming, 1986; Likert, 1967).

Employee Importance

Arthur Anderson and National Small Business United funded a nationwide research study of small and mid-sized businesses entitled “Trends for 2000.” The participating organizations were asked to name their most significant challenges to future growth and survival. The top challenge was in finding and retaining qualified workers (61%), followed by state and federal regulations (35%) and economic uncertainty (29%). The respondents then indicated the methods they used to motivate employees. The answers also included providing a team atmosphere (63%) and providing a greater sense of purpose (56%) (Arthur Anderson & National Small Business United, 2000). This survey helps validate the importance of employees and employee performance in the world of smaller businesses.

Coaching

The appraisal of performance appears to be used extensively in business to evaluate and track the outputs of employees. From “Leader to Leader”, a publication of the Drucker Foundation and Jossey-Bass (1992), the Paradox of Performance Appraisal advocates that the stand-alone performance appraisal is counter-productive and should be replaced with a variety of tools and delivery systems that are more effective. One of these is coaching, which, the author contends, should replace performance ratings, except when they are required by regulation, union contract, or are particularly appropriate in individual circumstances, such as a probationary appraisal for new employees. Coaching is not easy to accomplish effectively, but, unless this method is not used, performance appraisals by themselves will fail to accomplish their intended roles (McGehee, 2001).

Encouraging and providing feedback, coaching, and communicating with employees has long been acknowledged as beneficial in providing positive working relationships with employees (Deming, 1986; Likert, 1967). Some previous studies in organizational behavior have attempted to relate, more precisely, how coaching or providing feedback affect job performance (Vroom, 1964; Ilgen, Fisher, & Taylor, 1979).

Minter and Thomas (2000) advocate that the coaching process be employed to aid in the effectiveness of performance evaluation systems. Their definition of coaching includes a deep respect for all subordinate individuals and trusting that subordinates have the abilities to solve their own problems. If subordinates truly believe that their managers are understanding and cooperative, job performance will improve.

According to Meyer, Kay, and French (1990), coaching should be a day-to-day activity and goal setting, rather than criticism, should be used to improve employee performance. They also recommend that evaluations should have but one singular purpose. Their study presents the following conclusions:

1) The evaluation process has too many intended uses and purposes.
2) These uses and purposes are in conflict with each other.
3) An evaluation discussion does little to influence future job performance.
4) Job performance improves when mutually agreed upon goals are established.

Training

The training of supervisors to properly use the performance feedback system is extremely important to the HRD practitioner. Beyond this, McGehee (2001) advises businesses to train everyone about useful feedback, to provide
open systems and structures that encourage feedback, and to use other tools to stimulate commitment to improvement efforts throughout every organization.

Watson Wyatt, a management consulting firm in New York, conducted a study of 1,020 medium to large companies in North America and studied 17 of those in depth. It found that career workshops were among those activities that led to greater productivity in employees (Comeau-Kirshner, 1998).

Participation

Other research has recommended several approaches to improve the performance feedback process. McGregor (1990) encouraged that subordinates become active in the evaluation processes by taking responsibility for developing a plan for themselves and determining their own potential. McGregor’s research strongly supports the use of Management by Objectives (MBO).

Practitioners recently have published articles relating to the various issues pertaining to performance evaluation. Continuous feedback provides employers with very real and important opportunities to inform employees how successfully they are doing their jobs, feedback that employees, in general, truly desire. (Laumeyer, 1999). Pardue (1999) urges the development and use of performance evaluation systems that are truly participative in nature. Pardue (1999) reports that well documented performance appraisal forms help defend various employment decisions. Longer-term performance diaries have been recommended as an effective aid to performance raters for several decades (Bernardin & Walter, 1977; DeNisi, Robbins, & Cafferty, 1989).

Levinson (1990) recommends from his research that a detailed critical incident process be used to carefully document all incidents of behavior, both good and bad, and done as they occur. These incidents should be discussed with employees at the time of the occurrence in order to provide immediate feedback. This will help the employees to correct small problems before they develop and expand into larger ones. Levinson purports that these documented data then can be used during a subsequent review time to substantiate the details.

Needs

Levinson (1990) also suggests that the psychological needs of individuals be taken into consideration during the performance evaluation process. As an example, the supervisor should not only be asking questions pertaining to the individuals’ personal life goals but should also be inquiring as to what makes them feel good about themselves. Levinson’s premise for recommending this is that each person is working towards the attainment of his or her individual psychological needs. Therefore, the highest level of individual motivation will arise when a parallel relationship exists between the needs of an individual and those required in the job and by the employing organization.

Results and Findings

The survival of any business, large or small, depends upon the effective performance of tasks by its employees. Without feedback, however, employees usually are unable to maintain or improve the desired quality and quantity of their work.

As a result of the comprehensive literature review, it is evident that there is a substantial lack of research data on performance feedback that pertains specifically to small businesses.

All research studies that were explored in this review unanimously endorse the validity of performance feedback processes when designed and executed properly. These studies indicate that the benefits accrue to both employers and employees. However, given the scant amount of research on performance feedback in the small business environment, the assumption that these benefits apply to this group may not be accurate.

Conclusions and Recommendations

“Small businesses (firms with fewer than 500 employees) employ 53 percent of the private, non-farm work force, contribute 47 percent of all sales in the country, and are responsible for 51 percent of the private gross domestic product” (National Small Business United, 1999).

Small businesses contribute greatly to the economy of our country and contribute trillions of dollars worth of economic power annually to the global market. American small business ranks third in the world of economic powers, behind only that of the U.S. as a whole and that of Japan. The number of these operations is rapidly increasing by about three-quarters of million each year. Most of the new employment in the private sector is from
small businesses. The popularly expressed failure rate of small businesses is a myth; in fact, nearly 70 percent of all firms beginning in 1985 were still in operation after 10 years (Megginson, Byrd, & Meggison, 2000).

A recent survey by Arthur Anderson and National Small Business United of small and mid-sized businesses disclosed that 61 percent of employers expressed that finding and retaining qualified workers was their greatest challenge to growth and survival (Arthur Anderson, 2000).

The value of effective performance feedback systems is well accepted in HRD and large businesses. It has been illustrated that job performance improves when attention is given to employees through feedback, consultation, and coaching. However, the benefits of such feedback have not been evident in the realm of small businesses. Small businesses may not reap the same benefits as do their larger counterparts, mainly due to lack of money, staffing, and time to conduct effective performance feedback. A real need exists for additional study to expand the knowledge of performance feedback, specifically as it relates to the small business environment.

Implications for HRD

The value of effective performance feedback systems is well accepted in the HRD and business worlds. HRD practitioners often work in a consulting role to small businesses. For HRD professionals to effectively develop and assess feedback processes for small businesses, they first must have appropriate background information related to performance feedback. However, the scant amount of research regarding performance feedback processes in small businesses tends to limit the effectiveness of the HRD consulting efforts to smaller business entities. The purpose of this review is to demonstrate the opportunities and needs for further research of performance feedback in small businesses.

College Choice: The State of Marketing and Effective Student Recruitment Strategies

Fredrick Muyia Nafukho
University of Arkansas

Michael F. Burnett
Louisiana State University

The study examined recruitment strategies employed by Louisiana State University admissions offices and the College of Agriculture. Student financial aid, geographic location, mail pieces sent to prospective students, campus visitation programs and outreach programs were the most efficient factors in student recruitment. These factors had positive correlations with enrollment and were statistically significant at .05 level. HRD researchers could use the findings to save dollars in recruiting students who meet the mission of their programs.

Keywords: Marketing Education, College Choice, Student Recruitment

During the past 350 years, colleges and universities in the US have grown to over 3,100 baccalaureate-granting institutions, each with its own unique purpose, history, student body and faculty (Cerny, 1992, p.1). Prior to the mid-1960's, student enrollment grew without much recruitment efforts from higher education institutions (Hossler, 1986 and Sevier, 1989). The higher education industry witnessed increased student enrollment after World War II until 1980. This growth was due to the baby boom generation (Boyer, 1987). For the period ranging from 1975 to 1985, demographers projected a steady decline in the number of traditional college age students. This decline led to the enrollment crisis of the 1980's (Novak and Weiss, 1985). In response to this crisis, in December 1983, the College Board and Educational Testing Service conducted a study to better understand the enrollment practices of colleges across the country. College admissions officers' responses showed that the most frequently mentioned problems were: too few students to apply, too few accepted students enroll and too many students drop out (Novak and Weiss, 1985, p.2). For admission offices to be successful in their recruitment efforts today and in the future, they must use a growing knowledge base to guide their recruitment programs. There is need for the analysis of the huge student databases in order to understand student characteristics. The HRD professionals teaching in the universities should provide customer-capital services to their departments and colleges by helping in designing effective marketing strategies (Edvinsson and Malone, 1996). As noted, the business success of colleges and programs offered will depend upon “selling what the customer (student) wants to buy” (Rothwell & Sredl, 1992, p. 135; Albrecht & Bradford, 1990, p. 1). HRD professionals as facilitators of learning, have an obligation to students, the colleges they serve, and themselves to help their customers avoid making costly purchases that do not help improve organizational, group or individual effectiveness in terms of higher completion rates (Rothwell & Sredl, 1992).

Problem Statement and Purpose

The concern for having the optimal number of students is now more pronounced than it was in the 1980's and 1990's. Faced with competition and limited financial resources, colleges are using several recruitment tactics to attract students. But to attract the required number of students and save dollars allocated to student recruitment, efficient recruitment strategies must be employed. Every college must develop its own unique selling points. An understanding of student college choice decision-making is therefore critical in designing of unique selling points. This understanding is in line with investment in customer-capital. While designing recruitment strategies at the college level, it is important to understand what motivates students to choose a given college. On the lack of data about student characteristics in many colleges, Brodigan and Dehne (1997) noted: “We find it strange how little most colleges know about the opinions, expectations, and satisfaction of current students” (p.18). Human Resource Development professionals as marketers should use their marketing skills to research into the issue of college and program choice to develop innovative programs. The main purpose of this study was to describe the fall 1997 prospective freshmen in the Louisiana State University College of Agriculture based on the main recruitment
strategies employed by Louisiana State University's admissions offices and the College of Agriculture. The study also aimed at identifying the recruitment factors that had the highest association with college enrollment status.

Theoretical Framework

The language of marketing was introduced into higher education admissions no more than a decade ago, but colleges and universities have applied basic marketing techniques throughout their history to curricular planning and assessment (Ihlenfeldt, 1980). Marketing as applied to higher education is a concept that allows college decision makers to think systematically and sequentially about the mission of the organization, the services it offers, the markets it currently serves, and the extent to which these same markets and possibly new ones may demand its services in the future (Ihlenfeldt, 1980, p.13). Higher education and HRD practitioners in particular, deal with an intangible product that is more of a service than a commodity (Salee and Johnson, 1994). HRD researchers therefore need to be more careful when they apply marketing concepts to education. There is always some difficulty when it comes to quantifying intangible services such as education. Marketing can, however, enable college management and HRD program designers to determine whether their missions match student interests. Knight (1981) suggests that marketing is consistent with many ideas in higher education when it is understood and applied appropriately. In the 1970's and 1980's when the reality of declining students could no longer be denied, more astute college administrators recognized that marketing meant more than selling. It involved strategic decisions in other areas as well and the shift toward adopting more customer-oriented perspective began to surface in many institutions (Losher and Miller, 1983, p.9).

Kotler (1975, p.5) defines marketing as the analysis, planning, implementation, and control of carefully formulated programs designed to bring about voluntary exchange of values with target markets for the purpose of achieving organizational objectives. It relies heavily on designing the organization's offering in terms of the target market's needs and desires and on using effective pricing, communication and distribution to inform, motivate and service the markets. In higher education, Johnson (1979) observes that marketing tries to give first consideration to the student and societal needs. Losher and Miller (1983) note that one of the basic assumptions of an effective marketing program is that an institution is committed to the philosophy that colleges are in the people business and inflexible decision makers must yield to the needs of the consumers, the students, if they want to recruit them. Although marketing in higher education is mainly associated with promotion and recruitment, Johnson (1979), emphasizes that the scope of an effective marketing program should be more comprehensive and must include research, planning, communication and evaluation. Cox (1980) and Lovelock (1980) argue that marketing should be looked at as a total institutional concept, which integrates trustees, faculty, administration and staff efforts into a cohesive team approach. Rothwell and Sredl (1992) note that marketing is important to HRD field since people (students) can't benefit from products or services that are unsuitable or those they know nothing about. Therefore, when colleges market their products and services, they must tailor planned learning experiences to suit the needs of the learners they serve and to alert learners to products and services that are already offered (p. 136). Walton (1999) observes that HRD professionals as marketers should help enrollment admission officers by selling training and development view points, learning packages, programs and services to target audiences outside universities.

Methodology and Research Design

The Target Population

The target population for this study was defined as all prospective freshmen that were recruited to attend the College of Agriculture at LSU in the fall of 1997. The accessible population consisted of fall 1997 prospective freshmen who resided on both the undergraduate and college databases. The university undergraduate data base houses all undergraduate admissions contacts with students and is based upon a coding system with different contacts represented by a series of numbers corresponding to specific recruitment contact such as letters, telephone calls and events. The College of Agriculture data base equally houses all undergraduate admissions contacts with students and is based upon a coding system with different contacts such as: TAgger Day, telephone, WWW, and attendance at 4-H and FFA functions.

The accessible population from which the sample was drawn consisted of students who resided on both the university admissions database and the College of Agriculture database. The minimum required sample size for the study was determined using Cochran's (1953) sample size formula for categorical data with an a priori established alpha level of .05, an acceptable margin error set at 5% and the estimate of the variance in the population set at .25 (the most conservative estimate of variance calculated as p times q). A comparison of 1,130 students who resided
on the College of Agriculture's 1997 high school senior data base, with the university undergraduate recruitment data base gave a total of 226 students. This formed the accessible population of the study. From the accessible population, the actual sample size was determined to be 143. Since complete data on all the variables for all the subjects in the accessible population were obtained, all 226 subjects in the accessible population were included in the study instead of the 143 subjects.

Instrumentation and Data Collection

A computerized recording form was the main instrument used for data collection in this study. Specific variables from both the university undergraduate admissions database and the College of Agriculture admissions database were selected. The variables selected were those that addressed the objectives of the study. A file was established into which the variables were systematically copied. Data was collected during the spring and summer semesters of 1998 by copying over 70 variables of interest from the university's undergraduate admissions data base and another 27 variables from the College of Agriculture's admissions data base. Each student was drawn using his or her social security number.

Data Analysis

Data collected in this study was analyzed using the following procedures for each respective study objective. Objective one was to describe the Fall 1997 prospective freshmen in the Louisiana State University College of Agriculture based on the main recruitment strategies employed by Louisiana State University's admissions offices and the College of Agriculture. Since this objective was descriptive in nature it was analyzed using descriptive statistics. The variables that were measured on a categorical (nominal and ordinal) levels were summarized using frequencies and percentages in categories. Variables that were measured on interval or higher scale of measurement were summarized using means and standard deviations. The second objective aimed at identifying the recruitment strategy that had the highest association with college of Agriculture enrollment status among students recruited for admission to the college. This objective was accomplished by using zero order correlation coefficients. Before the correlations were determined, the researchers checked for the presence of multicollinearity by regressing each independent variable on all the other independent variables. This technique takes into account the relationship of each independent variable with all the other independent variables and a combination of other independent variables (Lewis-Beck, 1980). The variables that had high $R^2$ were removed from the analysis. The dependent variable enrollment was correlated with independent variables studied.

Results and Findings

The study was designed to answer one major question: Which recruitment strategy had the highest association with student enrollment during the year of investigation. There are numerous points in the recruitment of a student to attend the university that are either a mail strategy in and of themselves or cause the generation of a piece of mail to the student as a follow-up of the activity. Examples of these include invitations to attend selected activities, follow-up notes thanking the student for their participation in selected activities, and letters acknowledging receipt of pieces of information such as ACT scores, application, etc. The total number of mail pieces sent to prospective students by the university admissions office and the College of Agriculture ranged from a low of 2 to a high of 15. The average number of Mail pieces sent was 7.48 (SD = 2.498) for students in the study. The largest group of students ($n = 35, 16\%$) in the study received a combined total of 7 pieces of mail from the university admissions office and the College of Agriculture. This was followed by another 30 (13\%) who received six pieces of mail. The second recruitment strategy examined was financial assistance. Of the students who received scholarships, the highest number of scholarships received by any one student was ($n = 7, 4.5\%$), while 33 (21\%) of the students received only one scholarship. Out of 226 subjects studied, 154 (68\%) received scholarships. While the remaining 72 (32\%) of the students in the accessible population never received any form of financial assistance. To further examine financial aid as a factor in recruitment, the total dollar amount of the financial assistance awarded to the subjects in the study was measured. The students who received scholarships, the largest group ($n = 24, 16\%$) was in the amount range from $9000 to $9999. The next largest group of students was in the $2000 to $2999 range of scholarship amounts ($n = 21, 14\%$). The mean amount of scholarship awarded was $6263.18.

The third recruitment strategy examined was campus visitation programs. This was operationally defined as Preview LSU, Tiger Day, TAgger Day, and Campus Tour. TAgger Day is the College of Agriculture recruitment program in which high school seniors and juniors are invited to attend the College of Agriculture open house in the
spring of the year. Tiger Day, the largest Louisiana State University recruitment program is administered by the university admissions office. Approximately 30,000 high school seniors and juniors are invited to attend the Campus Open house in the fall of every year. Preview LSU is a program in which high achieving students are invited to participate in a day and a half program on the LSU campus. The program aims at giving students an in depth look at the program opportunities offered at Louisiana State University (Harris, 1997). The Campus Tour recruitment activity involves the Monday through Friday Admissions Session and student guided tour of the campus. Forms for application are readily accessible from the admissions office and LSU web page for students to complete and mail back. As a recruitment strategy, LSU admissions office encourages visits from students and parents at all occasions. Table 1 shows that 162 (72%) of the students in the study were invited to attend Tiger Day during their senior year and 38 (17%) of the them attended. It is shown further that 60 (27%) of the students were invited to attend Tiger Day in their junior year and 5 (2%) of the students came to the event. For the TAgger Day program, which is a similar activity just for the College of Agriculture, 48 (21%) of the students participated in the program.

</tbody>
</table>

In the case of the Preview LSU program, 26 (12%) of the subjects were invited to attend the program and 7 (3%) actually participated in the program. Finally, 48 (21%) of the subjects participated in a campus tour while the remaining 178 (79%) of the Fall 1997 prospective freshmen recruited to attend the College of Agriculture did not participate in a formal guided tour of the LSU campus. The fourth recruitment strategy examined was Outreach programs by both the university admissions office and the College of Agriculture. As seen in Table 2, the highest outreach program attended was the Explore program in the student’s senior year with 112 (50%) invited and 20 (9%) attending the program. This was followed by the Explore LSU Program in the students’ junior year of High School with 41 (18%) invited and only 6 (3%) attending the program.

</tbody>
</table>

In the case of College of Agriculture outreach programs, data in Table 3 show the highest event attended was Explore College of Agriculture program with 17 (8%) of the subjects attending. College explore programs included explore programs held in Texas, Alexandria, Shreveport, Slidell, Houma and De Ridder. The College of Agriculture recruitment personnel attend these explore events and initiate contacts with the prospective students for the college. The other important outreach recruitment activities carried out by the College of Agriculture included Local-4H. Eight (4%) of the students were initially contacted during the 4-H outreach functions, five (2%) were contacted by the College of Agriculture staff during the State FFA judging competition and another 5 (2%) of the prospective students were contacted by the college staff during Local FFA judging competition. Telecounseling was the other recruitment strategy examined. This strategy involves the prospective student receiving a telephone call from an LSU Ambassador and or College of Agriculture recruitment personnel. All students who receive a Tiger Call also receive a piece of correspondence, even if no direct contact is made.

The final recruitment strategy examined in the study was the use of the Internet. Louisiana State University has established a web page that contains programs offered by colleges and departments. Application procedures are also provided on the LSU home page. A prospective student interested in a particular program can initiate the first contact with the university admissions office and the College of Agriculture using the Internet. This is a very new and recent recruitment strategy. Only 2 (1%) of the students used the Internet to initiate their first contact with the College of Agriculture. The remaining 224 (99%) of the subjects in the study did not employ this recruitment strategy.

The recruitment strategy that had the highest association with the dependent variable enrollment status among the students recruited to attend the College of Agriculture during the 1997-98 academic year, was considered as the strategy that had the highest zero order correlation with the dependent variable, enrollment status. The most appropriate correlation coefficient was established between the dependent variable enrollment status, and each recruitment strategy. Data in Table 5 show that the independent variable, the total dollar amount awarded to the students from the various financial aid sources, had the highest correlation with enrollment \( r = .48; n = 226; p < .001 \). The variable SCHOLAR (whether the student received a scholarship or not) had the second highest correlation with enrollment \( r = .46; n = 226; p = .001 \). In addition, the variables that had positive significant correlations with enrollment included STATE (defined as whether the student recruited was from within the state of Louisiana or not), \( r = .40; n = 226; p = .001 \) and PLUS (defined as whether the student received a parent loan for undergraduate student award or not) was also significant with \( r = .31; n = 226; p = .001 \). The other independent variables that had positive and significant correlations with the dependent variable are whether or not the student received a departmental scholarship, whether or not the student received an award from any private sources, whether or not the student received an unsubsidized Stafford loan, and whether or not the student was awarded a Federal Pell grant. The entire results of the correlations between the independent variables and the dependent variable are presented in Table 5.

Conclusion and Recommendations

Financial Aid is an important recruitment strategy and has an effect on the enrollment status of students. This conclusion is based on the findings that the dollar amount awarded to the students in this study had the single highest correlation of any of the variables tested ($r = .484, n = 226, p < .001$). Also, the variable whether or not the student received a scholarship, which is still part of financial assistance had a substantial correlation with enrollment status ($r = .458, n = 226, p < .001$). This conclusion is also supported by earlier research which showed that financial aid has in the past been used by colleges as one of the most effective recruitment strategies (Harris, 1997; McPheson and Schapiro, 1995; Hossler, 1994; Rosiak, 1987; Swann, 1987).

The researchers recommend that directors of financial aid and enrollment management professionals who have the responsibility for setting scholarship policy should carefully examine financial award process to ensure financial assistance goes to the students who need this assistance. As shown in this study, offering of a complete scholarship to a student or several awards to one individual student increases the total dollar amount which in turn influences the student’s decision to enroll in the college. The highest number of students in the study who received financial aid fell into the range of $ 9000 to $ 9999. As established earlier by Harris (1997), the amount of monies awarded in the scholarship offer was the best method to recruit high ability students. The mean ACT score for the subjects in this study was 24.99 implying that the college admitted high ability students. To better understand how the dollar amount awarded to students influences their decision to attend a given college, the researchers recommend the need to carry out a qualitative study of students recruited to attend the college and awarded financial assistance. This will provide individual information on the role financial aid played in influencing student decisions to enroll in the college. The geographic location of the student is an important factor in recruitment. Whether or not the student came from the state of Louisiana had an effect on the enrollment status of a student. This is based on the findings that the variable state had a positive and statistically significant correlation with enrollment ($r = .399, n = 226; p < .001$). Since the variable state (student coming from within state) was highly significant in this study, the researcher recommends a qualitative study that will focus on the reasons why students from within the state of Louisiana choose to attend LSU.

The total number of mail pieces sent by the college to prospective students is an important recruitment strategy and has an effect on the enrollment status of a student at the college level. This conclusion is supported by earlier research, which established that direct mail is one of the most effective recruitment strategies (Affleck, 1991; Sanders and Perfetto, 1991; Wheatley, 1987; Rosiak, 1987; Lewis, 1985; Smith, 1985; Porter, 1986). Harris (1997) in a more recent study at LSU established that mail was an important recruitment strategy at the university level. In this study however, mail sent by university admissions office to students recruited by the College of Agriculture was not found to be a significant factor. This could be explained by the fact that prospective students who establish initial contacts with the college may have more interest in contacts from the college (especially dean’s office) instead of the general mail from the university admissions office.

Campus visitation programs specially designed for prospective freshmen by the College of Agriculture and the university admissions office are essential recruitment activities. Despite the fact that attendance to campus visitation programs had lower percentages, the variables, Tiger Day senior (17%), Tiger Day juniors (2%), TAgger Day (1%),...
Tour (21%), and Preview LSU (3%). The variables Tour, Tiger Day senior attendance, TAger Day and Preview LSU entered the comprehensive, comprehensive recruitment and the most efficient recruitment models. Recruitment via the Internet is equally a new phenomenon in the field of college recruitment. This variable tends to be impersonal as there is no direct personal contact with the prospective student (Stoner, 1996). The researchers however recommend for further study that will explore the effectiveness of using Telecounseling and the Internet in recruiting students.

Implications for the Field of HRD

This study provides useful information regarding effective strategies for recruiting college students. HRD professionals as marketers should find the results of this study useful in identifying the needs of HRD's chief "customers"- that is learners. The marketing framework employed in this study should help in identifying and promoting planned learning experiences as a way of recruiting students who meet the mission of various colleges and HRD programs countrywide. Designing efficient recruitment strategies is one important way of understanding the needs of the learners during the recruitment stage. This study in particular, shows the most effective recruitment strategies employed by Louisiana Sate University admissions' offices and College of Agriculture. HRD researchers interested in marketing their programs and recruiting students who meet the mission of their programs should find the results of this study useful.

The Perceived Influence of Industry-Sponsored Credentials on Recruitment and Training in the Information Technology Industry

Kenneth R. Bartlett
University of Minnesota

T. Marshall Egan
Texas A&M University

Minu Ipe
Sujin Kim
Yuwen Liu
University of Minnesota

As the interest in industry-sponsored credentials grows, so do questions on the influence of these credentials on both the employee and employing organization. Perceptions of the influence of industry-sponsored credentials in the information technology industry are examined in this study of senior human resource executives and their IT employees from a sample of U.S. large firms. Further analysis examined differences in perceptions of the influence of credentials on recruitment and training between IT employees with and without industry-sponsored credentials.

Keywords: Information Technology, Recruitment, Training.

The increasing recognition that information technology (IT) represents the most significant enabling technology for organizations has considerable implications for human resource development (HRD). According to a report from the U.S. Department of Commerce (1999), IT allows for better management of information and innovation; has resulted in improved productivity and quality of life; and has improved the national standard of living. The creation, application, and use of information technology has spilled over into every sector of the economy, from the traditional IT industry, to manufacturing and services, transportation, healthcare, education, and government. From an HRD perspective, it is noted that IT changes not only the workplace but also the learning that is required to maximize human performance and corporate success (Marquardt & Kearsley, 2000).

There is little doubt that the IT industry has risen to prominence and is playing a dramatic and significant role in the U.S. economy. The use of IT has not only led to increased efficiency and productivity, but it has also resulted in new business models and new approaches to the organization and completion of work. The demand for skilled IT employees remains high despite the recent slowdown in the economy and the demise of many dot.com firms and other Internet related businesses (Hilton, 2001). A recently published Information Technology Association of America (ITAA) study (2001) stated that although demand for IT workers is down 44% from forecasts just a year earlier, estimates are that U.S. companies plan to hire an additional 900,000 IT workers during 2001.

At the same time that tremendous expansion in IT career opportunities has occurred, and is projected to continue, the pace at which new two-and four-year postsecondary graduates in computer science, engineering, and mathematics entering the workforce has shown no signs of increase and may even have slowed down. The situation is so serious that the U.S. Department of Commerce (1997) issued a warning that the shortage of IT workers could undermine U.S. innovation, productivity, and competitiveness in world markets due to factors such as the inhibition of cutting-edge technology, constrained industry growth, loss of trade, and increased labor costs. As a result of projected IT workforce shortages the IT industry, and firms dependent on IT workers, are examining a variety of strategies related to recruitment and retention. Recruiters are looking beyond the traditional pool of graduates for new workers in addition to seeking ways to attract and recruit employees from the non-IT related incumbent workforce.

Employers have tried to fulfill their need for IT resources by aggressive recruiting (including offering very attractive salary and benefit packages) from the domestic market, training and skill updating of their existing IT workforce, and hiring immigrant workers with IT skills through the H1B visa program. However, the gap between supply and demand remains. As a result, focus on alternative educational pathways to provide IT workers with the needed key technical skill sets has been renewed (Adelman, 2000). In this scenario, credentials offered by industry-based groups are providing organizations with qualifications on which to make decisions related to recruiting and
training of IT employees.

Problem Statement

The rise in the number of credential and certification programs is one of the most significant trends related to education for IT careers. A credential is defined as "a designation, mark, or stamp given to a person, organization, or program that has satisfied a set of standards" (Hale, 2000, p. xx). A certification is a form of credential awarded by an employer, a vendor, or an association or independent agency requiring passage of an exam benchmarked to predetermined occupational or professional standards that may or may not also require prior education and experience (Carnevale & Desrochers, 2001; Hale 2000).

Industry-sponsored credentials and certifications were developed to update the skills of well-trained workers and to address the shortage of qualified employees within the IT industry. IT industry-sponsored credentials (such as CompTIA A+, Microsoft Certified Systems Engineer, Certified Novell Engineer, Sun Certified Programmer for the Java Platform) have the advantage of enabling people to quickly learn a clearly defined set of competencies. Upon completion of a credential, many employees find that current market demand provides them multiple hiring opportunities.

Yet, the influence of IT credentials in recruitment and training is largely unknown. This study addresses this issue.

Theoretical Framework

This section reviews literature in the different fields that contribute to the framing of this study. The aim of this review is to highlight issues and research findings of significance to the current study rather than provide an exhaustive review of the literature. Much existing economic and education theory and research rests on the role and impact of qualifications and credentials as the key to workplace success and higher levels of earnings. As Wonacott (2000) detailed, the most prominent credentials for explaining differences in workplace attainment are the traditional educational credentials of diplomas and degrees. However, a new trend is emerging raising many questions about the current and future role of both these traditional credentials and the more recently developed industry-sponsored credentials and certification.

Cervero (2001) recently listed the rise in credential programs, and their frequent connection to regulation of professional practice, as one of the top five trends in continuing professional education. Bassi (1999) suggested that organizations offering for-profit training and credentials are expanding to fill the growing need for highly skilled workers in corporate America. Argentsinger (2001) described credentials as being faster, cheaper, and more focused than traditional college credentials, resulting in industry-sponsored credentials becoming the continuing-education currency of choice. This trend has produced a delivery system for credentials and certificates that is "a labyrinth of for-profit and not-for-profit postsecondary institutions, professional, industry, and trade associations, commercial vendors, and government" (Carnevale & Desrochers, 2001, p. 26).

Perhaps no other industry has experienced the growth in credentials to the extent of the IT industry which now offers well over 100 industry-sponsored credentials (www.certmag.com). It is important to recognize that credentials extend far beyond the companies and organizations that create and maintain credential programs. Tittel (2001) described the size of the billion dollar per year "certification aftermarket" of testing centers, IT training companies, publishing companies, practice test vendors, credential authorities, online mentoring, and resource providers. IT credential programs appear to achieve multiple aims for both individuals and organizations. Most importantly credential programs provide employees, either looking to enter or to advance within the IT industry, with focused training (Adelman, 2000). IT credentials and certificates also enable people to learn a clearly defined set of competencies that are frequently tied to hiring opportunities (Carnevale & Desrochers, 2001). However, not just entry-level employees benefit from industry-sponsored IT credentials. Firms frequently tie promotion to the receipt of advanced level credentials involving job-related knowledge and experience. At the organizational level, industry-sponsored credentials are believed to play an important role in the determination of desired knowledge, skills, and abilities for IT employees. Requiring credentials and certifications specifically related to a job is said to make the recruitment process more efficient, and aid in assessments of applicant’s ability and influence decisions related to participation in firm-sponsored training (Ray & McCoy, 2000).

Regardless of the disagreement in the aims of IT credentials, a situation has emerged in which IT professionals, human resource (HR) executives, and trainers struggle with credentials while "the certification frenzy swirls about them" (Ray & McCoy, 2000, p.1). The recent development and rise in status of IT industry-sponsored credentials raises many questions in terms of their role as signaling devices for hiring, promotion, training and career development. Furthermore, it is not known what the value and impact of IT industry-sponsored credentials is for
both individuals and organizations. Despite the importance of recruitment and training to the IT profession, comparatively little research has been conducted in this area (Agarwal & Ferratt, 1998).

The perceived influence of different types of educational qualifications is an issue of great concern within the IT industry in light of the proliferation of industry-sponsored credential and certification programs. Despite potential reliability concerns, various IT-related firms highlight their own research into organizational results when comparing certified IT employees to those without credentials (IBM, 1999; IDC Incorporated, 1999; Lewis, & Sappington, 1993; The Computing Technology Industry Association, 2001). These studies suggest that managers view employees with credentials to possess greater knowledge, to be more productive, to provide improved customer support, and to have higher commitment while concurrently requiring less training investment (IDC, Incorporated, 1999). A study of IBM certification found positive influences on measures of business results such as increased revenue, employee productivity, and customer satisfaction from employees who hold IBM credentials (http://www1.ibm.com/certify/program/roistudy.shtml). An alternative view would support that a college qualification would be more highly valued than a credential offered by industry with existing research suggesting that a college baccalaureate degree is the most marketable qualification (Brown, 1999).

Existing theory provides a strong conceptual framework for examining the role of industry-sponsored credentials and certification in recruitment and training for IT workers. In terms of recruitment, qualifications and credentials have long served as signals for organizations. Signaling theory (Spence, 1972) suggests that because organizations have incomplete information regarding the knowledge, skills, and abilities of applicants, inferences are made by employers through the interpretation of qualifications and credentials presented by applicants (Barber, 1998). Prospective employees communicate to organizations, in part, by utilizing credentials as signals of their expertise and potential. This study examined the perceived influence of different qualifications and credentials on the recruitment and training process from both the employer and employee perspective. The value that organizations place on different qualifications can also act as a signal to applicants. For example, signaling theory suggests that organizational preferences for either IT industry-sponsored credentials or more traditional two or four-year college qualifications provide applicants with information about what it would be like to be a member of that organization and what type of skills and knowledge they value (Greening & Turban, 2000). Drawing on this theory, the current study examined the perceptions of HR executives and IT employees on the differences between industry-sponsored credentials and traditional college qualifications on influencing recruitment decisions for IT employees.

In addition to the signaling role for entry into an organization, qualifications and credentials also have served as a foundation for advancement and employee development decisions. Turner (1960) suggested that career mobility operates under two opposing systems—contest-mobility and sponsored-mobility. Under the sponsored-mobility system, select employees receive high levels of support, guidance, training, and mentorship from supervisors, whereas, the contest-mobility system implies an open and fair contest for each promotion decision. The contest-mobility system assumes that employee success is the result of level of effort, abilities, as well as the level of education and training. The current study adopted the contest-mobility approach in examining the perceptions of HR executives and IT employees towards training. Based on the contest-mobility approach, it was assumed a priori that these two employment categories would have different perceptions towards the influence of industry-sponsored credentials in ongoing training for IT employees. More specifically, it was thought that both HR executives and IT employees would perceive different benefits of having industry-sponsored credentials as compared to a college degree in terms of how this would influence their attitudes towards training. Given the lack of existing research the nature of this difference was not hypothesized and an exploratory approach was taken to this research question.

Research Questions

The core research question guiding this study was: what are the perceptions of HR executives and affiliated IT employees regarding the influence of IT industry-sponsored credentials on recruitment and training? This broad question was refined into three research questions.

Research Question 1: Do differences exist in the perceptions of HR executives as compared to IT employees on the benefits of industry-sponsored credentials on recruitment?

Research Question 2: Do differences exist in the perceptions of HR executives as compared to IT employees on the benefits of industry-sponsored credentials on training?
Research Question 3: Do differences exist in the perceptions of the role of industry-sponsored credentials on recruitment and training between IT employees with industry-sponsored credentials as compared to IT employees without industry-sponsored credentials?

Method

This study collected data from HR executives and incumbent IT workers to explore and compare differences in perceptions among employers and employees toward the influence of industry-sponsored credentials. These two employment categories were selected as both executives and employees are likely to have different attitudes toward the influence of certification on decisions related to hiring and training. A sample of HR executives provided data on both organizational policies associated with recruitment and training, as well as their individual perceptions of the influence of IT credentials in the recruitment and training process. In the second stage of data collection, a sample of incumbent IT employees from the same firms provided individual response data on the same issues.

Population and Sample. The sample was chosen from a population of large firms. For the purpose of this study, a large firm was defined as having 500 or more employees. Firms were identified from the ReferenceUSA database, which contains more than 12 million listings of U.S. and global organizations with offices in the United States. Employing the criteria of 500 or more employees resulted in the selection of 3,330 firms. Since access to sampling frames of individual IT employees was unavailable, a letter of invitation to participate was sent to the Vice President (or equivalent title for the most senior manager of HR) to all 3,330 firms with 500 or more employees. The letter detailed the purpose of the study and the commitment required from employers and employees. A total of 161 executives responded to the invitation with 111 indicating that their firms had policies prohibiting their employees from participating in this type of research. The remaining 50 firms agreed to participate in the study. A self-administered questionnaire was mailed to HR executives along with instructions on procedures to recruit their firm's incumbent IT workers for the employee study. At the end of the data collection period, a total of 33 out of the 50 HR executives returned complete questionnaires representing a 66% response rate. A total of 245 complete employee surveys were received from IT workers at 13 of the 50 firms agreeing to participate (26% response rate). As we relied on the HR executives to distribute information regarding data collection to their IT workers, it was not possible to calculate the response rate for IT employees at the individual firm level.

Instrument. The HR executive instrument was a self-administered paper-and-pencil questionnaire containing open-ended items to determine the existing number of IT employees, the number hired in the past year, the number of current IT vacancies, items related to firm characteristics, and the perceived influence of industry-sponsored credentials on recruitment and training. The IT employee survey was a self-administered Internet based questionnaire designed to assess the perceptions of incumbent IT workers regarding the number and type of credentials held and their perceived influence on recruitment and training. Apart from the demographic information and firm characteristics, the same questions were asked of both HR executives and IT employees. The response items were measured on a five point Likert-type scale, anchored with strongly disagree to strongly agree. This measurement of the response items was based on a previous study of human resource management issues in the IT industry (Tu, Ragunathan, & Ragunathan, 2001). The content validity of the instrument was determined with review from an expert panel of five academics and five IT managers.

Data Analysis. Data analysis included descriptive statistics and t-tests to determine if significant differences in the perceptions of the benefits offered by industry-sponsored credentials exists between HR executives and IT employees, and between IT employees with and without industry-sponsored credentials.

Limitations. The principal limitation of this study is the low response rate obtained from both HR executives and IT employees. However, the response rate from those firms that did agree to participate is at or above the levels generally considered acceptable for this type of research. The generalizability of the results is limited to the degree to which other populations resemble the one studied. Furthermore, the lack of definition of the term IT employee may have caused confusion given the well-documented difficulties in defining the boundaries of occupations within the IT industry. The sample was also limited to the degree to which the sampling frame provided correct information. Based on the number of returned surveys some concern can be leveled at the accuracy of the database on U.S. firms and HR executives used in the study.
Results

The 33 responding HR executives represented firms geographically dispersed across the U.S. The average number of IT employees in these firms was 423 employees with the mean number of current IT related vacancies 4.8, and the mean number of IT employees hired over the past year was 50.7. According to the HR executives, it takes an average of 7.5 weeks to hire a new IT employee. One third of the 245 IT employees who participated in the study had either a four-year college degree or master’s degree (34%). The largest reported education category for IT employees (38.5%; n = 94) was “some college or formal training” as the highest level of education. The attainment of a two-year associate’s degree was indicated as the highest level of education by 22.1% (n = 54), a four-year college degree by 25.4% (n = 62), and a master’s degree by 8.6% (n = 21). Almost seventy percent (69.4%, n = 170) of employee respondents indicated that they had earned one or more IT industry-sponsored credential. The 245 IT employee respondents in the study held a total of 406 IT credentials. The mean number of years employed in the IT industry was 7.3 years and the mean number of years employed in their current organization was 10.3 years.

Firm Characteristics. The perceptions of HR executives reveal that IT industry-sponsored credentials are becoming increasingly important to hiring decisions in many organizations. An overwhelming number of the HR executive respondents (84.8%, n = 28) pointed out that they notice an increasing number of applicants with industry-sponsored credentials responding to IT job advertisements. Employers (HR executives) also indicated that they were beginning to use IT industry-sponsored credentials as the qualification of choice for some of their IT positions. Over two thirds of the employer respondents (66.7%, n = 22) revealed that they specify IT certificates/credentials for certain IT positions. With a mean of 3.63 (on a five point scale), a large number of respondents (62.5%, n = 20) rated IT industry-sponsored credentials as either important or very important to their non-managerial level IT employee-hiring decisions. Nearly half the HR executives (42.4%, n = 14), either agreed or strongly agreed that their organizations require employees to maintain and update their IT related credentials. Finally, two thirds of the responding HR executives (66.7%, n = 22) either agreed or strongly agreed that their organizations provided funding for credentials programs facilitated by an outside vendor.

Perceived Influence of Credentials on Recruitment and Training. Table 1 compares the perceptions of HR executives and IT employees on the benefits of credentials to recruitment and training.

Note: The percentages and means represent those respondents who either agreed or strongly agreed to the above statements on a five-point scale. * Significant at p< 0.05.
Research question 1 examined if differences exist between the perception of HR executives and IT employees as to the influence of industry-sponsored credentials on the recruitment process. Both employers and employees perceive one of the main benefits of industry-sponsored credentials to be the identification of the applicants' job related skills and knowledge. Employees were stronger in their belief that industry sponsored credentials make the recruitment process easier, cheaper, and more time efficient than their HR executives. However, none of the differences between employers and employees related to recruitment were significant.

Research question 2 explored the differences between employers and employees in terms of the perceived benefits of credentials to training. Employers were more likely than IT employees to believe that industry-sponsored credentials reduce training costs, the time taken for new employees to learn the job, and improve problem solving abilities. However, the only significant difference was the perceived benefit that employees with IT credentials have improved theoretical understanding of IT products, networks, and customer needs.

Perceived Influence Between Employees With and Without IT Industry-sponsored Credentials. A series of independent-sample t-tests were conducted to answer research question 3 which explored differences between IT employees with and without industry-sponsored credentials on the perceived influence of industry-sponsored IT credentials on recruitment and training (see Table 2). An independent sample t-test comparing IT employees with no IT credentials to those with one or more IT credentials. The perception of the influence of credentials on recruitment produced a statistically significant difference ($t = 2.20, p = .01$) for the item "makes recruitment cheaper". A significant difference was also found ($t = -3.01, p = .002$) for the item "makes recruitment more time efficient". Significant differences were also found for two items related to training. The first item was "credentials improve theoretical understanding of IT products, networks, and customer needs" ($t = 2.40, p = .02$). The second item was "credentials increase the chance of success for new employees" ($t = -2.23, p = .02$).

Conclusion and Discussion

Certification and credentialing are noted as being hot topics for continuing education and training with Carnevale and Desrochers (2001) describing the challenges and opportunities they present to the delivery of IT training and development. Yet, the impact of industry-sponsored credentials remains largely unexamined, raising questions regarding their role and place in organizational decisions. This study provided an initial look at how both employers and employees view credentials. This research explored the perceptions of human resource executives and incumbent IT employees on the influence of IT industry-sponsored credentials in recruitment and training.

Examining the mean scores the findings from this study suggest that HR executives are more likely to agree than disagree that IT industry-sponsored credential assist in the recruitment process, especially in helping to identify skill sets required by applicants for IT positions. The majority of HR executives surveyed were more likely to agree than disagree that industry-sponsored credentials reduce training costs. However, the findings of this study show that very few significant difference exist between HR executives and IT employees in terms of the perceived influence of industry-sponsored credentials on recruitment and training. The only significant difference between the two groups (employers and employees) was a training related benefit that employees with IT credential have improved theoretical understanding of IT products, networks, and customer needs. This may suggest that employees with specific industry knowledge recognize the level of theoretical understanding that credentialled employees posses, whereas HR executives may believe that the product specific focus of credentials results in employees who lack a broader level of theoretical understanding of IT products, networks, and customer needs.

It is a reflection of the growth and acceptance of IT industry-sponsored credentials that almost 70% of the 245 employee respondents in this study have at least one IT-sponsored credential. In comparing employees with and those without industry-sponsored credentials we found a total of four significant differences, two related to recruitment and two related to training. The recent transition to many people earning credentials with little or no IT industry experience with expectations of finding immediate employment and a high salary has potentially created this situation where those IT employees with credentials view their perceived influence differently from employees without IT industry-sponsored credentials.

The perceptions of HR executives toward IT industry-sponsored credentials are seen as being important, as the attitude of senior ranking HR executives no doubt influence the policies and management practices of the firm. Credentials play an important role for defining the knowledge base and skill level for an industry. This then becomes a useful tool for human resource managers involved in recruiting IT employees and for HRD managers involved in making policies that support the required updating of their employees' credentials. The opinion that HR executives have towards industry-sponsored credentials has implications for educators, trainers, IT employees, and HR executives to share knowledge about various credentials, their individual reputations, and their influence on decisions related to recruitment and training and development. Based on the current findings it would be interesting to note where HR executives gain information about IT credentials. Given the shortage of research on IT industry-sponsored credentials it is possible that HR executive and employee attitudes are being shaped by the portrayal of IT credential in the media and in various trade and professional association publications.

The decision to hire, promote, or advance an IT employee is dependent on a complex array of factors that seek to match the knowledge, skills, and abilities of applicants to the vacancies or opportunities existing within the firm. The attitude of senior human resource executive, IT managers, IT staff, and applicants towards IT industry-sponsored credentials and their utility to the employee, the return to the organization, and responsibility of update are likely to be important issues. Much additional research on this issue is needed. The credentialing issue has created much interest for HRD as to the influence of an industry developed and sponsored credential of skill sets on decisions related to recruitment, training, and advancement. This study has focused on industry-sponsored credentials from one industry, yet it must be acknowledged that credentials are now a major issue in the education and training for many occupations and professions. However, much additional work remains to explore the differences in how employers and employees view credentials in terms of both initial entry and for the long-term development of necessary skills, knowledge, and abilities to ensure that an organization is able to realize the sustained competitive advantage represented in their human resources. The findings of this study suggest that a closer examination is needed to examine the perceived influence of credentials on specific aspects related to recruitment and training. For example, does the possession of a industry-sponsored credentials influence the selection of applicants invited to an interview, the type of pre-employment testing, and the examination of the applicants job background with contacts of references? Future research should also explore individual differences among IT employees with and without IT industry-sponsored credentials in terms of the amount and type of training participation as well as the resulting outcomes from training participation.

The Role of Training and Development in Newspaper Recruitment Advertisements

Kenneth R. Bartlett
Harriett R. Porter
University of Minnesota

This project examined newspaper job advertisements to identify if references to training and development are increasingly listed as a benefit of employment. The study is framed by psychological contract theory and the broader level social exchange theory. Using well-validated content analysis techniques, the newspaper job advertisements for three major U.S. metropolitan areas were examined for a one-week period in 2001 and compared to the same one-week period from 1991.

Keywords: Recruitment Advertisements, Psychological Contract, Training

In a rapidly changing business environment it is noted that training and development activities assume greater importance for organizations (Ulrich & Lake, 1990) with several studies supporting the documented increasing organizational expenditure on human resource development (HRD) in recent years (ASTD, 2001). The emergence of the knowledge economy only serves to increase the importance of a well-skilled labor force that receives ongoing training, development, and education in the face of the constant changes, which now define today's business environment. Based on figures from the organizations included in the 2001 Association for Training and Development (ASTD) State of Industry Report many U.S. companies are now spending over $1.2 million on training annually (p. 5). The report also indicates that at least 37 U.S. companies have an average expenditure on training of $33 million (p. 7). Goldstein (1993) noted that more than 90% of all private organizations have some type of systematic training program.

Problem Statement

Despite evidence on the increasing provision of training no research currently exists to determine the extent to which specific mention of training and development opportunities are made in newspaper job advertisements. Furthermore, it is not known if references to training and development may have changed over time, particularly in light of the new psychological contract between employers and employees in which additional features and benefits of a job are made available to prospective employees. If employers accept the new psychological contract they are likely to acknowledge this in their attitude, behavior, and communication with existing and potential employees.

One manifestation of this acknowledgment is the wording of recruitment advertisements. The significance of this acknowledgement and the value of this study examining changes in wording related to training in recruitment advertisements is that it supports the view that organizations increasingly recognize the strategic investment of training. This confirms the strategic role of human resources as a source of competitive advantage as advocated by the resource-based view of the firm (Wright, Dunford, & Snell, 2001).

Theoretical Framework

Two somewhat contradictory theoretical explanations are offered for the recent documented increase in organizational training expenditure. Martocchio and Baldwin (1997) suggested the rise in training, especially in large corporations, is the result from the on-going transition towards a more strategic approach to both human resource management and HRD. This viewpoint seems well supported in the largest, often times global, organizations who have developed strategic plans for every aspect of their business operation, including the development of their human resources. Yet, despite many calls for HRD to adopt a more strategic approach the literature suggests that an enormous amount of training expenditure produces no real competitive gain or strategic advantage for the firm (Swanson, 1995). Therefore, the adoption of a strategic approach to training seems to provide only a partial explanation for the increased role and investment in training.

Alternatively, it is argued that the increase in training and development investment can be attributed to the belief that training is viewed as a "right of membership and as a requisite for elevation to an elite position" (Scott & Meyer, 1991, p. 298). This is suggestive of a social desirability function of training. As firms compete for scarce
human talent they are required to alter their perception of what the organization is required to offer in return. This is in keeping with the concept of the psychological contract literature, which examines the employment relationship as being embedded in the context of social exchange theory (Blau, 1964). The terms and conditions of this reciprocal exchange between employee and their organization are defined in both formal written contracts and within in the psychological contract (Rousseau, 1989). In 1998 Paul Sparrow, a professor of international human resource management in the United Kingdom, argued that the field of human resource development could learn much from this construct.

Psychological contracts describe an individual’s beliefs about their employment relationship and are defined as “employees’ perceptions of what they owe to their employers and what their employers owe to them” (Robinson, 1996, p. 574). The psychological contract guides employee attitudes about what they think they are entitled to receive, or should receive, because of real or perceived promises from their employing organization. Although, it is yet to be separated from more general studies of human resource management, there is evidence to suggest that HRD policies and practices also affect the psychological contract (Rousseau & Wade-Benzoni, 1994). As the psychological contract between employer and employee has expanded from satisfying immediate safety and compensation needs to a broader range of job challenge and career development issues the role of HRD has assumed greater importance. In other words, it is hypothesized that prospective employees will expect training opportunities in recruitment advertisements in return for their efforts related to the job and employers in turn recognize the need to provide training and development opportunities to recruit and retain human resources.

The psychological contract concept represents an extension of social exchange theory as the employment relationship is embedded in the context of this broader theory. Social exchange theory (Blau, 1964; Homans, 1961) describes the social relations among individuals and organizations where the relationship involves the exchange of valued items (Cook & Whitmeyer, 1992). Sinclair and Tetrick (1995) noted that this is one of the most commonly used frameworks for understanding individuals’ work-related attitudes and behaviors. Social exchange theory suggests that self-interest drives people’s social interactions. When this theory is extended to employee interactions with the organization in which they work or are considering working for, it implies that interactions between employees and the organization will continue as long as both parties derive benefits from the exchange. When employees perceive that the interactions are more beneficial than the costs, e.g., they are treated fairly or their learning needs are being met, it is more likely that the employee will honor their side of the relationship by behaving in ways that benefit the organization (Konovsky & Pugh, 1994).

When an individual employee perceives that the contributions they make obligate the organization to reciprocate with contributions, a psychological contract emerges. It should be noted that psychological contracts are defined by their perceptual and individual nature, making them distinct from both formal written contracts and implied contracts (Robinson & Wolfe-Morrison, 1995). Furthermore, psychological contracts are highly subjective (Guzzo & Noonan, 1994). If the employee perceives their contract to have been violated by the organization, the result may be a lower level of commitment from the employee to their employing organization (Burack & Singh, 1995). Empirical support for this proposition was found in a longitudinal study of master of business administration (MBA) students who were tracked over the first years of their employment following graduation (Robinson, Kraatz, & Rousseau, 1994).

Existing research supports the idea that employees may perceive a psychological contract violation when the organization does not appear to fulfill important obligations (Lewis-McClear & Taylor, 1997). Harrell-Cook and Ferris (1997) noted that organizations face competing pressures from stockholders for short-term financial performance, which may limit the extent of HR investments such as training and development. These authors noted that “if employees perceive that they are slighted, they may conclude that they are receiving unfair treatment by the organization” (p. 332). Extending this argument, it maybe that applicants who do not see prominent mention of training and development in job recruitment advertisements may direct their job search efforts elsewhere. Schein (1980) argued that psychological contracts act as powerful determinants of organizational behavior. Human resource management practices are acknowledged as affecting the psychological contract (Lucero & Allen, 1994; McLean-Parks & Schmedemann, 1994). Examples of how HR practices shape the psychological contract are provided by Rousseau and Wade-Benzoni (1994):

How jobs are advertised ("great advancement potential," “opportunity for salary growth"), the way the organization is portrayed during recruitment interviews (“this organization provides plenty of training"), comments made in performance appraisal review (“keep up the good work and we will move you up"), and compensation systems (wages based on rank or time on the job), all send strong messages to individuals regarding what the organization expects of them and what they can expect in return (p.465).
Given the above examples it is not surprising that Rousseau and Greller (1994) stated "a major function of human resource management is to foster an appropriate psychological contract" (p. 385).

More recently, it has also been suggested that HRD managers have a role in defining and maintaining employees' psychological contracts (Sparrow, 1998). Training is viewed as a human resource practice that can be controlled or managed to elicit a desired set of unwritten reciprocal attitudes and behaviors. Desired work-related attitudes include job involvement, motivation, and organizational commitment. In return for demonstrations of desired work-related attitudes and behaviors employees have altered their view of many HR practices, including HRD. Many employees now view training as a benefit of employment as it is commonly regarded as a means for advancement (Ashenfelter & LaLonde, 1998). This could suggest that employees seek employment in firms that offer and promote training and development opportunities. At the same time, organizations involved in recruitment desire to have a large applicant pool of not only qualified applicants but of future employees likely to be highly committed and accepting of the need for lifelong learning.

This argument is supported by Finegold (1998) in his reflection of changes in employee loyalty. He suggested that historically an organization was able to offer job security in return for employee effort. However, times have changed as evidenced by repeated rounds of re-engineering, restructuring, downsizing, and outsourcing. The organization, although no longer able to offer employment security, promises to increase the employability of its workers by investing in their continuous skill development and provides opportunities and rewards for using these skills (Finegold, 1998). Additional support for this proposition was found in the recent content analysis study of the new employment relationship in that it is now considered the "employers' responsibility to provide training, education, and skill development opportunities and the employees' responsibility to take advantage of those opportunities to develop and maintain their skills" (Roehling, Cavanaugh, Moynihan, & Boswell, 2000, p. 312-313).

Extending this argument to the current study, it is suggested that firms now place greater emphasis on promoting training and development opportunities to assist in recruiting new employees. This is likely to be a key feature of the job interview and initial orientation training to promote the formation of desired psychological contract. This emphasis on training and development as a benefit of employment is also likely to be present in formal communication from the organization in order to attract applicants for vacant positions, such as recruitment advertisements in newspapers.

Research Question

The core research question guiding this study was: are references to training and development in newspaper job announcements more likely to be seen in 2001 than they were in 1991? More specifically, it was thought that based on existing literature and the changing nature of the psychological contract that the percentage of job advertisements referencing training and development would be higher in 2001 as compared to the same time period ten years ago. This was tested with the following two research hypotheses.

Hypothesis 1: The percentage of newspaper advertisements referencing training and development will be greater for one-week in 2001 as compared to the same time period in 1991.

Hypothesis 2: The proportion of advertisements referencing training and development for one week in 2001 will be significantly different as compared to the proportion from the same time period in 1991.

Method

To explore if firms are more likely to mention of training and development opportunities we used newspaper recruitment advertisements to examine the number of references made to training and development. It was thought that based on the existing literature that firms may view announcements of training and development in recruitment advertisements as a way to demonstrate their support and commitment towards individual development, improved organizational performance, as well as reflecting the recognition that training is a socially desirable aspect of the job that employees now view as a right of employment.

Previous research on newspaper job announcements found that opportunities for advancement have traditionally been ranked high among job attributes by job seekers (Jurgensen, 1978). Many job postings now provide more detailed information on the amount and type of training applicants can anticipate in addition to details on the job characteristics, salary, and benefits. This supports the findings of Barber and Roehling (1993) that applicants find job postings with more detailed information more attractive than advertisements that only provide sketchy details of the job. Existing studies have examined how newspaper job advertisements have changed over time to reflect the
changing job duties of HR managers (Redman & Mathews, 1995) and in the desired specialty field of physicians that hospitals seek (Seifer, Troupin, & Rubenfeld, 1996). Yet, no existing research has examined the wording of recruitment advertisements in relation to references of employer provided training and development.

This research study used a content analysis methodology to gather frequency and percentage data to examine if references to training in newspaper job announcements occur more frequent in 2001 than in 1991. The well-supported content analysis technique of Kassarjian (1977) was used to examine the text in newspaper job advertisements. Content analysis can be defined as "an observational research method that is used to systematically evaluate the symbolic content of all forms of communication" (Kolbe & Burnett, 1991, p. 243). It is noted as "being a scientific, objective, systematic, quantitative, and generalizable description of communication content" (Kassarjian, p.10). This method of research inquiry is well established in marketing, social psychology, political science, and consumer research yet no evidence exists within the HRD literature. Despite the existence of multiple options available for an employer seeking to promote a vacant position the newspaper advertisement remains the most commonly used method to advertise job opening (Schreier, 1983). To determine if references to training are more prevalent in 2001 than ten years ago we examined newspaper job advertisements from three major U.S. cities for a one-week period in 2001 and compared this to the same newspaper for the same week in 1991. The ten-year time period was selected as previous content analysis studies of related to changing aspects of employment have used this time horizon (Redman & Mathews, 1995). Additionally, it was thought that this would be an adequate time period in which to notice changing trends that have mirrored changes in the psychological contract (Sparrow, 1998).

Sample

The procedure for selecting the cities was designed to reduce a potential regional influence. The analysis was limited to newspapers from U.S. major cities. Recent U.S. Census (2000) data was used to identify cities having a population of or greater than 1,000,000 in their Metropolitan Statistical Area (a geographic entity defined by the Office of Management and Budget for use by federal statistical agencies, based on the concept of a core area with a large population nucleus, plus adjacent communities having a high degree of economic and social integration with that core" http://factfinder.census.gov/home/en/whatsinaff.html). To avoid over-representation of East Coast cities, the list of all 49 MSA's meeting the population requirement of 1,000,000 or more residents were divided into three categories based on their respective time zone. The cities in the Mountain and Pacific time zone were combined due to the small number of MSA's within the population parameters in the Mountain time zone. The ten largest cities in each of the three regions were listed (a total of 30 MSA's equally dispersed on 10 each on the the East Coast, Mid-section, and West Coast). A random number from one to ten was selected to produce one city from each region. The three selected cities were Atlanta, Minneapolis, and San Francisco. The reason that the study focused on only three cities is because of the quantity of data that one week of newspaper advertisements from both 1991 and 2001 generates. This selection procedure for the sample was thought to reduce any potential regional bias in selecting cities from which to examine newspaper recruitment advertisements. The largest daily newspaper in each of the three cities was selected. Initial analysis revealed that the vast majority of recruitment advertisements appear on a single day of the week, Sunday. Therefore, the final sample was all newspaper job recruitment advertisements from the Sunday edition of newspapers from three large U.S. cities for the same one-week in 1991 and 2001. This resulted in a total of 6,553 advertisements for 1991 and 5,249 for 2001.

Procedures

The newspaper job announcements were read and classified by the absence or presence of training opportunities mentioned as a feature of the advertisement text. Training was defined as reference to one or more of the following terms: training, development opportunities, career development opportunities, tuition reimbursement policies, CEU assistance, and organization supported advancement opportunities. All newspapers from 1991 are now contained only in microfilm format. All pages with job advertisements were printed directly from the microfilm reader. The advertisements from 2001 newspapers were cut directly from the purchased editions. Two copies of each advertisement were made with both researchers reading and highlighting each reference to HRD. This procedure provided an easily identifiable mark to assist in the inter-rater reliability process. Using this method an inter-rater reliability of 98.5% was achieved. A second reliability measure was conducted four weeks after the first analysis. Each researcher re-analyzed a random sample of 200 advertisements for a test-retest reliability measure. As detailed
in Table 1 all of the reliability coefficients exceed the .80 coefficient cutoff points suggested for content analysis (Kassarjian, 1977).

Results

Table 2 presents the total number of advertisements for the week for the two years under investigation, the frequency of advertisements referencing training, and the percentage of total advertisements that referenced training. The total frequency of newspaper job advertisements in the three selected cities for 1991 was 6,553 advertisements and 5,249 for 2001, representing a reduction of 1304 (19.89%) job advertisements over the one-week period for the two years under investigation. The number of newspaper job advertisements with reference to training in the three selected cities for 1991 was 445 and 408 for 2001.

</tr>
</tbody>
</table>

While the number of references to training actually decreased the findings support hypothesis 1 in that the percentage of job advertisements referencing HRD is higher in 2001 as compared to 1991. Approximately 7.77% of advertisements in 2001 contained a reference to HRD compared to 6.79% in 1991 despite the overall reduction in the number of job advertisements for the week under investigation.

To examine the significance of the difference between the proportion of advertisements referencing training and development in 2001 and 1991 a comparison test for two proportions was performed for each city. This test considered variation in a categorical variable and two categories. The categorical variable was the yes or no response to a reference to training and development in an advertisement and the two categories were the years 1991 and 2001. Given the large sample (number of total advertisements) the Z-score for the test statistic was calculated for the proportion of advertisements with reference to training for each of the three cities in both 1991 and 2001. The formula for this equation is presented below:

\[
Z = \frac{\left(\hat{p}_{1991} - \hat{p}_{2001}\right) - 0}{\text{s.e.}\left(\hat{p}_{1991} - \hat{p}_{2001}\right)}
\]

Results shown in Table 3 indicate that the proportion of advertisements referencing training in 1991 and 2001 is significantly different in two of the three cities. More specifically, a significant difference in the proportion of advertisements with reference to training as compared to all job advertisements was found in Atlanta and San Francisco but not Minneapolis. This offers partial support for hypothesis 2.

32-3
Discussion

Existing literature supports that there appears to be widespread agreement that organizations now recognize the value of providing training opportunities. Existing research also has suggested that employees are increasingly seeking growth and educational opportunities as a feature of their work in response to the changing psychological contract, which has placed more emphasis on employees being more self-directed in gaining the skills, knowledge, and abilities needed for not only their current job but also future jobs (Roehling et al., 2000). Yet, no research has investigated if employers are increasingly offering training as a benefit of employment in their communication with potential job applicants. This research study sought to address this situation by examining the text of newspaper advertisements to determine if references to training and development are more common in 2001 than in 1991.

Results from this study showed that despite a reduction in the overall number of job advertisements placed in the newspapers of three large U.S. cities the percentage of advertisements with reference to training has increased. The reasons for the overall drop in the both the number of advertisements and the numbers with reference to training is no doubt due to a wide variety of factors including the both the local and national labor market. Furthermore, the emergence of the Internet as a recruitment method may have reduced the number of advertisements placed in newspapers. It was for this reason that the research hypotheses examined the percentage and proportion of advertisements referencing training rather than the frequency.

The proportion of advertisements referencing training and development in 2001 was found to be significantly different that the proportion referencing training and development a decade earlier in two of the three cities we examined. We are unable to offer an explanation for why one city (Minneapolis) would not have produced a significant difference in proportion in the number of advertisements that reference training. This is perhaps a result of the type of jobs advertised for in this MSA. In conclusion, both research hypotheses in this study were supported or partly supported suggesting that employers' are more likely to make reference to training as an aspect of their communication with potential job applicants for positions advertised in the newspapers three selected major U.S. cities in 2001 than they were a decade earlier.

We believe that trends in recruitment advertising are an excellent way to track changes in how both employers and employees view the importance of training within the context of the changing psychological contract. More detailed analysis of the advertisement text is needed to fully understand the context of how employers' position training and development to potential job applicants. Additional future research should investigate variables related to the position or occupation being advertised to determine if training and development is more likely to be offered with certain occupations. Similarly, there may well be an industry affect so efforts to categorize the organizations placing advertisements into industry clusters would provide additional information on this topic. Finally, future research on references to training and development in newspaper advertisements should examine if the findings of this study are consistent in other countries. A potential international extension of this research would be to replicate this study in a sample of cities and countries to determine if the increased reference to training and development in newspaper advertisements is confined to the United States or if it reflects a global trend in response to the acknowledgement of both employers' and employees' to the growing importance of training and development for organizations and individuals.

Implications from the findings of this study suggest that HRD practitioners could play a greater role in the recruitment process. More specifically, HRD professionals should work closely with HR managers and recruiters to produce effective recruitment announcements that highlight the organizational commitment to development human resources. Additional research is needed to determine what reference to training and development job applicants are expecting to see in recruitment advertisements and if this influences the decision to apply.

The results from this research suggest that employers' are increasing the frequency with which they reference training in job advertisements, which may influence the expectation that employees' (both current and newly hired) have for both access to training and the amount of participation in training and development. This expectation that employees' have towards training has implication for how HRD is approached by the organization. Perhaps employee attitudes towards their expectations and the reality of HRD support from the firms influences work-place attitudes, such as organizational commitment, job satisfaction, and turnover intentions, as well as measures of individual performance. HRD professionals should continue their efforts to develop and deliver training, career development, and organization development for individual and organizational learning so that future replication studies of this research finds that the trend towards increased references to training and development in job advertisements continues.
The findings of this research should be interpreted with recognition of the limitation of this study. The primary limitation is the examination of only one day from three large U.S. cities. However, the quantity of data and time required to examine each advertisement impede attempts to get a more representative sample in terms of the number of days and cities from which to examine advertisements. As such the generalizability of the results from this study are limited to the degree to which other populations resemble the one studied. An additional limitation of the study was the lack of definition of the term training. In an attempt to be unique and creative in their recruitment efforts organizations use a variety of words to reflect their commitment of employee development. These words and phrases do not always confirm to the agreed upon definitions of HRD researchers. Future research should consider using existing definitions of training and HRD to generate words from which to analyze the text of newspaper advertisements.

Recruiting and Developing *HRDQ* Reviewers: Why You Should Do It and What You Should Look For

Christine M. Squillaci  
San Jose State University

Darlene F. Russ-Eft  
American Institutes for Research

Timothy G. Hatcher  
University of Louisville

Tonette S. Rocco  
Florida International University

Baiyin Yang  
University of Minnesota

The purpose of this innovative session is to recruit and develop reviewers for AHRD’s research journal, *Human Resources Development Quarterly (HRDQ)*. It will also serve as a refresher for current reviewers on what the process is and provide an opportunity for questions and/or comments about the review process.

Keywords: Peer Evaluation, Editorial Review

The need for talented manuscript reviewers is something that is always of importance and is especially important to the Editors of *Human Resources Development Quarterly (HRDQ)*. While *HRDQ* offers much to the Human Resource Development field, good quality reviewers can add even more by utilizing their expertise in the review of manuscripts submitted for publication. In order to bring the field forward and to have the journal cited more frequently, we need individuals from not only universities, but corporations as well. These two areas combined add to the value of our journal being applied in more areas and as a forerunner in research-to-practice literature. The notion of using both researcher and practitioner to review manuscripts has been suggested as having significance to the review process itself (Campion, 1993a).

Epstein (1995) proposed 10 guidelines to improve the journal review process. While these guidelines can be useful, some are not practical to the *HRDQ* review process. One of Epstein’s (1995) suggestions was to reveal the identity of the reviewer to the author. This was met with more resistance than agreement (Fine, 1996; Rabinovich, 1996). The current system of blind review used by *HRDQ* may allow for more truthful reviews, although the argument could be made otherwise. Others (Cowen, Spinell, Hightower, & Lotyczewski, 1987) question the validity and reliability of the review process itself. While our goal is not to change the current review process or to debate its relative value, we do intend to educate potential reviewers and explain why the current method is used.

It should be clarified that the review process is not a place for reviewers to take out their aggressions on authors nor to focus on the negative, which has on occasion appeared to be the case (Fiske & Fogg, 1990; Levinson, 1996). Instead, the review process should provide constructive criticism and suggestions for improvement in addition to any negative critique (Bedeian, 1996; Rabinovich, 1996). Each manuscript does have some merit and should be respected by the reviewers and the editors. That said, reviewers and editors need to be aware of any biases they may have and have a way to manage them (Epstein, 1995). Manuscript review and journal publication is a way to further expand the Human Resource Development field and spark more research and even debate into it.

Session Description

The proposed session will address these issues among others. It will serve as a forum of how to review an article and what constitutes a quality review versus a weak review. It will offer potential reviewers and any current reviewers an opportunity to ask the Editorial Board questions and allow them to gain further insight about the review process. Issues such as why we review manuscripts, how the process works, how one does it and what is

*Copyright © 2002 Christine M. Squillaci, Darlene F. Russ-Eft, Timothy G. Hatcher, Tonette S. Rocco, Baiyin Yang*
required of them, why academic and corporate reviewers are needed, and others that surround the review process will be addressed and clarified. Suggestions for improvements may be discussed including the pros and cons of the authors reviewing the reviewers. Most importantly, the value that an individual brings as a reviewer will be discussed and how that value adds to the greater good of the Human Resource Development field.

Presenters and Panelists

Five members of the HRDQ Editorial Board will conduct the innovative session, one of who will act as the moderator and facilitator for the audience. All members will discuss what reviewers should look for when reviewing a manuscript. More specifically, the Managing Editor will discuss the manuscript review process. The Editor and Associate Editor will discuss what the merits are for being a reviewer and why individuals from both the academic and practitioner worlds should consider the opportunity to contribute as a reviewer. To further develop reviewers, both the Qualitative and Quantitative Method Editors will discuss the methodologies often used to refresh potential reviewers and offer other relevant suggestions.

Session Objectives

In order to recruit and develop HRDQ reviewers, the innovative session will offer a ‘developmental session’ followed by a question and answer or discussion period to expose new and current reviewers on how to review a manuscript. The session will achieve this by completing the following goals:

- Give a background on what HRDQ is and does for the HRD community
- Introduce selected members of the Editorial Board and their relevant roles
- Allow key members of the Editorial Board to present what is important in a review
- Explain the role of the reviewer and its importance
- Elucidate the process that is in place and why this process is used
- Offer examples of ‘good’ versus ‘bad’ reviews, what can be done to improve them, and what constitutes valuable feedback
- Encourage members of both the academic and professional arenas to consider this opportunity and the advantages of doing so
- Facilitate a question and answer or discussion period
- Provide potential reviewers the General Guidelines for manuscript review and who they contact should they decide to pursue the opportunity

Session Structure

The session will be broken down into five sections as follows.

1. Introduction of what HRDQ is, how it contributes to the HRD community and brief introductions of select members of the HRDQ Editorial Board and their relevant roles and responsibilities. (Length: 15 minutes)
2. Panel discussion of the reviewer’s role and responsibilities, the current process that is used and some important aspects in a review. (Length: 15 minutes)
3. Small group discussion: distribute examples of good and bad reviews; develop basic principles of what constitutes a good or bad review. (Length: 30 minutes)
4. Presentation and discussion of small group suggestions. (Length: 20 minutes)
5. Wrap up and further encourage audience members to consider the opportunity to become a reviewer; distribution of General Guidelines for manuscript review and contact information. (Length: 10 minutes)

Contribution

The innovative session is planned so participants will receive a background of HRDQ and the manuscript review process. Participants will hear from active Editorial Board members about why the review process is important and what they can do to further add value. The format has been designed so enough information is presented as to facilitate a potential reviewer into making a well-informed decision by the end of the session.

Design, Demand, Development, and Desire:  
A Symposium on the Discourses of Workplace Learning

John M. Dirkx  
Michigan State University

With panelists:  
Richard A. Swanson  
University of Minnesota  
Karen E. Watkins  
University of Georgia  
Maria Cseh  
Oakland University

The purpose of this session is to explore more fully how each of these dominant discourses conceptualize the phenomenon of workplace learning, with particular attention to understandings of the self in relation work. The emerging discourse of desire is then used to make problematic prevailing assumptions within the dominant discourses of self, learning, and the meaning of work. Thoughtful consideration of these four discourses may help lead us to a deeper appreciation for the complexity and contradictions of learning in and through work.

Keywords: Workplace Learning, Adult Learning, Learning Organization

The idea of learning in and through work challenges common, everyday, person-on-the-street understandings of learning. If randomly selected adults were asked what learning means to them, they would undoubtedly say it involved studying books they are assigned to read or listening to someone lecture in a classroom setting. In the minds of many adults, learning is associated with hierarchically structured, authoritarian environments in which they had little to say over what they learned or how. Such an image of learning so prevalent among adults is understandable, given the twelve or more years in which we are socialized into a particular form of teaching and learning. This image of learning as something we do in a special place, in locations and buildings quite distinct from the everydayness of our lives, particularly our work lives, has dominated education and training in the United States and much of the western world for many years. Despite its roots in a progressive philosophy, even the term “adult education” conjures up for many images of highly structured classroom-based activities oriented to helping adults master the basics of reading, writing, and math - grown-up versions of elementary and secondary education.

Within the fields of HRD and adult education, however, we have seen an alternative understanding of learning emerge, the idea of work and the workplace as a major location for adult learning and development (Garrick, 1998; Welton, 1991). The breadth and scope of work-related learning is one of the most well-kept secrets in the United States. While considerable public debate surrounds policy and practice of elementary, secondary, and higher education at all levels of government, workplace learning continues to emerge as a sleeping giant of educational practice. Each year American corporations spend more on training than is spent for all of k-12 and higher education combined (Galvin, 2001). In the year 2001, over 14 million adults received workplace training. These figures largely reflect formal efforts in workplace learning, events which are organized and structured in somewhat formal and traditional ways. Yet, recent research clearly demonstrates that workplace learning is increasingly constituted by informal learning as well (Marsick and Watkins, 1990). When adults engaged in these forms of learning are included, the total number participating in workplace learning dwarfs other forms of educational practice. The phenomenon of workplace learning has clearly arrived as a legitimate and significant focus for educational research and theory.

Human Resource Development (HRD) has emerged as the field most closely aligned with understanding and fostering workplace learning. Over the last 20 years, the field has begun to develop a strong theoretical base that guides both its research and practice. As scholars continue to clarify and elaborate the phenomenon of workplace learning,
differing and potentially contradictory conceptions have surfaced (Rowden, 1996), reflecting quite different understandings of the self, the meaning of work to the self and what it means to learn in and through work. In this symposium, we explore the major discourses surrounding workplace learning. For purposes of discussion, we refer to these ideas within three dominant discourses, design, demand, and development. We then examine the theory of desire, an emerging perspective in workplace learning (Fenwick, 2001), to help tease out assumptions and issues regarding the problem of subjectivity and meaning inherent in these two perspectives. Finally, the symposium poses further questions for exploration and research raised through an analysis of desire in workplace learning.

Before we review the dominant discourses of workplace learning within the field of HRD, it may be helpful to first clarify our understanding of what is meant by the term “workplace learning.” We then situate our discussion of the dominant discourses within this understanding.

The Meaning of Workplace Learning

While we might agree that the workplace is an important location for adult learning, there is less agreement as to just what that means or what is meant by the term “workplace learning.” Increased attention to this phenomenon has also highlighted the various ways in which this term has come to be understood. For example, formal learning in the workplace is typically associated with hierarchically structured technical training programs, with a formal curriculum that has been constructed by professional educators or trainers, and teachers or facilitators who “deliver” the curriculum to workers. This form of workplace learning perhaps most closely approximates common understandings of what it means to learn in and through work, these critics focus on how the language of workplace learning tends to distract us from more fundamental issues with regard to the worker and the organization of work. In this sense, individual learning promotes and encourages group and organizational learning and change. For some within this viewpoint, the ideas of learning and work are inseparable.

Still, for others, the rhetoric of workplace learning masks the organizations’ real concerns for increased performance and productivity (Garrick, 1998; Hart, 1990, 1995, Welton, 1991). While not necessarily denying the fact that learning occurs in and through work, these critics focus on how the language of workplace learning tends to distract us from more fundamental issues with regard to the worker and the organization of work. They point to “very important links between the ways in which work is organised, the content of work and ‘opportunities’ for employees and learning” (Garrick, 1998, pp. 56-57). They suggest the ways in which our understandings of workplace learning have paralleled historical changes in the workplace, from scientifically managed environments to “cybernetic learning organizations and enterprises (p. 56). According to these theorists, attention to workplace learning is subtly transforming our understandings and notions of knowledge to align more closely with the skills of “competent performance” and with pre-specified industry standards. Hart (1995), in particular, explores the ideological assumptions inherent in dominant notions of workplace learning and how these various conceptions have influenced women’s work. Reflected in these historical changes are transformations of our sense of who we are as workers, as well as our broader sense of identity..

Despite the rhetoric surrounding workplace learning, its problematic nature remains with us. Employers expect immediate transfer of what is learned to the work performed and are often disappointed to see what little effect formal training has on long-term productivity or efficiency. Educators and trainers often find themselves caught between a rock and a hard place - trying to appease the goals of their employers yet trying to address the needs, interests, and desires of the workers themselves. Responding to employer demands and expectations, workplace educators plan and implement brief training programs they know to be of questionable value in the development of needed knowledge and skills.
Employers seek a number of skills among their desirable workers but seldom is adequate time devoted to the fostering and development of these complex skills. Workers often have little choice about participating in these programs, which typically fosters resentment and resistance to the employer's learning objectives. Workers often see formal learning programs irrelevant to the real needs they have in their work and largely a waste of time. In a recent national study of the use of integrated curriculum within adult literacy education, a middle-aged man participating in a workplace literacy program succinctly captured this tension. A welder in a large manufacturing plant, he was told to participate in a work-based program to help improve his reading skills. The curriculum was presumably grounded in the context of his work at the plant. When asked by a researcher what he thought about the reading program in which he was a student, he said that it was largely a waste of time. He perceived what they were teaching as having nothing to do with what he does on the job. He added, "Now if they would teach me how to read to my grandson, that would be something" (Dirkx & Prenger, 1997).

The phenomenon of workplace learning is constituted by numerous structures and processes and framed by broader organizational and social politics. Our understandings of this phenomenon-how we make sense of these questions, tensions, and potential contradictions-are shaped by three dominant discourses. For purposes of discussion, we have labeled these as the discourses of design, demand, and development. Within these different discourses, our understandings of workplace learning are shaped and bounded by particular assumptions about "self-in-context"-the organizational contexts of particular institutions and corporations, and the broader socio-cultural contexts in which workplace learning and these organizations are embedded. Differing conceptions of workplace learning both shape and are shaped by differing understandings of the self that is engaged in the learning process.

The Discourses of Design and Demand

The discourse of design stresses specific products to be derived from the design and implementation of specific workplace learning activities. These products are clearly specified prior to the learning experience and serve to guide all phases of the planning, implementation, and assessment of workplace learning (Yelon, 1996). The notion of performance improvement within HRD and workplace learning are framed within a discourse of design (Torraco, 1999). While reflecting more contemporary issues and contexts, this perspective has its roots in early 20th century scientific management (Taylor, 1911) and scientific curriculum-making (Bobbitt, 1918) movements. Grounded in a behavioral psychology, the design perspective understands work as a composite of specific skills and knowledge that, with analysis, can be readily identified. The idea is to specify the knowledge and skills reflected in and needed by "real-world" performance and to select activities most appropriate to yielding these performances (Yelon, 1996). The difference between what the job requires and what workers already know and are able to do is considered the "gap" that workplace learning needs to address. Through their work, HRD practitioners aim to provide the specific skills and competencies workers need to know and do in order to meet the requirements of their jobs. Through the design and implementation of specific training interventions, workplace learning is intended to eliminate these deficiencies and contribute to the workers' overall productivity and performance.

In this discourse, workers are constructed as "knowable objects," (Fenwick, 2000, p. 295) and largely viewed and understood through measures of productivity and performance. It is a common language within the literature on workplace literacy and is reflected in modern-day versions of task analyses being applied to developing training curriculum, such as the increasingly popular WorkKeys program produced by ACT (http://www.act.org/workkeys). According to ACT, WorkKeys can help "employers identify and develop workers for a wide range of skilled jobs, students and workers document and advance their employability skills, and educators tailor instructional programs to help students acquire the skills employers need." In helping to foster a stronger workforce, ACT believes WorkKeys is contributing to the economic health of our nation. This discourse stresses the importance of competency-based curricula and measurable outcomes of training, carefully linked to both local and global measures of productivity and economic well-being.

As it was initially conceived, the discourse of design reflects a largely individualistic and causal perspective on the process of workplace learning. Individuals are responsible for production and performance, and training is targeted to address the skills they need to contribute to the overall performance of the organization. For the most part, worker-learners are seen as largely passive recipients of knowledge and skill they are determined to need in order to be more productive and effective. Increasingly, however, this "design" perspective is yielding to a somewhat more complex understanding of the relationship of the worker to the work and the organizational context in which this work is done. We refer to this emerging discourse as the discourse of demand. This discourse, shaped and influenced by performance
interconnectedness of all aspects of organizational life, including the overall well-being and development of the individual
demand, through its stress on the learning organization (Watkins, 1996; Watkins and Marsick, 1993), and the
inherently make decisions that cause an organization to prosper” (p. 22).
her particular job. According to Bierema (1996), “A holistic approach to the development of individuals in the context of a
focus on the development of the worker as a whole person, not merely the particular knowledge and skills related to his or
skills and knowledge is viewed as the primary focus for workplace learning. The practice of HRD, then, is understood to
Seeking to further his or her self-actualization within and through work, the worker’s development, rather than specific
Freiburg, 1994). This discourse stresses development, fulfillment, and self-actualization of the worker (Bierema, 1996).
and his or her experience at the center of the educational endeavor (Lindeman, 1926). The progressive movement
stressed the idea of education as a continuous reconstruction of living experience (Dewey, 1938), with the adult learner
and his or her experience at the center of the educational endeavor (Lindeman, 1926). The progressive movement
challenged what many perceived to be the mechanistic and functional views of education being fostered through
scientific curriculum making. The discourse of development stresses the active role that the worker plays in the process
of learning and the relationship of the “curriculum” of work to the experience, beliefs, and perceptions that the worker
brings to the workplace. While it would be inaccurate to characterize this perspective solely as a “learner-centered”
approach, the process of learning is conceptualized as starting with what the learner brings to the context of learning.
The discourse of demand focuses our attention on motivational issues and broader organizational contexts neglected
by the discourse of design. It stresses the limitations to our understanding of approaches which rely almost exclusively
on mechanistic assumptions of workplace learning (Bierema, 1996). Yet, the discourse of demand ultimately seems
concerned with organizational performance rather than learning and development of individual workers. In a sense, the
individual learner is a kind of “cog” (albeit an important one) in a complex system of interacting components. In contrast
to the discourses of design and demand, the discourse of development offers a more organismic perspective on the
workplace and the self as worker in these contexts.

The Discourse of Development

In contrast to the discourse of design and, to some degree, the discourse of demand, the fundamental assumptions which
characterize the discourse of development are grounded in the progressive education movement of the late 19th and
20th centuries. While it maintained close connections with industrial training and agriculture, the progressive movement
stressed the idea of education as a continuous reconstruction of living experience (Dewey, 1938), with the adult learner
and his or her experience at the center of the educational endeavor (Lindeman, 1926). The progressive movement
challenged what many perceived to be the mechanistic and functional views of education being fostered through
scientific curriculum making. The discourse of development stresses the active role that the worker plays in the process
of learning and the relationship of the “curriculum” of work to the experience, beliefs, and perceptions that the worker
brings to the workplace. While it would be inaccurate to characterize this perspective solely as a “learner-centered”
approach, the process of learning is conceptualized as starting with what the learner brings to the context of learning.
What workers come to know and understand through the process of workplace learning reflects who they are as persons
and how they are making sense of their experiences in the workplace.

The discourse of development is also heavily informed by a humanistic psychology (Maslow, 1968; Rogers &
Freiburg, 1994). This discourse stresses development, fulfillment, and self-actualization of the worker (Bierema, 1996).
Seeking to further his or her self-actualization within and through work, the worker’s development, rather than specific
skills and knowledge is viewed as the primary focus for workplace learning. The practice of HRD, then, is understood to
focus on the development of the worker as a whole person, not merely the particular knowledge and skills related to his or
her particular job. According to Bierema (1996), “A holistic approach to the development of individuals in the context of a
learning organization produces well-informed, knowledgeable, critical-thinking adults who have a sense of fulfillment and
inherently make decisions that cause an organization to prosper” (p. 22).

While rejecting the mechanistic discourse of design, the discourse of development reflects aspects of the discourse
of demand, through its stress on the learning organization (Watkins, 1996; Watkins and Marsick, 1993), and the
interconnectedness of all aspects of organizational life, including the overall well-being and development of the individual
worker. It is an organic understanding of wholes and relationships. While the systems view and the concept of the learning organization seek to move us from the machine-like structures and processes which dominate the discourse of design to more fluid, connected networks, Bierema (1996) reminds us that the fundamental task of organizational learning and development is development of the individual worker. Within this view, workplace learning is understood as a process of reflectively learning from and acting on one's experience within the workplace. Rather than a passive recipient of knowledge and skills perceived by others to be needed by the workers, in the discourse of development the worker is viewed as more actively involved in identifying what he or she already knows and how that knowledge can serve as a platform or structure for further learning and development. Typically, this learning occurs within the context of self-directed or self-managed groups or teams organized to promote both individual and organizational learning.

Implicit in each of these dominant views of workplace learning are assumptions about the nature of the self and the processes of self-formation that are at least potentially present within the workplace. In the next section, we will summarize an emerging perspective within workplace learning, that of desire. By looking at workplace learning through the lens of desire, we will make more explicit and problematic the assumptions of the self and learning reflected in the discourses of design, demand, and development.

The Discourse of Desire

A discourse of desire represents postmodern and poststructuralist perspectives on workplace learning and is grounded in the work of the psychoanalytic scholar Jacque Lacan (Fuery, 1995), among others. For the most part, dominant discourses around workplace learning suggest that the process is characterized largely by a linear progression. This process results in a one-way path from ignorance to knowledge, in which knowledge is viewed as a substance (Felman, 1987). The discourse of desire challenges both this way of thinking about learning and our understanding of knowledge (Butler, 1999; Todd, 1997). Unlike the progressive understanding of learning reflected in the discourses of design and development, a psychodynamic view suggests learning proceeds through “breakthroughs, leaps, discontinuities, regressions, and deferred action” (Felman, 1987). Knowledge is considered not a substance but a structural dynamic, arising from and characterizing the interactions between and among persons. It is not restricted to a single individual but is inherently dialogical. From the perspective of a theory of desire, learning requires the presence of an “other” and it is in that relationship with the other that learning, if it occurs at all, takes place. In this sense, the discourse of desire shares with the sociotechnical view a reliance on and concern for unconscious motivations and drives in the process of workplace learning. A discourse of desire points us to the unconscious dynamics of learning, and the complexity and paradoxes which characterize its presence in our lives.

The discourse of desire seeks to make problematic our dominant perspectives of workplace learning and their underlying assumptions. It takes its cue from the rumblings of alienation and disaffection which continue to haunt workplace learning efforts, despite the seemingly humanistic organizational reforms of the past 25 years. In this sense, we might think of the discourse of desire as a discourse of unmasking the inherently problematic nature of workplace learning. According to Fenwick (2000), educators who seek to “help workers thrive and serve a vocational community [confront] workers’ struggles to find meaning and purpose in jobs where they seem increasingly to experience anxiety, stress, sadness, and despair. These are fundamental issues of identity related to work and the human quest to understand and unfold self” (Fenwick, 2000, p. 297). The study of self and identity strongly suggests that this struggle is integrally bound up with an impulse to learn and develop. The workplace, then, becomes a location for constructing a sense of self in the world (Britzman, 1998). Fenwick argues that, from a psychoanalytic perspective, this human quest involves recognition of the psychic events that make up our lives, the ways in which we often push many of these events - anxieties, fears, disruptions, mistakes, vicissitudes of love and hate - into the background out of conscious awareness. Learning something new and the prospects of change can bring us face to face with these unconscious aspects of ourselves. While the ego might perceive this learning as a threat to itself and garner defenses against the change, significant learning involves a working through of the “conflicts of all these psychic events and gradually coming to tolerate the self and its desires” (p. 299). Thus, the discourse of desire and how it frames our discernment of the self suggests our studies of workplace learning must be grounded in a deeper understanding of the complex relationship that exists between a person’s psyche and their experience in the workplace. Discourses of design, demand, and development do not adequately address either the complexities or the possibilities of the self or its relationships within the workplace. They may even circumscribe a practitioner’s ability to perceive and address the gnawing existential problems surfacing within the world of work.

At the heart of work, then, are notions of desire and interference (Fenwick, 2001). Desire itself surfaces a sense of
change, arising from this deep sense of the unfolding self, of wanting something to be different. But at the same time, desire also evokes a sense of resistance to change and to learning. Recognition of this fact allows for an appreciation of work and workplace learning as a place where profound pedagogical encounters can occur. When we recognize and tap into this paradoxical situation, we often find new energies and enthusiasm emerging for our work. These energies, however, might be running counter to the established order or those purposes prescribed by educators or organizational leaders. For example, workers may at times subvert explicit efforts to "empower" them or other efforts to shape them in a particular way. They may resist such "learning-centered" approaches which seek actively engage the learner within his or her experience. Dominant discourses of workplace learning might lead us to interpret such acts as not going along with the organization’s purposes or not wanting to learn and grow. When viewed through the discourse of desire, however, we might recognize workers as increasingly constructing and regulating their own “human capital.” In this sense, workplace learning is interpreted through the discourse of desire as a form of transgression and resistance (Fenwick, 2001). Through these opportunities for and various forms of resistance, workplace educators seek the possibilities for work, learning, and identity construction.

Implications for Research and Practice in Workplace Learning

One of the objectives of this symposium is to foster awareness of the different ways in which we frame and come to understand workplace learning, and the consequences that ensue from such an understanding for ourselves as scholars-practitioners, for the organizations for which we work, and for the worker-learners. When we begin to think about our work in terms of the discourse itself, we develop a deeper appreciation for the complexities at the core of workplace learning. Ideas such as workplace literacy, informal learning, and the learning organization have dramatically increased our attention to the notion of workplace learning. Much of this rhetoric suggests a powerful potential for learning waiting to be tapped within the workplace. Yet, in reality the idea of work and the workplace as a location for adult learning and development remains problematic. Different groups with different interests attempt to control the discourse of workplace learning and the ways it comes to be understood within the organization and the broader community. Profound ideological differences bubble away just below the surface of workplace learning programs. Workers and educators alike struggle with the consequences of attempting to enact grand visions for workplace learning with the broader political spheres of the organization.

Both the problematic nature of work and efforts to reform and improve organizations and the workplace underscore the problem of meaning in workplace learning. Despite the press of these reform efforts, or perhaps because of them, workers continue to feel alienated and disenfranchised from their work (Hart, 1993; Saul, 1995; Rifkin, 1995). Employees’ perceptions of themselves as workers has been eroded through organizational restructuring, downsizing, and re-engineering. Many are now seeking greater alignment between the work they do and personal values they hold deeply, such as attachment and spirituality (Fox, 1994; Mitroff & Denton, 1999).

Ongoing tensions continue to float in and around the nature of the work, its organization and structure, its capacity for fostering learning and development, and the personal desires of individual workers. These symptoms raise questions regarding the meaningfulness of formal workplace learning programs. Depending within what discourse of workplace learning we are framing these problems, we come to understand them differently and seek different “solutions.” Implementing these solutions often becomes part of and further elaborates the fundamental nature of the problem. For example, emphasis is being placed on working and learning collaboratively and relationally, empowering workers, creating learning organizations, learning communities, communities of practice, and fostering reflection in practice. But organizational emphasis on quality standards, measurable performance, and competition tends to reinforce the organization’s authority, sending mixed messages to both workers and educators and contributing to worker disenchantment and frustration with workplace learning programs. And both perspectives tend to ignore the complex workings of desire which shape the worker’s thinking and feeling about learning.

The various discourses we use to frame our conversations and actions in workplace learning serve to help us see some important dimensions of this phenomenon but they also prevent us from perceiving other critical aspects. Consideration of these different discourses and the ways in which they shape our theory and practice in HRD provide for a deeper understanding of the complexity and contradictory nature of workplace learning.

Dirks is chair and organizer of this session, and the primary author of this paper. In the session, the panelists will respond, from their respective theoretical positions, to the principle points of the paper.

Two Approaches to Conflict Management in Teams: A Case Study

Mychal Coleman  
Gary N. McLean  
University of Minnesota

Two employee teams received conflict management training using lecture and exercises, and cooperative learning. A survey was administered at the end of training and three months later. After three months, observations were made and management interviewed. Initially, both groups were optimistic about their conflict management skills. In follow-up, only the cooperative learning group remained optimistic; the traditional group was less optimistic, primarily because of a lack of management support. Both approaches appear to be effective.

Keywords: Conflict Management, Team Building, Cooperative Learning

This paper describes and interprets two intervention strategies, a cooperative learning (CL) interactive approach to conflict management and a conflict management seminar taught under the traditional lecture method. These interventions were offered to two start-up self-directed work teams (SDWT) in a mid-sized surface-to-air medical trauma company.

The use of teams in organizations continues to grow rapidly. Joinson (1999) reported that the Center for the Study of Work Teams indicated that by the year 2000 80% of the Fortune 500 organizations would have half of their employees on teams (p. 30). Teams have been suggested as ways to increase productivity, reduce costs, and improve customer relationships. Change agents have been called upon to design Six Sigma, reengineering, TQM, CQI, and strategic partnership teams. Yet, with the use of such teams often comes conflict. We assume that employees know how to work together when, in fact, they do not. Most employees on teams lack the basic tools to manage conflict. So the question for such organizations becomes, how can we best provide our employees who are working in teams with appropriate conflict management facilitation and training?

Statement of the Problem

There are countless studies that present evidence to support the need for training to resolve conflict in SDWTs. Friedman, Todd, Curral, and Tsai (2000) concluded that training should use an integrative style. Donovan (1996) suggested a 3-step team building training process before empowering teams with managerial responsibilities. Moravec (1999) recommended that training be structured to deal with employee resistance to teams and change.

The problems, however, still persist: what type of training methods is best to use? How do we translate research into effective training interventions? Carroll (1998) believed that most of what has been written about teams has focused on introducing the reader to concepts and the rationale for teams. Further, he stated that these accounts meet the needs of people who are at the conceptual, exploratory stage but are not much help to individuals who need a how-to model (p.21).

With the growing popularity of teams, there has also been an explosion of commercial training programs. However, workshops tend to be somewhat vague about the psychological processes underlying teams (Magney, 1996, p. 565). Tsang (1997) made a similar observation on prescriptive books about team building and conflict management. Further, Joinson (1999) cited informal and anecdotal evidence that the failure rate of SDWTs due to various forms of unresolved conflict is 50% (p. 3). HRD professionals are under enormous pressure to design training interventions and to create change more efficiently the first time. Therefore, knowing what type of training method to use would be beneficial to the HRD profession.

This paper, then, will explore the effects of two types of training methods that were given to two start-up teams during their initial phase of development. Following are a brief review of the literature on conflict management (CM) and cooperative learning (CL); a description of the study's context and methods used (observations, interviews, and surveys); and conclusions about the efficacy of both approaches. No other case study has been identified that attempts to examine the effects of implementation of CL as a conflict management approach that is observed and studied in the context of one of two groups.

Literature Review

This literature review examines conflict management (CM) research, including both the traditional lecture and cooperative learning (CL) training methods.

Conflict Management

At the organization level, Meyer (1999) suggested that it is management's responsibility to know the appropriate application for teams. If there is a lack of clarity in this organizational vision, conflict can arise in teams. Seaman (1995) argued that the major source of team conflict is management's strategic misalignment of teams. Seaman saw strategy as driving the development of all other elements, such as values, structure, culture, and information systems. All of these elements must line up to avoid conflict. Team leaders can also be a source of conflict. At this level, conflict may arise from issues of traditional command and control (Carroll, 1998) and management resistance to teams (Carroll, 1999; Seaman, 1995; Yeatts, Hyten, & Barnes, 1996). Yeatts et al. (1996) and Dreachslin, Hunt, and Sprainer (1999) cited research that suggested that the best teams are those of equal rank. Seaman (1995) argued that conflict arises from the lack of team autonomy.

The traditional lecture method or some variation of it is the preferred method for companies who train in conflict management. Kreitner and Kinicki (1998) found that Deloitte Touche sends both employees and teams to retreats to engage in relationship building. Team members are trained in CM by facilitators who help the groups interpret the meaning of the individual and team traits in order to build future relations. Carroll (1999) found in one organization that its traditional command and control structure of supervisors was the problem. Therefore, CM consisted of training to eliminate the company's old structure and to build interdependence. Liebowitz and Holden (1995) detailed how the Corning Corporation and Motorola use the traditional method to train its teams on participatory style.

Cooperative Learning

Cooperative learning (CL) is nothing new in the field of education. Educational psychologists have been recommending this technique for teachers in secondary and primary education for years. Recently, scholars have begun to look at its potential for preparing business students for the corporate world. The theory of CL was defined by Deutsch (1949) and further developed by Johnson and Johnson (1998), Slavin (1985), and Kohn (1992). While the literature is rich on CL, no references were found on the use of the actual implementation of CL for conflict management purposes within a corporate setting.

Carroll (1999) noted that task sharing among teams increased productivity. Seaman (1995) suggested that employees who interface on teams competitively instead of collaboratively produced negative outcomes. Dreachslin et al. (1999) found that defined roles in teams produced positive perceptions among team members. Kirkman, Jones, and Shapiro (2000) indicated that, if employees are more individualistic than collectivist, they will resist teams, producing lower levels of team effectiveness. Liden, Wayne, and Bradway (1997) and Pearce and Gergersen (1991) found that the relationship between group control over decision-making and group performance became more positive with increased levels of task interdependence. Thus, group control over decisions may result in higher performance.

While the previous studies implicitly touched on certain aspects of CL, Alper, Tjosvold, and Law (1998) explicitly cited the work of Deutsch (1949) and Johnson, Johnson, and Holubec (1998). They found that, when blue-collar employees created cooperative goals, their teams gained confidence and improved work productivity. Janz (1998) applied CL theory to a group of IT professionals, using cooperation, positive interdependence, face-to-face interaction, social skills, and group processing. Janz found that the autonomy inherent in SDWT might lead to increased levels of satisfaction, motivation, and performance. The level of CL that takes place on a team may be important in achieving improved work outcomes, according to Presutti, Williams, and Buzzi (1995) and Lindquist and Abraham (1996), who implemented CL in business classrooms.

Corporate Setting

Before the field research was conducted, the senior author served as the Director of Strategic Planning and Human Resources for the company involved. This surface-to-air emergency medical service (EMS) unit is headquartered in the upper Midwest, is a little more than 30 years old and has approximately 1,250 employees. It has a reputation that is second to none within its industry and is owned by a competing yet cooperative consortium of hospitals. The
company competes freely within and outside of its home state. Although the rotor wing division produces the highest volume of revenue per mission, it is the ground division that produces the highest revenue, while the fixed wing division currently operates at a loss.

The management team and the staff have a culture of close interactions and relationships, which at certain times draws the administrative process into chaos. This is perhaps due to the company’s beginning as a sole proprietorship, in which every employee had to rely on each other, with a minimum of infrastructures and protocols. Employees often bypass line management to discuss issues of concern with the CEO.

The organization’s position has fluctuated within the industry, partly because of economic cycles, and partly because of withdrawal of consortium subsidization, which had made the group complacent. The firm managed to stay afloat by quickly implementing cost reduction measures, such as outsourcing certain divisions, restructuring and reengineering other departments, and layoffs. In addition, the company closed several key bases that gave them market presence in rural areas.

Politically and economically, factors in health care demanded that companies do their work faster, more efficiently, and at less cost, while still maneuvering through truckloads of red tape for third party reimbursements. However, the oligopoly in which the firm competes makes increasing market share difficult. The firm is one of three leaders in its regional industry, and each has recognized that price cuts would trigger full-scale corporate warfare that none of the three wants. Finally, upgrading computer software during the impending Y2K issue had every EMS firm in the industry worried about costs.

Conflict occurred between the old ways of doing things and new approaches. Management believed that, in order to answer changing industry trends, changes must be made. The employees believed that the old ways were what established the firm’s superior reputation. To some extent, both were correct. This company was no longer in its infancy; it was no longer a startup family business. It was now a mature company in a mature industry, seeking to find ways to survive, by, as the CEO remarked, “confronting our paradigms and culture.”

The management team decided that one approach to developing a competitive advantage was to develop core skills to market billing services, which required developing the Billing Center. The Director of Operations suggested that the process begin by forming a team that would assess the current processes and perform business process mapping of the current billing situation. Two objectives were assigned to the senior author, both of which would require team building: integrate and build infrastructures of the strategic business unit (SBU) (a recent merger with a small, rural company), and develop and market billing services by 2000.

Billing Team. The creation of a Billing Center was to expand into untested markets in billing and claims services by expanding reach and becoming more competitive within the health care industry, which was suffering because of the maturity of that market. They hoped to capitalize on targeting smaller firms that were facing near extinction due to additional government restrictions and compliance issues, as well as the impending Y2K issues.

Following intensive analysis, however, the project team found that the company’s performance measures were considerably worse than those of competing organizations. The project team determined that these problems arose from outdated computer systems, duplication of processes, and incomplete data gathering by the clinical staff after transports. The Billing Team was given the responsibility of designing a new policies and procedures manual based on changes in the billing process. New job descriptions were also to be developed.

Within days of the final project meeting, the Billing Team started having problems with their assigned objectives. Members of the team expressed their concerns one by one to the CEO, lodging complaints against each other, about the lack of appropriate meeting procedures, and the massive assignment that lay before them. The Director of Strategic Planning and Human Resources was asked by the CEO to observe a team meeting and interview the members. Many arrived late for the meeting and were horrified that someone from management was there and had caught them late. Then, some who were late got upset with their counterparts for not warning them.

There were no team rules; those who had the floor never got a chance to complete their point. There was mistrust in the air, with apparent factions that enforced their will by overruling other points of view. The agenda had 8 items listed, but only two were completed in the two-hour meeting. The day of the interviews, two of the six members called in sick. The other four told me of his or her distrust of management. “Management didn’t take note of these concerns for years. These problems with billing didn’t just happen over night.” They also expressed their distrust of each other in ways one could not believe. A third theme was a lack of training and control. Finally, the employees had serious charges about the hostile work environment created by the former Director of Finance.
The situation had reached a boiling point. This group was a long way from becoming a cost center, let alone processing the company’s claims. The CEO and the Director of Strategic Planning and Human Resources agreed that a skilled consultant was needed to assess the situation. The second author was hired for this purpose. In addition to several technical items, the consultant recommended training in team processes and conflict management. He also recommended that the teams be set up as cross functional. Therefore, for the purposes of conflict management training, the teams would be made up of all six billing employees, one from the clinical ranks, and two from the communication center. Another consultant was retained to offer a five-day conflict management seminar, using a traditional lecture approach.

**Strategic Business Unit Team.** The strategic business unit (SBU) is located in a neighboring state within a small rural town. The same initiatives that went into creating a revenue generating cost center were behind the decision to form a joint partnership. However, the objectives were quite different. The firm was looking to expand its reach and presence within the market. This partnership was the company’s second attempt at expansion. Numerous problems started developing. The firm failed to account for how both companies’ employees would react to each other. The rural employees resented the fact that most of the firm’s employees did not consider them to have expertise and felt shut out during patient assessment. In truth, they did not have the high caliber of training that the company’s employees were expected to have. Further, the rural employees also did not like the fact that most hospitals now referred to them as the company’s name instead of their original name. They felt that having two types of supervisors and two different uniforms were confusing to the hospitals. Finally, the rural partner’s employees were fiercely loyal to their base supervisor, and they believed that the firm’s RN’s were superceding their authority. The company employees were also loyal to the firm and its uniforms. They believed that respect must be earned, not just given away to employees who had no training or no critical care expertise. The Director of Strategic Planning and Human Resources was assigned solve the problems. Cooperative learning was the intervention selected.

**Methods**

The research was based on Tjosvold and Morishima (1999), Liden et al. (1983), Barker et al. (1997), Alper et al. (1999), and Janz (1998). The instructional methods used are provided below.

Following the training, both groups were surveyed using a survey similar to the earlier researchers. Second, the Linquist and Abraham (1996) White Peak survey instrument was selected because the authors actually implemented the jigsaw II CL method to college students, which is the closest survey instrument to our research intent. The company’s management team reviewed the survey as well as administered it to another SDWT. The survey instrument was then modified to increase its reliability and validity. Because of the senior author's relationship to one of the sites, both surveys were administered and scored by Human Resources Assistants to increase controls.

The first survey instrument assessed all dependent measures (employee attitudes, perceptions of self-esteem, interpersonal skills building, and perceived achievements) at the end of the training. The survey was comprised of 13 statements to which participants responded “strongly agree,” “agree,” “undecided,” “disagree,” or “strongly disagree,” with “strongly agree” = 1.

The second survey was administered three months after training. It was slightly modified to include CL terms. The inclusion of the CL terms was an attempt to examine differences between a team taught by the actual CL method and a team not trained in CL but which was given the CL terms, consistent with prior research. In addition, observations were made three months after training. The managing stakeholders of the process were also interviewed three months after the interventions to address productivity through the eyes of management. Productivity was also assessed through the group’s timetables to completion of key initiatives.

**Conflict Management Lecture Method**

The traditional lecture method can best be defined as Instructional Objectives Learning (IOL). There are three components to IOL: performance, in which an objective always says what a learner is expected to be able to do; condition, in which an objective always describes the important conditions (if any) under which the performance is to occur; and criteria, where an objective describes the criteria of acceptable performance. The traditional conflict management lecture approach was used with the billing team. The consultant selected had solid experience in HRD, as well as an extensive theoretical background with a Ph.D. in HRD. There were three meetings between the consultant and the Director of Strategic Planning and Human Resources. Of the seven objectives that the group developed, the consultant focused on improving teamwork.
The first meeting covered and incorporated issues in the literature review, such as team failure, barriers to team success, and CM strategies. The second meeting addressed the current conflicts resulting from the assessments. We agreed that the best approach for the consultant to take was to focus on relationship improvements. The rationale was that, if relationship conflict could be resolved, task conflict could be managed and the team goals implemented. During the third meeting, the consultant presented her proposal, which was accepted after several revisions were made.

The seminar was designed for three sessions in which the consultant instructed using an instructional objectives learning approach. The Director of Strategic Planning and Human Resources added a fourth session, which lasted about 2 hours, to go over terms and definitions of CL without facilitating a CL lesson structure. This was done to prepare the team for the final survey on CL terms.

Cooperative Learning Methods

CL is a technique that requires students to work together in small, fixed groups on a structured learning task. In the literature CL was found to enhance student attitudes, perceptions of interpersonal skill building, and self-esteem. Common to all CL structures are four key components. First, positive interdependence must exist whereby students perceive that they must "sink or swim" together. This is achieved through goal, task, and role interdependence (Slavin, 1985). Second, face-to-face interaction among teammates must take place involving verbal interchanges. This allows students to talk aloud, challenge one another's points of view, and focus on the problem-solving process rather than the answer. Third, individual accountability must exist, requiring that every group member be accountable to learn all required material. Finally, interpersonal and small-group skills must be built into the CL structure. One such skill is group processing, whereby students analyze their own and their teammates' performance in the group. All of these components were built into the training.

The facilitator of the CL approach with the SBU was the Director of Strategic Planning and Human Resources, who has extensive experience in the traditional lecture methods and has an M.Ed. in HRD. The SBU consisted of thirty employees, fifteen of whom were selected by their peers to go to training, ten females and five males, eight nurses and seven technicians. The conflict management training for the SBU was longer than for the Billing Team because time was needed to train the SBU employees on strategic planning and continuous quality improvement. CL is different from the traditional lecture method in that the facilitator can structure a lesson (training) plan while developing the group's social skills (team building). Discussions with the co-partners resulted in an approved training agenda that included the barriers to teams, team failures, and CM strategies.

Results

Results are presented, in order, of the surveys, the observations, the management interviews, and the progress being made by the teams on their timelines for accomplishing their objectives.

Surveys

The surveys measured participants' perceptions of their attitudes, self in relation to teams, interpersonal factors, and training contributing to achievement, while the second survey added one question on accomplishments and four questions on CL. All nine members of the Billing Team responded, as did all 15 of the SBU team. See Table 1 for the results immediately after training and Table 2 for the results three months after the training.

Both groups were optimistic about their abilities to handle conflict and accomplish their goals immediately after the training. However, after three months, the SBU team was more optimistic, while there was considerable deterioration in the perceptions of the Billing Team. Although the Billing Team optimism had deteriorated, they still perceived that their goals were interdependent. However, they did not believe they were working together. The SBU also believed that their goals were interrelated, but they perceived that the team was working together to complete them. Of course, there is no way to know whether these differences occurred because of the training approach, the support offered to the teams by management, the personalities involved on the teams, or some other cause.

Observations

Observations made three months after the training revealed that the Billing Team relied heavily on the team champion who was the former supervisor of the dispatch team. She set the direction and accountabilities and
resolved sticking points, just as she had in her prior role, which had been eliminated. She agreed to allow observation at the next meeting without her presence. The group had problems deciding how to choose a facilitator,

</table>
which caused tension among the members. During the discussion, alliances became clear, with two informal leaders emerging, with each having an equal number of followers. This is consistent with team comments made after training where one team member stated, "The trainer was outstanding but how will we pick who will lead the team?" It appears that the group did not choose formally, so informal combatant roles developed. Another team comment was, "The training helped us get a start on how to relate to each other, but what will we do about assigning the many tasks that are ahead of us?" Responsibilities assigned were consistent with those laid out by the team champion. No other objectives were completed subsequent to her starting to lead the team. No one was held accountable. The only assignments that had been completed were those done by the team's cross-functional members. The remaining objectives were the billing employees' sole responsibilities. This meant that the team's timetable for completion was at least 5 to 6 months behind.

The observations of the SBU team were delayed an additional two months. As the group was assembling, they were deciding who would be the recorder, who would sum up each point, and so on. One person said, "I was gatekeeper last time, so that makes me the facilitator." The team members were all wearing the same uniforms, in response to their goal of providing consistent care. The meeting started with a sub-committee report with members from both groups of employees. The gatekeeper cautioned them about how much time was left. Various committees spoke on objectives that had emerged since the training. One committee report presented two opposing solutions to a problem. This was done with consideration, and the other members of the committee paid close attention to both perspectives and asked questions. This team was ahead of schedule and had exceeded expectations.

Management Interviews

The interview regarding the Billing Team revealed that the goals and the team's timetable were not done, even though it was two months past the target completion date. Only 30% of the objectives had been accomplished, and that portion was credited to the team leader who had facilitated the effort. The Director was shocked to hear that the other objectives had not even been begun. The team champion commented, "they (the team) seem to have gravitated back to the way they were." The senior manager involved acknowledged that he had let the team down by not staying on top of the situation. His team champion had not kept him abreast of the unfolding events on the team.

A conference call was arranged with the Director of Marketing and the co-partner at the SBU site. Customer complaints had fallen by 55% in the last six months, and sales were up by 5%; internal complaints about each other had stopped completely. The only negative comment was that "there still was a lack of management communication by both co-partners. The team was nearing 73% of completion of its objectives, and management was keeping them from completing more."

Conclusions

There are many limitations to this research case study. First, the two groups had different facilitators with different backgrounds and styles. Second, one author was the facilitator for the CL intervention. Third, the Billing Team had a long history of conflictive interaction, which is much more difficult to turn around than when the focus is on a team that has no previous experience of working together. The objectives for the two teams were also different, and the location (corporate headquarters in the city and the SBU site was in a rural setting in another state) also created some problems for the research.

Nevertheless, it is clear that the training itself was effective in both settings, based on the observations and the participants' perceptions as reflected in the surveys. The Billing Team perceived that they had moved to another level. The team was energized, upbeat, and open to possibilities of continuous change, and to that extent the traditional method worked well. The problem was that management failed to provide the time, resources, and support needed for the objectives to be met. As a result, the team gravitated back to their original level. Finally, while the Billing Team believed their goals were interrelated their productivity, as judged by management was below standards, a result inconsistent with prior research.

CL is promising as an application in the business environment. CL methods were also extremely cost effective, as it took twelve meetings to facilitate a strategy for the billing department plus another four days for conflict management training. The CL tool was able to do both in four days.

There is clearly a need for much more research on this topic. It would be appropriate, perhaps in a larger corporate setting, to carry out a similar study, but to follow experimental methodology. CL has been around for a long time in education and has proven to be effective in a business context.
Implications for HRD Practice

HRD is always seeking cost effective approaches. CL may be a way for organizations to deal with the need for conflict management, while at the same time accomplishing some other strategic initiative, thus killing two birds with one stone. CL appeared to have a consistent way of having teams remember their roles and leadership procedures during meetings, whereas the team trained under the traditional lecture method appeared not to use their CM training. This study is of importance because there is no identified attempt to implement CL training for purposes of conflict management in a corporate environment.

A Force-Field Analysis of Factors Affecting Men and Women Choosing to Become Professional Pilots

Steven L. Anderson
St. Cloud State University

David J. Pucel
University of Minnesota

This study investigated the use of force-field analysis to identify factors that could influence people to enter fields where there are critical shortages. The procedure was applied to factors that might positively or negatively influence men and women choosing to become professional pilots. Twenty factors were identified as having significantly different importance to the recruitment of both men and women. Implications for the design of recruitment efforts for both men and women are significant.

Keywords: Recruitment, Professional Pilots, Force-field Analysis

Recruitment of personnel into positions where there is a serious shortage is a problem that affects many fields. This study investigated the use of force-field analysis to identify positive factors that could be emphasized during recruitment and negative factors that might be minimized to remove barriers to recruitment.

The procedure was applied to the recruitment of professional pilots. The air transportation industry is currently experiencing a shortage of qualified professional pilots. This shortage is affecting all levels of the industry. Flight schools, charter operators, corporations, and regional and major airlines are all having difficulty finding and retaining professional pilots.

The shortage is attributed to a combination of rapid growth in the air transportation industry and the increasing number of airline pilots (mainly Vietnam era military trained pilots) reaching mandatory retirement age. Activity in the air transportation industry is expanding at rates of five to ten percent a year. At the same time pilots are expected to retire at rates from ten to twenty percent a year during the next decade (Hedden, 2000; Mark, 1999).

Although there is a need for more men and women to become interested in becoming pilots, the small numbers of women pilots suggests that women may be a particularly untapped source. They represent only 3.75% of all Federal Aviation Administration (FAA) certified professional pilots in the United States (AOPA, 2000). In addition, over the past ten years that number only increased by about one percent (FAA, 2000).

Many factors have been barriers to women becoming professional pilots. One major factor has been the military as the primary source of professional pilots. Until recently women were not trained as military pilots. Another has been the historical negative sentiment toward women becoming professional pilots (Thornberg, 2000; Turney, 2000; Turney, 1995).

Problem

Increasing the number of men and women pilots to meet future needs will require recruitment efforts based on an understanding of factors affecting the choice to be a professional pilot. It will be important to not only understand factors that might positively influence choice but also factors that might negatively influence it. Such information can be helpful to human resources departments, educators, and industry leaders in emphasizing the positive factors and trying to take action to remove the negative factors.

This report presents a study that investigated the factors that might positively or negatively influence men and women choosing to become professional pilots. In addition, it investigated whether the factors differ for women and men.

Career Choice Literature

There is a large body of research on general career choice, career development, and non-traditional career choice. Although this research does not specifically include aviation career choice, it does offer insight into factors that might influence career choice and recruitment in general. Past research suggests many recurring themes that

Copyright © 2002 Steven L. Anderson and David J. Pucel
influence career choice among men and women such as: their tendencies to pick traditional work roles, family influences, societal influences, peer pressure (Freeman, 1997; Bee, 1996; Lankard, 1995; Gunn, 1994), the importance of role models and mentors (Kerka, 1998; Jewett, 1996; Kelly, 1993), the influence of teachers and guidance counselors, the impact of early experiences (Furlong & Biggart, 1999; Stitt-Gohdes, 1997; Lent, Hackett, & Brown, 1996), and the differing views of men and women about what is important in a career (Gati, Osipow, & Givon, 1995).

Method

The study was conducted using a methodology called force-field analysis (Harrison, Shirom, 1999; Lewin, 1951). It is based on the premise that there are both positive and negative factors that influence individual decision-making. The extent to which each factor influences a person's decision is based on how important it is to the individual. This level of importance is called factor strength. If the sum of the strengths of the positive factors influencing a choice outweigh the sum of the strengths of the negative factors, it is believed that a person will make a positive choice. The reverse is also true.

The first phase of implementing this methodology is to identify the range of factors that might have positive or negative influences on a decision. The second phase is to ask those knowledgeable about the particular decision to rate each factor according to its strength as a positive or negative factor (Harrison, Shirom, 1999; Rothwell, Sullivan, McLean, 1995).

This study implemented the force-field methodology in three stages. First, factors that might affect a person's decision to become a professional pilot were identified. This was done by developing an initial list based on a review of the literature, and two brainstorming sessions with seven female and 13 male volunteer university bachelor's degree aviation majors. The list was then sent to a selected group of 15 female and 15 male aviation experts identified by the staff of St. Cloud University's aviation program. They were asked to add additional factors that might be missing. During this first stage the goal was to identify as large a list of brainstormed factors as possible. All factors suggested were added to the list. Editing was done only to remove duplicate items. Seventy factors were identified.

The second stage was to send the list of factors in the form of a rating scale survey instrument to a sample of professional pilots to determine which factors influenced their choices. It was not possible to identify people who might have considered becoming a pilot and did not. Therefore, an assumption was made that by studying women and men who were already professional pilots, inferences could be made about individuals who did not choose to become pilots.

The population of professional pilots within the United States was identified through a commercially sold CD containing the 1998 FAA database of pilots' names and addresses (Avantext, Inc.). Random samples of 300 female and 300 male pilots were drawn. The first 250 within each sample were considered to be the primary sample. The 50 additional people in each sample were designated as random alternates to replace people whose surveys were never delivered due to an inaccurate address.

The survey instrument had two parts. The first gathered demographic data from the subjects on three variables: gender, number of years as a professional pilot, and type of pilot. The three types of professional pilots were airline, corporate/charter, and "other" pilots. The second part contained a rating scale designed to allow subjects to rate the extent to which they felt each of the 70 factors identified during brainstorming influenced their decision to become a pilot. Subjects rated each factor using the following scale.

<table>
<thead>
<tr>
<th>-3</th>
<th>-2</th>
<th>-1</th>
<th>0</th>
<th>+1</th>
<th>+2</th>
<th>+3</th>
</tr>
</thead>
<tbody>
<tr>
<td>strong negative influence</td>
<td>no influence</td>
<td>strong positive influence</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Positive ratings indicated a factor had a positive influence and negative ratings indicated it had a negative influence. A rating of zero indicated it had no influence. It was decided that a zero rating would be defined as a rating between -.5 and +.5 because less than .5 would be rounded to zero. Therefore, in order for a rating to be considered it would have to be less than -.5 or to be positive it would have to larger than +.5.

Data Gathering

Once the instrument was developed it was sent with a cover letter explaining the study to all 300 male and 300 female pilots. In addition two follow-up mailings were sent to those who did not respond. During the three mailings
52 male and 56 female survey instruments were returned incomplete because of bad addresses. Since two more inaccurate addresses were found for males and 6 more were found for females the effective sample was 248 males and 244 females. This resulted in an overall response rate was 68% (333/492). The response rate from the males was 66% (163/248) and the response rate from the females was 70% (170/244).

Results

Demographic Data

The demographic variables of type of pilot and years as a professional pilot were analyzed to determine if there were significant differences between males and females. The data are presented in Tables 1 and 2. Results of chi-square analyses revealed that there was no significant difference in the distributions of types of pilots between males and females ($X^2 = 1.853, p = .396$). The largest number of pilots were airline pilot and the smallest number were corporate. However, there was a significant difference in the length of time the males and females had been pilots ($X^2 = 36.732, p < .000$). The males tended to have been pilots for a longer period of time than females.

Positive and Negative Influences

The factors that positively and negatively influenced choices to become professional pilots were analyzed by first calculating the mean ratings to each factor for males and females. Positive means meant the factors had a positive influence and negative means meant they had a negative influence. The factors were then placed in rank-order according to the means separately for the females and males. The rank-orders assigned by males and by females were compared using a rank-order correlation. The rank order correlation indicated that the ordering of the factors by both men and women was very similar ($r = .77, p < .05$). Because of this overall similarity the ratings of the men and women were combined and overall mean ratings were placed in rank order to represent the ratings of the total group as presented in Table 3.

Sixty of the 70 factors were found to have a positive influence on career choice and 10 were found to have a negative influence. After applying the decision rule that mean ratings between -.5 and +.5 would be treated as zero ratings, 33 factors were identified as positive and only one was negative. Those that fell between - .5 and + .5 are indicated in Table 3 in italics. Cost of required training/education was the only negative factor remaining.

A review of the positive factors suggests that they can be categorized into the following themes: enjoyment of aviation, support of peers and flight instructors, perception of career and education requirements, desire for challenge and responsibility, early exposure to aviation, science, and technology, perception of potential income and lifestyle.

Differences Between Male and Females. Although the relative ordering of the factors by males and females were similar as indicated by the rank order correlation, differences the actual magnitude of the influence of the factors for females and males were examined for each of the factors separately. It was possible that although males and females would view the various factors similarly in terms of their rank order of influence, the actual amount or strength of influence of the factors for males and females could be different.

T-tests analyses were conducted on those factors for which either the males or females had average ratings of less than -0.5 or more than +0.5. Those analyzes indicated there were significant differences between the male and female ratings at the .05 level on 20 factors even though both groups felt the 20 factors were positive. The analyses are presented in Table 4. The differences were calculated by subtracting the male mean from the female mean to show the direction of the difference in reference to the female responses.

Table 5 presents a summary of the factors that have a more positive influence on men and women becoming pilots and those that seem to affect both groups equally. Men appear to be influenced most by monetary reward, the technical and scientific nature of the occupation, the military career potential, and the glamour and mystique of flying. Also, men found having same gender teachers and mentors more important than women. Women found factors such as exposure to and desire to choose a non-traditional work role, opposite gender mentors and role models, desire for a challenging career and to prove their personal abilities as more positive factors than men. They also saw possibilities of travel and flight instructor encouragement as more important factors. Although both groups saw cost of training as a negative influence, men were less influenced by the cost of training than women.

Discussion and Implications

This study demonstrated that force-field analysis is a viable technique for identifying factors that could affect the recruitment of people into various occupations. When applied to the role of professional pilot it was able to
identify factors that have tended to motivate males and females to become professional pilots. Although it also identified some factors that might have a negative influence, it only identified one that might be considered to be a significant negative influence. However, this is probably not a shortcoming of the force-field analysis procedure but a shortcoming of this study. It was not possible to identify a group of people who decided not to become professional pilots. Therefore, the data were gathered from a group of people who became pilots and who therefore personally decided in the past that the positive factors outweighed the negative factors.

The study also indicated that although men and women seem to be affected by the same factors, some are more important to men and some are more important to women. Although people have suggested this in the literature studies have not been available to provide firm information on such differences. The discussion around Table 5 above presents those differences for men and women professional pilots.

The information generated from this study can have a major impact on the ways in which aviation personnel address the shortage of professional pilots. In the past, aviation educators and industry leaders have mainly tried to recruit both men and women at the same time. A new strategy of recruiting men and women separately, especially women, is now starting to emerge in the industry. A better understanding of the impact on career choice of the influence factors identified in this study could improve the effectiveness of both of these recruitment strategies.
By examining the career choice influence factors identified as being common to both men and women, aviation educators and industry leaders should be able to focus their resources on recruitment strategies that will have more appeal to both men and women. However, the greatest increases in the numbers of both female and male pilots would more likely be obtained by developing recruitment strategies that appeal separately to men and women. To do this, influence factors identified in this study where men and women differed significantly need to be considered in recruitment.

Some of the factors that were identified to be positive and negative influences on career choice in this study are familiar to aviation educators, but many are not. Past recruitment strategies have often revolved around the fun and challenge of flying, the potential income and lifestyle of being a pilot, and the cost of learning to fly. However, past recruitment efforts have not displayed an understanding of many of the other themes identified in this study such as, the importance of role models and mentors, the impact of perceived training requirements, peer support, and the desire for responsibility. To develop more effective recruitment strategies aviation educators need to become better informed about these less understood influence factors.

Literature on general and non-traditional career choice identified many of the same important influence factors as this study. For example, the importance of role models was identified as important in the literature and in this study. Aviation educators and aviation industry members should take note of the existing studies on career choice, along with the information found in this study, to help develop strategies for increasing the number of professional pilots. Intervention strategies suggested by researchers such as Jewett (1996) for providing role models and early exposure to mathematics, science, and technology could be helpful guides for increasing the number of men and women choosing careers as professional pilots.

Many items were also identified as having no or very little influence on professional pilot career choice. Identifying these factors can also be important. Given the limited resources available for recruitment, such information can be useful in discontinuing past practices that may have little influence.

The results of this study have general implications for the recruitment of personnel. They suggest that using force-field analysis it is possible to identify factors that positively and negatively occupational choice. They also suggest that some factors affect men and women differently. This information can be extremely valuable in encouraging people to enter occupations where there are critical shortages. Some examples of how the information might be used are: developing recruitment efforts around factors which influence both men and women, developing separate recruitment efforts for men and women, minimizing recruitment efforts focused on factors not found to be significant, and trying to remove factors that have a negative influence. With knowledge generated from a study of this type, the effectiveness of recruitment efforts can be significantly increased.

Decision-making Processes in Novice and Expert Airplane Pilots

Edward L. Deitch
Albert K. Wiswell
Virginia Tech at Northern Virginia

Subjects were interviewed about their decision-making processes as they related to four aeronautical decision-making scenarios. Experts exhibited characteristics and themes that differed noticeably from that of the novices. One of the more pertinent differences involved what some writers have referred to as cognitive maps. These mental guides appeared to be used effectively by experts in attempting to cope with problems associated with decision-making scenarios. Novices also appeared to make use of cognitive maps in their decision-making processes. Their maps, however, were primitive in comparison to the experts and resulted in difficulties when attempting to address specific scenarios.

Keywords: Decision-making, Novice, Expert

General Aviation (GA) includes all aviation activities that are not directly related to either the military or the airlines. Both the military and commercial airlines have stressed formal decision-making training in their initial and recurrent pilot training programs. Such has not, however, been the case in GA. Although the Federal Aviation Administration (FAA) has mandated that aeronautical decision-making (ADM) be included in GA training programs, there are few current guidelines regarding the scope of such training. In addition, there is little specific information related to the conditions under which such training could best be delivered.

Judgment errors among GA pilots are well documented (e.g., Jensen and Chappell, 1983; National Transportation Safety Board, 2000). These errors have contributed to numerous accidents, injuries and fatalities. This study reviewed the decision-making processes of expert and novice aviators. It identified differences and suggested activities that could be incorporated into a Private Pilot Ground School (PPGS) course to assist novices in becoming better decision-makers.

The type of decision-making most pertinent to aviation-related activities has been referred to by numerous writers (e.g., Kaempf and Klein, 1994; Stokes, Kemper and Kite, 1997) as naturalistic decision-making (NDM). This particular type of decision-making, according to Orasanu and Connolly (1993), is characterized by decisions made under stress and involve ill-structured problems in which the decision-maker must react quickly in a dynamic and uncertain environment.

Problem Statement

There has been little written about decision-making and GA student pilots. Most of the more recent ADM studies (e.g., Driskill, Weissmuller, Quebe & Hand, 1998; Kochan, Jensen & Chubb, 1997; Stokes, Kemper and Kite, 1997) involved subjects with considerably more experience than that of the typical student pilot (under 100 hours of flying time). This study identified the ADM weaknesses of student pilot subjects and the ADM proficiencies of expert pilot subjects.

Two assumptions were made. First, it was assumed that the “expert” pilots were representative of experienced professionals. Second, it was assumed that the ADM written and video scenarios, that were used to obtain data, served as practical surrogates for pre-flight and in-flight experiences of the subjects.

Although most of the ADM literature originates from the discipline of psychology, this study was viewed through the lens of an educator and certified flight instructor. Nevertheless, this study examined some of the cognitive processes as they related to ADM. The primary emphasis of the study was to better understand the thought processes of student and expert subjects and to use the data to help student pilots develop a practical foundation in ADM.

The research question explored the differences in pre-flight and in-flight decision-making processes between novice and expert subjects. The study determined that significant differences did exist. These differences are summarized in Figure 1.

Method

Four student pilot (SP) subjects were selected from students enrolled in a PPGS course that was taught at Montgomery County Airpark, Gaithersburg, MD. Two preliminary studies were conducted during the Spring and Fall of 2000. During the preliminary studies it was determined that SPs needed to have acquired a minimum of flying time and experiences to be useful participants in the study. The minimum requirements for SPs, therefore, consisted of: a. twenty hours of flight time; b. soloed (subjects had flown an aircraft by themselves); c. currently involved in cross-country flight training; d. had acquired knowledge applicable to ADM scenarios (in PPGS and during flight training). All of the student subjects were males between the ages of twenty-one and thirty-eight.

Four expert pilot (EP) subjects were also selected for inclusion in the study. Criteria for their selection was based on several requirements that included: a. a minimum of five thousand hours of flight time; b. currently working as a professional pilot; c. had worked as a professional pilot in a minimum of two mediums (e.g., flight instructor, charter pilot, airline pilot, etc.). The researcher was fortunate to locate four EPs whose experience and flying time far exceeded these minimums. All of the expert pilots were males between the ages of thirty-six and sixty-two.

The data for the study was acquired through interviews of the subjects. The interviews were based on three ADM written scenarios and one video scenario. The written scenarios were selected from fifty-one ADM scenarios contained in an FAA study (Driskill, Weismuller, Quebe, Hand and Hunter, 1998). The written scenarios were revised during the pilot studies to include more variables that would, it was assumed, be useful in eliciting additional information from the subjects. Two of the written scenarios involved in-flight decision-making. One of the written scenarios involved pre-flight decision-making. The video scenario (FAA, 1991), included both pre-flight and in-flight decision-making segments.

Each of the subjects was presented with the three ADM written scenarios. The first part of each interview consisted of the subject’s general reaction to the scenario. A variety of topic areas were compiled by the researcher.
into an Interview Guide that was used to help focus the conversation on pertinent issues. The second part of the interview consisted of presenting the subjects with four written alternatives. The subjects were asked to rank order the alternatives and to explain their reasons for ranking the alternatives as they did. An example of one of the scenarios used in the study is presented in Figure 2.

Figure 2. Scenario 3: Presented to Students and Expert Subjects

You are at a small airport with minimal facilities and at the end of your walk around pre-flight, the flaps refuse to retract from 30 degrees. It was a planned two hour flight back to your home airport. The weather, which was good, seems to be deteriorating with higher winds and lower ceilings than were forecast. A friend, who is a student pilot, at your home airport, has scheduled your aircraft for his Private Pilot flight test with the FAA in four hours. An airport attendant (who is not a mechanic) says he has seen this problem before and states that the “limit switch is stuck.” There is no Airframe and Powerplant (A&P) mechanic at this airport, but there is an A&P mechanic at an airport 35 miles away. The attendant says he knows where a switch for this exact model aircraft can be quickly picked-up and he could install it. He says he also could reach up through the inspection port and free the switch enough to raise the flaps but cannot guarantee they will work when airborne. You call the flight school and get their answering machine. You are on your own. You decide to:

<table>
<thead>
<tr>
<th>Rank Order</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3 4</td>
<td>a. leave the flaps down and fly to the nearby (35 miles) airport and have a certified (A&amp;P) mechanic fix the problem</td>
</tr>
<tr>
<td>1 2 3 4</td>
<td>b. have the attendant reset the switch, get the flaps up and fly home.</td>
</tr>
<tr>
<td>1 2 3 4</td>
<td>c. have the attendant change the switch, check it out then fly home and have the flight school’s mechanic inspect the work</td>
</tr>
<tr>
<td>1 2 3 4</td>
<td>d. wait until the flight school can fly an A&amp;P mechanic in and change the switch</td>
</tr>
</tbody>
</table>

The response format for the video scenario was also changed from what had been done during the initial pilot study. The first portion of the video scenario involved pre-flight actions. This was followed by an in-flight section. During the pilot studies, it was determined that stopping the video after each segment (pre-flight and in-flight) and interviewing the subjects about each portion of the video independently, resulted in an increase in the quantity and quality of data.

The data acquired during the interviews was transcribed and coded by the researcher. Open coding, a process that involves fracturing the data, was followed by axial and selective coding as described by several writers (e.g., Strauss and Corbin, 1998; Yin, 1994). The identification of characteristics and general themes began to emerge during that process. The characteristics and themes were subjected to peer review during several coding seminar sessions.

The research design sought to establish the pre-flight and in-flight decision-making characteristics and themes of student pilot and expert pilot subjects. The design also sought to make direct comparisons. These comparisons included: a. SP pre-flight with SP in-flight; b. EP pre-flight with EP in-flight; c. SP pre-flight with EP pre-flight; d. SP in-flight with EP in-flight; e. SP in-flight with EP pre-flight and f. SP pre-flight with EP in-flight.

Relating Findings to the Literature

Numerous researchers (e.g., Cannon-Bowers, Salas & Pruitt, 1996; Orasanu and Connolly, 1993; Simon, 1981, etc.), have written about NDM. This type of decision-making is characterized by “real world” conditions in which dynamic environments, time constraints, stress and uncertainty affect one’s thought processes. The subjects in this study were presented with scenarios that included such conditions. The extent to which the subjects were able to cope with the issues inherent in the scenarios was dependent on their respective experience levels, training and knowledge of the subjects. Overall, and not surprisingly, the EP subjects were better able to cope with issues included in the scenarios than were the SP subjects. One of the possible explanations for the superior judgment abilities of EPs in naturalistic settings was what some writers (e.g., Craig, 1998; Klein, 1997; Stokes, Kemper & Kite, 1997) have referred to as “recognition-primed decision-making” (RPD).

RPD was described by Klein (1997) as a process in which decision makers used a combination of knowledge, experiences and wisdom to make intuitive judgments. He emphasized that accumulated experiences were important and significant factors in helping make quick and effective decisions. Klein explained that these experiences helped decision makers recognize important “cues” that were used as guides for developing responses to specific problems.
It was apparent that the EP subjects made use of their experiences in addressing the issues inherent in the scenarios presented to them during their interviews.

Another useful explanation for the superior judgment abilities of EPs in naturalistic environments involves the concept of "cognitive maps." Tolman (1948) in his experiments with rats, stated that:

The stimuli, which are allowed in, are not connected by just simple one-to-one switches to the outgoing responses. Rather, the incoming impulses are usually worked over and elaborated in the central control room into a tentative, cognitive-like map of the environment (p. 191).

Cognitive maps have been used by numerous researchers (e.g., Csanyi, 1993; Laszlo, Artigiani, Combs and Csanyi, 1996) to examine behaviors and to explain the resolution of problems in a variety of settings. Laszlo, et al. defined cognitive maps as:

...mental representations of the worlds in which we live. They are built of our individual experiences, recorded as memories and tested against the unceasing demands of reality. These maps, however, do not simply represent the worlds of our experiences in a passive and unchanging way. They are, in fact, dynamic models of the environments in which we carry out our daily lives, and as such determine much of what we expect, and even what we see. Thus, they represent and at the same time participate in the creation of our experience of reality itself (p. 3).

Student subjects in this study appeared to make use of mental maps in their thought processes. The cognitive maps of SP subjects, however, were primitive in comparison to those of the experts. Although the SP subjects attempted to rely on pertinent experiences, their maps were rudimentary and consisted of numerous gaps. Many of these cognitive gaps could have contributed to the presence of several observed characteristics that included; uncertainty, inability to recognize alternatives, an emphasis on rules and procedures and the presence of hazardous attitudes.

In contrast, the cognitive maps of EPs in this study appeared to be significantly more developed. The experts were able to quickly make connections between problems presented in the scenarios and their experiences. These experiences provided them with a more detailed map and enabled them to find alternate routes to a desired end. The result was that they were able to quickly and effectively formulate viable alternatives. For example, one expert pilot, reflecting on an electrical problem that almost resulted in an accident remarked:

But you know, you know from your experiences you learn to look for certain things and do certain things. You know, I know if I have a flickering light on a display, I’m gonna look real close at those alternators. Make sure they’re charging; make sure the battery is charging.

When experts were unable, because of time constraints, to rely on their cognitive maps they were quick to rely on another process that some writers (e.g., Jensen, 1995) have referred to as “satisficing.” The concept of "satisficing" involves making decisions within the time constraints of a naturalistic environment. It involves choosing a course of action that, while not the absolute best alternative, would not necessarily result in negative consequences and would represent a viable option. During interviews with expert subjects, several related incidents in which a "satisficing" based response was evident.

But you know, you know from your experiences you learn to look for certain things and do certain things. You know, I know if I have a flickering light on a display, I’m gonna look real close at those alternators. Make sure they’re charging; make sure the battery is charging.

When experts were unable, because of time constraints, to rely on their cognitive maps they were quick to rely on another process that some writers (e.g., Jensen, 1995) have referred to as “satisficing.” The concept of "satisficing" involves making decisions within the time constraints of a naturalistic environment. It involves choosing a course of action that, while not the absolute best alternative, would not necessarily result in negative consequences and would represent a viable option. During interviews with expert subjects, several related incidents in which a "satisficing" based response was evident.

Student subjects were unable to depend heavily on either cognitive maps or the concept of "satisficing" to resolve problems. Student subjects, therefore, tended to rely on established procedures. In addition, they frequently exhibited hazardous attitudes that had the effect of making a bad situation worse.

Diehl, Hwoschinsky, Lawton & Livak (1987) identified five hazardous attitudes. They included: a. anti-authority (not willing to comply with rules and regulations); b. impulsiveness (acting quickly without thinking); c. invulnerability (refusing to believe that negative events could occur); d. macho (overestimating one’s competencies) and e. resignation (giving up — taking no action to improve a situation). During student subject interviews, three of these attitudes (impulsiveness, invulnerability and macho) were evident on numerous occasions. In addition, SPs demonstrated another dimension that I included as a hazardous attitude. That dimension was their tendency to allow “irrelevant factors” to influence their decision-making processes. None of the EP subjects revealed any of the hazardous attitudes during their respective interviews.

Two of the five hazardous attitudes were not observed during interviews with student subjects. None of the SPs displayed resignation during their interviews. In addition, the anti-authority hazardous attitude was not only absent but, to the contrary, student subjects were concerned about assuring they followed guidelines and procedures
and did not break any rules. This appears to confirm the findings of Dreyfus & Dreyfus (1986) who wrote about one's journey from novice to expert. Dreyfus & Dreyfus stated that this journey consisted of specific stages.

The Dreyfus' termed the first part of this journey as the *novice* stage. The writers stated that this initial level was characterized by learners receiving initial instruction in a particular subject. They also indicated that learners in this stage typically relied on facts and guidelines presented by their instructors without much regard to the context within which the situation (or scenario) occurred. The SP subjects were representative of the *novice* stage of the Dreyfus model. They consistently relied on established guidelines and procedures. In addition, the student subjects often relied on specific lessons that were either taught by their instructors or acquired through independent study.

Findings

There were differences in the decision-making characteristics of expert and student subjects. These differences are depicted in Table 1. The EP subjects in this study exhibited similar ADM thought processes as did experts in previous studies (e.g., Dreyfus and Dreyfus, 1986; Stokes, Kemper and Kite, 1997). They were quick to recognize cues from their experiences to help resolve scenarios. It was apparent that their respective cognitive maps served as useful and effective guides. For example, prior to making their "go-no/go" decision, EP subjects exhibited detailed pre-flight planning that included everything from reviewing the legal aspects of a planned flight to the cumulative effects of fatigue and stress. The SP subjects ignored these important pre-flight considerations.

The expert subjects also attempted to place each of the scenarios in its larger context. They frequently asked questions to assure they completely understood the overall framework within which the scenarios occurred.

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Differences in Decision-making Characteristics</th>
</tr>
</thead>
</table>
| **SP Pre-flight and In-flight** | -Limited number of items to consider while In-flight, but not in Pre-flight  
-Made Attempts to calm down and take time to assess risks while In-flight, but not in Pre-flight |
| **EP Pre-flight and In-flight** | -Sought information only from qualified individuals in Pre-flight ADM  
-Considered effects of stress and fatigue during Pre-flight ADM |
| **SP and EP Pre-flight** | -SPs: inadequate information - adhered to rules and procedures - exhibited Hazardous Attitudes  
-EPs: Sought information only from qualified individuals - planned diligently (detailed analysis of all pertinent issues) |
| **SP and EP In-flight** | SPs: recalled experiences they believed to be helpful - recognized few alternatives - purposely limited number of items to consider  
EPs: used prior experiences to help resolve problems - prioritized plans and back-up plans |
| **SP In-flight and EP Pre-flight** | SPs: hesitant and uncertain - stressed importance of calming down and take time to assess risks  
EPs: considered effects of stress and fatigue - ignored options that they believed involved excessive risks |
| **SP Pre-flight and EP In-flight** | SPs: adhered to rules and procedures - realized their inexperience but nevertheless chose demanding and sometimes dangerous alternatives (hazardous attitudes)  
EPs: established the general context within which the scenario existed - defined the specific conditions of the scenario - reluctant to depend on others (self-reliant) |

In addition, the experts asked numerous questions about each of the scenarios in an attempt to acquire as many specific details as possible.

Student subjects, responding to in-flight decision-making scenarios, frequently attempted to limit the amount of information available for processing. Two SPs remarked that they did not want to be "overloaded" with information. This sometimes resulted in SPs stressing information that was not particularly pertinent while ignoring factors that were relevant. Several of the student subjects also talked about trying to "calm down" while attempting...
to resolve in-flight decision-making scenarios and discussed methods (e.g., departing the traffic pattern at an airport) to allow themselves time to determine an appropriate course of action.

Student subjects stressed rules and procedures in their responses to issues related to the scenarios. These rules and procedures emanated from a variety of sources including: a. pilot's operating handbook; b. Air Traffic Control; c. FAA rules and regulations; d. guidelines established by flight and ground instructors and e. procedures and guidelines obtained during self-directed learning. In addition, the student subjects often hesitated in attempting to chose an alternative and frequently changed their minds.

All of the SP subjects, in their responses to decision-making scenarios, demonstrated hazardous attitudes. Even though they seemed to recognize the fact that they were inexperienced, and attempted to abide by rules and guidelines, SP subjects often chose alternatives that involved difficult and sometimes even dangerous options. The student subjects also frequently elected to chose alternatives without acquiring all pertinent information. This could be a result of their incomplete cognitive maps.

Need for Further Research

This study established differences between the ADM characteristics of expert and novice subjects. The study did not, however, result in findings necessarily generalizable to a larger population of pilots or to decision-making in other contexts. Additional research will be required to accomplish that goal. A variety of additional studies could prove beneficial.

A quantitative study, including relatively large numbers of student pilot subjects, could build on the findings of this study. For example, such a study could measure (via. pre-tests and post-tests) the presence of hazardous attitudes (or other attributes) among student pilots. Acceptable subjects would be divided into a control group and a treatment group that received ADM training within, for example, the context of a Private Pilot Ground School (PPGS). In addition, it would be interesting to note how those involved in such a study progressed in their respective careers as pilots. Although challenging to conduct, such a longitudinal study could reveal important data related to the value of ADM training received early in one's flying career.

As noted previously, all of the SP subjects had displayed hazardous attitudes in their ADM thought processes. None of the EP subjects displayed such attitudes. Was this due exclusively to the differences in the relative experience levels of the subjects? Additional research will be needed to confirm that assumption and to identify specific training methods that could prove productive in reducing hazardous attitudes. In addition to the hazardous attitudes noted by numerous writers (e.g., Berlin, Gruber, Jensen, Holmes, Lau, Mills & O'Kane, 1982; Diehl, Hwoschinsky, Lawton & Livak, 1987) I included a tendency to rely on outside factors (factors that have no relevant bearing on a particular problem) as a hazardous attitude. The extent to which these outside factors affect decision-making of novice pilots, and what can be done to eliminate them, remains to be discovered.

The use of simulators, rather than written and video scenarios, could also be useful in obtaining data from subjects. Although ADM studies involving simulators had been done in the past, (e.g., Connolly, 1990; Stokes, Kemper & Kite, 1997) none of the subjects involved student pilots (students who had not earned their private pilot licenses). Providing subjects with ADM scenarios in simulators as student pilots could prove to be useful both to the researcher (in acquiring data) and also to the subjects (whose ADM experiences could result in a more profound and lasting impression).

As stated previously, the student subjects in this study had all soloed and had begun their cross-country flight training. In addition, all of the student subjects had acquired a minimum of twenty hours of flying time and had received flight and ground instruction in subject matter pertinent to the written scenarios. One wonders, however, if the results would have been different had the student pilot subjects been more experienced. For example, would the findings have been different had the student pilot subjects consisted of those who had completed their cross-country training, ground school training and were in the process of preparing for their Private Pilot flight test with the FAA?

The concept of cognitive maps, as they relate to expert and novice ADM is another area in need of additional research. The evolution of such maps and methods to assist novices in their development could produce useful data. In addition, it would be interesting to examine individuals who are pre-disposed to developing cognitive maps. Determining the characteristics of such individuals and the basis of their pre-dispositions could yield important insights into helping students acquire the ADM skills of experts.

Two of the student subjects discussed how they had read a variety of publications (e.g., books, magazine articles, etc.) that they assumed had helped them become better decision-makers. These readings were in addition to the required readings related to the PPGS course in which they were enrolled. One of these self-directed learners (SP3) appeared to be more proficient than the other subjects in coping with the scenarios presented in the study. A study involving the role of self-directed learning in the acquisition of ADM skills could prove enlightening. It
would also be interesting to note whether there was a relationship between those who were prone to self-directed learning and those who were predisposed to forming and using cognitive maps. One could also study the relationship and possible correlations of those attributes to the acquisition of ADM competencies.

It would also be interesting to determine whether this research has wider applications. Research involving expert and novice decision-making in naturalistic environments could have many possible applications. For example, one might consider conducting research among fire-fighters or police officers. In addition, one might acquire useful information from expert and novice managers or administrators, in a variety of settings, who find themselves in environments characterized by time constraints, stress and problems that are difficult to define.

Recommendations

The data obtained in this study made it clear that there were notable differences in the pre-flight and in-flight ADM thought processes of expert and novice subjects. Furthermore, the study demonstrated that expert subjects, in naturalistic settings, relied on their cognitive maps to assist them in coping with issues in each of the scenarios. It seemed clear that the student subjects would benefit from training designed to assist them in developing more detailed and comprehensive cognitive maps. The specific components of such training could be based on the research of numerous writers.

For example, several researchers (O'Byrne, Clark and Malakuti, 1997) suggested methods to assist novices in acquiring the skills of experts. Generally, the researchers emphasized that such programs should stress both basic principles and theories as well as opportunities to apply these principles and strategies to realistic and relevant scenarios. Other researchers (Dreyfus and Dreyfus, 1979), in their research related to training pilots to cope with emergency situations, emphasized that effective training must be based on specific contexts. The writers suggested that pilots should be exposed to a large number of relevant scenarios to enhance their abilities to recall appropriate courses of action. Wiggins (1997) stressed that teaching cognitive skills to novice aviators was vital to their development. He stated that such cognitive training could include such activities as protocol analysis (thinking aloud while performing a task) and the analysis of errors (reviewing accident reports). These suggestions could potentially serve as effective cognitive map builders and assist novices in both pre-flight and in-flight ADM.

As previously mentioned, hazardous attitudes are well documented in the literature and were apparent in all of the SP subjects involved in this study. Accordingly, a discussion of these attitudes that includes their causes and possible remedies should be included early in the PPGS and could serve as an excellent introduction to the ADM portion of the PPGS. If possible, instructors should also attempt to include scenarios that demonstrate these hazardous attitudes.

Conclusion

Furnishing students with the knowledge necessary to pass an FAA examination has always been the primary focus of PPGSs. A PPGS could also, however, provide students with a unique opportunity to enhance their ADM competencies. By substituting knowledge, in the form of ADM scenarios, for actual experiences, instructors could help students form more extensive and relevant cognitive maps. The enhancement of such maps could prove to be just as important and, perhaps, even more important than any specific topic covered in a PPGS. It is essential, therefore, that instructors consider including ADM training along with relevant scenarios within the context of PPGSs and other ground based, aviation-related courses. It is a pursuit worthy of our time, patience and best efforts.

Leading the Learning Organization

James R. Johnson
Purdue University Calumet

This paper examines the actions that a leader can take in order to transform an organization into a learning organization. Four leaders of widely diverse organizations were studied. The research indicated that leaders who were successful in implementing the learning organization concept used it as the solution to a business problem, while devoting time and attention to the transformation. The findings have widespread implications for HRD practitioners, adult educators and for future research.

Key words: Leadership, Learning Organizations, Organization Development

The topic of the learning organization has commanded a great deal of attention. Senge's (1990a) writing was an important contribution to the avalanche of literature on the subject. Although the literature base pertaining to learning organizations is expansive, the vast majority of the writing is descriptive in nature. Few authors and researchers have offered suggestions to senior managers on how to transform their organization into a learning organization.

The purpose of this research was to capture the specific actions of those leaders who have successfully implemented the learning organization concept. It addresses the question of how senior managers and chief executive officers (CEOs) might apply specific leadership actions and behaviors in order to foster organizational learning. Argyris (1992), commenting on barriers to organizational learning, stated that: researchers did not focus upon producing actionable knowledge on how to reduce or lower these barriers. In those cases where they did, the advice was either disconnected from the world of practice, or, when examined carefully, the advice could actually strengthen the very barriers that were supposed to be overcome. (p. 1)

Theoretical Framework

Two bodies of literature provide the theoretical framework for this research: the learning organization literature is relatively new, while the leadership literature is vast. At the intersection of the two lies very little, and provides the subject of this research.

The Learning Organization

Watkins and Marsick (1996) wrote that three frameworks are useful for examining the 22 learning organizations contained in their edited work, In Action: Creating the Learning Organization. These three frameworks, from the simplest to the most complex, are that of:

1. Watkins and Marsick (1993);
2. Pedlar, Burgoyne, and Boydell (1991); and

Watkins and Marsick (1993) offered the simplest definition when they defined a learning organization as one "that learns continuously and transforms itself" (p. 8). Pedlar et al. (1991) defined the learning company as "an organization that facilitates the learning of all of its members and continuously transforms itself in order to meet its strategic goals" (p. 1). Senge's (1990a) definition is the most complex. He defined the learning organization as one "where people continuously expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together" (p. 7).

Although these frameworks capture the fundamentals of the learning organization, two others deserve note. Marquardt (1996) defined the learning organization as one "which learns powerfully and collectively and is continuously transforming itself to better collect, manage, and use knowledge for corporate success" (p. 80). Garvin (1993) described the learning organization as one "skilled at creating, acquiring, and transferring knowledge, and at modifying its behavior to reflect new knowledge and insights" (p. 80).

Widely cited in the literature were such diverse organizations as Shell Oil, Motorola, TRW Space and Defense Group (Redding & Catalanallo, 1994), Arthur Andersen, Caterair International, Royal Bank of Canada (Marquardt,
1996), Johnsonville Foods, and Chaparral Steel (Watkins & Marsick, 1993). All of these organizations have achieved the transformation to learning organization status.

**Leadership**

Heilbrun (1994) pointed out that rigorous study of leadership is divided into three stages. The earliest stage attempted to identify traits of leaders. The next stage focused on the behavior of leaders, and the third and current stage centers on the interaction between leaders and those they lead. Heilbrun (1994) went on to say that the future of leadership studies might lie in the understanding that the most significant aspects of leadership are far beyond the ability to study them.

Many hundreds or even thousands of definitions of leadership exist, ranging from the abstract to the simple. Locke, Kirkpatrick, Wheeler, Schneider, Niles, Goldstein, Welsh, & Chah, (1991) offered one definition: "We define leadership as the process of inducing others to take action toward a common goal" (p. 2). Bethel (1990) proposed a more precise definition of leadership as simply "influencing others" (p. 6).

However, a more current definition of leadership was provided by Senge (1996), who defined leaders as people "who are genuinely committed to deep change in themselves and in their organizations" (p. 36). The most useful definition, though, was provided by Bennis (1984), who noted that "leaders are people who do the right things; managers are people who do things right" (p. 19). This separation of leaders from managers takes on great importance. Bennis and Nanus (1985) clarified this when they wrote that the "problem with many organizations, and especially the ones that are failing, is that they tend to be overmanaged and underled" (p. 21).

Although the discussion of leadership is important as a foundation for this research, the focus here is on leadership actions that transform organizations. Burns (1978) differentiated between transactional and transforming leadership. Transforming leadership, according to Burns, is the type of leadership that raises both leader and follower to "higher levels of motivation and morality" (p. 20). This idea was further amplified (Locke et al., 1993) to define transformational leadership as a type of leadership that changes organizations rather than maintaining them in their current state.

Bennis (1994) wrote that leaders are, by definition, "innovators" (p. 143). They must envision the desired state of an organization and take required action to enable the organization to achieve that state. Kotter (1996) identified eight stages of leading change: the first four involve reducing the forces that lead to the status quo, the middle stages introduce change, and the last steps incorporate the changed state into the fiber of the organization. The most detailed view of transformational leadership comes from Tichy and Devanna (1986). They wrote that transformational leaders revitalize organizations by recognizing the need for change, creating the vision for change, and enlisting the organization in the change process.

**Leadership and the Learning Organization**

At the intersection of the broad concept of leadership and the "murky" notion of the learning organization (Johnson, 1998, p. 148), there is little to provide specific guidance. Pagonis (1992) wrote that this must be accomplished "through rigorous and systematic organizational development" (p. 118). Senge (1993) posited that there is no formula or seminar for creating learning organizations.

Redding and Catalanello (1994) recommended that pockets of learning can form within an organization and may be shared with the rest of the organization. Senge (1990b) proposed that leaders need to be responsible for learning by building learning organizations, and Bennis (1984) wrote that leaders must value learning. Bennis and Nanus (1985) argued that leaders become expert at learning in the context of the organization, and Argyris (1991) insisted that leaders must learn how to learn. Senge (1990b) and others have stated that leaders must assume the role of teacher (Denton & Wisdom, 1991) in learning organizations.

Marquardt (1996) proposed what is possibly the most specific series of steps for leaders. He provided the "keys to success" along with the steps and strategies to achieve that positive outcome. According to Marquardt, the "keys" (p. 211) to a successful transformation to a learning organization are:

1. Establish a strong sense of urgency,
2. Form a coalition,
3. Create a vision,
4. Communicate the vision,
5. Remove obstacles,
6. Find short-term wins,
7. Consolidate progress and continue movement, and
8. Anchor change to the culture.
Three Emergent Themes. Three areas emerge from the literature base that merit further consideration: visioning, empowerment, and the leader's role in learning (Johnson, 1998; Senge, 1993). The ability to create a collective vision of the future with other members of the organization (Watkins & Marsick, 1993) appears to be a crucial action for leaders of learning organizations. Communicating the common vision to the organization (Wheatley, 1992) seems to be of collateral importance. Marquardt and Reynolds (1994) referred to the information flow throughout the worldwide organization. Senge (1990c) called this the "purpose story" (p. 353) or the "overarching explanation of why they do what they do." He described the difference between the current and the desired state as building "creative tension" (Senge, 1990a, p. 357), or the force that can move followers toward the vision by allowing them to share it as they understand their current reality.

A second theme that emerged from the literature deals with empowerment. Marsick (1994) defined empowerment as "interactive, mutual decision making about work challenges in which power for work outcomes is truly shared" (p. 19). Linda Honold, formerly director of Member Development at Johnsonville Foods (Watkins & Marsick, 1993), was quoted as saying "the learning organization is the result of empowerment" (p. 208).

A third theme derived from the literature involves the leader's role in learning. Argyris (1993) called it the competence of "leading-learning" (p. 5). Marquardt and Reynolds (1994) indicated that the leader must model continuous learning. Barrow and McLaughlin (1992) indicated that this new kind of leadership would, by necessity, tie learning to strategy. Johnson (1998) provided a "Learning Organisation Leadership Model" (p. 146) that contains an "alignment" of the three leadership themes and Woolner's (1995) five-stage model of the learning organization. In this model, he essentially posits that the three leadership qualities, when blended in a specific fashion, allow an organization to move through the five stages as identified by Woolner (1995). This blending of qualities, according to the model, allows the organization to reach the ultimate goal as a learning organization.

Research Design and Methodology

Creswell (1998) referred to research design as the entire research process, not simply the methods. Yin (1989) similarly offered that the research design is a plan of action for getting from the original set of questions to the narrative containing the findings and conclusions. Merriam and Simpson (1995) wrote that the use of case-study research is appropriate when a gap exists in the knowledge base. The design of this research effort was a qualitative case study, and the unit of analysis was four individual leaders who had engaged in the process of transforming an organization into a learning organization. Stake (1995) indicated that the case is "a specific, a complex, functioning thing" (p. 2). In this study, in an attempt to understand this complex functioning, several selection criteria were used to select the individuals or the cases. First, there needed to be a commitment within the organization to become a learning organization. Second, the organization had to be cited in the current learning organization literature or must have as a written strategic business objective the learning organization outcome. Table 1 presents the demographics of the four research cases.

Data were collected using semi-structured interviews, document and archived record reviews, and researcher observations. To ensure validity, like questions were asked of each respondent (Merriam, 1988) and at least two
other sources were interviewed within each leader's organization. Interviews were recorded and later transcribed verbatim by the researcher. Interview transcripts were coded and analyzed by the researcher to determine themes. The 'Data Analysis Spiral' (Creswell, 1998, p. 143) was utilized as the basis for data analysis. In order to minimize the effects of researcher bias, two trusted peers continually provided feedback during the research process.

Guiding this study were three research questions:
1. What precipitated the decision to transform the organization into a learning organization?
2. Why is the learning organization concept chosen as a desired outcome?
3. What specific actions by leaders enable them to develop a learning organization?

Research Findings

Results drawn from the data are organized and presented according to research question and are summarized in Table 2. Research Question 1 asked, "What precipitated the decision to transform the organization into a learning organization?" The data showed that two factors contributed to the decision to embark on a learning organization initiative. The first was a clearly delineated business problem. One of the leaders typified this when he indicated that:

Basically, what it was is we had just suffered through a year in which we had lost $50 million. And we were on the blocks in 1992 when [the former CEO] was still in charge. He was pretty disappointed with us and we were always hearing rumors that we were going to be gone. And what we realized we needed to do was we needed to do a couple of things. We needed new technology. We had to have the design and release of our own parts. We had basically just been an assembler of parts that were designed by engineers. So we needed our own technology. We needed to become full service, be responsible for our own design and responsibility; we had to go global.

The second contributing factor reported was that learning was either implicitly or explicitly stated in the charter of the organization. Another leader amplified this by saying:

I think there was always a grounding that this was a place of learning, this is a community that needs to reflect on what is known, that needs to create feedback mechanisms to insure that learning is known and mutually shared, that needs to develop a collective sense of ownership, that needs to be grounded because of the feeling that the stronger and clearer our beliefs and mission were, the more freedom people would have to implement and act [on] those in their own way. We all always wanted, I think, a sense of adaptation and flexibility.

The common theme discovered was that the leader must clearly identify the need for increased learning, while articulating this need to the organization in a way that makes sense. Identification of this need may take many forms; economic survival, or a core function of the organization. Regardless, this research showed that a logical rationale must underlie the inception of the learning organization initiative. This notion supports many of the tenets found in the leadership literature but was best presented by Tichy and Devanna (1986) when they wrote that leaders must recognize the need for change.

Research Question 2 asked, "Why is the learning organization concept chosen as a desired outcome?" The research indicated three reasons. First, the learning organization concept was chosen as a solution to a real business problem. It can not be viewed as simply a "quick fix or panacea" (Senge et al., 1994, p. xii). One leader described this when he said,

And it was shortly thereafter that we needed to tap our biggest problem at that time, which was launching new products. And we had some launches going on at that time that were very difficult. They just devoured the whole division. And we said, we've got to learn from these things because we are going to be launching a lot of new products in the future. We can't go through this pain. So we put together a cross-functional team involved with launching new products. And they immediately decided that they needed to expand to incorporate more of the other departments that are involved in the launch of a new product.

Second, the leaders chose the learning organization concept because it fit their own mental models. All four leaders chose this as an organizational outcome because it fit with their previous life experience. One leader provided an example when she said:

We didn't think about being a learning organization. And that is why I don't believe it was a conscious decision to be a learning organization. I think people maybe read about it and maybe people decide they want to do it, but certainly in our case, it didn't evolve that way. There was an interest in learning and our organization was about learning and the agency was about learning. It was about the agency learning.

Third, none of the leaders studied utilized a specific model or framework to guide them in their journey. Such
an abstract concept as the learning organization appeared to be difficult for the organizations to understand.

Research Question 3 asked, "What specific actions by leaders enable them to develop a learning organization?" This question rested at the center of this research project. The research uncovered several effective leadership actions. First is that they paid attention themselves to the learning organization initiative. One of the interviewees said, "What he did was he basically endorsed it, made sure it was part of the strategic initiative so he gave it visibility, and then he attended as many dialogue sessions or team learning project meetings as he possibly could." This supports the importance of "leading-learning," proposed by Johnson (1998) in the Learning Organization Leadership Model and drawn from Argyris (1991, 1992, 1993).

Second, and allied to the importance of personal attention by the leader, was the importance of the leaders insisting that others in the organization pay attention to the initiative. The idea that everyone in the organization must pay attention to learning ran through the data. In practice, this may mean the inclusion of organizational learning as a strategic planning initiative. One leader clarified this when she reported:

We began a formal strategic planning process, which created a team of stakeholders where you have to craft a belief statement—and your mission, and your objectives, and strategies, and action plans. And this is a new way of thinking for the organization. We were brand new, and we had all come together and [been] drawn in some way to a mission and a vision of what was articulated and drawn to a sense of possibility that every person brought to the institution. Table 2 summarizes the results of this research.

Summary and Discussion

By studying four leaders who embarked on learning organization initiatives, this research indicated that:

1. The decision to develop a learning organization should be based on a clearly defined business need, or business problem, or was stated in the charter of the organization.
2. The learning organization notion must be analyzed and determined to be the rational solution to this business need or problem. Even though none of the leaders used a specific framework, the learning organization concept must fit their own mental model.
3. Leaders need to pay attention to this initiative, ensure that others in the organization are focused on it, and institute an appropriate reward system. The attention and focus required may take place in the strategic planning process.

Several additional findings were uncovered by this research:

1. The process of crafting a learning organization cannot be initiated or sustained by those who do not hold a position of power within an organization. For example, it is doubtful that human resource development directors can successfully begin this process. Top business leadership must initiate or at least fully sanction this effort. This supported by Watkins and Marsick (1993) when they asserted that "You cannot build a learning organization from within the training department" (p. xvii). Leaders must then make others aware of the need for carefully chosen strategic initiatives. The initiative must be tied to strategy in order for it to be successful. Successful implementation of the learning-organization concept is dependent upon practitioners who reside in positions of organizational influence or obtain clear support from those in positions of power. This research indicates that successful implementa-
tion cannot be achieved without access to positions of power and influence. Thus, leaders must devote personal attention to the initiative, and others in the organization need to also focus attention on it.

2. Leaders need to have the tools for analyzing problems and selecting appropriate solutions. Widely accepted are tools that described a rational decision-making process that includes establishing goals and objectives, identifying problems, developing alternatives, choosing among alternatives, and evaluating outcomes. Leaders need to be skilled at analyzing business situations, diagnosing the causal factors, then selecting appropriate interventions, such as the learning organization.

3. Once it is deemed appropriate for the situation, leaders need to be skilled in communicating the learning organization concept in a manner that fits as a solution to the business problem, while motivating others in the organization. People in the organization must be able to clearly see this fit. Kepner and Tregoe (1997) wrote that:

People do not resist practical and useful ideas that promise to be supportive of their own best interests.

People do resist obscure theorizing that has no apparent helpful reference to their lives, threatens them because of their strangeness, and must be taken widely on faith. (p. 221)

4. Learning about learning is important; people need to know more about their own and the organization's learning processes.

Implications for Future Research

This research looked closely at four organizational leaders who had embraced the learning-organization concept and offered valuable insight into this phenomenon. However, more research is needed to expand the literature base. Additional case studies of both successful and unsuccessful learning organization implementations can provide further insight into this nebulous arena. Several research questions that pertain to this topic need to be addressed:

1. What types of data can indicate the need for increased learning in an organization?
2. In what ways can increased organizational learning provide the solution to this delineated problem?
3. How can leaders successfully engage the members of an organization in this initiative?
4. How can successful organizational learning be measured?

Findings from these research initiatives then need to be empirically tested and confirmed through quantitative methods. In some ways, this research indicates that theorists are working at a level that is too abstract for practitioner leaders to comprehend and utilize. A clear model or framework must be developed that will allow practitioners and adult educators to more fully understand the learning organization. This model needs to answer the dual questions: "What exactly is the learning organization?" and "What specifically must I do as a leader in order to implement it?" In addition, methods need to be developed that will allow for the translation of organizational performance measures into learning outcomes.

This paper reports a study designed to examine psychometric properties of Chinese version of the Dimensions of Learning Organization Questionnaire (DLOQ) instrument. The instrument was translated into Chinese by a team of researchers and data was sought from organizations in Taiwan. The results of psychometric analyses revealed that the Chinese version of the DLOQ demonstrated reasonable reliability estimate and seven-dimension factor structure was stable in Taiwanese contexts. The evidence of predictive validity was obtained as the seven dimensions of learning could successfully predict different types of organization and had statistically significant correlation with perceptual measures of organizational performance.

Keywords: Learning Organization, International HRD, Organizational Performance

Learning organization is one of the key concepts in the field of human resource development. Although this concept has been introduced in many Asian countries, few empirical studies have been conducted to examine the validity of such concept in Asian contexts. Especially in Taiwan, through the translation of Senge’s (1994) The Fifth Discipline, companies fascination about the concept of learning organizations. The more theoretical advantages of the learning organizations were discussed in the practice and scholars (Hong & Chang, 1998; Yang & Hu, 1994; Sun, 1995), the more empirical study was needed (Chou, 2000; Li, 2001; Guan, 1999; Guan, 2001). The following questions were raised the attention among the practitioners and scholars: What are the indicators or characteristics of a learning organization? To what extent, a learning organization can be measured in terms of the organizational performance? To what extent, Taiwanese companies can adapt the concept of learning organizations and apply to their situation and even create more benefits?

The purpose of study is to translate, validate and adapt an English version of a scale measuring the characteristics of learning organization so that it can be used in Chinese-speaking population. The Dimension of Learning Organization (DLOQ) was used to test if the concept of learning organization and proposed dimensions by the authors are valid in Taiwanese context.

The Dimensions of Learning Organization Questionnaire (DLOQ) was developed by Watkins and Marsick (1997) and have been widely used to assess the characteristics of learning organization. This scale includes 43 items assessing learning activities in the organization. Six (6) additional items were included to measure Knowledge Performance and another six (6) items were used to assess Financial Performance. The knowledge performance was defined as enhancement of products and services because of learning and knowledge capacity; and financial performance was defined as the state of financial health and resources available for growth. A number of studies have already examined psychometric properties of the DLOQ in terms of its reliability and validity (Watkins, Selden, Marsick, 1997; Watkins, Yang, Marsick, 1997; Yang, Watkins, Marsick, 1998). Ellinger, Ellinger, Yang and Howton (2000) examined the association between measures included in the DLOQ and several objective measures of firm financial performance. It was reported that more than 10% of variance in firm the financial indicators could be explained by seven dimensions of leaning organization measured on the DLOQ. The DLOQ has been translated and used in different cultural contexts. It has been used in Malaysian organizations (Sta. Maria & Watkins, 2001). It was found that the dimensions of learning organization and concerns about the innovation together explained 36%
of the variance in the use of innovation. Hernandez (2000) reported findings from translation, validation and adaptation study of the DLOQ in Latin American context. It was found that the Spanish version of the instrument was a reliable and valid instrument.

Theoretical Framework

The theoretical foundation for this study is the Watkins and Marsick conceptualization of the learning organization (1993, 1996, 1999). They define the learning organization as one that captures, shares, and uses knowledge to change the way the organization responds to challenges. They further suggest that the design of learning organization depends on seven complimentary action imperatives: (1) create continuous learning opportunities (Continuous Learning); (2) promote inquiry and dialogue (Dialogue and Inquiry); (3) encourage collaboration and team learning (Team Learning); (4) empower people toward a collective vision (Empowerment); (5) establish systems to capture and share learning (Embedded System); (6) connect the organization to its environment (System Connection); and (7) provide strategic leadership for learning (Strategic Leadership).

Research Questions

This study sought to examine psychometric properties of the Chinese version of the DLOQ in Taiwanese context. Specifically, this study addresses the following research questions:

1. Is the Chinese version of the DLOQ a reliable instrument in terms of internal consistency for the proposed dimensions of learning organization?
2. Is the seven-dimension framework of learning organization proposed by Watkins and Marsick applicable to Taiwanese organizations?
3. Does the Chinese version of the DLOQ demonstrate predictive validity in terms of discriminating different types of organizations in Taiwanese contexts?
4. To what extent that perceived measures of organizational performance can be explained by learning characteristics measured by the Chinese version of the DLOQ?

Methods

Translation

The English version of the DLOQ (Watkins & Marsick, 1997) was first translated into Chinese by three researchers. Two of them conducted initial translation. Both of the researchers were native Chinese and they all obtained graduate degrees of HRD in American universities. One of them has returned to China as a faculty member in a business school, and the other is currently teaching in an American university. In this initial translation process, efforts were made to use common Chinese equivalents for all words and phrases and to translate the original text as close as possible. This initial translation was done independently. After each of the researchers has finished the first translation, each of them critiqued and evaluated the other's work. It was found that two researchers shared same or very close translations for the majority of the instrument. The consensus part was kept, and the different areas were debated and modified until a consensus was reached. Very few areas were found too difficult to reach the consensus and they tend to be words or phrases with particular meanings that have different usages in Chinese. For example, there is no exact word or phrase that represents the word of “vision.” In fact, there are two common usages in research and business world. One implies “long-term picture” and the other refers to “shared long-term goals.” It was decided to use the later one after consulting with other Chinese HRD scholars and practitioners.

A third researcher, whose native language is Chinese, served as an independent judge for the previous translations. The person is on faculty in a Taiwanese university and has obtained graduate degree of HRD from an American university. Due to the context differences between Mainland China and Taiwan, the habitual usage of the Chinese language in words or phases was slightly different between two places. However, two other Taiwanese HR professors, who both graduated from the American universities, were invited to confirm the minor changes between the simplified Chinese version and the traditional Chinese version. With slightly modification of several specific words or phases, the traditional Chinese version of DLOQ was distributed for Taiwanese organizations.
**Sample**

After contact several Taiwanese companies, five medium to large size private corporations, which are known or promoted the learning organization concept, were invited to participate in this study. Two of them were highly reputed finance/insurance companies, three of them were considered as high-tech companies. With the full response rate, a total of 679 subjects consist of a random sample from multiple organizations. Three hundred and forty (340) subjects out of all six hundred and seventy-nine (679) subjects were randomly selected from the two finance/insurance companies. Most of the subjects are on the management and administration position, others are sales. In addition, three hundred and thirty-nine (339) subjects out of six hundred and seventy-nine (679) subjects were randomly selected from the three high-tech companies. Most subjects selected from the high-tech companies are both include management and non-management (technical/professional).

**Data Analysis**

To address the first research question, item analysis procedure was used to assess the internal consistency for each of seven proposed dimensions of learning organization in a different context. Each of the items included in the DLOQ was examined in terms of its correlation with proposed dimension. Cronbach’s coefficient alpha was used to assess the reliability of the scale.

Confirmatory factor analysis (CFA) was utilized to determine the dimensionality and factor structure of the Chinese version of the DLOQ. The CFA was conducted with LISREL 8 program (Jöreskog & Sörbom, 1989, 1993a, 1993b). CFA is a statistical procedure that examines the construct validity of an instrument with pre-specified dimensions and associated measurement items. In this study, we are particularly interested in assessing whether the seven-dimension structure proposed in the DLOQ constitutes an adequate measurement model for the learning organization concept in Taiwanese context. Yang, Watkins and Marsick (2000) conducted an extensive series of exploratory and confirmatory factor analysis and found that a reduced 21-item measurement model yielded superior fit indices than the original 43-item model. Consequently, two measurement models were examined to assess the adequacy of seven-dimension factor structure of the DLOQ in the new context: one for all 43 learning organization items and another for the reduced set of 21 items.

Discriminant analysis was used to assess the extent to which the Chinese version of the DLOQ could be used to successfully classify different types of organizations. It was reasoned that different type organizations could be predicted from the measures in the DLOQ because of their different backgrounds and emphasis in learning activity. Predictive discriminant analysis (PDA) was used to predict group memberships based on a linear combination of set of predictors (Huberty, 1994). We reasoned that the predictive validity is evident for the measures of learning organization when they can be used to predict different types of organizations. In the current case, two major types of organizations were included, finance/insurance and high-tech companies.

In answer fourth research question, canonical correlation was selected to assess the association between dimensions of the learning organization and perceptual measures of firm performance. This is a technique for examining the association between two sets of variables (Stevens, 1996). The underlying principle is to develop a linear combination of each set of variables (both dependent and independent variables) in a manner that maximizes the correlation between the two sets. The canonical analysis was conducted by MANOVA procedure using SPSS program (Norusis & SPSS Inc., 1990).

**Results**

**Estimating Reliability**

Table 1 presents a comparison of the reliability estimates of the DLOQ among different studies. Cronbach’s coefficient alpha was used to estimate the reliability for the measures included in the DLOQ. The table also reports corresponding estimates in other studies. In all but two subscales, the reliability estimate was comparable with previous studies conducted in America and Colombia. Three subscales, Continuous Learning, Empowerment and Embedded System, had relatively low internal consistency. A careful examination of the item analysis results revealed that each of these three subscales was crippled by one measurement item. Item 5, “In my organization, people are given time to support learning,” had a relatively low item-total correlation. This might be caused by the fact that this item implies slight different meaning in the Chinese version. The Chinese version might have caused the respondents to perceive as to “be given learning time” rather than to “be given time to support learning.”
Consequently, the respondents might have viewed this question as a reflection of reward rather than something indicating organization's effort to create continuous learning opportunities for employees. Therefore further modification of item 5 is needed in future instrument refinement. Nevertheless, the coefficient alpha for the subscale of "Continuous Learning" has reached .81 when item 5 was removed from this subscale.

Although the reliability estimate for "Empowerment" (α = .75) was somewhat lower than those revealed in other studies, it reached an acceptable level (α = .82) when item 29 was excluded from the scale. Item 29 was stated as: "My organization give people control over the resources they need to accomplish their work." A careful re-examination of the Chinese translation failed to reveal any linguistic mismatch with the original English version. Special attention needs to be paid to monitor the performance of this item in future study.

The reliability estimate for "Embedded System" in this study (α = .71) was significantly lower than those in other studies (ranging from .80 to .85). Item 24, "My organization makes its lessons available to all employees," was the one that contributed the decreased internal consistency. The coefficient alpha reached slightly higher level (α = .75) when item 24 was deleted from the item analysis. No obvious linguistic difference was found in examining the English and Chinese versions of this item and other items included in this subscale. This unexpected performance of item 24 in Taiwanese context might be explained by the influence of traditional Chinese culture. "Face-saving" tends to be very important in the Chinese society (Earley, 1997). Thus it is quite rare for a formal organization to openly admit any lessons because such action implies some mistakes or wrong doing. The fact of relative low internal consistency for the measures of "Embedded System" in a Chinese context might also be explained by different managerial approaches between the West and the East. Yang and Zhang (2001) contend that Western managerial emphasis is placed on system and structure of the organization, and that the Eastern managerial emphasis tends to target on the human side of organization (i.e., process and practice). Consequently, measures of "Embedded System" developed in a Western culture might be less consistent when they were used in an Eastern context. Although few subscales tend to demonstrate less desirable reliability estimates, none of the reliability estimate was below .70 and most of them have shown acceptable reliability estimates.

Assessing Factor Structure

Table 2 presents the fit indices for the two measurement models as the results of confirmatory factor analysis. Six criterion indices were chosen to evaluate the fit between the proposed measurement model and that generated from the sample. The indices selected were the traditional chi-square ($\chi^2$) test, Jöreskog and Sörbom's (1989) goodness of fit index (GFI) and goodness of fit index adjusted for degree of freedom (AGFI), Bentler's (1990) comparative fit index (CFI), Bentler and Bonett's (1980) non-normed fit index (NNFI), Steiger's (1990) root mean square error of approximation (RMSEA) and Jöreskog and Sörbom's (1989) root mean square residual (RMR). The GFI and AGFI reflect the proportion of joint amount of data variance and covariance that can be explained by the measurement model being tested. The NNFI is a relative fit index that compares the model being tested to a baseline model (null model), taking into account the degrees of freedom. The CFI indicates the degree of fit between the hypothesized and null measurement models. The RMR is a measure of the average of the fitted residuals. The RMSEA represents a real advance in the evaluation of model fit from both a statistical and a conceptual viewpoint. Browne and Cudeck (1993) argue that because theoretical models are at best approximations of reality, the null hypothesis for any measurement/structural equation model (i.e., the conventional chi-square test that the data fits the
model perfectly) will rarely be true. Rather than testing the null hypothesis of exact fit between the covariance matrix of sample and that of model for population, RMSEA establishes a hypothesis of close fit between the model and population. RMSEA values of .05 or less indicate a very close fit between sample and theoretical model, accounting for degrees of freedom. Values less than .08 reflect reasonably well fitting models (Browne & Cudeck, 1993).

</tbody>
</table>

The CFA results for the Chinese version of the DLOQ offered further evidence for the dimensionality of learning organization proposed by the theorists. Although the seven-dimension factor structure with 43 items fitted the data moderately well, reduced 21 items of the same factor structure fitted the data reasonably well. Nearly 90% of item variance and covariance was explained by the seven-dimension factor structure (GFI = .89). Both non-normed fit index (.92) and comparative fit index (.93) were above .90, a critical level that has been normally regarded as an indication of good mode-data fit. Furthermore, RMR and RMSEA have been reasonably low (RMR < .05 and RMSEA < .08) and that suggested overall fit between the proposed seven-dimension model and the data. In sum, the seven-dimension framework of learning organization proposed by Watkins and Marsick has demonstrated its applicability to Taiwanese organizations when their learning activities were measured by the Chinese version of the DLOQ.

Determining Predictive Validity

Predictive validity is the extent to which an instrument can successfully predict criterion measurement (Crocker & Algina, 1986). It was reasoned that the predictive validity would be evident if measures on the DLOQ could successfully predict different types of organization and organizational performance. Table 3 reports the prediction results for two organizations based on seven dimensions of learning organization measured on the Chinese version of the DLOQ. Prior probabilities were set at the proportions of two types of organizations. The results indicate that 63.9% of all participants were correctly classified as belong to either finance/insurance or high-tech organizations.

Percent classified correctly: 63.9%
Note: Numbers of participants are shown in brackets.

To further assess the predictive power of the seven dimensions of learning organization measured on the Chinese version of the DLOQ, we evaluated the effectiveness of the prediction by the discriminant function based on a formula suggested by Hubert (1994, pp. 103-106). For the current prediction results, we obtained that the standard normal statistic is $z = 7.25$ ($p < .001$), which clearly indicates a better-than-chance results. In other words, by using a classification rule of the discriminant function based on the seven dimension of learning organization, significant fewer errors would be made than if classification were done by chance. The above results suggest that the Chinese version of the DLOQ has demonstrated a strong predictive power in classifying different types of organizations.
The second type of predictive validity evidence was found when a canonical correlation analysis was conducted where the perceptual measures of organizational performance were treated as a set of dependent variables and seven dimensions of learning organizations were put as predictors. Table 4 shows the results of the canonical correlation analysis and demonstrates the overall effects of the seven dimensions of learning organization on organizational performance.

The multivariate tests for the canonical correlation analysis indicate a statistically significant relationship between the seven dimensions of learning organization and the two perceptual measures of organizational performance (p < .001). Effect sizes of the canonical correlation range from .216 to .270, suggesting that more than one fifth of the variability in the respondents' perceptions of organizational performance can be attributed to the seven dimensions of learning organization. The above results are comparable to the previous studies (Ellinger et al., 2000; Yang et al., 1998). In summary, our analyses offer support for the predictive validity of the Chinese version of the DLOQ instrument in Taiwanese contexts.

Conclusions and Discussions

The Chinese version of the DLOQ has revealed similar psychometric properties to the original instrument. First of all, the Chinese version has demonstrated acceptable reliability estimates in terms of internal consistency. Few items seem to imply different meanings because of cultural contexts and thus have caused somewhat decrease of the reliability estimates. Future studies should pay attention to these items and be aware of the cultural differences in utilizing the instrument. Maybe in translating and adapting an instrument, there is a need of modifying and developing more culturally relevant items.

Secondly, the seven-dimension factor structure proposed by the learning organization theorists was stable in Taiwanese contexts. In fact, the results for the statistical indices of data-model fit have been better than those registered with the original one. The proposed seven dimensions accounted for nearly three quarters of learning activities reported in the full 43-item instrument, and it explained nearly 90% of variations of the learning activities reported in the selected 21 questions. The results of model fit indices suggested that the proposed seven dimensions of learning organization are applicable in Taiwanese contexts.

Thirdly, the Chinese version of the DLOQ has demonstrated strong predictive validity in terms of classifying different types of organization and predicting perceived organizational performance. The results of data analysis show that a discriminant function could be built on the measures of the DLOQ to successfully predict participant's organizational type. Forty-three percent of the participants could be classified into correct organizational memberships based on the seven dimensions of learning organization proposed in the DLOQ. Moreover, the seven dimensions of learning could be used to predict perceived organizational performance. It is thus concluded that the Chinese version of the DLOQ has demonstrated reasonable predictive validity.

Implications for Research and Practice in HRD

This study has implications for both research and practice in human resource development. This study offers some preliminary evidences of reliability and validity for a Chinese version of the DLOQ. The Chinese version of the DLOQ thus can be used in organizational studies in several regions where Chinese is official language (i.e., China, Hong Kong, Singapore, Taiwan). The positive evidence of psychometric properties of the Chinese version of the DLOQ suggests some potential cross-culture avenues. However, this study provides an empirical data on which seven-dimensions as determinants of learning organization in Taiwanese context. It offers a cross validity evidence for the DLOQ in Taiwanese context. The results of the study show that the seven-dimension concept of learning organization proposed in the USA tends to be applicable to organizations with different culture. It also suggests that the DLOQ can be used to assess cultural differences in building learning organization. The instrument can also be used along with other valid assessment tools to reveal cultural factors influencing the effort of organization development.
This study also has practical implications for the HRD practice. For those multi-national and international organizations that have branches or joint ventures in Chinese-speaking region, the DLOQ offers a valid tool in evaluating and planning organization development efforts across the regions. For native organizations in the Chinese-speaking countries, the Chinese version of the DLOQ offers a timely assessment device.

This paper reports a study designed to examine psychometric properties of Chinese version of the Dimensions of Learning Organization Questionnaire (DLOQ) instrument. The instrument was translated into Chinese by a team of researchers and data was sought from organizations in Taiwan. The results of psychometric analyses revealed that the Chinese version of the DLOQ demonstrated reasonable reliability estimate and seven-dimension factor structure was stable in Taiwanese contexts. The evidence of predictive validity was obtained as the seven dimensions of learning could successfully predict different types of organization and had statistically significant correlation with perceptual measures of organizational performance.

Keywords: Learning Organization, International HRD, Organizational Performance

Learning organization is one of the key concepts in the field of human resource development. Although this concept has been introduced in many Asian countries, few empirical studies have been conducted to examine the validity of such concept in Asian contexts. Especially in Taiwan, through the translation of Senge’s (1994) *The Fifth Discipline*, companies fascinate about the concept of learning organizations. The more theoretical advantages of the learning organizations were discussed in the practice and scholars (Hong & Chang, 1998; Yang & Hu, 1994; Sun, 1995), the more empirical study was needed (Chou, 2000; Li, 2001; Guan, 1999; Guan, 2001). The following questions were raised the attention among the practitioners and scholars: What are the indicators or characteristics of a learning organization? To what extend, a learning organization can be measured in terms of the organizational performance? To what extend, Taiwanese companies can adapt the concept of learning organizations and apply to their situation and even create more benefits?

The purpose of study is to translate, validate and adapt an English version of a scale measuring the characteristics of learning organization so that it can be used in Chinese-speaking population. The Dimension of Learning Organization (DLOQ) was used to test if the concept of learning organization and proposed dimensions by the authors are valid in Taiwanese context.

The Dimensions of Learning Organization Questionnaire (DLOQ) was developed by Watkins and Marsick (1997) and have been widely used to assess the characteristics of learning organization. This scale includes 43 items assessing learning activities in the organization. Six (6) additional items were included to measure Knowledge Performance and another six (6) items were used to assess Financial Performance. The knowledge performance was defined as enhancement of products and services because of learning and knowledge capacity; and financial performance was defined as the state of financial health and resources available for growth. A number of studies have already examined psychometric properties of the DLOQ in terms of its reliability and validity (Watkins, Selden, Marsick, 1997; Watkins, Yang, Marsick, 1997; Yang, Watkins, Marsick, 1998). Ellinger, Ellinger, Yang and Howton (2000) examined the association between measures included in the DLOQ and several objective measures of firm financial performance. It was reported that more than 10% of variance in firm the financial indicators could be explained by seven dimensions of learning organization measured on the DLOQ. The DLOQ has been translated and used in different cultural contexts. It has been used in Malaysian organizations (Sta. Maria & Watkins, 2001). It was found that the dimensions of learning organization and concerns about the innovation together explained 36%
of the variance in the use of innovation. Hernandez (2000) reported findings from translation, validation and adaptation study of the DLOQ in Latin American context. It was found that the Spanish version of the instrument was a reliable and valid instrument.

Theoretical Framework

The theoretical foundation for this study is the Watkins and Marsick conceptualization of the learning organization (1993, 1996, 1999). They define the learning organization as one that captures, shares, and uses knowledge to change the way the organization responds to challenges. They further suggest that the design of learning organization depends on seven complimentary action imperatives: (1) create continuous learning opportunities (Continuous Learning); (2) promote inquiry and dialogue (Dialogue and Inquiry); (3) encourage collaboration and team learning (Team Learning); (4) empower people toward a collective vision (Empowerment); (5) establish systems to capture and share learning (Embedded System); (6) connect the organization to its environment (System Connection); and (7) provide strategic leadership for learning (Strategic Leadership).

Research Questions

This study sought to examine psychometric properties of the Chinese version of the DLOQ in Taiwanese context. Specifically, this study addresses the following research questions:

1. Is the Chinese version of the DLOQ a reliable instrument in terms of internal consistency for the proposed dimensions of learning organization?
2. Is the seven-dimension framework of learning organization proposed by Watkins and Marsick applicable to Taiwanese organizations?
3. Does the Chinese version of the DLOQ demonstrate predictive validity in terms of discriminating different types of organizations in Taiwanese contexts?
4. To what extent that perceived measures of organizational performance can be explained by learning characteristics measured by the Chinese version of the DLOQ?

Methods

Translation

The English version of the DLOQ (Watkins & Marsick, 1997) was first translated into Chinese by three researchers. Two of them conducted initial translation. Both of the researchers were native Chinese and they all obtained graduate degrees of HRD in American universities. One of them has returned to China as a faculty member in a business school, and the other is currently teaching in an American university. In this initial translation process, efforts were made to use common Chinese equivalents for all words and phrases and to translate the original text as close as possible. This initial translation was done independently. After each of the researchers has finished the first translation, each of them critiqued and evaluated the other’s work. It was found that two researchers shared same or very close translations for the majority of the instrument. The consensus part was kept, and the different areas were debated and modified until a consensus was reached. Very few areas were found too difficult to reach the consensus and they tend to be words or phrases with particular meanings that have different usages in Chinese. For example, there is no exact word or phrase that represents the word of “vision.” In fact, there are two common usages in research and business world. One implies “long-term picture” and the other refers to “shared long-term goals.” It was decided to use the later one after consulting with other Chinese HRD scholars and practitioners.

A third researcher, whose native language is Chinese, served as an independent judge for the previous translations. The person is on faculty in a Taiwanese university and has obtained graduate degree of HRD from an American university. Due to the context differences between Mainland China and Taiwan, the habitual usage of the Chinese language in words or phases was slightly different between two places. However, two other Taiwanese HR professors, who both graduated from the American universities, were invited to confirm the minor changes between the simplified Chinese version and the traditional Chinese version. With slightly modification of several specific words or phases, the traditional Chinese version of DLOQ was distributed for Taiwanese organizations.
Sample

After contact several Taiwanese companies, five medium to large size private corporation, which are known or promoted the learning organization concept, were invited to participate this study. Two of them were highly reputed finance/insurance companies, three of them were considered as high-tech companies. With the full response rate, a total of 679 subjects consist of a random sample from multiple organizations. Three hundred and forty (340) subjects out of all six hundred and seventy-nine (679) subjects were randomly selected from the two finance/insurance companies. Most of the subjects are on the management and administration position, others are sales. In addition, three hundred and thirty-nine (339) subjects out if six hundred and seventy-nine (679) subjects were randomly selected from the three high-tech companies. Most subjects selected from the high-tech companies are both include management and non-management (technical/professional).

Data Analysis

To address the first research question, item analysis procedure was used to assess the internal consistency for each of seven proposed dimensions of learning organization in a different context. Each of the items included in the DLOQ was examine in terms of its correlation with proposed dimension. Cronbach's coefficient alpha was used to assess the reliability of the scale.

Confirmatory factor analysis (CFA) was utilized to determine the dimensionality and factor structure of the Chinese version of the DLOQ. The CFA was conducted with LISREL 8 program (Joreskog & Sorbom, 1989, 1993a, 1993b). CFA is a statistical procedure that examines the construct validity of an instrument with pre-specified dimensions and associated measurement items. In this study, we are particularly interested in assessing whether the seven-dimension structure proposed in the DLOQ constitutes an adequate measurement model for the learning organization concept in Taiwanese context. Yang, Watkins and Marsick (2000) conducted an extensive series of exploratory and confirmatory factor analysis and found that a reduced 21-item measurement model yielded superior fit indices than the original 43-item model. Consequently, two measurement models were examined to assess the adequacy of seven-dimension factor structure of the DLOQ in the new context: one for all 43 learning organization items and another for the reduced set of 21 items.

Discriminant analysis was used to assess the extent to which the Chinese version of the DLOQ could be used to successfully classify different types of organizations. It was reasoned that different type organizations could be predicted from the measures in the DLOQ because of their different backgrounds and emphasis in learning activity. Predictive discriminant analysis (PDA) was used to predict group memberships based on a linear combination of set of predictors (Huberty, 1994). We reasoned that the predictive validity is evident for the measures of learning organization when they can be used to predict different types of organizations. In the current case, two major types of organizations were included, finance/insurance and high-tech companies.

In answer fourth research question, canonical correlation was selected to assess the association between dimensions of the learning organization and perceptual measures of firm performance. This is a technique for examining the association between two sets of variables (Stevens, 1996). The underlying principle is to develop a linear combination of each set of variables (both dependent and independent variables) in a manner that maximizes the correlation between the two sets. The canonical analysis was conducted by MANOVA procedure using SPSS program (Norusis & SPSS Inc., 1990).

Results

Estimating Reliability

Table 1 presents a comparison of the reliability estimates of the DLOQ among different studies. Cronbach's coefficient alpha was used to estimate the reliability for the measures included in the DLOQ. The table also reports corresponding estimates in other studies. In all but two subscales, the reliability estimate was comparable with previous studies conducted in America and Colombia. Three subscales, Continuous Learning, Empowerment and Embedded System, had relatively low internal consistency. A careful examination of the item analysis results revealed that each of these three subscales was crippled by one measurement item. Item 5, "In my organization, people are given time to support learning," had relative low item-total correlation. This might be caused by the fact that this item implies slight different meaning in the Chinese version. The Chinese version might have caused the respondents to perceive as to "be given learning time" rather than to "be given time to support learning."
Consequently, the respondents might have viewed this question as a reflection of reward rather than something indicating organization’s effort to create continuous learning opportunities for employees. Therefore further modification of item 5 is needed in future instrument refinement. Nevertheless, the coefficient alpha for the subscale of “Continuous Learning” has reached .81 when item 5 was removed from this subscale.

Although the reliability estimate for “Empowerment” (α = .75) was somewhat lower than those revealed in other studies, it reached an acceptable level (α = .82) when item 29 was excluded from the scale. Item 29 was stated as: “My organization give people control over the resources they need to accomplish their work.” A careful re-examination of the Chinese translation failed to reveal any linguistic mismatch with the original English version. Special attention needs to be paid to monitor the performance of this item in future study.

The reliability estimate for “Embedded System” in this study (α = .71) was significantly lower than those in other studies (ranging from .80 to .85). Item 24, “My organization makes its lessons available to all employees,” was the one that contributed the decreased internal consistency. The coefficient alpha reached slightly higher level (α = .75) when item 24 was deleted from the item analysis. No obvious linguistic difference was found in examining the English and Chinese versions of this item and other items included in this subscale. This unexpected performance of item 24 in Taiwanese context might be explained by the influence of traditional Chinese culture. “Face-saving” tends to be very important in the Chinese society (Earley, 1997). Thus it is quite rare for a formal organization to openly admit any lessons because such action implies some mistakes or wrong doing. The fact of relative low internal consistency for the measures of “Embedded System” in a Chinese context might also be explained by different managerial approaches between the West and the East. Yang and Zhang (2001) contend that Western managerial emphasis is placed on system and structure of the organization, and that the Eastern managerial emphasis tends to target on the human side of organization (i.e., process and practice). Consequently, measures of “Embedded System” developed in a Western culture might be less consistent when they were used in an Eastern context. Although few subscales tend to demonstrate less desirable reliability estimates, none of the reliability estimate was below .70 and most of them have shown acceptable reliability estimates.

Assessing Factor Structure

Table 2 presents the fit indices for the two measurement models as the results of confirmatory factor analysis. Six criterion indices were chosen to evaluate the fit between the proposed measurement model and that generated from the sample. The indices selected were the traditional chi-square ($\chi^2$) test, Jöreskog and Sörbom’s (1989) goodness of fit index (GFI) and goodness of fit index adjusted for degree of freedom (AGFI), Bentler’s (1990) comparative fit index (CFI), Bentler and Bonett’s (1980) non-normed fit index (NNFI), Steiger’s (1990) root mean square error of approximation (RMSEA) and Jöreskog and Sörbom’s (1989) root mean square residual (RMR). The GFI and AGFI reflect the proportion of joint amount of data variance and covariance that can be explained by the measurement model being tested. The NNFI is a relative fit index that compares the model being tested to a baseline model (null model), taking into account the degrees of freedom. The CFI indicates the degree of fit between the hypothesized and null measurement models. The RMR is a measure of the average of the fitted residuals. The RMSEA represents a real advance in the evaluation of model fit from both a statistical and a conceptual viewpoint. Browne and Cudeck (1993) argue that because theoretical models are at best approximations of reality, the null hypothesis for any measurement/structural equation model (i.e., the conventional chi-square test that the data fits the
model perfectly) will rarely be true. Rather than testing the null hypothesis of exact fit between the covariance matrix of sample and that of model for population, RMSEA establishes a hypothesis of close fit between the model and population. RMSEA values of .05 or less indicate a very close fit between sample and theoretical model, accounting for degrees of freedom. Values less than .08 reflect reasonably well fitting models (Browne & Cudeck, 1993).

The CFA results for the Chinese version of the DLOQ offered further evidence for the dimensionality of learning organization proposed by the theorists. Although the seven-dimension factor structure with 43 items fitted the data moderately well, reduced 21 items of the same factor structure fitted the data reasonably well. Nearly 90% of item variance and covariance was explained by the seven-dimension factor structure (GFI = .89). Both non-normed fit index (.92) and comparative fit index (.93) were above .90, a critical level that has been normally regarded as an indication of good model-data fit. Furthermore, RMR and RMSEA have been reasonably low (RMR < .05 and RMSEA < .08) and that suggested overall fit between the proposed seven-dimension model and the data. In sum, the seven-dimension framework of learning organization proposed by Watkins and Marsick has demonstrated its applicability to Taiwanese organizations when their learning activities were measured by the Chinese version of the DLOQ.

Determining Predictive Validity

Predictive validity is the extent to which an instrument can successfully predict criterion measurement (Crocker & Algina, 1986). It was reasoned that the predictive validity would be evident if measures on the DLOQ could successfully predict different types of organization and organizational performance. Table 3 reports the prediction results for two organizations based on seven dimensions of learning organization measured on the Chinese version of the DLOQ. Prior probabilities were set at the proportions of two types of organizations. The results indicate that 63.9% of all participants were correctly classified as belong to either finance/insurance or high-tech organizations.

<td>36.9%(125)</td>
</tr>
</tbody>
</table>

Percent classified correctly: 63.9%

Note: Numbers of participants are shown in brackets.

To further assess the predictive power of the seven dimensions of learning organization measured on the Chinese version of the DLOQ, we evaluated the effectiveness of the prediction by the discriminant function based on a formula suggested by Huberty (1994, pp. 103-106). For the current prediction results, we obtained that the standard normal statistic is $z = 7.25 \ (p < .001)$, which clearly indicates a better-than-chance results. In other words, by using a classification rule of the discriminant function based on the seven dimension of learning organization, significant fewer errors would be made than if classification were done by chance. The above results suggest that the Chinese version of the DLOQ has demonstrated a strong predictive power in classifying different types of organizations.
The second type of predictive validity evidence was found when a canonical correlation analysis was conducted where the perceptual measures of organizational performance were treated as a set of dependent variables and seven dimensions of learning organizations were put as predictors. Table 4 shows the results of the canonical correlation analysis and demonstrates the overall effects of the seven dimensions of learning organization on organizational performance.

The multivariate tests for the canonical correlation analysis indicate a statistically significant relationship between the seven dimensions of learning organization and the two perceptual measures of organizational performance (p < .001). Effect sizes of the canonical correlation range from .216 to .270, suggesting that more than one fifth of the variability in the respondents’ perceptions of organizational performance can be attributed to the seven dimensions of leaning organization. The above results are comparable to the previous studies (Ellinger et al., 2000; Yang et al., 1998). In summary, our analyses offer support for the predictive validity of the Chinese version of the DLOQ instrument in Taiwanese contexts.

Conclusions and Discussions

The Chinese version of the DLOQ has revealed similar psychometric properties to the original instrument. First of all, the Chinese version has demonstrated acceptable reliability estimates in terms of internal consistency. Few items seem to imply different meanings because of cultural contexts and thus have caused somewhat decrease of the reliability estimates. Future studies should pay attention to these items and be aware of the cultural differences in utilizing the instrument. Maybe in translating and adapting an instrument, there is a need of modifying and developing more culturally relevant items.

Secondly, the seven-dimension factor structure proposed by the learning organization theorists was stable in Taiwanese contexts. In fact, the results for the statistical indices of data-model fit have been better than those registered with the original one. The proposed seven dimensions accounted for nearly three quarters of learning activities reported in the full 43-item instrument, and it explained nearly 90% of variations of the learning activities reported in the selected 21 questions. The results of model fit indices suggested that the proposed seven dimensions of learning organization are applicable in Taiwanese contexts.

Thirdly, the Chinese version of the DLOQ has demonstrated strong predictive validity in terms of classifying different types of organization and predicting perceived organizational performance. The results of data analysis show that a discriminant function could be built on the measures of the DLOQ to successfully predict participant’s organizational type. Forty-three percent of the participants could be classified into correct organizational memberships based on the seven dimensions of learning organization proposed in the DLOQ. Moreover, the seven dimensions of learning could be used to predict perceived organizational performance. It is thus concluded that the Chinese version of the DLOQ has demonstrated reasonable predictive validity.

Implications for Research and Practice in HRD

This study has implications for both research and practice in human resource development. This study offers some preliminary evidences of reliability and validity for a Chinese version of the DLOQ. The Chinese version of the DLOQ thus can be used in organizational studies in several regions where Chinese is official language (i.e., China, Hong Kong, Singapore, Taiwan). The positive evidence of psychometric properties of the Chinese version of the DLOQ suggests some potential cross-culture avenues. However, this study provides an empirical data on which seven-dimensions as determinants of learning organization in Taiwanese context. It offers a cross validity evidence for the DLOQ in Taiwanese context. The results of the study show that the seven-dimension concept of learning organization proposed in the USA tends to be applicable to organizations with different culture. It also suggests that the DLOQ can be used to assess cultural differences in building learning organization. The instrument can also be used along with other valid assessment tools to reveal cultural factors influencing the effort of organization development.
This study also has practical implications for the HRD practice. For those multi-national and international organizations that have branches or joint ventures in Chinese-speaking region, the DLOQ offers a valid tool in evaluating and planning organization development efforts across the regions. For native organizations in the Chinese-speaking countries, the Chinese version of the DLOQ offers a timely assessment device.

Our Two-Tiered Learning Organizations:
Investigating the Knowledge Divide in Work-Related Learning

Thomas S. Westbrook
Drake University

James R. Veale
Statistical/Research Consultant & Educator

This study investigated differences in work-related learning patterns and awareness of organizational policies that impacted the level of learning among 1,031 full-time employed adults. Significant differences were found in the adults' self-reported current and preferred learning patterns and awareness of work-related learning policies when examined by education level and occupation category. The findings suggest that a knowledge divide is evident in our organizations. The results have programmatic and policy implications for HRD professionals.

Keywords: Knowledge Divide, Work-related Learning, Learning Organizations

In their book, *The Monster Under the Bed*, Davis and Botkin (1994) warn us of a two-tiered society inhabited by knowledge haves and have-nots (p. 158). It is proposed in this paper that a knowledge divide exists in some organizations and that their concern was well-founded.

Despite steady increases in dollars allocated to training and development, all is not equal in our learning organizations. We know, for instance, that:

1. The extent to which organizations embrace learning varies. On average, corporations spend about 2.0% of payroll on education for their employees (up from 1.8% in 1997), ranging from negligible amounts to as much as 4.4% for leading edge corporations (McMurrer, Van Buren, and Woodwell, 2000).

2. The level of training that employees receive is not evenly shared across organizations. For example, organizations with the highest level of training tend to be in the areas of transportation, communications, and utilities with the lowest levels in public administration, education, and health services (Industry Report, 1998 & 1999).

3. There is wide variance in the amount of training individuals receive by occupation, pay, and by education level (McMurrer, Van Buren, and Woodwell, 2000). Employee education centers upon learning for managers and professionals, productivity for service workers, and basic schooling for unskilled workers, in that order (Davis and Botkin, 1994, pp. 85-86).

4. The greater one's education level the more likely one will receive additional training. The typical firm trained 77% of workers with some higher education compared to 49% of employees with less than a high school education (Bassi and Van Buren, 1999, p. 13). Hight (1998) found in his survey of over 12,000 adults that only 6% of workers with less than a high school education participated in employer training during the previous twelve months. In contrast, 46% of workers with some college and 63% of workers with college degrees received employer provided training. A similar variation was found in the level of training by education by Frazis, Gittleman, Horrigan, and Joyce (1998), and by Barron, Berger, and Black (1997).

5. The illiteracy rate continues to climb while corporations dedicate fewer dollars to basic skills training. Literacy problems cost American companies an estimated $60 billion dollars in lost productivity with 90 million adults defined as functionally illiterate (Baynton, 2001). As many as 38% of job applicants lack the necessary basic skills in reading, writing, and math to do the jobs they desired, an increase of 15% over the past two years (Baynton, 2001). It is estimated that only 13% of American companies offered remedial training to employees—a decrease from a high of 24% in 1993 (Baynton, 2001).

6. "At present, too many of us view learning as a nice addition to our lives, but not as the essential characteristic that contributes to our ability to prosper in business" (Wheatley, 1994, s47).

The purpose of this study was to determine if a two-tiered system of knowledge haves and have-nots was discernable in adults' self-reported work-related learning patterns and behaviors. This study was part of a larger research project that explored the extent to which working adults indicated they embraced work-related learning as an essential characteristic or core value in their work setting and lives, and their awareness of organizational policies.
and benefits that impacted their level of learning. This paper supplements and highlights aspects of the research published in the Fall 2001 issues of the Human Resource Development Quarterly (Westbrook and Veale, 2001a) and the Journal of Continuing Higher Education (Westbrook and Veale, 2001b). It is the intention of this paper to share research results that provide evidence of a knowledge divide existing in our organizations. It is hoped that the information presented in this paper will prompt discussion about the implications of the knowledge divide for our work as HRD professionals.

Work-related learning was defined as the formal and informal education and training adults completed at work or at home to assist them in their current and/or future employment. Two demographic or background variables were investigated to determine if a knowledge divide could be identified in numerous work-related survey questions. The variables were education level and occupation category. The following research questions guided this study:

1. Is there a significant relationship between the education level and occupation category of adult workers in the sample?
2. Is there a significant difference in the amount of time adult workers devote and would prefer to devote to various work-related learning activities when examined by education level and occupation category?
3. Is there a significant difference in the comfort level of adult workers regarding the amount of time dedicated to self-directed, work-related learning while at work when examined by education level and occupation category?
4. Is there a significant difference in the awareness of adult workers regarding various organizational policies that support work-related learning when examined by education level and occupation category?

Sample & Methodology

The data from this study were obtained by 73 students enrolled in a graduate adult education class facilitated by one of the researchers from 1996 to 1998. In 1997 the class was held via a fiber-optic interactive telecommunications system at eight locations in Iowa. The sample consisted of 1,031 adults employed full-time in 60 organizations in Iowa. The organizations included manufacturing and service providers, profit and nonprofit corporations, as well as state government and educational institutions. The sample, delineated by education level and occupation category, is listed in Table 1.

A snowball sampling method was used to derive the sample. Snowball sampling is a method whereby individuals with desired traits survey another set of subjects with desired traits (Black, 1999). In this instance, working adults enrolled in a graduate credit class at a private university in Iowa surveyed other adults working in their organizations. This type of sampling is applied when there are no lists of population members – or, as in this case, where that list would be extremely difficult to develop. A drawback of this procedure is its lack of randomness. Thus, there is no assurance that the sample is representative of the population of adult employees in Iowa.

After reviewing pertinent literature, an author-constructed questionnaire was designed, administered, and analyzed during the fall semester of 1995. Upon tabulating and evaluating the results, the questionnaire was edited and used during the summer and fall terms of 1996 through 1998.
Various statistical operations were performed on the data obtained from the survey. The demographic variables of education level and occupation category were analyzed to determine the influences of each variable on the responses to the questions of the survey. Only statistically significant results are reported in this paper. Because of the non-normality of the data, nonparametric tests were applied. Differences were reported at the .05 level of significance. The Bonferroni adjustment was used for conducting multiple comparisons to control the overall Type I error rate (Milliken and Johnson, 1992; Fuchs and Kenett, 1980).

Findings

Research Question 1. Is there a significant relationship between the education level and occupation category of adult workers in the sample?

A significant relationship (P=.000) was found between the education level and occupation categories of the adult workers in the sample. Upon inspection of the cross-tabulations, the difference was attributed to the occupation categories of clerical/support and manufacturing/processing when compared with the categories of supervisory/management and professional. Among those adults who have earned two-year, four-year and graduate degrees, there was a much higher percentage of adults who were employed in supervisory/management and professional occupations, while among high school graduates there was a higher percentage of adults in clerical/support and manufacturing/processing occupations (see Figure 1).

Figure 1. Occupation category by level of education.

Research Question 2. Is there a significant difference in the amount of time adult workers devote and would prefer to devote to various work-related learning activities when examined by education level and occupation category?

The respondents were asked to list the average number of hours spent on eleven work-related learning activities. These activities ranged from reading professional/educational literature and attending in-house staff development/training programs to attending conferences, seminars and other continuing education programs. The respondents were then asked to list the average number of hours they would prefer to spend on each activity to stay current of the knowledge needed to remain current in their line of work.

Utilizing the Wilcoxon signed ranks test, the differences between the current and preferred amount of time dedicated to the work-related learning activities were tested. A significant difference was found in each of the eleven activities (see Westbrook and Veale, 2001a). In each instance the individuals indicated a preference for spending an increased amount of time on work-related learning activities to stay current of the knowledge in their line of work.

Significant differences were also found in the current and preferred number of hours devoted and the preference gap (preferred minus current) when examined by the adults' education level and occupation category. For education level, the areas were “reading professional/educational literature,” “use of company or local library,” and “attendance at regional, national, or international conferences.” In nearly all instances the results were attributed to
the differences in current hours, preferred hours, and the preference gap between those adults with a four-year or graduate degree when compared with those with only a high school education or some college. Those with increasing levels of education spent more time on each educational activity and preferred to spend more time on each activity than those with only a high school or some college education.

For the occupation category, the areas yielding significant differences included “reading professional/educational literature,” “in-house staff development/training programs,” “use of company or local library,” and “attendance at regional, national, or international conferences.” In nearly all instances, the results were attributed to the differences in current hours, preferred hours, and preference gap between those adults employed in supervisory/management and professional positions when compared with those adults employed in clerical/support and manufacturing/processing jobs. Those adults working in supervisory/management and professional occupations spent more time and would prefer to spend more time on each educational activity than those in clerical/support and manufacturing/processing jobs.

For example, the current and preferred number of hours expended for the activity “reading professional and educational literature,” as well as the difference between them increased by education level (P=.000, all three tests). These findings are illustrated in Figure 2.

Figure 2. Time devoted to reading by education level.

Research Question 3. Is there a significant difference in the comfort level of adult workers regarding the amount of time dedicated to self-directed, work-related learning while at work when examined by education level and occupation category?

The participants were asked to indicate their level of comfort if individuals of increasingly higher occupational status entered their workspace while they were reading a professional journal, newsletter, or textbook. The individuals listed as entering the respondent’s workspace were “a peer at work,” “someone who reports to you (list ‘NA’ if not applicable),” “your immediate supervisor,” and “a top-level executive.” Of the total sample, 613 adults responded to all four categories, and 1000 employees responded to the all but the category “Someone who reports to you.” They used the following scale to answer this question:

1 = feel comfortable about spending work time in this manner.
2 = have mixed feelings about spending work time in this manner.
3 = feel uncomfortable about spending work time in this manner.
4 = feel like I was doing work best done on my own time.

Using the Friedman nonparametric test, significant differences were found in the ratings of the four categories of individuals who hypothetically entered the respondent’s workspace (P=.000). The individuals became
increasingly less comfortable dedicating work time to learning as individuals with increasingly higher levels of occupational status entered their workspace (see Westbrook and Veale, 2001a).

When examined by education level, one significant difference was found in the area "someone who reports to you" (P = .018). In this instance the adults with only a high school education were more uncomfortable spending time on work-related learning activities than those with a graduate degree.

When viewed by occupation category, significant results were obtained. Upon inspection, the major differences occurred when those employed in manufacturing/processing occupations were compared with those in supervisory/management and professional categories. In each instance, the adults employed in manufacturing/processing occupations indicated they were more uncomfortable reading a journal, newsletter, or textbook when a "peer," "someone who reports to you," "your immediate supervisor," or a "top level executive" entered their workspace.

Research Question 4. Is there a significant difference in the awareness of adult workers regarding various organizational policies that support work-related learning when examined by education level and occupation category?

Several questions were asked related to the adults’ awareness and use of various work related organizational policies. First, the respondents were asked if the need for work-related learning was expressed within key corporate communications such as the mission or vision statement. The answer were "yes," "no," and "I don’t know." Fewer than half responded affirmatively to this question. In fact, almost a quarter of the respondents did not know if the need for work-related learning was stated within company communications. No significant difference was attributed to the education level of the adults. In contrast, a significant difference was obtained when viewed by occupation category (P = .000). Upon inspection, the difference was attributed to the relatively large number of clerical/support workers and the relatively small number of supervisory/management personnel who indicated that they did not know if the need for work-related learning was expressed in such corporate communications.

Second, the adults were asked if their employer had explained the availability of work-related education and development benefits or educational opportunities available at their place of employment. Over 80% or the respondents indicated that they were informed of such benefits or educational opportunities. When viewed by education level, a significant difference was found (P = .032) and was attributed to the relatively large number of adults with only a high school education who answered that they did not know about such benefits or opportunities. Likewise, when viewed by occupation category, a significant difference (P = .004) was found and was attributed to the relatively large number of adults in the manufacturing/processing category who indicated they did not know if such benefits had been communicated.

Third, the vast majority of respondents (83.9%) indicated that their employer had a defined amount of funds or a tuition reimbursement policy that they could use to attend work-related learning activities. When viewed by education level, a significant difference was found (P = .003) and was attributed to the relatively large number of adults with only a high school education who answered that they did not know about such funds or policies. Likewise, when viewed by occupation category, a significant difference was found (P = .000) and was attributed to the relatively large number of adults in the manufacturing/processing category who indicated they did not know of such funds or policies.

In general, the respondents with only a high school diploma and those employed in clerical/support and manufacturing/processing occupations seemed much less aware of the work-related learning policies and benefits when compared with the others. These respondents were significantly more likely to indicate, “I don’t know” if work-related learning policies and benefits were communicated to them or if their employer had budgeted funds for their use. It is important to note that 70.4% of the adults employed in clerical/support and manufacturing/processing occupations had only a high school education.

Discussion

The purpose of this research was to examine if evidence of a knowledge divide existed in the self-reported work-related learning patterns and attitudes of 1,031 working adults in Iowa. An author-constructed survey served as the basis of an optional graduate research project that involved 73 part-time graduate students between 1996 and 1998. The data were examined by investigating the possible influence of the adults’ educational level and occupation category on the responses to the survey questions.

To date, few research studies have investigated the level to which adults indicate they place learning as a priority or core value in their lives, or the extent to which organizational factors enhance or inhibit individual
learning (Merriam & Caffarella, 1999; Gallup Organization, 1998). Thus, this research was helpful in providing a descriptive measure of adults' attitudes about individual and organizational factors impacting their level of learning.

The results of this study support the existence of a knowledge divide in our organizations. This divide is related to the adult's education level and occupation category. The divide by education level occurred between those with only a high school education or some college compared to those with a four-year or graduate degree. The divide by occupation level occurred between those individuals employed in clerical/support or manufacturing/processing jobs as compared to those adults working in supervisory/management or professional occupations.

In comparison to adults with a four-year or graduate degree, those with only a high school education or some college spend less time in work-related learning activities, prefer to spend less time in work-related learning activities, and are considerably less aware of organizational policies related to work-related learning benefits. These results are indicative of the knowledge divide referenced by Davis and Botkin (1994).

This research calls into question the premise of a learning organization where all employees continually learn. Senge (1990) described the learning organization as a place "where people continually expand their capacity to create results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together" (p. 3). Thompson (1995) stated, "A company's ability to learn and innovate is a direct driver of the company's capability to increase revenues, profits, and economic value" (p. 85). This study suggests that the learning organization may exist only for those with the highest levels of education working in higher status occupations. If true, there seems to be a disconnect between what is advocated as necessary for learning organizations and the actual state of learning in some, and perhaps most, corporations (see Westbrook and Veale, 2001a).

Specifically, the conclusions from this study suggest the following:
1. Differences in current and preferred learning patterns exist across education levels and occupation categories.
2. Differences in the awareness of organizational work-related learning policies and benefits exist across education levels and occupation categories.
3. Employees in the manufacturing/processing occupations are the least comfortable spending time in self-directed work-related learning.
4. Employees with only a high school education or some college seem the most at-risk of becoming the knowledge have-nots in our society.

The results of this study may be helpful to professionals within the human resource development field as they provide an opportunity to examine the specific learning culture within organizations and the extent to which a knowledge divide exists in various corporations. Using the instrument of this study, an organizational audit of current and preferred levels of work-related learning as well as awareness of organizational policies that advance learning could be conducted and would be helpful to assess an organization's learning culture.

For those involved in academic research, this study advances our understanding of the extent to which learning serves as a core value for most adults and the organizations in which they are employed. It would be of interest to determine whether the apparent knowledge divide is the intended or unintended consequence of the practices of most organizations. Such research would shed light on the extent to which the tenants of the learning organization are actually practiced within most organizations.

Limitations to the Research

The sample of this study was comprised of adults employed full-time in Iowa. The sample of the study was derived from volunteers enrolled in a graduate degree program who surveyed employees at their place of employment. The sample, while large, is not random. Thus, there is no assurance that the sample is representative of the population of adults working in organizations in Iowa.

Recommendations for Further Research

This study should be viewed as an initial step in determining the existence of a knowledge divide in our organizations. The results provide encouragement for additional research on the work-related learning preferences and attitudes of adults. A national, statewide, or organization-wide study using a random sample would be a good next step in identifying the work-related attitudes of adults and the extent to which the knowledge divide is a reality in our society.
References

Research and theory indicated that training practices using adult learning principles can increase learning for employees in the workplace. The purpose of this qualitative research study was to examine how theory is being practiced in the workplace. The paper presents four existing adult learning principles and relates the information to interviews with participants in one organization. Finally, it provides conclusions and recommendations on how this information can contribute to the field of HRD.

Keywords: Training, Adult Learning Concepts, Learning

It has been estimated that organizations spend over $200 billion each year on training and human resource development (HRD) (Carnevale, Gainer & Villet, 1990. Recent shifts in the economy of the United States have forced trainers and human resource developers to re-examine their training strategies to insure that employees learn in the workplace (Willyard and Conti, 2001). Many sources in the literature discuss how adults learn in the workplace through application of principles of adult education (Noe, 2001; Knowles, 1980, 1995; Gilley and Eggland, 1989; Gilley and Maycunich, 2000). Because of the tremendous costs spent on training each year, both human and financial, it is important to constantly add to the research and literature to create more effective programs in HRD. In this qualitative case study, the CEO and the Senior Management Team (SMT) are responsible for designing and implementing the training procedures with employees in this organization. The SMT is well known throughout the industry for creating innovative training practices utilizing adult learning principles. These practices have been credited with increasing the learning and performance of their employees in the workplace. Training is defined as “Learning that is provided in order to improve performance on the present job” (Gilley and Eggland, 1989, p.7). Therefore, the purpose of this study was to examine how the principles of adult learning were used in the design of formal and informal training practices to increase learning for employees in the workplace and relate the findings to the field of HRD. Through the lived experiences of the CEO, the SMT and several employees, five major themes emerged. This paper first reviews the literature, then, it examines the principles in the data, and last, conclusions and recommendations are related to the field of HRD.

Theoretical Framework

The research study began by focusing on the concept of Andragogy by Malcolm Knowles, defined as “the art and science of helping adults learn” (Knowles, 1980, p. 43). Andragogy transformed the study of adult learning. However, throughout the year long study, qualitative methods allowed themes to emerge from interviews with the CEO, members of the SMT and employees that revealed that SMT also utilizes other adult learning principles in their training practices. One of the characteristics of qualitative case study is its ability to illuminate a phenomena in its context that enables themes to be identified and examined (Yin, 1994). A review of the literature acknowledged that the following concepts and approaches have been used to help adults learn in organizations; each approach has its own preferred approach to learning (Gilley and Maycunich, 2000; Gilley and Eggland, 1989). The principles that emerged were examined in the literature, and they formed the basis for the continued research at this organization.

Andragogy

Malcolm Knowles (1980, 1995) concept of Andragogy, adult learning theory, formed the basis for this study. Andragogy is based on the assumption that learning is an internal process of which the locus of control resides with the learner, and therefore the teacher or trainer is to facilitate the learning. Five key assumptions form the tenets of Andragogy by Knowles (1980; 1995): (a) Self-concept of the Learner. Adults have a deep psychological need to be self-directing, (b) Role of experience. Adults bring with them a rich background of experiences that is a valuable resource for their own learning and that of other students, (c) Readiness to Learn. Adults learn more effectively when adults see that the information is relevant to their lives. It assumes that the facilitators need to help adults see how the training or
courses can help them perform more effectively in their jobs, (d) Orientation to Learn. Adults enter into educational or training activities to acquire prescribed subject-matter. Educational activities need to help adults in the process of acquiring content in organized units, sequenced according to logic of the subject matter, (e) Motivation to Learn. “Each person is unique and brings with his/her own goals and internal motivators; it assumes that learning plans and strategies must be highly individualized” (Knowles, 1995, pp. 1-3).

**Experiential Learning**

Another approach to learning is the experiential model by Kolb (1984). In this model, true learning depicted as a four-part process. Kolb (1984) proposed that learners have “concrete experiences;” then they reflect on the experiences from a variety of perspectives. From these “reflective observations,” learners engage in “abstract conceptualization” in which they create generalizations or principles that they integrate their observations into theories. Learners use these generalizations as guides to engage in further action called “active experimentation,” which they test what they have learned in more complex situations.

**Humanist Theory**

This approach exemplified by Carl Rogers’s (1974) states that all people are unique and possess individual potential; and all people have a natural capacity to learn. This approach upholds the idea that the purpose of learning is to encourage individuals to develop his/her full potential (Gilley and Eggland, 1989). Humans have the ability to learn almost anything. The combination of external factors and internal fears can prohibit humans from learning unless they receive warmth, care and understanding (Wiltsher, 1999). Maslow (1970) argued that people have personal factors that influence the need for learning, and Maslow proposed a theory of human motivation for learning, based on the “Hierarchy of Needs,” individuals first learn to satisfy basic needs such as hunger and thirst and they progress towards self-actualization.

**Transformative Learning Theory**

Mezirow (1978) said that this approach is associated with meaning-making processes, by examining how a more inclusive integrative understanding of one’s experience can be used to solve complex problems. In this concept, it is not just the mere accumulation of experience that matters, but instead, the way in which individuals make meaning of their experiences that facilitates growth and learning. Mezirow (1978) defines learning as a meaning-making activity: “Learning is understood as the process of using a prior interpretation to construe a new or a revised interpretation of the meaning of one’s experience in order to guide future action” (p. 162). Transformative learning centers more on the cognitive process of learning, and key is that people are changed from the learning. Mental construction of experience, inner meaning, and reflection are common components of this approach. “Adult learning can be viewed as an interpretation of information utilizing one’s existing set of expectations through which meaning and ultimately one’s life are constructed (Willyard and Conti, 2001, p. 325). The literature of HRD stresses the importance for employees to be able to ask questions to learn and develop (Gilley and Eggland, 1989). Central to Mezirow’s concept (1991) is reflection as a “process of critically assessing the content, process, or premise(s) of our efforts to interpret and give meaning to experience. We are able to examine our action and begin posing a problem, and it ends with taking action, and the emphasis on action as the end product of the reflective process” (p. 104).

**Research Questions**

Since this organization is known for creating innovative formal and informal training practices using adult learning principles, this research study sought to learn what principles they used, how they were practiced, and how that information could be used to design programs in HRD. Research can add to understanding theory and practice. In order to gather that information, the following questions were designed:

1. What adult learning principles and concepts are used in the formal and informal training of employees in this organization?
2. How are these principles applied in the training practices in the workplace?
3. What are the lessons for training adults using these principles that can be applied to the field of HRD?

Methodology

This study used qualitative case study for the research design. A fundamental characteristic of case study is an intensive analysis of a phenomenon in its context that can uncover significant factors or characteristics (Merriam, 1988). A case problem approach consists of a written account of a situation that provides rich details of a phenomena (Yin, 1994). The information was gathered through formal and informal interviews and observations with the CEO, members of the SMT and 30 employees. The study lasted for one year.

Sample

Participants included the CEO and owner, six members of the SMT and 30 employees from the Cite’ Fine Dining Organization located in Chicago, Illinois. The CEO and six leaders of the organization are responsible for designing and implementing the training and management procedures for the organization. The employees were very diverse; of the thirty employees: (a) more than half were men, (b) ranged from age from mid-twenties through sixties, and (c) held positions from janitorial to executives. The CEO and the SMT includes seven leaders who manage the organization; their profiles are as follows: The CEO and owner, Evangeline Gouletas, is the only women in a top leadership role in this organization. She is 40 plus years of age; she has 32 years of experience as a leader, educator and trainer. She has a master’s degree, and she has completed all course work for her dissertation. She regularly takes continuing education to maintain several professional licensees, and she serves in leadership positions for many organizations and professional associations in the business. The men are between the ages from their late twenties to early sixties, and they have been successful in the business for over ten years. The men have all received their baccalaureate degrees, and one holds a law degree. In addition, several members hold licenses to practice in one or more areas of the business, maintain membership in professional organizations in the field, and take continuing education programs on a regular basis to maintain licensees and acquire new information.

Data Collection and Analysis

The information was gathered through formal and informal interviews, observation, review of documents and articles on the organization. Formal taped interviews lasted for approximately one hour. The interviews were first transcribed verbatim. The participants also received copies of the final transcribed tapes of the formal taped interviews, and they edited any personal information that they did not want in the final case study. In order to examine the data, tables were designed to display the data, and quotations from participants and further explanations were presented by the researcher as needed to clarify the data. The characteristics that emerged from the research were validated through review of tapes, transcriptions and field notes. The researcher contacted the participants several times during this study as well as reviewed all published information about their company and themselves in order to obtain accurate information. The information was further validated through documents, journals, literature review, and discussions with other professionals and educators in the field. After the completion of the data analysis process, another phase of data analysis, a search for themes, was begun. The process used "concept mapping" (Smith and Associates, 1990) as a diagnostic tool. "A concept map depicts in a diagrammatic form, ideas, examples, relationships, and implications about a particular concept. The center or core idea is placed at the center or top of the page, and radiating from it are a number of spokes or lines leading to other concepts related to, or indicated of the central idea" (Smith and Associates, 1990, p. 49). Concept mapping enabled the researcher to group similar examples of large concepts together, and smaller concepts were set aside until they could be integrated into the larger themes; this process allowed the dominant themes to emerge from the data. The similarity of the process of the information gained in the case studies made possible the rich, descriptive data needed to interpret the phenomenon being investigated (Merriam, 1988).

Limitations of the Study
Since the study was limited to the training techniques used in one organization, the study does not attempt to predict if this information is utilized by all workplaces. Although case studies can lead to deeper insights into this area of the study, findings from case studies cannot be generalized in the same way as the findings from random samples. For this reason, this research should lead to further research on the subject.

Results and Findings

The results provided information and data that lead to deeper understanding on all three research questions. This section reviews statements by participants that describe the effect that utilizing adult learning principles in training had on employees in the organization.

Andragogy

**Role of Experience.** First, one of the key principles of Andragogy by Knowles (1980, 1995) is the role of the learner's experience. Andragogy assumes that adults come to situations with a depth and breadth of experience than can be used as a resource for theirs and other learning (Knowles, 1980, 1995). Participants commented that the CEO and SMT in the organization use several training techniques to draw upon the life experiences of their employees. One participant said:

Employees regularly attend meetings where they listen to tapes from inspirational people such as: Dr. Wayne Dyer, Anthony Robbins and Depoc Chopraw. After they have reflected on how the story in the tape parallels their own experiences, they are asked to share a story from their life experiences in relationship to tapes with other employees and explain what they learned from the tapes.

The CEO commented:

I believe that listening to tapes is a great way to learn and see the connections with your life/work.

One participant’s statements reflected those made by many employees:

By reflecting and sharing my experiences with others, I realized how valuable my past experiences are to my work.

**Readiness to Learn.** A second tenet of Andragogy, states that adults learn more effectively when they see that the information is relevant to their lives, and it assumes that the facilitators need to help adults see how the training or courses can help them perform more effectively in their jobs. Throughout this study, participants discussed how the organization provides learning opportunities that help employees see how their learning improves their performance at work. One participant said:

Once a month, famous speakers are asked to come in and discuss the changes and challenges in the business. Afterwards, we analyze how the information can improve our work. This is terrific way to learn.

Another participants added:

Speakers provide many new ideas in the business, and a discussion afterwards allows us to tie the information to our work. We have the opportunity to network and learn from knowledgeable people in the field.

**Orientation to Learning.** A third tenet of Andragogy according to Knowles (1980, 1995), is that adults are problem-centered rather than subject centered. Adults need to know why they are learning new skills, acquiring new knowledge, or changing their behavior and they want explanations of how the proposed learning will benefit them. The implication for this is that learning experiences should be organized around tasks or problems (Knowles, 1995). A member of the SMT explained how they solve problems as part of a team:

The CEO and the SMT hold a luncheon meeting each month, in which each member of the team presents pertinent details of all current projects that they are working on in their department, and then, the team members get the opportunity to analyze how their work will contribute to the success of the project. For example, the marketing department will review how it will create a marketing campaign for the organization. We all learn from the experience. Sharing ideas with team members, is a terrific way to get new ideas and solve problems.

Another participant added:

When I am working on a problem, I collaborate with other employees or ask for advise from the CEO. Collaboration really helps me gain insight and learn. All employees work well in teams from wait staff to SMT. Each department holds formal and informal meetings where they share ideas to solve problems as part of a team.
Motivation to Learn. The third tenet of Andragogy is that adults are motivated to learn. Knowles (1995) asserts that although adults will respond to some external motivators such as a job promotion or a change in technology, he proposes that the most powerful motivators for adults are internal motivators such as: self-esteem, recognition, self-confidence, self-actualization, and he suggests that training should emphasize these kinds of benefits. One participant said:

We are motivated to learn because of our personal needs, also, because continued learning, creativity and innovation are valued in our organization. We are encouraged to attend courses and join organizations.

One participant added:

Our organization holds dinner meetings of professional organizations at work. We are encouraged to attend and serve in leadership positions of the organizations. It is a very convenient, and it is a productive way to learn and to network. It gives me an opportunity to meet others in my field and stay up on new ideas without traveling.

Another participant added:

I really appreciate that my boss realizes my personal motivation to learn and provides many opportunities for continued learning and networking in the field. The Organization has also established programs to help employees pursue their independent learning projects. We have a Corporate Library where tapes, journals and books are available, and employees are encouraged to use the material.

It was apparent from statements made from participants that the CEO and SMT in this organization not only values continued learning, but they also recognize the personal motivation of their employees. The CEO stated:

This year I encouraged employees to read: Jesus CEO: Using Ancient Wisdom for Visionary Leadership by Laurie Beth Jones published in 1995; reading is a wonderful way to learn. Also, you encompass people and make them feel valued and part of a team. And, I encourage for my teammates to be self-reliant, to be innovative, to not just do what is listed on the job description, but to create their own goals, their own visions and to be self-motivated. Anybody will do what the boss says. It becomes a checklist and you do those ten things. But it is when you go to item number 11, 12, 13, 14, 15, goals that you have placed on yourself for your own self-development in your own department, where you develop beyond the scope of the job, and I see employees do that in every single department.

Experiential Learning

Experiential Learning by Kolb (1984) is another concept that focuses on experiences as a basis for learning new ideas. Kolb (1984) explained that in addition to adults having had many rich life experiences, it is well established that they learn from experiences. Kolb proposed that learning is a process where knowledge is created through the transformation of experiences, and that often, learning is a four-part process. According to Gilley and Maycunich (2000), "experiential learning can enable learners to develop highly complex cognitive skills As such as decision making, evaluating, and synthesizing, to sharpen interpersonal communication skills" (p. 128). One participant explained how they learn from experience:

In spring of this year, we took the wait staff from busboys to the dining room manager of the restaurant to a Winery in Illinois, and they learned all about wines. Then, they used what they had learned in their jobs.

Another participant stated:

This Spring, we also took the chefs from the restaurant to New York, and they toured many of the fine dining restaurants. After each trip, employees had the opportunity to reflect on their experiences and share what they had learned with each other. Then, they were able to use the information to solve problems at work.

One participant noted:

Trips allows us to really experience and see first hand many practices that we can incorporate into our organization. We really learn from these experiences, because it gives us the opportunity to reflect on experiences, and share experiences with my coworkers. Then, we are able to apply the information directly to our current jobs.

Humanism

The third adult learning principle practiced in this organization was "Humanistic Philosophy." Based on the work of Carl Rogers (1974) and Maslow (1970), one needs to place a high value on human beings. The Humanism stressed the importance of valuing employees and satisfying their needs in the workplace; it has been voiced in the literature of human resource development by several authors (Knowles, 1995; Gilley and Maycunich, 2000; Gilley and Eggland, 1989).
Humanist philosophy describes how people want to learn to improve their fit with the organization so they can progress in their career, and they should be encouraged to develop their potential (Wilson 1999). The CEO's statements reflected thoughts made by several participants on how employees are made to feel part of a family:

We are all part of a family here. Everyone is invited to the corporate dining room from top executives through maintenance people. We are all equals. No one feels less than an executive here, from the janitorial people to top executives. We all sit together, and no one is made to feel like less than a CEO.

Another participant confirmed this thought:
I feel that my contributions are of value to the organization; I really feel part of the organization. Although we have all the departments necessary to provide integrated services, we work together as one team.

Humanist's theories also recognize that people respond to a stimulus or need to upgrade their skills in order to keep their jobs (Wiltsher, 1999). In Spring of 2001, the organization was able to retain all its employees using this approach during difficult economic periods in the United States. One participant expressed:

In spring of 2001, when the economy was experiencing a recession, the restaurant was closed for remodeling. To keep valuable employees, thirty employees remained on the payroll and came in during normal working hours from Monday through Friday for training sessions to learn about all aspects of the business. This allowed us to keep our jobs. Normally, we would have been forced to take other jobs; because of this, we are loyal to the organization.

Another participant added:

In the restaurant business, very few organizations value their employees enough to keep them on the payroll in hard times, especially employees such as myself, who do not have much work experience or background in the business, but I was able to stay and learn about the business. This increased my desire to work for this organization.

Research supports that loyalty is very important in an organization, and that the culture of the organization should embrace the Humanistic Philosophy (Gilley and Eggland, 1989). During the research, several participants described how loyal the CEO and SMT of this organization are to its employees. The CEO expressed her philosophy:

What makes a company are the teammates; I am loyal to them, and they are loyal to me.

Another participant made statements that were reflective of thoughts made by many of the employees:

Our CEO knows when people are going to work hard, and she values her people. It cost the Organization a tremendous amount of money to keep people during this period, but she believed that her people were essential to growth of the company. In my experience, it unusual to work for an organization that values all its employees.

**Transformative Learning Theory**

The Fourth principle of adult learning practiced in this organization is *Transformative Learning Theory* by Mezirow (1978, 1991). "Adult learning can be viewed as an interpretation of information utilizing one's existing set of expectations through which meaning and ultimately one's life are constructed (Willyard and Conti, 2001, p. 325). By sharing personal experiences and asking questions, employees can grow and develop (Gilley and Maycunich, 2000). The company holds both formal and informal meetings in which employees have the opportunity to ask questions and to converse with other employees from all levels of the Organization. One participant said:

At the recent training sessions for all the employees at the restaurant, many employees were not really sure what different departments such as the marketing department did. Employees watched videos, prepared reports; executives and managers of each department made presentations about the functions of their department. I was able to explain what the marketing department did for the restaurant. Employees were able to ask questions and learn about every aspect of the Company. We have a better informed and trained workforce, and employees see how they can be of value in the organization.

Another participant added statements that were similar to those made by many employees:

After reflecting on what I had learned at the meeting, I was not only able to do my job better, but I saw how I could perform other jobs in the company. I am now taking courses at a cooking school, as well as examining other jobs.

It is very rare that someone like myself with limited formal education and job experience, who works in a position in the wait staff at a restaurant, has the opportunity to work and learn from employees throughout an organization. I feel more qualified and confident in my abilities, and I see many opportunities for growth in my career.

One member of the SMT reported:

I have observed how employees have learned new ideas, and it has improved their performance on the job.

Literature on Transformative Practices supports ideas that open, honest, communication enables employees to learn and develop by allowing them to examine and reflect on their work (Gilley and Eggland, 1989). Employees often
share information informally in employee's offices or at luncheon meetings held in the corporate dining room. The CEO said:

Our philosophy is an “open door policy,” and it is practiced by everyone in the Company. For example, I have a list of what I am now working on my computer in my office, and I encourage employees to come in and look at the list and share what they are working on with everyone. Sharing ideas with others leads to problem-solving.

Another participant added:

I feel comfortable in sharing information on my desk and on my computer with other employees. This Organization instills loyalty and trust that is practiced by everyone; we solve problems as part of one team.

Conclusions and Recommendations

The following section summarizes data and provides an analysis of participants’ statements:

First, this study suggests that the training practices increased employees’ understanding of the business and their ability to improve their performance on the job. The results indicated that the following training practices aided them in these endeavors: sharing life experiences in story telling, field trips, and monthly formal and informal meetings. Both the SMT and employees responded in interviews that employees learned as a result of these training practices. Employees reported feeling more qualified and confident, and the SMT reported that they observed employees' improved job performance. Further research could examine how the training techniques in this study could be used to increase participants' learning and training effectiveness in other organizations. This research supports ideas in the literature (Knowles, 1995; Willyard and Conti, 2001).

Second, this study affirms the importance of utilizing adults' life experiences in training. The study examined adults' life experience through three adult learning concepts: (1) Knowles, concept of Andragogy, was used effectively when employees shared their rich life experiences after listening to tapes, (2) Kolb's 4-step learning cycle was employed when employees learned through trips to wineries and restaurants, and (3) Mezirow's Transformational Theory was effectively used both in the formal and the informal training practices with employees from all levels of the organization. Participants statements confirmed that they not only learned from examination of their past experiences, but that the new experiences also led to valuable new learning. Many of the practices used in this organization could be used in many other organizations.

Third, this research illustrated the connections in training, learning and development. Participants continually commented that the training practices allowed employees to feel valued and essential to the success of the organization. Furthermore, participants statements indicted that these practices promoted continued development of employees and high involvement in work processes. For example, employees ate lunch with each other in the corporate dining room daily. This practice enabled employees to get to know each other, ask questions and share their ideas. Also, employees felt valued when they were kept on the payroll during the remodeling of the establishment, and they received training on the operation of the business. Normally, when a restaurant is closed for any reason, employees are terminated. Statements made by employees illustrated how this made them feel valued, and it also increased their desire to work for the organization. Several participants credited these practices for attracting and retaining its employees and the continued growth of the organization.

Fourth, participants' statements indicated that the training practices described in this study promoted collaboration, teamwork and problem solving skills, “which is becoming a fundamental requirement of work” (Willyard and Conti, 2001, p. 330). Participants reported learning in various shared learning experiences and collaboration through monthly team meetings, group collaboration and informal communications. According to several authors, (Gilley and Eggland, 1989; Gilley and Maycunich, 2000; Knowles, 1995), these skills are required in today’s workplaces.

Finally, the data from this study indicated that the support of top management in an organization can increase the learning and development for employees; this theme has been written about by several authors (Knowles, 1995; Gilley and Eggland, 1989; Gilley and Maycunich, 2000; Watson and Marsick, 1993). The CEO and the members of the SMT encouraged employees to share information with employees from all levels of the organization. Further research should examine how the support of top management of an organization increases or impedes the application of adult learning strategies in training programs.

How Research adds to AHRD and Recommendations for Further Research

35-1
This study adds to the field of HRD by examining theory and practice in the restaurant business. As in this study, "the role of training has broadened beyond training. Trainers are increasingly being asked to create systems to motivate employees to learn, create knowledge and share that knowledge with other employees in the company" (Noe, 2001, p. vii).

The underlying theme that emerged from this study appeared to suggest that individuals not only learned from using different approaches to learning from experience through trips, life experiences, story telling, collaboration, but that these practices benefited the organization. Although the CEO, SMT and employees often used different words and examples to describe their perceptions of how they learned and how the learning was applied in the workplace, patterns arose from that data of the participants that confirmed that the transfer of learning did occur. This research also suggests strong connections with the training practices used and the learning, development and high involvement for participants in their work. Support of top management was an important component for success using these training practices. Also, these training practices using life experiences promoted learning and problem solving which are essential in today's workplaces.

Future studies should focus in more detail on how training principles used in this workplace can advance these factors. As we continue to spend billions on training and human resource development, it is important to examine how the theory is being used in practice. Expectations that the role of trainers will continue to expand to meet learning challenges for employees in the workplaces, basic concepts, theories, and principles of adult education in this research provides in formation that can add to literature of HRD.

This paper describes the examination of a portion of Malcolm Knowles personal correspondence. This paper also details the unique journey of four graduate students as they struggled to understand andragogy and the man who developed it, using the methods and approaches that he advocated. This study does not intend to reach any conclusions about the father of andragogy. It does however present examples of Knowles' correspondence and outlines content themes, which emerged as a result of this research project. The end product of this research was the creation of a database that may be accessed for further research and study into the life of Malcolm Knowles.

Keywords: Andragogy, Adult learning, Malcolm Knowles

When Malcolm S. Knowles, father of andragogy, passed away in November 1997, he left behind a great legacy of his work for all who study the field of adult learning and Human Resource Development (HRD). At the time of his first official retirement from North Carolina State University, portions of his personal and professional correspondence as well as much of his library were donated to Syracuse University. In January 1999, his heirs donated the remaining portion of his personal and professional legacy to a professor of Human Resource Development at Louisiana State University (LSU). The donation consisted of his personal library, personal correspondence, date books, articles, workshop materials, and lecture notes. Most of this work was dated from the last twenty years of his life.

In September 2000, four LSU graduate students in the HRD doctoral program, enrolled in an independent study course to explore adult learning theory. During a description of course objectives, the availability of the Knowles' collection was discussed as a rich resource for a potential andragogical project. Several qualitative research projects were discussed including analysis of his book collection, lecture notes, articles, and personal correspondence. The students and professor decided upon a team project consisting of an exploratory content analysis of correspondence personally written by Knowles. The ultimate outcome of the research project was the creation of a database that would be available for future research and scholarly study.

The purpose of this paper is to describe the qualitative project and the andragogical process undertaken. This paper will report the research methodology utilized, identify themes that emerged from the content analysis and provide descriptions and quotations from each identified theme category. This paper also describes the unique experience of the student research team as they explored the personal correspondence of Malcolm Knowles using an andragogical process.

Theoretical Framework: The Project and the Learning Process

Andragogy is a set of core adult learning principles that apply to adult learning situations (Knowles, 1994). Malcolm Knowles spent the majority of his life linking these principles into a theory he entitled andragogy. The six core principles of andragogy include: 1) the learner's need to know, 2) self-concept of the learner, 3) prior experience of the learner 4) readiness to learn, 5) orientation to learning, and 6) motivation to learn (Knowles, Holton, & Swanson, 1998). Other factors that affect adult learning are individual learner differences, situational differences, and goals and purposes of learning. Andragogy works best in practice when it is adapted to fit the uniqueness of the learners and the learning situation (Knowles, Holton, & Swanson, 1998).

The Project

This section describes the project itself in terms of data collection and data analysis. Some preliminary data are presented to describe the project and its purposes. A more thorough presentation of findings appears after the process used by the authors is described in detail.

Data Collection. There were six file drawers of personal correspondence containing letters between friends, family, students and colleagues. “Personal letters between friends and family members provide a source of rich qualitative data” (Bogdan & Bilken, 1982, p. 99). Bogden & Bilken state, “The phrase personal documents is used broadly to refer to any first-person narrative produced by an individual which describes his or her own actions, experiences, and beliefs.” (p. 97). Allport (1942) suggests that a review of personal written documents or material reveals a person’s view of experiences.

Correspondence was sampled according to the qualitative data collection method for personal documents espoused by Bogden & Bilken (1982). Five criteria were used to screen pertinent pieces of correspondence. These criteria included any letter that pertained to Knowles’ philosophy, andragogy, family, learning, and mentoring. Only letters written by Knowles were sampled. However, letters written to Knowles may have been selected to provide further clarification or explanation. Additionally, text written by Knowles and text sent for Knowles’ review were not included in the sample. Approximately one-third, or about 360 letters, of the entire correspondence collection were selected for team review and analysis. All selected letters were photocopied so as to preserve the integrity of the original documents.

The team used Bogdan & Bilken’s (1982) process of developing coding categories. The team read through the data keying in on, “certain words, phrases, patterns of behavior, subjects’ ways of thinking, and events” (p. 156) that were repeated and/or stood out. A coding system was developed to identify categories representing topics and patterns that emerged from the correspondence. Descriptive data collected was sorted so that the “material bearing on a given topic could be physically separated from other data” (Bogdan & Bilken, 1982, p. 156). The process of collection and coding began with an initial review of the 360 letters by each team member. The correspondence sample was divided into four sections, which were reviewed and circulated by all four team members. Passages or phrases, which met the criteria stated above, were highlighted for further data analysis.

Data Analysis. Data analysis was conducted according to Guba’s comparative pattern analysis methods (1978). Guba (1978) suggests looking for recurring regularities in the data and sorting data into categories. “Categories should then be judged by two criteria: internal homogeneity and external heterogeneity” (1978, p. 53). Internal homogeneity refers to the extent to which the data that belongs in a certain category hold together, while external homogeneity concerns the extent to which differences among categories are clear (Patton, 1990). The researcher then works back and forth between the data and the categories, verifying the meaningfulness and differentiation of the categories (Guba, 1978).

From this first stage of analysis common themes began to emerge in Knowles' writing. The project team began to capture the themes on 3x5 cards. From this exercise, 37 themes emerged and several overarching categories appeared which lead to the formulation of five major categories. Some themes appeared in more than one category to reflect different perspectives on the same idea. The five categories included: professional, learning, philosophy, personality, and personal. The project team established internal and external homogeneity (Guba, 1978, Patton, 1990) through an iterative process encompassing data analysis, category creation and lively debate. Originally thirty-seven themes emerged with some themes appearing in more than one category to reflect different perspectives on the same idea. Through a reiterative process of cycling between the data and the categories, the researchers refined the meaningfulness of the themes that emerged and made adjustments (collapsed or expanded categories) as was directed by the data (Guba, 1978).

Once the initial categories and themes were recorded, the team reviewed each highlighted passage and assigned it to the appropriate theme and category. For example, a mention of a Knowles book in the correspondence would receive a code of 1-B. New themes and categories were established as the passages dictated. Categories and themes were added or collapsed in order to reflect an accurate representation of the correspondence. Figure 1 provides the complete listing of themes and categories developed.

Once the final categories and themes were revealed, the passages were ready to be entered into a database. Several options were considered, and upon the consultation of a local database expert, Microsoft Access was chosen. An initial form was created for data entry, and the team once again divided the correspondence to share the work of data entry. Form fields included: letter number, date of letter, recipient of letter, recipient organization, location, theme codes, passages, and frame of reference. The passages were input exactly as typed by Malcolm Knowles, including spelling, grammatical and typographical errors. After the completion of data entry, two stages of data verification were completed. The first involved ensuring the accuracy of the input of the passages and coding. The second involved reviewing each passage for clerical errors; correct assignment of codes, and to ensure the correspondence was preserved in its original format.
As the four students in this course began cataloging Knowles' personal correspondence, they discovered several handouts and other teaching materials that had been created and used by Dr. Knowles. One such teaching aid was entitled, “The Assumptions and Process Elements of the Pedagogical and Andragogical Models of Learning”. In this handout, Knowles compared and contrasted the differences between pedagogical and andragogical learning. Knowles suggested in his handout “these two models do not represent bad/good or child/adult dichotomies, but rather a continuum of assumptions to be checked out in terms of their rightness for particular learners in particular situations.”

In the original handout, Knowles described seven process elements of andragogy (See Figure 2). Subsequent literature outlines eight factors that are to be considered in the design of an adult learning experience (Knowles, 1995; Holton, Swanson, & Naquin, 2000). The learning process is described here according to all eight elements.

Preparing the Learners. The course was initially designed as an independent study course. In reviewing these process elements, it is clear that they were manifested in the course from the beginning. The first class meeting met all of the andragogical approaches in preparing the learners. The professor provided information about the course, general expectations were made clear, possibilities for participation and collaboration were offered, and exploration of the content was discussed.

Creating the Climate. Because the course was formulated in an independent study format, the group was mostly responsible for creating the climate. However, the professor played a key role by demonstrating his trust in their academic abilities. One student commented the facilitator (professor) empowered the group by demonstrating confidence in their ability to be self-directing and to accomplish their goals. Another student stated that the professor, being a true facilitator, did not impose his “educational will” on the students, but rather served as consultant for the project. Throughout the course, all of the andragogical approaches to climate were present including a relaxed, trusting, informal, warm, supportive, collaborative and mutually respectful environment.

Planning. The group conducted its own educational experience planning. However, occasional meetings were held with the facilitator to solidify the project’s path and obtain suggestions for proceeding. One student stated that periodic input was needed from the professor, but more as a guide than as a tool to “force his research will” on the group. These meetings involved a team analysis of the materials available for review, thoughts on the most efficient way to approach the subject, research methodology options, and ways to satisfy learner needs, interests, and objectives.

Diagnosis of Needs. Diagnosis of needs, setting objectives, and designing learning were all steps completed through mutual assessment and negotiation among group members and with the facilitator. Although there were no written learning contracts, learning objectives were identified through the project the professor and students had chosen to complete. The most difficult part of the course was deciding on a learning project.

Setting of Objectives. The group brainstormed project possibilities, considered individual learning outcome expectations, and compared learning style differences. The group understood that they had at their fingertips something special with the Knowles’ collection. However, initially its contribution to the group’s learning experience was somewhat unclear. One student debated the value of such a project due in part to her background and mental model of research being grounded in quantitative research. Another student seemed to agree when she commented that the group brought to the table its educational research biases and schema. Another student found that the group’s “reservoir of experiences” was a definite plus in the exploration process of the life of the “father of andragogy”.

Designing Learning Plans. One major cause of frustration for the group was the fact that this was the group’s first totally andragogical learning experience. Most of the group members exhibited some discomfort with the lack of structure and direction associated with the nature of the learning project. One student’s frustration was evident when she remarked that she was “most uncomfortable with the ambiguity that comes from no direction from an instructor”. Another student described the first few meetings as though she was “moving through the learning process blindfolded, feeling the way as she went.” The andragogical learning process was not an easy one, at first.

Several students commented that the composition of the group was complimentary and critical to the overall direction of the learning experience. Two of the students were firmly grounded and biased toward quantitative research, while the other two were comfortable with either a qualitative or quantitative research direction. The difference in views of research turned out to be positive. One student remarked that the two students who exhibited an appreciation of and comfort level with qualitative research were able to “create a vision and excitement” for the Knowles research project. The two students, both grounded in quantitative research, remarked that it was a “stretch” to embrace the project in its early stages, but the direction became clear as time passed. One student commented that the group’s ultimate success was due to their ability to “work within our strengths and demonstrate patience and understanding when weaknesses were evident.” Yet another student stated that “tension existed between meeting group and individual needs as well as meeting all course expectations.” While some group members initially struggled with the lack of structure and direction, they quickly became self-directed when our project began taking shape.

Learning Activities. Learning activities were discussed. In actuality, they were lively debated. As one student said, “it also took some time for the group to become fully understanding and respectful of each other’s individual
differences, but I don’t think anyone ever felt rejected or hurt by our dialogues.” Finally, jointly decided-upon activities were outlined, and a tentative timeline was developed. Learning activities included reviewing the correspondence, creating a paper database, scanning and reviewing the correspondence for themes, categorizing, labeling, constructing a computer database, proofing, and finally, reviewing the data obtained. Many hours and substantial group revisions were necessary to complete these activities. The group entered the performing phase through the learning activities (Tuckman, 1965), and one student commented that the professor/facilitator came to the group’s “educational rescue whenever a research roadblock surfaced.”

**Evaluation.** Regarding the last process element of evaluation, several discussions were held among the students with the facilitator to discuss the criteria. There was some concern regarding the ambiguity related to the determination of final grades by those students most comfortable with a traditional method of learning. Evidence of learning for this group would come from a final exam and through examination of the group’s final project: a complete and accurate database, an outline of the research methodology, the submission of all materials produced, and a sampling of the database reports.

Each student commented on the value of having this learning experience. One student remarked, “I have exceeded my personal learning objectives for the course”. Another student commented, “For the first time, theories/models came alive.” Experiencing andragogy first-hand was proof that engaging adult learners in the entire learning process was of value and produced positive learning outcomes. One student remarked, “as was evident in my experiences in this course, andragogy is flexible enough to be used effectively in group situations, and because of the flexibility inherent in the model, andragogy deserves to be a core part of learning design in HRD.”

**Presentation of Data**

Malcolm Knowles came back to life for each of the team participants. His warmth, understanding, consideration, and love for adult learning were obvious in his personal correspondence. There were 356 piece of correspondence used to develop the database. Seventeen (17) of the pieces of correspondence were from 1951-1979. The majority of the correspondence (180 pieces) occurred between 1980-1989. The remaining 159 pieces were written between 1990-1997.

**Seven Emergent Themes**

According to Guba (1978), the task of converting the passages or phrases found in Knowles’ personal correspondence into systematic categories is a difficult one and no infallible procedures exist for performing it. The coding system used to organize the descriptive data that was collected consisted of seven categories with 37 themes as shown in Figure 1. The seven categories were based on Malcolm Knowles the person: his professional life, his strategies for learning, his philosophy for learning, his personality, philosophy for life and learning, his relationships with friends and family, his futuristic approach to adult education, and his closing remarks in his correspondence. Category 1, “professional”, had the largest number of passages or phrases coded with 29 percent. The number with the smallest number of passages or phrases coded was “field of adult education” with six percent. Only three pieces of correspondence did not have some type of closing remarks, category 7.

Descriptions and quotations are the essential ingredients of qualitative inquiry (Patton, 1990). Based on the categories that were developed, there were some 1,429 entries that became part of the database. A breakdown of these entries by category is shown in Figure 3.

**Professional Life and Legacy.** In Category 1, the team looked at Knowles’ correspondence relating to his professional life and his numerous accomplishments. His correspondence reflected his interest in writing as well as his desire to assist others in their writings by reviewing their works. In his letter of October, 1989 pertaining to materials for an advisory panel meeting he writes “I have read them carefully, mostly on airplanes to and from Seattle, and I am impressed with their comprehensiveness, clarity, and scholarliness.” In another letter of September, 1990 he writes “I started reading (name of book) . . . last night and could hardly put it down to get some sleep. I took it up again right after breakfast this morning and am feeling exhilarated. What a beautiful piece of work. So well written. So very comprehensive.” He was adamant about shaping the marketing strategies for his books and he kept detailed records of his royalties. He traveled all over the world to countries such as Australia, Japan, Sweden, Korea, Okinawa, Malaysia, and Thailand as well as the United States to attend conferences, make presentations, and conduct workshops as noted in the letter Knowles wrote in May, 1982: “Since my retirement from NC State University two years ago I have been doing an average of four faculty-development workshops each week in community colleges and universities across the country. Attendance at these workshops averages between 300 and
400 participants each week”. This passage reflects Knowles personal work ethic and commitment to the field—where in actuality he did not “retire” when he left “official” employment but continued to have an active professional life. Even in March, 1994 he was staying active and in contact with students. He wrote “I am keeping some contacts with students by doing an 8-session-per-semester research seminar at the U. of Ark.” In another letter during the same time period he wrote “I still do some writing—mostly doing forewords to other people’s books—and very occasional traveling.” In January, 1995 Knowles admits that he was beginning to slow down: “I donated my computer to an adult school a couple of years ago, so am even off the information highway.”

suggestion is found in his letter of August, 1990: "I have reread the three pieces of your writing that you sent me on June 20, and they are very congruent with the guidelines I have for myself: (1) Talk out of my personal experience rather than from a pedantic podium. (2) Avoid pontificating. (3) Illustrate generalizations with examples. (4) Select a handful of people you know who are representative of the audience you are trying to reach and dialog with them. (5) Think of writing as a form of self-expression, like painting a picture, as a way to have some fun."

The setting of priorities changed for Knowles after he retired. He stated in his letter of February, 1986: "Within a couple of years I found myself accepting assignments in which I really wasn't interested merely to cover the overhead and spending more time that I wanted to on administrivia. . . . I am so enjoying my freedom since retiring from the university—doing only what I want to do and do best, and doing it for myself—that I wouldn't want to pull myself into a position of becoming obligated to doing things to support institutional overhead."

**Personality.** In Category 4, Knowles' personality, wit, and humor were examined in his personal correspondence. "I stamped him 'approved' with the award of The Malcolm Knowles Seal of Andragogy." His warmth was revealed in his letter of January, 1984 in which he states: "Above all, though, know that I love you and respect you, and worry about something that I don't understand. I need you to love and respect me, too, and help me understand." He did enjoy politics and commented on President Clinton's stand on issues on several occasions. Knowles wrote to President Clinton in February, 1993 and provided the following comments: "The fact that the concept of lifelong learning was mentioned so often by the presenters and in the discussion has led me to believe that the enclosed document Creating Lifelong Learning Communities, might be useful to the people who will be planning the educational proposals for the new administration. I am also enclosing a contribution to support the work of the transition team and confirm my enthusiasm for the start is has made. I prepared the document for a task force of the UNESCO Institute for Education about ten years ago, and it has been cited frequently in the educational literature. I am enclosing a brief biographical summary simply to establish my qualifications for writing on this subject." There was a certain format that he used in writing. He always offered a positive comment in the first sentence, then he provided suggestions, and finally, he would close based on what seemed to be the level of friendship that existed between him and the recipient of the correspondence. The team really felt his presence through his writings.

**Family, Friends and Colleagues.** In Category 5, we discovered the meaning of family and friends to Knowles. He and his wife had worked on several books together and traveled together to conferences. She was his "right hand". Therefore, when she became ill and couldn't travel anymore, it was an extreme disappointment for him. Their first retirement was in North Carolina. However, he eventually retired to Arkansas in order to be close to his son and family as his own health began to fail. Knowles wrote of his family situation in February, 1994: "We, too, would be much happier living in Cambridge. We feel so good about living five minutes from our son and his family. We have one grandson in his second year at Harvard and a granddaughter who is going there next year, so we would have family in Cambridge, too. During the last several years I have cut down greatly on my travel, since Hulda can't go with me any longer." In September, 1994 he writes of his relationship with his wife: "Hulda and I are doing just fine, enjoying being lovebirds in our eighties." In correspondence in January, 1995 he admits to being fully retired: "I'll be eighty-two next August, and am now fully retired and living in a life-care home with my wife, who is the same age and very disabled from a stroke she had eight years ago. So I don't give any more speeches, attend conferences, or travel further than to the supermarket." He further provides insight into his retirement in April, 1995: "As you probably know, I am no longer traveling, so the mailman is my primary contact with the outside world."

**Field of Adult Education.** Category 6 primarily referred to the field of adult education, the changes that were taking place, and the technology that was providing more opportunities for adult educators. In correspondence of November, 1981 Knowles writes, "The last time I was in Columbus I picked up the folder describing options and was terribly impressed by the imaginative way you folks are meeting the needs of nontraditional students." In correspondence of April, 1983 related to a grant application he states "I think that your project is the most exciting approach to reorienting elementary education to self-directed learning that I have seen." The importance of andragogy can be seen in his correspondence of February, 1986 where he writes: "I have been thinking (in between other tasks) about your idea of starting an Andragogy Institute, and am ready to start sharing ideas. I see this though as only starting a dialog—not presenting a plan. . . . I have lots of evidence that there is a growing need for this kind of service as higher education institutions experience and influx of adult learners and as industry expands its human resource development programs. I can visualize that if we created an Andragogy Institute I could train a cadre of people to do what I do so it wouldn't be dependent upon my availability, interests, or anger."

Knowles' letter in
February, 1989 wrote of an institution with an external degree program that he was associated with and considered a model for future graduate education "...for the simple reason that they make it possible for experienced practitioners to pursue graduate studies without leaving their jobs to live on campus or to attend classes that interfere with their work schedules." Other comments about this institution's program were "... has found ways to provide the interaction among students and between faculty and students, that is often associated with campus living, through short-term summer sessions and regional seminars, the telephone, and an electronic network".

Closings. The closings in Category 7 were coded because they provided an insight into the level of intimacy that existed between Knowles and the recipient of the correspondence. When Knowles accepted his position at North Carolina State University in 1974 his closing was “I am looking forward to working with you and your colleagues with great pleasure.” His closing for a letter to a colleague in November, 1981 was “I hope that you can restore my morale.” The closing in a letter February, 1984 was “Hulda sends her love.” Correspondence to a student in April, 1989 was closed using “With pride in you,” and another in August, 1994 closed “With pride and appreciation.” Some other closings were “Affectionately,” “Lot of hugs,” “Warmly,” and “With tender caring.” A closing that also showed Knowles wit as well as the level of intimacy was in November, 1989 which was “Give (name of person) our love and keep some for yourself.”. In February, 1997 after Knowles had become ill, his closing was “Painfully yours.”

Implications for Future Research and Contributions to HRD

The database produced as a result of this effort will provide scholars in the years to come a window into the personal and professional ideals of Malcolm Knowles. As a result of this analysis, the research team gained valuable insight into certain aspects of his life that are ripe for future exploratory study. First, a picture emerges from his words of a man possessed with great wit, humor, warmth, and kindness. Further study of this personality, as witnessed through his correspondence, can provide scholars with rich biographical information. Second, Knowles demonstrated a strong commitment to the value of a mentoring relationship throughout his correspondence. He continued, up until his final days, to be a mentor to students and colleagues across the field. Future study of these mentoring relationships will provide researchers with a gauge of his impact across the field of adult learning and HRD. Additionally, his correspondence may provide insight into his use of andragogical principles in the mentoring process.

Malcolm Knowles was a man dedicated to his beliefs. By further analysis of his correspondence, scholars may find evidence of his convictions and philosophies related to adults, life and learning. Finally, a strong theme throughout his correspondence was the importance of his relationship with his wife, Hulda. Her role in his life and its subsequent impact upon his personal and professional successes should be studied further. Preliminary analysis suggests she played a larger role in his professional life than may have been noticed.

Malcolm Knowles, as one of the founding fathers of our field, is worthy of the focus of future research. By delving into his personal writings, HRD scholars will have the opportunity for a more intimate look at the man, his ideas and beliefs. The creation of this database represents the first brush strokes in painting a portrait of Malcolm Knowles.

Facilitating Learning with Graduate Students in Human Resource Development

Barbara J. Daley
University of Wisconsin – Milwaukee

The purpose of this study was to investigate the ways in which constructivist teaching strategies influence the learning processes of human resource development (HRD) graduate students in the context of higher education. Two groups of students were taught to use concept mapping as a constructivist strategy and then were followed over the course of a year to determine the impact this strategy had on their learning. Implications for teaching in higher education are drawn.

Keywords: Constructivist Learning, Concept Maps, Learning Strategies

Human resource development (HRD) graduate students often enter higher education programs relying on learning strategies that have worked well for them in the past (Merriam & Caffarella, 1999). These previous learning strategies often include rote learning, passive learning, memorization and recall of facts. Assisting HRD graduate students to broaden their learning strategies is a major factor contributing to their academic success in higher education (Gibbons, 1990; Novak, 1990; Smith, 1982) and to their ability to function in the workplace. The purpose of this study was to assist HRD graduate students to enhance their learning through the application of teaching strategies that foster a constructivist approach to learning.

Conceptual Framework

Merriam and Caffarella (1999) define five different learning orientations including: behavioral, social, humanistic, cognitive and constructivist learning. They believe that within each of these learning orientations different assumptions exist about the nature of learning and the strategies that instructors can use to facilitate learning. Since the purpose of this study was to assist HRD graduate student to broaden their learning strategies, the constructivist learning orientation provided the overall conceptual framework for this study.

Constructivist learning has evolved to include multiple approaches and perspectives. For the purpose of this study, constructivist learning is seen as a cognitive approach that locates cognition and understanding within the individual. The most salient feature of this perspective is the "notion that learners respond to their sensory experience by building or constructing in their minds, schemas or cognitive structures which constitute the meaning and understanding of their world" (Saunders, 1992, p. 136). Constructivists, writing from this cognitive approach (Ausubel, 1986; Brunner, 1990; Novak, 1998; Piaget, 1966), express the belief that individuals create knowledge by linking new information with past experiences to create a personal process for meaning-making. Within a constructivist framework, the learner progressively differentiates concepts into more and more complex understandings and also reconciles abstract understanding with concepts garnered from previous experience (Novak, 1998). New knowledge is made meaningful by the ways in which learners establish connections among knowledge learned, previous experiences, and the context in which learners find themselves. Lambert et al. (1995) identify multiple principles of constructivist learning theory, which include the following major points: (1) knowledge and beliefs are formed within the learner, (2) learners personally imbue experiences with meaning, (3) learning activities should cause learners to gain access to their experiences, knowledge and beliefs, (4) learning is a social activity that is enhanced by shared inquiry, and (5) reflection and meta-cognition are essential aspects of constructing knowledge and meaning (pp. 17-18).

Novak (1998) operationalized constructivist learning theory by creating concept maps. A concept map is a schematic device for representing a set of concept meanings embedded in a framework of propositions (Novak, 1998). Concept maps are created with the broader, more inclusive concepts at the top of the hierarchy, connecting through linking words with other concepts that can be subsumed. This tool helps facilitate understanding of conceptual relationships and the structure of knowledge. Novak (1990) found in an analysis of multiple studies using concept maps that the technique promoted novel problem solving abilities, raised mean scores on achievement of content units, decreased students' anxiety levels and increased students' positive attitudes toward the content of study.

Three important processes are employed in the creation concept maps. First, lower order concepts are subsumed under higher order concepts. This subsumption process assists learners to understand the nature and
structure of knowledge by locating concepts in relation to each other. Second, concepts are progressively differentiated into more and more complex structures. The process of progressive differentiation is similar to the analysis process, as the learner breaks down concepts leading to finer distinctions. Third, the process of integrative reconciliation is used to create horizontal links and synthesize information from the left and right side of the map. These horizontal links represent the learner’s ability to synthesize conceptual information during the process of creating unique meaning structures.

In order to study how constructivist strategies impact the learning of HRD graduate students, constructivist teaching strategies were employed in two graduate courses in an HRD/adult education graduate program.

Research Questions

In this study, HRD graduate students were taught to use concept maps. The extent to which this strategy contributed to a change in learning strategies was assessed by evaluating: (1.) the change in student concept map scores during a one-year time frame, and, (2.) HRD graduate student responses to tape-recorded interviews. The following research questions were advanced to guide this investigation.

* When HRD graduate students learn to use concept maps in one course, will that learning strategy carry over to subsequent courses in which the student enrolls?
* How does the use of concept maps as a learning strategy change the thinking of HRD graduate students?
* Can concept maps transform HRD graduate students’ prior learning strategies?

Methodology

During semester one, HRD graduate students in two different courses were taught to use concept maps as an integrated part of their course work. Students developed concept maps to reflect the course readings, plan course projects, and to compare and contrast information from course discussions. In learning to use concept maps, students were taught to follow the steps outlined in Table 1.

<table>
<thead>
<tr>
<th>Table 1. Steps in Constructing a Concept Map</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Identify the most general concepts first and place them at the top of the map.</td>
</tr>
<tr>
<td>2. Identify the more specific concepts that relate in some way to the general concepts.</td>
</tr>
<tr>
<td>3. Tie the general and specific concepts together with linking words in some fashion that makes sense or has meaning to you.</td>
</tr>
<tr>
<td>4. Look for cross-linkages between the general and more specific concepts.</td>
</tr>
<tr>
<td>5. Discuss, share, think about and revise your map.</td>
</tr>
</tbody>
</table>

Twenty-one students from these courses were randomly selected and invited to participate in this study. Following IRB approval, students gave consent to have their course work reviewed and to be interviewed twice over the academic year.

A mixed-method design using both quantitative and qualitative analysis was created for this study. The first and final concept maps created by study participants in the first semester were scored according to the scoring formula created by Novak and Gowin (1984) and depicted in Table 2. Reliability was established by obtaining two independent scores on each map. Inter-rater reliability was established at .80. Data analysis included calculation of group means and comparison of these means using a dependent t-test.

At the end of semester one, interviews were conducted with participants about their use of concept mapping. During the interviews, HRD graduate students were asked the following questions: 1. What was it like to use concept maps as a learning strategy? 2. What did you learn while doing concept maps? 3. Where else have you used the maps since the completion of your course (if at all)? 4. How was doing the
maps the same or different than other learning strategies you have used previously? 5. What did you like most/or like least about using concept maps? 6. What changes, if any, did you see in your thinking ability since using concept maps? 7. What was the most significant learning you remember from this course? 8. If you were going to describe concept mapping to another graduate student, what would you say? 9. How do you see using/or not using this learning strategy in the future?

Study participants were followed during semester two. Concept maps created by the HRD graduate students at the end of semester two were scored. At the end of semester two, study participants were interviewed a second time to determine if they continued to use concept maps as a learning strategy and how that strategy impacted their thinking and learning.

Interview data was analyzed using a modified constant comparative method (Glaser & Strauss, 1967; Patton, 1990). First, all interviews were coded and themes identified using the qualitative data analysis software package N*VIVO. Then, coded data were compared from the first set of interviews to the final set of interviews by developing a system of matrices for comparison and contrast (Miles & Huberman, 1994). Finally, a summary concept map was created to synthesize the themes identified in both sets of interviews.

Findings

Findings from this study indicate that using concept maps impacts HRD graduate student learning. The presentation of findings from this study will first focus on the changes in concept map scores and then explore student interview data related to learning with maps and the use or non-use of maps at a one-year follow-up.

Changes in Concept Map Scores

In this study concept maps were collected from participants at three separate points. In the first semester of the study, the first and final map created by the students were collected and scored. During the second semester, the final map that participants created, (if they did create a map in semester two), was collected and scored.

Data analysis (Table 3) demonstrates a group mean of 44.81 on the first concept map and 121.43 on the final concept map of the first semester, for a difference of 76.62. The t-value comparing the first to final map was -6.614 (p=.001). The data indicate a statistically significant difference between the first and final map scores of the first semester.

<td>121.43</td>
<td></td>
</tr>
</tbody>
</table>

P = .001 t-value = -6.614

Students were followed during the second semester of the study, to determine if they continued to use mapping as a learning strategy and if they did how the maps compared to the first semester. Data indicate that 65% of students in this study continued to use mapping into the second semester. Data indicate the mean score for the last map during semester one was 121.43 and the mean score for the last map in semester two was 120.22, for a change score of -1.21. The data indicate no significant difference between those participants mapping at the end of semester one and those mapping at the end of semester two.
Participants were also interviewed at two points during this study, at the conclusion of semester one and at the conclusion of semester two. Participants were asked during the interviews to describe their experiences with mapping as a learning strategy and to analyze how their thinking had changed or not changed through the use of mapping. Participant responses were categorized into two areas for presentation of findings: learning with maps and map use on follow-up.

**Learning with Maps**

Study participants indicated that to learn effectively with maps, they first had to develop the skills in map construction and to understand the mechanics of mapping. Additionally, participants reported that often their initial reaction to mapping changed and developed over the time that they used mapping.

Participants stated that part of what they enjoyed about the process of mapping was the focus on organization, analysis and understanding. Participants indicated that through the process of organizing and analyzing, they developed a more holistic picture of what they were learning. One participant stated:

*It made you look at whatever it was you were doing in its entirety. It made you look at it as a whole. And then start breaking it down by concepts and then you would rebuild it by linking... You feel the knowledge building. You just feel yourself seeing things differently than before you started doing that.*

However, some participants expressed difficulties in developing maps including: finding time to complete the maps, deciding on the level of detail to include and overcoming their lack of desire to change how they learned. Participants indicated that mapping as a learning strategy was too demanding and took up too much time.

*It is just another task to do when you feel overwhelmed. It takes more time than just reading the text... I think it has a lot more value than what it feels like you are doing at the moment.*

Participants also expressed how difficult it was to change learning strategies that they had used in the past. Changing old habits was time-consuming and difficult for most participants in this study. One participant indicated:

*But, I guess what I hated the most was that I had to change my thinking mode. It is before, like, well, I am just reading this information, and I am picking out what I see is in the writing or what the writer is trying to present. I guess I just didn’t like the idea of changing old habits and doing things differently.*

**Understanding One’s Own Learning**

A major finding of this study was that concept mapping helped HRD graduate students to understand their own learning processes. Additionally, they were able to explain that they developed their learning processes through the use of learning strategies such as linking, developing interrelationships, creating meaning schemes, and constructing knowledge. Participants reported that the maps helped them to understand how they think, to think in a broader fashion, to search out complicated relationships, and to organize information so that they remembered it in a much more comprehensive way. For example,

*I learned a little bit about how I think based on how I put the concept map together. I learned a little bit about what challenges me, what comes easy to me. I tried to pick things to concept map that I didn’t understand so that I would understand them afterwards.*

Another participant described how she developed understanding by moving from larger concepts to smaller concepts and back again.

*I learned to use another part of my brain. I learned also to think globally because this is going from big ideas and main ideas to smaller ideas, subtopics, so I learned to modify how I think about information. I also learned to show more linkage of information.*

Finally, participants discussed how the maps helped them apply information to their experiences and at the same time remember that information in a new way.

*... instead of it being information given to me and stored away in my head, the most significant thing is that when I can apply things to my real life experience, I have a better time understanding them, better time remembering them. So to me that is a big deal.*

**Learning Strategies**

As participants came to understand their own learning, they also developed an understanding of a number of learning strategies that they developed as a result of using concept maps. Participants reported that their understanding of how to link concepts, develop interrelationships, create meaning schemes, and construct a knowledge base developed through the use of mapping.
Linking. Participants in this study were asked to describe their most significant lesson learned from the course in which they were enrolled during the first semester. A large percentage of the participants expressed the opinion that learning to link concepts was a new learning strategy for them and a major discovery in their own learning. The following participant expressed the value of learning to link concepts this way:

What I discovered in my own learning was that indeed there were connections between ideas and concepts that I hadn't picked up on just in reading the material. But it was in the diagramming of the concept map and I usually did it in two stages. My first stage was I threw enough stuff down on paper as I could [sic]. My second stage, I let it sort of sit and simmer like a pot on the back burner for awhile. Then I would come back and make some aha's, oh I see some relationships here. And that helped to open up the interconnectedness of what I had been looking at and didn't initially see.

Another participant expressed a common theme evident in many HRD graduate learners' experiences in this study. Participants indicated that they just had not thought about the relationships between concepts previously until confronted with a learning strategy that asked them to make those connections.

The linking. I never gave it thought before the relationships between levels in the hierarchy and between different concepts within the map. That would probably change my approach to a lot of things now.

Interrelationships. Participants in this study also described a step beyond linking. They indicated that as a result of making links between concepts, they began to understand and search out interrelationships between concepts that created new meaning for them. As one participant explained:

As I did the concept maps, I was particularly sensitive to find what the interconnections were. I did our case studies and I went through the readings; whatever we had to concept map, I was more aware of the connections, what are the relationships, because I knew eventually I had to produce that in the map.

Another participant described how after learning to make links, the process of developing interconnections helped him critique his own thinking by highlighting false connections he had made previously. As a result, he felt that finding the connections was a way of double-checking his understanding of new material.

After I did a couple of maps I realized that these were the things that I was trying to do mentally. Sometimes I would see the mistakes or let's say just mis-connections. Like no, this really doesn't connect to this. This really should connect over here. You could almost, like, check your math. It is like doing math the long way as opposed to taking some shortcuts. Every once in awhile you made a mistake and then you had to go back. It was kind of like long division.

Creating Meaning Schemes. A number of participants also indicated that subsequent to linking and searching out interconnections, the mapping exercise fostered the learning process or strategy of creating meaning schemes. Most participants described these schemes as a way to organize and structure information. Additionally, participants indicated that in the process of creating schemes of information their ability to recall the information was improved.

Well, doing the concept map forms the schemes for learning. It forced me where the author didn't put a framework, to put one. So I believe that although it takes longer to read and do a concept map in order to retain what you are doing or to develop an idea that way, that I definitely knew after doing a couple that the retention was going to be greater because the scheme was etched in your mind then.

Knowledge Construction. Finally, participants indicated that through the process of developing a concept map, they learned that linking, developing interrelationships and creating mental schemes all helped them develop their ability to construct a knowledge base for themselves. One participant expressed the way she began to understand the process of creating a concept map as similar to creating a mosaic. She stated:

I think that helped with the whole process because with a mosaic you have a bunch of little pieces and you are kind of figuring out what is the best way to array them, how many little pieces you have, and what comes after what. That concept plus the learning fell in with my understanding or belief of how adults learn. I guess it would be kind of a constructivist approach as we build on what we already know, we add too, we might reshape what we already have in our brains, based on what new stuff comes in. It may be reshaped or you may just add to your database. I felt like the concept mapping process really helped with that.

Another participant describes a similar connection between developing concept maps and constructing knowledge. She stated:
I really believe in concept mapping because I believe in constructing knowledge. Dialog, discovery, constructing knowledge, all that stuff. It really does fit in. Maybe that is why I do like it because it does give you a chance to kind of sort stuff out and construct knowledge.

Changes in Thinking

At the conclusion of the first semester of this study, participants were asked if their thinking changed as a result of the use of concept maps and, if so, how. Participants described how this strategy was different than other learning strategies and that their thinking did change. Participants expressed how they analyzed concepts in more depth and they felt they had the ability to make connections across multiple bodies of knowledge. For example, one participant stated:

*It is different because any other strategy, taking notes, putting together a formal outline, one thing after another. Whereas, the concept map gets you to think outside of the box. It gets you to see how things relate rather than how one thing is broken down. So it was a different way of approaching something, taking a different perspective on learning, I thought, which was refreshing for me.*

Finally, one participant indicated that the mapping process helped her to think better and also helped her to recognize that she really developed an understanding of what she learned.

*I don't know if this makes sense, but concept mapping allowed me to think better. It really allows you to understand what you are reading and as you are doing it, you are putting it together, and all of a sudden when you are done and you think to yourself when you look at sort of the arrows that are going back and forth and the connections that you have made, and you sort of look at yourself and you think, wow, I guess I really get that. I get it thoroughly as opposed to something you just read and five minutes later you asked me what I just read and I am not able to answer the first question.*

Follow-Up After One Year

One of the major research questions this study addressed was do HRD graduate students continue to use concept mapping as a learning strategy even when they are in courses that do not require them to do so. In this study, 65% of HRD graduate learners reported that they did continue to use this strategy. Those participants who reported that they continued to use mapping explained that they did so for a number of reasons. They seemed to use maps to understand course material in subsequent graduate courses. They also relied on the maps as a way to understand particularly difficulty material. Many participants reported that when they felt “in trouble” in a course or that they “did not get it,” they would try mapping out the material as a way to develop their understanding. Additionally, learners tended to use maps to frame projects for subsequent courses or work-related projects. One participant described how he had a big project to do at work and as a way to help his team understand the scope of the project, he mapped it out and shared the map with them. Another student described how she used a concept map in a subsequent class to demonstrate decision making.

The HRD graduate students who did not use concept maps in the subsequent semester (35%), reported that they chose not to because they were not required, they did not have time or they did not have the software they needed to develop the maps. However, the biggest barrier to creating maps for this group was time. Over and over again, these learners complained that the process took more time than they felt they could invest in their course work.

Interestingly, in this study both learners who used concept maps in subsequent semesters and those who did not still reported changes in their thinking at one-year follow up. For example, students who used the mapping tended to report that the maps increased their focus, understanding of relationships, and thinking processes. The following quote is from a learner who did use the maps in the follow up semester:

*I am more conscious, especially in the class I just had, I was conscious of how do these different concepts interrelate. What are the connections that I am making in my mind? That is why I went to the concept map. Because my mind was doing stuff, but I wanted to get it down on paper so I could look at it.*

On the other hand, the learners who chose not to use concept maps in subsequent semesters still reported changes in their thinking. These learners reported being able to identify interconnections, organize information and develop mental schemes for their reading. The following quote is from a learner who had not used mapping in the subsequent semester:

*Although I haven't used them, I think in the way I organize my textbook and in how I write some of my notes, that it is actually a variance of a map. I never used those little stickies before. I highlight them in different colors now. What I will try to do is try to group them according to color, so that when go back I*
Discussion

Results of this study indicate that HRD graduate students learned to develop concept maps and, through the process of using this constructivist learning strategy they developed their thinking abilities and grew to understand their own learning processes. Also, the quality of the maps constructed at the end of the first and second semesters was virtually the same. This was somewhat surprising as one would anticipate that students' mapping skills could deteriorate if they were not required to construct maps. Rather, findings indicate that the mapping skills remained constant throughout this study. This finding is encouraging as it indicates that mapping potentially has a long-term impact on HRD students' learning strategies. As such, more research is needed on when, how and for how long these changes in thinking are evident.

A number of issues surfaced in this study. First, it was surprising that many HRD students participating in this study began with so little understanding of their own learning processes. Students often indicated that they “never thought about” their own learning and they just “took for granted that reading and studying” would foster an understanding of course material. Understanding their learning was often exciting and energizing as students felt they had mastered a skill they could continue to use in multiple settings. Second, it was evident, however, that some students were resistant to changing their learning processes, even when they were unsure of the nature of those processes. It took a great deal of work for many students who participated in this study to find the willingness to try this learning strategy and to learn how to use concept maps. This again points out the depth to which learning strategies are engrained. Finally, it was interesting to note that once study participants did understand their own learning, they continued to move forward in developing their thinking abilities even if they did not use the concept map explicitly. Again, this finding is encouraging, as it demonstrates the long-term impact that mapping may have with HRD students.

On the other hand, students did identify time as the major barrier to creating concept maps. Creating concept maps fosters a higher level of understanding of course material - but it takes more time. For HRD students' time is a carefully managed resource. One way to overcome the lack of time is to encourage students to use technology to create their concept maps. The technology streamlines the logistics of creating the maps and thus, can decrease the time required and maintain the gains in learning and thinking abilities.

Implications for Graduate Education in HRD

This study has implications for graduate education in HRD. As Watkins (2000) indicates, “the aims of HRD are to bring about learning and change in an organizational context” (p. 54). It is this researcher’s belief that for HRD graduate students to develop into HRD professionals who foster learning and change, the first step is for HRD graduate students to understand their own learning processes. Once students in this study were able to learn in this fashion and explain their own learning, they were much better prepared to function as HRD professionals promoting learning and change. A number of students shared examples and cases where they used mapping in their organizations to analyze performance projects, develop strategic plans, teach leadership, support decision-making and brainstorm new ideas. This use of concept mapping in the workplace seems to indicate the wider application and implications that this learning strategy has for HRD. The major implication here, for faculty in HRD programs, is that students often do not understand their own learning processes and need practice with learning strategies that will help them develop their learning and thinking abilities. Once students develop more complex learning strategies, they are then better prepared to think critically and analytically about specific content they are learning.

The biggest challenge for faculty in HRD programs is changing teaching approaches to incorporate research on student learning. Using concept maps necessitates that faculty have a good understanding of constructivist learning and the ways in which maps represent students' thinking. To use mapping, faculty need to be willing to foster an approach to learning as meaning construction. This means that the focus of courses shifts from teaching and presenting information to learning and creating meaning. The role of the faculty member shifts from content expert to facilitator of learning. Often this is a demanding change that requires a new way of thinking about teaching and learning.

This study indicates that concept maps can effectively promote learning of HRD graduate students and thus, can be added to the teaching strategies of faculty in HRD. The maps support both constructivist teaching and learning approaches and seem to have wider applicability to the work world as well.

Determinants of Supply of Technical Training Opportunities for Human Capital Development in Kenya

Moses Waithanji Ngware
Egerton University, Kenya

Fredrick Muyia Nafukho
University of Arkansas

In slow growing economies, an increased supply of human capital acts as an impetus for socio-economic development. Graduates of technical skills in Kenya act as job creators as opposed to school leavers who are inclined to job seeking. In this paper, the authors develop a supply function model that explains the factors influencing the supply of training opportunities in Technical Education Programs in Kenya.

Keywords: Technical Training, Supply of Training, Human Capital

Resources used on education and training are investments in socio-economic development of a nation. In developing countries, studies have shown that rates of return to expenditures on education and training are very high (Psacharopoulos, 1995). In Kenya, studies show that farmers and informal sector workers with primary education are one-third more productive than their counterparts without this basic education (Ndewa, 1991; Thias & Carnoy, 1972). Investment in human capital is a critical consideration to the success of an industrialization process of any nation. It assures the supply of well-trained managers and skilled technicians at both shop floor and supervisory levels. This calls for a collaborative effort between the training institutes and employers in order to bridge the gap between supply of training places, graduate outputs and demand for technical skills. In Kenya, it is estimated that 59 per cent of the population is below 20 years of age (Republic of Kenya, 1996, 1997). The government of Kenya through the sessional paper No. 2 of 1996 observed that, there existed a mismatch between demand and supply in the labor market. Thus, majority of the youth lack vocational and technical skills that are required in the labor market. While the training institutions are offering courses that may not be required by employers.

Problem Statement and Purpose

To remove the mismatch between demand for and supply of technical training opportunities in Kenya requires economic analysis. Training potential and opportunities for school leavers and workers is an area that needs to be explored using economic principles. The ministry of education does not have data on the number of places available for technical training and the factors determining demand for and supply of technical training opportunities. This reduces planning for development of human capital to guesswork. Thus, in the absence of empirical data relating to factors influencing the supply of technical training opportunities, one is not able to determine whether new institutions should be built or the existing ones, should be expanded.

The main purpose of this study was develop a supply function model that explains the factors determining the supply of training opportunities in Institutes of Technology (IT) in Kenya. The study sought to answer one major question: What factors affect the supply of training places in Institutes of Technology studied?

Study Hypotheses

It was hypothesized that:

1. There existed a positive and significant relationship between the diversity of the technical courses offered by the departments and the supply of training opportunities.
2. There existed a positive and significant relationship between the cost of the training programs and the supply of training opportunities.
3. There existed a positive and significant relationship between departmental capacity and the supply of training opportunities.

Theoretical Framework

The theory of human capital postulates that individuals are motivated to spend on themselves in diverse ways by purchasing education, not for its own sake, but for the sake of future pecuniary and non-pecuniary returns. That both direct and indirect cost is incurred when individuals and governments spend on education (Shultz 1961, 1962). From the theory of human capital, expenditures made by individuals and governments on education and training are investments that will provide returns in the future. Becker (1993) shows that investing in education and training increases individuals' lifetime earnings. Thus, education and training are processes of human capital formation. In fact, Shultz (1962) and Mincer (1962) note that all activities aimed at improving quality of human life such as spending on health, job search, and migration are part of human capital.

Training, which is the main focus of this paper, is a form of human capital. As in education, training influences the variation in wages and earnings. Mincer (1962, p. 50) observes: “the training process is usually the end of a more general and preparatory stage, and the beginning of a more specialized and often prolonged process of acquisition of occupational skill, after entry into the labor force.” The cost of training incurred by the training institutions and the trainees including expenditures on foregone earnings are considered investments (Aliaga, 2001).

Factors Influencing Supply of Training

The literature show that the main factors influencing supply of training can be derived from the reasons why training is provided. From the economic theory of the firm, inputs are utilized to obtain output. Thus, training institutions incur costs such as building of learning facilities, paying the trainers, time and purchase of equipment. All these include the inputs. The output includes, the graduates. From the Input-Output model, training institutions, as firms must optimally combine inputs to obtain the desired output.

Becker (1993) identified two types of training, general training and specific training. General training is the type of training that is useful in many firms besides those providing it. The knowledge and skills learned can be used in the firm providing or sponsoring the training as well as in others. Thus, knowledge and skills are transferable from organization to organization (Aliaga, 2001; Nafukho & Kang’ethe in the Press). Firms that incur the direct and indirect cost of general training obtain returns from the investment but also take the risk of other firms obtaining the returns when the trained employees change jobs. Employees who take general training in most cases pay for their own cost of training. Hence, cost of training is an important factor that may determine the supply of training. General training provides workers with increased negotiation capability within the existing labor market. Most firms are unwilling to directly sponsor general type of training since it is easy to outsource such services.

Unlike general training, specific training has been defined as training “that has no effect on the productivity of trainees that would be useful in other firms” (Becker, 1993, p. 40). The skills and knowledge learned will only be useful to the organization sponsoring the training. A good example of specific training in Kenya is the kind of training provided by banks. When banks train their own employees in Kenya, they focus on specific training with the objective of obtaining increased marginal productivity from the employees since the skills and knowledge learned are only applicable to the banks paying for training. Flamholtz & Lacey (1981) observe that the purpose of specific training is to increase the employee’s marginal productivity. That is both the firm and the employee will benefit from increased marginal productivity since the overall performance improves. The employee will benefit especially in the private sector where payment is pegged on good performance. This is in line with the theory of human capital since the trained employee receives additional earnings as a result of investment in training.

Both general and specific types of training influence the supply of training in Institutes of Technology in Kenya. Employers sponsor their employees by paying for direct and indirect cost of specific training. In the case of general training, many high school students meet the direct cost of their training.

Departmental Capacity, Program Diversity and Supply of Training

World Bank (1993) study concluded that meeting academic entry requirements and private costs were the major determinants of access to technical training institutions. According to this study, major determinants of access had to do with admission policies based on departmental and institutional capacity. The study further established that despite girls scoring high grades in pre-training examinations, they were under-represented. Under-representation of girls in technical and vocational training institutions was also highlighted (Burge, 1990). These studies found out that females enrolled in business education related courses and teacher-training programs while males dominated agriculture, auto mechanics, building trades and technology education. Gender stereotyping and household duties were established to be the major barriers to female participation in courses perceived as male domain. Access by location was found to favor urban dwellers. Urban schools had high average entrance grades (80.3%) compared to rural schools (27.6%). If admission criteria were based on minimum academic entry requirements, then students from rural areas will be under-represented in technical and vocational training institutions. This situation was
reinforced by the fact that most technical and vocational training institutions in Kenya were concentrated in urban areas. The issue of under-representation of girls in vocational and technical education in Kenya is also expounded by Nafukho (1994).

The UNESCO Conference on Education For All held in Kenya, found the participation rates in technical institutions to be low (UNESCO, 1992). The conference also heard that out of School Education and Training Programs were male dominated. Such a scenario was partly explained by ignorance on the part of school leavers; inadequate facilities; academic qualification syndrome; and cultural inhibitions and lack of career guidance (UNESCO, 1992). The literature points to the need for training skills for all members of our society regardless of their gender. For this to happen, the Kenya Government and the private sector should provide training opportunities in terms of more access to training facilities. Such facilities should be supplied equitably by gender, region and socio-economic status if regional inequalities existing in Kenya have to be addressed. While the costs of training, departmental capacity and program diversity influence the supply of training as shown by the literature review, no study shows the extent of the influence in Kenya. This study therefore aimed at filling this gap.

Methodology

An ex-post facto design was employed in the study. The research design was found relevant to the study since the researchers used existing data in the technical institutions. Thus, an after-the-fact analysis was conducted. This design was found appropriate for the study as it enabled the researchers to establish subsequent relationships between the dependent and independent variables. The 17 Institutes of Technology in Kenya comprised the target population of the study. A sample size of seven (7) institutions was selected. The sample size was arrived at after considering institutional size (enrolment) as an indicator of how the population was distributed. Other considerations made in order to achieve sample design efficiency included cost of study, heterogeneity of the sample frame, number of trait to be measured and size of the acceptable sampling error set at 5%. Stratified sampling was used in the first stage of sampling ITs. Institutions were stratified into three strata based on institutional size deviation from the population mean (Mr). Simple random sampling was used to select ITs from the strata. Sample allocation from the strata was computed from Neyman's formula for optimal sample allocation (Rossi, Wright, & Anderson, 1983). The institutions selected and their enrolment as per the time of data collection included Mathenge (167), Kaimosi (205), Kimathi (401), Ramogi Institute of Advanced Technology- RIAT (541), Kiambu (558), Murang'a (693) and Rift Valley Institute of Science and Technology-RVIST (1204).

Description of the Instrument for Data Collection

In order to collect data, a questionnaire was developed and administered to 37 Heads of Departments of the Institutes studied. All the departmental Heads were given enough time to respond to the questionnaire. The instrument sought information on the independent variables such as number of instructors, number of students enrolled in the institute by department and program, fees required per year, mean score in national examinations, composition of the students, course and programs offered. Also sought was the information on the dependent variable number of student places in each department.

Validity and Reliability of the Instrument

Prior to embarking on actual data collection, the instrument was presented to experts in the field of vocational and technical education in the Faculty of Education at Egerton and Moi Universities, Kenya for refining. The comments provided were incorporated. In addition, a pilot study was conducted. Four Departments in similar institutes completed the questionnaire. The researchers used the feedback from the pilot to further refine the instrument. Care was taken to ensure that the four Department Heads did not participate in the final study.

Besides the 37 Heads of departments, 7 principals, 7 registrars, and 7 finance officers were interviewed. Interview schedules on the factors influencing supply of training were employed in data collection. Data were collected from both primary and secondary sources. Cronbach's alpha (α) was used to estimate the reliability of the questionnaire items (Rossi et al., 1983). The instrument had a reliability coefficient of 0.9924. This indicated that the instrument was consistent in measuring the variables studied.

Findings

The hypothesis under investigation postulated that availability of technical training places was not related to shortage of trainers and inputs required for training. Explanatory models for the relationship between variables in this hypothesis have been presented. Availability of Technical education training opportunity (SsTep) was the
dependent variable \((Y)\), measured by the number of first-year trainees that qualified and were admitted to undertake a three-year TEP course. Each department in an institution provided one single observation (which was independent of any other observation). Table 1 defines explanatory variables used in the model.

Table 1. Explanatory Variables Used in Modeling Supply of Technical Training Opportunities

<table>
<thead>
<tr>
<th>Variable</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRT ((X_1))</td>
<td>Pupil-teacher ratio</td>
</tr>
<tr>
<td>NuCos ((X_2))</td>
<td>Number of three-year programs (course) offered in a department</td>
</tr>
<tr>
<td>RdpCap ((X_3))</td>
<td>Real departmental capacity. This was measured by the number of students' places in each department</td>
</tr>
<tr>
<td>PpRDpCap ((X_4))</td>
<td>Proportion of real departmental capacity to total enrolment</td>
</tr>
<tr>
<td>AdpCap ((X_5))</td>
<td>Actual number of trainees enrolled in each department for a three-year course</td>
</tr>
<tr>
<td>SchFe ((X_6))</td>
<td>Training fees per year in each institution</td>
</tr>
<tr>
<td>GQLY ((X_7))</td>
<td>Quality of graduates. A mean score based on national examination performance for each department measured this variable</td>
</tr>
<tr>
<td>GQTTY ((X_8))</td>
<td>Quantity of graduates from a department</td>
</tr>
<tr>
<td>PpGQTTY ((X_9))</td>
<td>The proportion of graduates to the total number of candidates in a department</td>
</tr>
</tbody>
</table>

The correlation coefficients \((r)\) between the dependent variable \(Y\) and the independent variables \(X_i\) showed that NuCos \((X_2)\), RdpCap \((X_3)\), AdpCap \((X_5)\), SchFe \((X_6)\) and GQTTY \((X_8)\) had positive and significant relationships with the dependent variable \((Y)\) at 0.01 significance level. Variable PpRDpCap \((X_4)\) also had a positive and significant relationship with the independent variable at 0.05 significance level. Variables PRT \((X_1)\), GQLY \((X_7)\) and PpGQTTY \((X_9)\) had a weak and insignificant relationship with the independent variable.

A multiple linear model was estimated to explain the relationship between the dependent variable \((Y)\) and the independent variables. In order to come up with the best model, it was found necessary to address the assumptions that go with linear modeling. Rossi et al., (1983) argued that correlations among pairs of independent variables that exceed plus or minus 0.8 can be used to detect multicollinearity. However this is not always a good strategy to deal with multicollinearity as it could introduce omitted variable bias. To deal with the problem, the study relied on SPSS, which could check internally and exclude the independent variables that were highly related to others from the regression analyses. To ascertain that a linear relationship existed between the dependent variable and explanatory variables, scatter diagrams were plotted. Explanatory variables whose points did not seem to cluster around a straight line even after transformations were done, were dropped from the model. Scatter plots of residuals versus independent variables and residuals versus the predicted values showed no pattern for the variable of the final model, thus confirming homoscedasticity. Using a probability of F-to-enter less or equal to 0.05 and F-to-remove greater or equal to 0.1, regression analysis methods estimated three models as shown in Table 2. Only three variables met the specified criteria of F-to-enter and F-to-remove.

* Significant for a two-tailed t-test at 5% significance level

1. \( \text{SsTep} = 1.100 + 0.366 \text{ ADpCap} \) .......... (Eq. 1) 
   \((0.524) (20.312)\)

2. \( \text{SsTep} = -0.327 + 0.315 \text{ ADpCap} + 2.702 \text{ NuCos} \) ........ (Eq. 2) 
   \((-0.157) (11.064) (2.215)\)

3. \( \text{SsTep} = -13.832 + 0.299 \text{ ADpCap} + 2.742 \text{ NuCos} + 0.00054 \text{ SchFe} \) 
   \((-2.054) (10.644) (2.372) (2.097)\) (Eq. 3)

Equations 1, 2 and 3 explained 92.8%, 93.6% and 94.2% respectively of the total variance observed in the supply of training opportunities. Equation 3 \((\text{adj } R^2 = 94.2\%\) offers the best model that could be adopted to explain the variation. The F-values from ANOVA undertaken for each equation are significant at 0.01 level. This indicates that regression coefficients are different from zero. From Equation 3, the number of applicants who qualify and could be admitted to undertake a three-year course in a department can be predicted. This equation shows that the estimated supply of training opportunities in TEP departments at the beginning of an academic year is equal to 0.299 times the actual departmental capacity, plus 2.742 times the number of programs offered by the department, plus 0.00054 times school fees, minus 13.832. This model is important in planning the supply and allocation of training resources within an institution. Equation 3 has a high predictive value (94.2%) and therefore could forecast with increased accuracy. The remaining 58% of total variance unexplained by Equation 3 could be due to measurement error or variables not included in the model. If Equation 3 was applied to the seven institutions in the study, supply of training places in those institutions would be 1,007 in one intake. Table 3 shows the supply of TEP in the seven institutions as estimated by model 3.

Notes: Entries in columns 2, 3, and 4 are averages for each institution.

Entries in column 5 are the number of technical departments in an institution that were used to multiply the results of equation 3 (and thus remove the effect of averaging) in order to get SsTep in each institution.

Conclusion

Number of courses offered by an institution, amount of fees paid and departmental capacity were found to explain the supply of training places. Increasing the number of courses offered by an institution increased students' opportunity of being admitted to such an institution and hence the supply of training places went up. Also, a high admission as a result of increased supply does not necessarily result to decreased school fees, as would be the case if economies of large scale were to be realized. The positive regression coefficient for school fees indicates the contrary. This is likely to happen because institutions operate inefficiently and have failed to utilize economies of large scale. Institutions with high enrolments are the most likely to charge high fees. In case of departmental capacity, a positive regression coefficient was observed. This means that expanding the holding capacity of departments will allow the institutions to admit more students. Equation 3 can be used to forecast effective supply of training places in a department in future. Holding other things constant, by the year 2010, a department may predict the number of new trainees who could be admitted given a capacity of 100, three courses and school fees of Kshs 25,000 per annum. This can be shown as follows: SsTep = $-13.832 + (0.299 \times 100) + (2.742 \times 3) + (0.00054 \times 25,000) = 36.894$. Such a department would prepare for 37 first-year students, other things being the same.

Implications to Human Resource Development Field

The economic theory of demand and supply has been used in this study to develop a supply function model of factors determining supply of training opportunities by Institutes of Technical Training. The capacity of such institutions to offer training opportunities is a major issue in the development of human capital in Kenya. Since human capital is a key factor in wealth creation, it is imperative that the supply of training places be a major consideration wherever the ministries of Education and Labor draw their short, medium and long-term plans. Technical Training Institutions need to expand their physical resources both quantitatively and qualitatively to develop human capital. The economic theories of demand and supply and the theory of the firm used in this study have great significance to HRD discipline. While supply of training opportunities may not be a major issue in developed economies such as that of UK, and US, it is an issue in Kenya. HRD Researchers interested in studying...
provision of training and human capital development in Africa should find the results of this study useful. Specifically, the model developed in this study should be of great interest to training institutions and human resource experts who are actively engaged in training in developing countries.

Dancing with the Cherokee: Reflections on Learning from the 2001 AHRD Globalization Pre-Conference

Theresa J. Kraemer
University of South Florida

Darren C. Short
Perspectives, UK

This paper reports the design of, and participants' accounts from, the visit to the Cherokee Nation undertaken in the 2001 AHRD Globalization Pre-conference. The impact of globalization on national and sub-national cultures can be great. With major corporations as significant players in globalization, HRD professionals have key supporting roles and the potential to influence the globalization process. The 2001 pre-conference acted as a case study in exploring the impact, the steps peoples can take to preserve their identity, and the implications for HRD.

Keywords: Globalization, Cherokee, HRD Practitioners

Globalization...is the inexorable integration of markets, nation-states and technologies to a degree never witnessed before--in a way that is enabling individuals, corporations and nation-states to reach around the world farther, faster, deeper and cheaper than ever before, and in a way that is enabling the world to reach into individuals, corporations and nation-states farther, faster, deeper, cheaper than ever before (Friedman, 2000, p. 9).

This paper reports the content from the 2001 Academy of HRD (AHRD) Globalization Pre-conference, and the reflections of those who participated. It was the fourth annual pre-conference on the topic, the previous three dealing with theories and research on globalization and implications for HRD. The 2001 pre-conference dealt instead with exploring the 'experience' of globalization, with the intention of generating more reflective practice in HRD practitioners and new strands of HRD research.

With the AHRD conference based in Tulsa in 2001, pre-conference attendees had an ideal opportunity to visit the Cherokee Nation in nearby Tahlequah. The broad purpose of the visit was to engage in dialogue with Cherokee leaders and community members on how they maintain their cultural identity in the face of pressures for cultural change, and in particular to examine the role of education in that maintenance process. The goals were to:

- Increase participants' understanding of globalization, the impact on HRD, and the role of HRD professionals.
- Encourage new ways of looking at, and thinking about, globalization.
- Help positioning the pre-conference as a significant contributor to the dialogue on the relationship between HRD and globalization.
- Support networking and facilitate a network of HRD scholars committed to the exploration and enhancing of globalization research.
- Provide an innovative, participative, and fun experience.

Purpose and Structure

Because of the unique design of the pre-conference activities, organizers were encouraged to record and report both the design and accounts of the experience. This paper gives that report. In presenting the paper, we are not claiming to be building new theories, but to be sharing our experience in the hope that it encourages others to reflect on the experiencing of globalization and how innovative learning designs can be incorporated into their study of globalization and HRD more generally.

The paper is structured to first describe a generalized background of the Cherokee as global players as well as globalization, present the methods of data collection, followed by a discussion of the results, and then the implications for HRD. The final section describes the need for further research.

Background on Globalization

In 2000, the United Nations reported that the phenomenon of globalization had attracted more significant global attention than perhaps any other issue in recent memory (United Nations, 2000). Although, it has been a part of our history for millennia, the rate and scope of globalization have increased dramatically over the last fifty years to the point where, for the first time in our history, almost everyone now is feeling the pressures, constraints and opportunities to adapt to the globalization system (Friedman, 2000).

Globalization is a complex and controversial process of worldwide changes in economy, politics, and culture. From a world systems perspective, globalization may be seen as the dominant international system that has replaced the Cold War system (Friedman, 2000). According to the UNRISD (1995), transformations toward globalization took different forms in different places, but six consistent trends shaped institutional change: the spread of liberal democracy; the dominance of market forces associated with capitalism; the integration of the global economy; the transformation of production systems and labor markets; the speed of technological change; and the media revolution and consumerism.

There are many published accounts of the impact of globalization on culture. Short and Callahan (2001) described these in more detail, but to summarize a few here:

- How the effects of globalization in the Philippines threatened traditional manufacturing and work roles (Heinrich Boe1 Foundation, 2001).
- The reaction to American companies setting up in China – for example, when Starbucks opened a store in the Forbidden City, how Kentucky Fried Chicken could be “booted out” of another Imperial site when its lease expires in 2002, and how McDonald’s had removed its golden arches from outlets by Tiananmen Square (CNN, “Starbucks Brews Storm,” 2000).
- In 1998, the minister of culture in Canada held an international conference with cultural ministers from Europe, Latin America, and Africa in an attempt to find ways to protect cultural diversity from the intrusion of, primarily, American culture (DePalma, 1998). It was claimed that Americanization is largely linked to the entertainment industry that brings us “Mickey Mouse and Rambo.” The conference led to the establishment of a working group to place more emphasis on cultural issues in global economic and political negotiations.
- The website of the charity Mary Knoll Catholic Mission contains short personal descriptions of the human face of globalization as described by 16 residents of countries south of the United States (Mary Knoll Catholic Mission, 2001). Included among them is an account of how the Venezuelan culture is threatened by US baseball hats, Michael Jordan shoes, cable TV, and English-language rap music.
- The Dutch Development Assistance and Research Council (RAWOO) recently ran workshops in Bolivia and Tanzania to gather first-hand accounts of globalization. During the Bolivian workshop, the impact on culture was reflected in the comment that ‘the knowledge maps that helped us fix horizons and select possible routes have been destroyed.’ (RAWOO, 2001).

Major corporations are central to the globalization story; hence, the clear links between globalization and HRD. As organizations look to go global or remain global, they are likely to look to HRD professionals for advice and support. Hart (1999), when considering corporations as agents of global sustainability, argued that organizations in the global era needed new socio-technical systems, new strategic models, and the development of leaders who could lead the transformation to sustainability – all ethical roles for HRD professionals. Other requests may include: We need help to ...

- Develop managers who can think, lead, and act from a global perspective, with global skills and a global mindset (Kim, 1999)
- Understand other cultures and increase employees’ cultural competence
- Design more responsive organizational structures (Monge & Fulk, 1999)
- Push decision making authority to lower levels, employ cross-functional teams, and encourage organizational learning (Branscomb, et al., 1999)
- Increase and improve external communication with international suppliers, subsidiaries, alliance partners, and customers (Parker, 1996)
- Prepare our employees for periods of expatriation.
- Increase employee competence in strategic communication knowledge (conflict avoidance, showing respect, and using correct language), tactical communication skills (giving instructions/orders, networking, and writing, listening, and persuading), and behavioral traits/cognitive abilities such as empathy, cognition, and complexity (Sriussadaporn-Charoenngam & Jablin, 1999).
There is therefore a strategic role for HRD practitioners in supporting organizations as they increase their global position and role. At the same time, Short and Callahan (2001) argued the importance of HRD practitioners understanding the ethical issues in globalization, part of which must include understanding the impact of globalization on cultures and national identity. The 2001 AHRD Globalization Pre-conference was designed, in part, to raise awareness of that impact.

Pre-conference Design

All the conference participants, and so all those whose post-event reflections have been included in this paper, were members of AHRD. All attended the full pre-conference; and all were practitioners, educators, researchers, or students engaged in HRD.

The pre-conference was designed to be an active learning / experiential program held over two days. The first day, until 4 pm, was held at a hotel in Tulsa, and the participants were bused to Cherokee Tribal lands in Tahlequah (pronounced: tell-lah-quah), about 60 miles away.

On the first day, participants:
- Explored the issue of globalization and how it affects organizations and national cultures in developed and developing nations.
- Viewed a 45-minute videotape that provided historical background on the Cherokee and created a common point of reference for all participants prior to visiting Tahlequah.
- On arriving in Tahlequah, participants experienced a traditional Cherokee dinner prepared and served by local Native American people. They were then addressed by the Chief of the Cherokee Nation who gave a speech on the importance of language preservation and various Cherokee actions taken to preserve and promote their language as well as the Cherokee nation’s desire to become participants in the global marketplace.
- Participants then completed a 90-minute active learning session involving observation of traditional Native American drum group and participation in traditional Native American dances. Explanations as well as the importance of each dance were provided by the Drum leader and, per Cherokee tradition, global participants were able to exchange token gifts of appreciation and friendship.

On the second day, informants participated in a 90-minute case-based dialogue session with representatives of the Cherokee National Enterprises, during which they discussed how the Cherokee Nation has supported various Cherokee businesses and enterprises. That was followed by a 30-minute presentation by the Northeastern State University’s President on the unique relationship and mechanisms by which the University works with the Cherokee Nation. Local experts provided a 90-minute tour and presentation on the history of the Cherokee Nation and the original Cherokee school, Seminary Hall. Following the tour, specialists at the Center for Tribal Studies presented 30-minute program for promoting the local tribal culture and language.

Data Collection and Analysis

Data were gathered through a survey, observation, and document analysis:

Survey. A semi-structured open-ended ethnographic survey was used to collect reactions from pre-conference participants describing the Cherokee culture, the learning experience, and participant meanings of effective HRD with respect to globalization. The survey instruments were distributed approximately one month after the 2-day pre-conference session, with data gathered between April 1, 2001, and June 30, 2001. Two follow-up reminders were sent – one at the start of each month. Whilst 21 participants attended the pre-conference, only 12 completed the survey.

Observation. The researcher maintained handwritten field notes (documents generated from observations) of the informant’s nonverbal behaviors in the survey setting for each survey. The field notes were transferred into the HyperResearch computer program for storage and to categorize the data. A detailed record was maintained of the environment, including the participant’s comfort level, choice of environments, interruptions during the course, and institutional atmosphere. A complete record of informant’s nonverbal behaviors, expressions, mannerisms, actions, reactions, and interactions was maintained throughout the study. This technique allowed the researcher to understand the meanings constructed during the surveys.

Document Analysis. Professional documents and artifacts reviewed included: course notes, handouts, articles, and other materials. Written items in the environment, including all memos, announcements, meetings, and postings
of events, were reviewed and analyzed for cultural references as well. All documents and materials were reviewed in-depth for HRD and culture-related content as well as cross-cultural references. The references were categorized and compared with informants' statements and observed non-behaviors.

Data Analysis

Inductive data analysis was utilized for this study and was an ongoing process. Once surveys were transcribed, data were tagged and coded using HyperResearch. For each case record, non-alphanumerical symbols were used to tag words, phrases, and sentences. Using a constant-comparative approach, each subsequent survey was compared with previous data for similarities, differences, and consistencies of meaning across the data. Data were analyzed not only within each case, but also across cases. All data were coded into minor codes, which were collapsed into major codes and then placed into categories. This inductive and emergent analysis procedure allowed for emerging categories, themes, patterns, and domains to emerge and be identified from the data.

Triangulation, which involves the process of using data from different sources (surveys, observations with field notes, and documents) to corroborate, elaborate, or illuminate the research in question, was performed. Triangulation was done on the documents and artifacts reviewed in relation to the second-year curricular materials presented by faculty, materials accumulated by the randomly selected students for review, and content and experiences reported by informants. In addition, these materials were reviewed and analyzed for similarities and dissimilarities with the informants' reported exposure and experiences. This information was then used to cross-validate additional cross-cultural findings and informants' meanings from the data against the surveys, recorded observations, and document analysis. The authors also checked for potential biases resulting from the researcher role.

Learning Points From the Experience

Participants reported learning points that could be categorized under four headings: the Cherokee as a People; Cultural Integration; Globalization; and Pre-conference design. These are considered, in turn, in this section.

The Cherokee

Participants' noted that the Cherokee are a people and not a geographical community. Several commented on how sometimes they were able to recognize native Indian people by their appearance (the faces). Generally, participants reported overriding impressions of the Cherokee as intelligent, quick-witted, proud, strong of heart, generous, and compassionate. Several times throughout the visit, the Cherokee demonstrated their humor and generosity to the global participants as well as their sense of pride.

Several participants were saddened, but not surprised to hear the way that the Cherokee have been treated. The most commonly cited reference was the Trail of Tears. Participants noted that this action taken by the US government was a sad commentary and the Trail of Tear story brought out the Cherokee's pride in their heritage. Several participants noted that there is no choice for the Cherokee in the US other than to act as "white" Americans do. However, US participants noted that they were satisfied that the Cherokee are able to express Indian folklore. Some participants noted that some of the "real stuff" (herbal medicine, certain rituals) continues to remain more hidden.

Participants also reported that the Cherokee appeared very proud of their heritage, considered broad and active participation in community activities as important, demonstrated the power of positive thinking, and also demonstrated how a revival and dissemination of some of the 'old' knowledge is possible.

Participants were asked to identify similarities and differences between their own and the Cherokee cultures. The differences were generally connected to symbols, actions, behaviors, and attitudes. For example, the most common "value" mentioned was the Cherokee value of education. The strongest differences reported were in relation to the Cherokee's native food and dance. They have a strong sense of their family, ethnic, and national (tribal) heritage. Also, participants noted that the Cherokee demonstrated different attitudes towards family, wealth (i.e. the lack of value of material goods), and stories. There were also visible differences in behavior and symbols, for example expressing gratitude with small denomination notes, the very visible Seal of the Cherokee Nation. As one person stated,

Symbols are also important – the Cherokee Seal was everywhere as a symbol of their identity.
Perhaps that's an important point to ... when with the Cherokee, I sensed the importance of
identity more than the importance of culture – who we are seemed more pivotal than what we do and how we do it

With respect to commonalities that participants noted between their own culture and that of the Cherokee culture, participants reported that their daily life seems quite the same and for some, far more than they expected. While the participants noted that the Cherokee dress was not too different, nor were the houses, several participants noted not only were they surprised by the lack of differences, but also that the experience increased their awareness to just how ignorant of the Cherokee way of life they were prior to the learning session.

**Cultural Integration**

These learning points pertained to trying to maintain one’s culture and cultural identity both on a personal level and on a community level. While the participants noted that the Cherokee have certainly integrated their tribal culture with U.S. ways, maintaining the integrity and continuity of a culture is always a matter of great difficulty, no matter what culture is being discussed. However, participants were struck by the passion with which the Cherokee discussed maintaining their cultural identity – for example, when discussing the Cherokee’s vision for the future. The majority of participants noted that Chief of the Cherokee Nation, Chief Chad Smith, had a clear and inspiring vision for the Cherokee – a 100-year vision. Several of the participants noted that their own culture did not possess a vision, let alone a 100 year one for their culture, but instead saw their own culture often just going with the flow and suffering as a result. Several of the participants noted that cultures around the world could benefit from following the Cherokee’s example of a 100-year vision.

Many participants commented on how the Cherokee maintained an understanding of their history through stories, also stressed the importance of language to maintaining cultural identity. The following are representative commentaries:

I was struck by how often the Cherokee referred to their history, to the Trail of Tears...events that happened over 100 years ago are fresh in the stories being told today, and drive actions today. That contrasts with the culture I live in, where history is visited occasionally, but is basically something studied in school and then forgotten about in the rapid pace of change.

Language is certainly a key part of that integrity and continuity – something clearly understood by indigenous cultures around the World (the Welsh, for example, are promoting their language in schools and the media far more now than for centuries).

Language is something important. Over here when I talk about my trip, I compare the Cherokees with the Basque people in Northern Spain and South of France. They also maintain their language, e.g. traffic signs, in schools.

**Globalization**

While the participants were mixed on whether or not their views of globalization changed during or after participation in the pre-conference course, they did identify and agree on several key learning points.

Defining globalization appeared to be a challenging task for the participants. While several noted that they had a pre-conceived or “book” definition of globalization, they found that it did not necessarily apply when in the presence of the Cherokee people. Instead, several participants noted that the exposure to the Cherokee, made them re-evaluate their perspective and understanding of the term “globalization” and to reflect upon the most critical aspect(s). Similarly, several participants noted that there was a significant difference between what they perceived as the beginnings of globalization and what the Cherokee defined as the “beginnings”. One essential difference was the point of reference: for many participants, the origins of globalization were theoretical, research, or practical based, while for the Cherokee, it is, again, the issue of their culture.

While several of the participants could readily identify economic challenges, geographic factors, and technological limitations, the responses were more limited when it came to applying it to the Cherokee. Some noted that the challenge is coming up with solutions that all members of a culture can live with when it comes to maintaining the integrity and cultural continuity of a culture. Others noted that the challenge is knowing one’s own culture and having respect for others. Another identified challenge involved not imposing one’s own values and cultural expectations onto an individual or group from a different culture. All of the participants agreed that this last approach limits learning. One participant provided the following example:
Imposing our own values and cultural expectations is a really stupid thing to do...we are well advised to listen more, observe more, and ask if we do not understand. Most cultures not our own are more than happy to explain how they view things or what role customs play or how clothing and other objects enter into cultural meaning. All we have to do is ask.

On the dangers of globalization, participants' comments covered stereotyping, economic survival, and cultural protection, amongst many reactions. For example, participants commented on people's tendency to stereotype others based on color or location and the potential for quantitative instruments to encourage stereotyping in certain circumstances. The following are representative statements:

It is easy with quantitative instruments to stereotype people – to see US Americans as individualistic, and Chinese as more community-focused. However, those instruments hide so much. There clearly is a core of the Cherokee culture that is very US white American (not sure about the exact label to use there!), but there are aspects of their culture, which are very different. Where, for example, is storytelling picked up by those instruments? I certainly wouldn't make any assumptions about cultures now without visiting them and experiencing them for myself.

The approach to business and the examples given about the economic survival made me think even more to the impact of economy, which is becoming more global, on the preservation of a nation and its cultural heritage.

Bottom line – people need more time to talk through what they are experiencing and there is a need to consider what parts of the culture that is being integrated are sacred and should be protected.

It struck me how careful we have to be about tampering with cultures. There is so much richness in diversity and globalization threatens to homogenize more than is good for the world. Without retaining the identities of peoples, and their stories and languages, there is a risk that people will lose their roots...drifting from one materialistic trend or fashion to the next. The Cherokee stand a good change of protecting their identity because of their language, the emphasis on stories and their commitment to both democracy and education. They also have a leader who emphasizes progress (a 100 year vision)...progress includes protecting the identity of the Cherokee.

When questioned on how the pre-conference had impacted their outlook on globalization, some participants reported that they didn’t know if their views were particularly changed. However, they also noted that they would allow a good deal more time for conversation in future cross-cultural interactions. The following are examples:

It was a great experience in such a short time. I am grateful for our belief that an experience like this could be possible! I would like to spend more time with the members of the Cherokee nation and talk to people inside the nation that have different opinions about the rebirth/preservation of their culture in order to gain a deeper understanding of their issues.

I suspect the most important lesson learned is the need for time to engage in meaningful dialogue with people. And I think the local can become more and more important despite of all the global that is coming to us... I’m not sure the research stresses this enough.

This was a truly special event that role modeled adult learning theory and group dynamics. Jack Mezirow talks about perspective transformations coming from disorienting events – and this event really encouraged me to identify and reflect on my own habits of the mind relative to globalization and cross-cultural ventures.

Pre-conference Design

All of the respondents noted new insights, realizations, and shifts in paradigmatic thinking as a result of the pre-conference experience. Some reported that the learning event had a deeply personal impact, while others took a more distant stance. Participants described the event as beneficial, powerful, interesting, and designed for learning. The following are representative statements made by participants:
What a powerful and moving experience to “walk among the Cherokee” if only for a few days.

Spending time, even for a short period, with representatives of a culture in their own environment adds always several dimensions (e.g., hearing, seeing, smelling, tasting) to the understanding of that culture.

What I learned was the power of the experience over reading. I learned the power of visiting over inviting people to visit me. I learned the importance of story telling, of identity as well as culture, of language, or traditions, of food. I learned that identity and culture has LESS to do with a geographic location and MORE to do with your heritage, vision, and community.

This was far more powerful than any book or video, or even a talk from the Cherokee in my own culture. Nothing could beat actually visiting with the Cherokee, hearing the stories from them and eating their foods. By being with the people, I could pick up their pain about the past, their determination about the future, and their openness to share that with us.

I think that I would now approach the researching of other cultures in a different way (more experiential), and would initiate more conversations with others about their cultural differences and about the importance of language.

Several participants noted the benefits of the pre-conference being attended by people from many countries and cultures. It was reported that this “reinforced the experience,” and gave participants the opportunity to explore differing opinions, perceptions, and views. For many, the work in Tulsa and the bus journey to and from Tahlequah helped generate the beneficial group dynamics, and that those dynamics benefited them throughout the main AHRD conference. As one participant stated,

We had two Norwegians, a Dutch guy, a Brit, a South African, a New Zealander, and more. I think that we learned much about each other—again with language having center stage.

Conclusion

The 2001 AHRD Globalization Pre-conference was a special event for many people. Through a collaboration between the pre-conference organizers, local organizers, and the people of the Cherokee Nation, participants were able to dip into a culture and meet key people to discuss the importance of identity and culture and possible actions to retain them under pressure from global forces for change. Participants reported new insights on the importance of identity and culture, and described new approaches they would take when dealing with global and cross-cultural situations.

One aspect of the many learning points was that globalization, whatever form it takes, should not necessarily erode distinct cultures, even if they are a sub-culture of a more dominant society, but should foster stronger cross-cultural awareness and understanding. As participants described, HRD has an important role to play in educating our organizations about the culture and identity of peoples, how to learn about culture/identity, and how to approach globalization in an ethical manner. As some suggested, HRD has a role to play in helping peoples protect their identity through national culture programs supported in the workplace. There are also the challenges of coming up with solutions that all members of a culture can live with when it comes to the maintaining the integrity and continuity of a culture. And finally, globalization has placed differences between nations with respect to vision, human capital, and business ethics in the spotlight.

While various levels of learning occurred throughout this session, it became clear that the pre-conference certainly encouraged participants to reflect upon their learning, values, attitudes, assumptions, beliefs, etc. Perhaps, we as HRD professionals should at the very least, learn how not to integrate a culture. In closing, as one participant stated, “Understand the culture and values of others. Respect others and their right to believe and practice the way they choose; and immerse yourself in a culture in order to understand it better”.

Limitations

The purpose of this paper is not to present findings from a study using representative samples. It reports the content of a pre-conference and the reactions of those who attended. For those looking for generalizability, a major
limitation of this study was the population itself. The informants were homogenous with respect to age, race, educational level, and socioeconomic status although selection attempted to be representative of the AHRD membership population. It was unevenly distributed with respect to race, mainly monocultural, and gender, both of which are reflective of the overall HRD profession. Finally, while the pre-conference was not designed with replication in mind, it may provide a foundation for future research.

References

This study consists of two parts. Present and expected developments in the field of training and development in work organizations are being studied, with specific attention to their consequences for the knowledge and skills (competencies) of training specialists. A survey among a select group of respondents attempted to gain an insight into the costs of and participation in training activities by employees in work organizations.

Keywords: HRD Trends, Survey Study, Comparative Study

In the 1980s the Faculty of Educational Science & Technology conducted the ‘HRD in the Netherlands’ (BEDON) study (Mulder, Akkerman & Bentvelsen, 1989). Since that time there have been many changes in the field of HRD (Streumer, Van der Klink, & Van de Brink, 1999) due to trends and developments within organizations as well as in society. There has not, however, been much research conducted into the impact of these new trends and developments on the training function. Consequently, the gap between training reality and theory development in the field of training has not yet been bridged. This was the reason for the Faculty of Educational Science & Technology of the University of Twente to decide to conduct the BEDON study once again together with the Faculty of Technology and Management. The results of the first part-study (Kwakman, Van der Heijden, Streumer, Wognum, & Van Zolingen, 2001) will be reported separately. The results of the survey are presented in this paper.

Research Questions

The following research questions are central to this part of the BEDON study:
(1) To what extent was there participation in training activities within companies in the year 1998 and what costs were involved?; (2) To what extent is this participation subject to change (situation year 2002)?; and (3) To what extent can participation and costs be ascribed to developments in work organizations and the training function within these organizations?

The term training activities refers to a wide range of interventions in the field of training and development of personnel within work organizations, including learning within development paths, on-the-job and off-the-job training, self-study activities and forms of ‘learning while working’.

Method

Research Population. This part of the study made use of a targeted sample survey. Our own data files, which are compiled from a selection of respondents from the NVvO file [Dutch Association of Training Officers], a selection from the O&O file [Training & Development Journal] and a selection from the TOPOS file (alumni of the Faculty of Educational Science & Technology employed in training positions), were used to select the names of people who hold management positions in the world of training and personnel policy. This involved a sample survey of 180 people. All these people were telephoned by a research assistant and asked if they would be prepared to take part in the study; a total of 150 people were willing to do so. They were all sent questionnaires with an accompanying letter. Upon receipt of the questionnaire a total of 15 people immediately informed us that on reflection they were unable to participate in the study. From the remaining total of 135 people, after reminders 50 questionnaires were returned (37% response)
Data Collection. For the data collection a written questionnaire was used that had been developed to be able to answer the research questions listed above. The first and second research questions (To what extent was there participation in training activities within companies in the year 1998 and what costs were involved? To what extent is this participation subject to change—situation year 2002—?) were developed for this purpose into a number of sub-questions, which were divided into a 'participation' part and a 'costs' part.

The sub-questions for participation are as follows:
1. In which type of training activities have employees participated (reference date 1998) and is an increase or a decrease in the participation expected in the training activities mentioned (reference date 2002)?
2. How can the training activities mentioned under 1 best be characterized (on-the-job versus off-the-job, internal versus external, time invested within versus outside working hours, participation of men versus women)?
3. In which substantive training domains have employees participated (reference date 1998) and is an increase or decrease in participation expected in the above-mentioned training domains (reference date 2002)?
4. To what extent are the strategic goals of the organization of importance when participating in training activities (reference date 1998) and is an increase or decrease in that importance expected (reference date 2002)?
5. What type of training providers conducted the training activities (reference date 1998) and is an increase or decrease expected in the type of training providers mentioned (reference date 2002)?

The sub-questions for costs are as follows:
6. How large is the budget for training activities and what percentage of the gross wage bill does that involve (reference date 1998)?
7. What types of training costs have been included in the budget calculations mentioned under question 6?

A questionnaire was drawn up based on the research questions and sub-questions. This questionnaire consisted of three parts: a part relating to general details (type of official and level of education, branch of industry and sector to which the organisation belongs, etc.), a part in which questions were raised about 'participation', and finally, a part dealing with 'costs'.

Analysis. The data were entered in an SPSS data file and analyzed with the aid of descriptive analysis techniques and crosstabs. Problems relating to scoring the analysis of the open questions and the classification of continuous variables were dealt with in the project team and, where necessary, unambiguous scoring rules were drawn up to avoid differences in interpretation.

Results

The results will be dealt with in line with the three parts mentioned above that comprise the questionnaire.

General Data. Fifty respondents completed the questionnaire: 34 men and 16 women. Of the respondent group, 67% are part of senior management; 28% of middle management and 4% have a position as director. Of the respondents, 84% have full-time employment, and 16% a part-time job. Of the respondents, 56% have had a university education, 32% have gone through higher professional education, 6% senior secondary vocational education, and of 6% the level of education is unknown.

The companies where the respondents are employed operate in the following branches: 11 companies (22%) fall under 'industry', 2 companies (4%) are involved in the 'construction industry', or are technical contractors, 8 companies (16%) are occupied in 'trade or the hotel and catering sector', 6 companies (12%) belong to the 'transport, storage and communication' category, 13 companies (26%) provide commercial services, while 10 companies (20%) are engaged in the 'other services' branch. Of the above-mentioned companies, 41 (82%) are in the profit sector, and 9 (18%) the non-profit sector. The company size (in employee numbers) 0-100 is not found among companies that are part of the 'industry' branch; among 'other services' the company size 101-500 is missing. The largest companies (3001 and above) are found most frequently in the commercial services category. The companies are fairly equally divided as regards numbers over the various categories of branches.

The companies taking part in the study can in general be characterized as large companies (the average number of employees is 3054). This applies even more so when taking into consideration the fact that at least 32% of the respondents completed the question about numbers of employees for the unit where they work, or for which they have full or partial responsibility. Of the respondents, 24% completed the questionnaire from the perspective of the entire organization (both national and international), 44% from the perspective of the organization at national level, 18% for that part of the organization where the respondent works and 14% for the part of the organization for which he has full or partial responsibility.
Participation

Question 1: In which Type of Training Activities have Employees Participated? The questionnaire included a total of 10 types of training activities in which employees had participated in 1998: long, medium or short training, one or two-day activities, short sessions of a few hours' duration, short instruction provided informally on-the-job, self-study, learning while working, learning in a development path, and others. For each of the training activities, employees were asked if they had participated (yes, no, don't know) and whether participation was expected to increase (remain the same, decrease, increase) (reference date 2002). The respondents were allowed to tick more than one training activity. It can be deduced from the data that short training programmes with fewer than 10 sessions were the most frequently used (98%), closely followed by short one or two-day activities, such as a conference or workshop (96%). Learning while working, where employees themselves try something out, learn the ropes or practise a new activity, also had a high score (91%).

The respondents expressed the expectation that learning within development paths, such as job rotation and management development, would experience the strongest growth (57%). Following some way behind were 'learning while working' (trying out new activities oneself, learning the ropes on new activities), with 43% of the respondents believing that this training activity would increase and, more or less equal, with 39% and 38% respectively, 'informal, short instruction and coaching, mainly on-the-job, and 'self-study"

Question 2: How can the Training Activities Mentioned under 1 best be Characterised (on-the-job versus off-the-job, internal versus external, time invested within versus outside working hours, participation of men versus women)? The respondents were asked to express as a percentage the proportion of training conducted on the job or off it, internal versus external training, training within and outside working hours and the participation of men and women. In addition, the respondents gave an estimate of the percentage of employees who had participated in training in 1998. The results show that the most training (65%) still takes place off the job, 46% of training is provided at an external location. The research results indicate that 70% of the training enjoyed by employees takes place during working hours. The percentage of training that is attended by men is almost twice as great as that by women (66% and 34% respectively). The results further show that 62% of the total number of employees about whom the respondents reported had participated in training activities in 1998.

Question 3: In which Substantive Training Domains have Employees Participated (reference date 1998) and is an Increase or Decrease in Participation Expected in the above-mentioned Training Domains (reference date 2002)? In the questionnaire, a total of 14 substantive training domains were identified, in which employees had participated in the training activities. These included sector and branch-specific training, communication skills, personal effectiveness, quality assurance, computer usage and automation and internal company organization. Table 1 reflects these substantive domains and the respondents' answers have been incorporated in it, with a distinction being made between participation in 1998 and the expected decrease or growth up to 2002. The respondents were allowed to give more than one answer.

From the results in table 1, it can be deduced that both the sector and branch-specific training programs and the training programs in the field of management, enterprise and policy occur frequently (in 94% and 93% respectively of the companies on which the respondents reported), followed at a slight distance behind by training programs in the field of verbal communication skills, and computer usage and automation (both 89%). The respondents expected the greatest increase in training in the field of personal effectiveness (56%) and personal growth (56%), while a sharp increase is also expected in training activities in the field of management, enterprise and policy (45%) and marketing, sales and public relations (42%).

Question 4: To what Extent are the Strategic Goals of the Organisation of Importance when Participating in Training Activities (reference date 1998) and is an Increase or Decrease in that Importance Expected (reference date 2002)? In the questionnaire, the strategic goals were broken down into eight specific goals that may be of importance for participation in training activities (including effective deployment of personnel, meeting quality standards, organizational development, and profit increase). The respondents were asked to what extent these goals were of importance for participation in training programs in 1998, and to what extent they are expected to become more or less important up to the year 2002. Table 2 shows the average and standard deviations from the results, where respondents were allowed to give more than one answer. It can be deduced from the results in this table that being able to deploy personnel effectively in 1998 in particular was an important strategic goal for training participation in the responding organizations (M=4.04 on a scale of 1 - very unimportant - to 5 - very important -, SD = .88). The 'meeting quality standards' strategic goal also had a high score (M=3.98, SD=1.00). The respondents did not differ significantly from each other in respect of the importance of these two strategic goals (p>.05). This is
the case, however, for the strategic goals of 'organizational development' and 'product innovation'. Respondents who mentioned these as important strategic goals for training participation in 1998 differed significantly from the respondents who indicated that 'being able to deploy personnel effectively' was important for their organization in 1998 (p = .02 and p = .03 respectively).

N=50

With the exception of the 'other strategic goals' column, respondents expected a significant increase in the importance of all strategic goals up to 2002 (p<.05). For 'effective deployment of personnel' and 'meeting quality standards', for example, the average expected for 2002 is 4.62 and 4.18 respectively (SD=.72 and SD=.84 respectively). These are rated significantly higher in importance than was the case in 1998 (M=4.04 and 3.98 respectively). Which strategic goals were considered to be the most important does not, however, depend on the branch of industry or sector (profit or non-profit) to which the respondents' company belongs, with the exception of the 'market share' strategic goal, where significant differences between branches were observed (chi-square = .18).

Question 5: What type of Training Providers conducted the Training Activities (reference date 1998) and is an Increase or Decrease expected in the Type of Training Providers (reference date 2002)? The questionnaire distinguished six types of organisation offering training, including regional training centers, higher vocational colleges, universities, private training agencies, and branch organizations, in addition to the in-house training department. A remainder category ('other') was also identified. The respondents were asked to indicate which providers had conducted the training activities in 1998 (choice of answers: yes, no, don't know) and to what extent they expected the share of such organisations to increase or decrease (in percentage terms) up to 2002. The respondents were allowed to give more than one answer. These results are presented in Table 3.
and costs. The high standard deviations show that the budgets available for education and training and the resources accounting at many companies is not in order. Standard deviations have been calculated for the training budgets the respondents are not well informed about the costs involved in training programmes or that the financial 'training abandoned attempts to complete both questions. The maximum number of respondents per part of the two questions section of the respondents managed to answer in part one or both questions. In total, 11 respondents (22%) entirely organizational units, depending on the information they had available. Both the budgets and the costs had to be asked to fill in the budget and the actual costs for the entire organization (both national and international), the actually incurred in total in 1998 for all imaginable training activities. At the same time, the respondents were also asked in multiples of Euro 1,000.

From the data in table 3, it can be seen that training activities in 1998 were provided principally by private training agencies (91%) and the in-house training department (85%). An increase in the provision of training activities is expected for both providers by 50% and 55% respectively of the respondents. For the remaining categories of training providers, the majority of the respondents expected the provision of activities to remain the same: 75% of the respondents believed that to be the case for regional training centers, 63% for institutions of higher professional education, 81% for universities and 60% for branch institutions.

Costs

Question 6: How Large is the Budget for Training Activities and What Percentage of the Gross Wage Bill does that Involve (reference date 1998)? The respondents were first of all asked to indicate how large the budget was in 1998 for all imaginable forms of training activities in their organization. They were then asked what costs were actually incurred in total in 1998 for all imaginable training activities. At the same time, the respondents were also asked to fill in the budget and the actual costs for the entire organization (both national and international), the organization at national level, the organizational unit where the respondent was employed, the organizational unit for which the respondent was responsible. The respondents were allowed to complete the questions for one or more organizational units, depending on the information they had available. Both the budgets and the costs had to be stated in multiples of Euro 1,000.

Judging by the respondents' reactions, it appears that they found both questions extremely difficult. Only a section of the respondents managed to answer in part one or both questions. In total, 11 respondents (22%) entirely abandoned attempts to complete both questions. The maximum number of respondents per part of the two questions was 18 (for the question relating to the budget for the national part of the organisation). This indicates the fact that the respondents are not very well informed about the costs involved in training programmes or that the financial 'training accounting' at many companies is not in order. Standard deviations have been calculated for the training budgets and costs. The high standard deviations show that the budgets available for education and training and the resources invested in them vary very greatly. One important factor here is that company size also varies greatly, and some respondents mentioned the training budgets of the whole multinational (national and international), without breaking them down. Since, moreover, there is insufficient insight into the numbers of employees who have participated in education and training in the relevant companies, these amounts have very little meaning. For these reasons (scant reliability of the data, insufficient insight into the investments per trainee, etc.), it was not possible for the questions relating to training budgets and the resources actually invested to be answered adequately.

The respondents were further asked to indicate what percentage of the gross wage bill, including employer's expenses, was in their opinion spent on training activities in 1998. They were also able to answer this question for the whole organization (both national and international), the entire organization at national level, the organizational unit where the respondent worked, the organizational unit for which the respondent was responsible. When the percentage was unknown, they were able to indicate that too; nine respondents did so. From the data, it can be concluded that work organizations spend on average between 2.29% and 3.38% of their gross wage bill on training programs. There, however, are large differences between companies and business units. There were extreme percentages of 8% and 0.2% mentioned. Many of the 50 respondents did not know what percentage of the wage bill was spent on training programs at the different organizational levels and units. One common problem - which also had an influence here on the percentage of the gross wage bill spent on all the forms of education and training mentioned by the respondents - is that work organizations differ in what they understand by 'gross wage bill'. This may 'pollute' the percentage found in this study.

Question 7: What types of training costs have been included in the budget calculations mentioned in question 6? Another problem that plays a role in determining the costs invested in education and training is that there is
ambiguity as regards the types of costs that are included in the calculation of training costs. The respondents were therefore asked to indicate which types of training costs they believed were included in the calculations for determining the amounts invested in education and training. Table 4 contains the results of this question. From these results, it can be deduced that the costs are mainly trainer-linked (according to 84% of the respondents). As far as the other types of costs are concerned, fewer respondents were of the opinion that these are a part of the training costs: 65% thought that the costs for training facilities must be included in the calculation, 64% believed that this applies to student-linked costs, 57% for costs for training development, and only 49% included in administrative and management costs.

Conclusions and Discussion

The conclusions will be discussed in the same order in which the subjects were raised in this article. At the same time, an answer is provided to the third research question (To what extent can participation and costs be ascribed to developments in work organizations and the training function within these organizations?) by commenting on the results that were collected in this study, in the light of internal developments on the labor market, which, of course, cannot be viewed separately from external developments. During the discussion occasioned by these results, a recent study is used that was conducted in the United States, under the auspices of the American Society of Training & Development, Industry Report 2001, of the current situation in the field of company training (Van Buren, 2001). In addition, reference is made to the Intermediair Opleidingsenquete [Training Survey] (Witziers, 2001; Intermediair, 7 June, 2001). Finally, provisional data from the CBS Bedrijfsopleidingenonderzoek [Company training study] is used, based on the press release of May 2001.

General. Comparatively speaking, many large to very large work organizations participated in this study; 30% of the participating organizations even have more than 3000 employees. The data file reveals that in this category of companies 'well-known Dutch and foreign multinationals' were amply represented. The fact that proportionately more large to very large companies form a part of the population implies that the data are not wholly representative of Dutch trade and industry. It is common knowledge that in the Netherlands there are many more companies in the company size up to 100 and from 100-500 than above (NV Databank, Chambers of Commerce and Industry, 1995). Research has also shown that small and large companies differ considerably from each other as regards the type of training and learning activities that they provide to their employees and the nature and extent of such efforts (CBS press release 22 May, 2001, Wognum & Bartlett, 2001; Smits, Wognum & Pye, 2001).

Participation. It was established in this study that, as regards types of training activities, short training programs with fewer than 10 sessions and one or two-day activities, such as conferences and workshops, were, according to the respondents, the most frequently used, and that these training activities would also remain of importance in the years ahead. The training activity 'learning while working' is now highly regarded and its importance in the coming years was expected to increase further.

Growth was mainly to be found, according to the respondents, in more 'informal' forms of learning, such as learning within a development pathway, job rotation and management development.

The findings of this study as regards training activities tally with the results of the Industry Report 2001 by the ASTD (Van Buren, 2001). It is true that this report concluded that 'classroom training' still has an important share of the training activities, and will even increase in importance, but that companies will start to operate a more 'blended approach', where both 'classroom training' and 'informal' forms of learning (including 'job rotation' and 'cross training') are used.

It is striking that both in this study and the Industry Report 2001 'instructor-led classroom training' (traditional training programs) appears not to have been superseded by more 'informal' forms of training and learning and, more particularly, as appears in the Industry Report 2001, by e-learning. This last form of training and learning is still receiving mainly lip service. The prediction that 23% of all education and training in the United States in 2000
would be provided via e-learning does not appear to be based on facts. From the results of the *Industry Report*, it would even appear that the percentage of e-learning fell from 9.1% in 1997 to 8.4% in 1999. In the current study e-learning has not yet been included as a specific type of training activity. An explanation for this omission is that the study has been designed in 1998.

When the training domains are studied, it is striking that ‘sector and branch-specific training’ and ‘management, enterprise and policy’ training domains attracted the most participants in 1998. The *Intermediair Opleidingsenquete* [Training Survey] (Witziers, 2001) also indicated that management training programs were the most popular. What is also interesting in the *Intermediair Opleidingsenquete* is that participation in training programs, particularly by highly educated personnel, has fallen drastically, but that the participation of board members and management in training activities is declining less rapidly.

The *Industry Report 2001* is very clear as far as the demand made by ‘branch-specific, job-related and methodical training’ on the training expenses of organizations: it absorbs 13% of funds. The American study shows that 10% of the financial resources for education and training go on management training programs’. It is striking that the share of ‘job-related and methodical training programs’ in the United States is decreasing in favor of, for example, ‘interpersonal communication’.

Table 3 of this study reveals further that participation in the ‘personal growth’ and ‘personal effectiveness’ training domains is expected to show the strongest growth. This indicates a tendency to bolster the ability of individual employees to exercise self-responsibility in relation to their learning and development pathway. This observation is in line with the results from the *Industry Report 2001*.

As regards the relationship of strategic goals and participation in training, it was established in this study that ‘effective deployment of personnel and ‘meeting quality standards’ were the leaders in 1998. Both strategic goals will increase in importance still further.

It is, moreover, striking that the strategic functions of HRD are already strong right across the board and will strengthen even further. As a result, training will be placed more and more in the function of the strategic policy of the organization and will thus not be an isolated activity.

If we can believe the respondents, growth has, however, now come to an end. It is striking that regional training centers, higher vocational colleges and universities have acquired a good position in the training market. As far as training providers are concerned, it can be ascertained, on the basis of the results of this study, that the private training agencies had the greatest share of this in 1998. As for the position of the private training agencies, approximately half of the respondents were of the opinion that their share of ‘out-of-pocket expenses’ would continue to grow up to 2002. The *Industry Report 2001*, on the other hand, reported that growth relating to the outsourcing of training activities had come to an end. Training agencies were, according to the *Industry Report 2001*, still responsible for approximately 20% of the training expenses of companies in 1999, against approximately 25% in 1998. One possible explanation for this may be the previously mentioned growth towards more ‘informal’ forms of learning within work organizations and the ‘blended approach’ that is linked to them, which companies are starting to operate.

**Costs.** The survey data show that it is not simple for the respondents to convert participation in company training and the costs involved into figures. This is caused, on the one hand, by the fact that ‘training accounting’ is not geared to it; on the other hand, it is becoming increasingly difficult to determine exactly what is occurring and what the costs are, particularly due to the growth of more ‘informal’ forms of training and learning.

The amount of training costs was assessed by the respondents at an average of 2.84% of the gross wage bill for the total organization (national and international), 3.38% for the national part of an organization (or an organization operating exclusively in the Netherlands), 2.29% for the organizational unit where the respondent worked and 3.03% for the organizational unit for which the respondent was directly responsible.

In comparison, the recently published press release from the CBS about ‘company training in the Netherlands’ shows that companies in the Netherlands spent Euro 3.1 billion on training programs in 1999, which amounts to 2.7% of labor costs. Large companies spend more on training than do small companies: companies with between 10-99 employees spend 1.8% of labor costs; companies with between 100-499 spend 2.8% of labor costs on training and companies with 500 and more employees beat them all, with 3.8%. These data are fairly in line with the results that were found in the current study.

From the recently published *Industry Report 2001*, it appears that companies with a maximum of 500 employees spend 2.4% of their gross wage bill on education and training, against 1.3% by companies with more than 2000 employees. This is thus substantially less than what has been established in this study and the CBS survey in the Netherlands.

Research into the costs of company training will have to start focusing more on establishing the expenses for ‘informal’ forms of training in the future. This matter has not yet been explicitly addressed in the current study, and
also in the recently available data from the CBS survey participation in congresses, seminars, organized group discussions and self-study was not included. Informal forms of training and learning go still further than the activities mentioned by the CBS, because they involve all forms of learning and acquisition of knowledge on the job (Streumer & Van der Klink, 2001).

In order to gain a reliable picture of training efforts, it is also desirable for small and medium-sized businesses to include ‘informal’ training and learning activities. This is because the study shows that small companies learn more through ‘work arrangements’ and the like than through traditional courses/training programs (Wognum & Bartlett, 2001; Van Buren, 2001).

Furthermore, changes appear to be occurring in the length of formal training. In the United States, the length of training has declined from an average of 23.4 hours per employee in 1998 to an average of 19.6 hours in 2001. Here too, the explanation for this may be that a shift is taking place in favor of ‘informal’ forms of training and learning and that these have not been taken into account in the figures.

This paper has attempted to provide an answer to the three research questions mentioned. The first two questions have been answered in the ‘Results’ section, in which the participation in and costs of company training programs were discussed consecutively. As far as the third question is concerned – whether participation and costs are influenced by developments in the work organization and the training function within it – a discussion of the developments in the environment of work organizations and the way in which these developments affect the strategic policy of the work organizations is to be found in the introduction to this article. In this respect, it was also indicated that a shift is occurring in the training function. The training function is moving upwards in the organization, which implies that management realizes the importance of the human capital within organizations and regards its development as crucial.

Employability By Sector of Industry: Taking Account of Supply and Demand Characteristics

Andries de Grip
Jasper B. van Loo
Jos M.A.F. Sanders
Maastricht University, The Netherlands

In this paper, we investigate the development of an Industry Employability Index taking into account supply and demand determinants of workers' employability as well as industry-dependent facilitating conditions. Although employability is a key element in recent policy debates, both a sound theoretical base and quantitative research on the concept are lacking. This paper integrates various factors in a synthesized index, enabling comparisons between workforce employability in the various industries.

Keywords: Employability, Training, Flexibility

In the last decade the employability concept has received considerable attention in the international media. Both in scientific publications and in government and business policies, the concept of employability has become increasingly important (See e.g. European Commission, 1996). Partly, this interest is aroused by new opinions concerning career development. It is argued that the 'lifetime employment' contract with one employer is no longer relevant for a large share of the working population (Bridges, 1994) and has been replaced by a more dynamic view towards careers (Hyatt, 1995). Hyatt notes that modern careers are characterized by a high degree of flexibility and employees are meant to become 'entrepreneurs of their own career'. Arthur (1994) also predicted a future in which peoples' careers are no longer bounded by a single organization. He states that individual careers in time will become increasingly 'boundaryless'. Hall (1996) empirically proves that the so-called 'protean' career has had its U.S. breakthrough in the late nineteen-eighties and early nineteen-nineties. A protean career is considered to be a pattern of varied experiences in education, training, work in several organizations and changes in occupational field. An important characteristic of a protean career is that individual workers themselves, not organizations, manage it. Hirsch (1987) shows that at least some of the more able and ambitious working people take charge of their careers rather than following an organization's definition of career development.

Problem Statement and Research Questions

In this paper we investigate whether it is possible to develop an Industry Employability Index, which indicates the employability of the workforce in the various sectors of industry taking into account both supply and demand determinants of workers' employability as well as the facilitating conditions in the various sectors of industry. Such an index is highly relevant for HRD as it (1) can be seen as a benchmark for firms with respect to the various aspects of the employability of the workers in their sector of industry and (2) informs workers on their career perspectives and risks in the various sectors of industry. There has, however, been a lot of debate about what is meant exactly by the employability concept. Adding more and more related 'ingredients' to the concept has made it somewhat fuzzy. This leads to a first research question:

1. What is a proper definition of workers' employability based on both Human Resource Development (HRD) and economic literature?

The literature on employability has usually taken individuals as main units of investigation. This paper takes a different view. Employability is approached from the perspective of sectors of industry Building on the definition of employability developed we will conceptualise the various relevant aspects of workers' employability and integrate these factors in a synthesized model which enables us to make comparisons between the employability of the workforce in the various sectors of industry. This leads to the second research question of this paper:

2. How can we characterize the employability of the workforce in the various sectors of industry that takes account of both supply and demand factors?

Copyright © 2002 Andries de Grip, Jasper B. van Loo and Jos M.A.F. Sanders
For this purpose we develop an industry employability index that relates individual employability to the need for employability and the current opportunities to effectuate employability. This industry employability index can be seen as a stylized facts approach synthesizing the relevant supply and demand side determinants of workers' employability and the facilitating conditions discussed in the literature.

Employability: Meaning of the Concept

Notwithstanding the current attention for employability, it is not a new concept. The first publications on employability date from the mid-fifties (Feintuch, 1955). Thijssen (1998) distinguishes between three types of employability definitions: A core definition, a broader definition, and an all-embracing definition. The core definition of employability encompasses all individual possibilities to be successful in a diversity of jobs in a given labor market situation. In its core definition, employability is therefore only concerned with a worker's capacities; wishes, aspirations or contextual conditions are not relevant here. The broader definition of employability incorporates the capacity as well as the willingness to be successful in a diversity of jobs. In addition, the ability to learn is included. Moreover, contextual factors and so-called 'effectuation conditions' are added. Effectuation conditions are context-bound factors that facilitate a worker's employability, such as e.g. the employer provision of training. In the all-embracing definition, employability encompasses all individual and contextual conditions that determine the future position on the labor market. We therefore define employability as follows: Being employable involves both the capacity and the willingness to be and to remain attractive for the labor market, by reacting and anticipating on changes in tasks and work environment. From an economic point of view it is worthwhile to note that this definition refers to both labor supply and demand characteristics and developments.

Theoretical Framework

In this paper, employability is looked at from the perspective of the various sectors of industry. This contrasts with the existing literature in which no distinction is made between the segments in which employees are employed. The latter means that differences in the need for employability between the various sectors are not taken into account. In this section we will further develop the conceptual model underlying the measurement of employability at the sector level. This will enable us to indicate the employability of the workforce of the various sectors of industry by using a single index (Industry Employability Index, or IEI). An adequate index of the employability of the workers in the various sectors of industry should take into account both supply and demand determinants of workers' employability as well as the facilitating conditions in the various sectors of industry For this purpose the development of the IEI will be divided into four stages:

Stage 1: Current Personnel Employability

The first stage concerns the measurement of the employability of the current personnel in the various sectors of industry. Two dimensions of individual employability will be used. Firstly, willingness measures peoples' desire to engage in activities that keep them attractive on the labor market. Secondly, capacity is concerned with the power to broadly develop one's position on the labor market.

The willingness to be mobile across jobs concerns changing jobs as well as changing work location, both internally and externally. Various authors consider this attribute of workers a key factor in their employability since changes allow workers to gain more knowledge and experience (Hall, 1976). It also prevents a 'concentration of experience' (Thijssen, 1997). Concentration of experience refers to the process that a worker's competences become more and more job-specific due to a long tenure in the same job in the same firm. This concentration of experience can be damaging for workers, since their opportunities to switch to another job in the case of job loss will decrease. The capacity to be mobile across jobs is the extent to which employees are actually able to change jobs or work locations. Becoming mobile across jobs starts with willingness but when people lack the capacities to become mobile this willingness is of course less valuable. Therefore, the capacity to be mobile across jobs is the second indicator for a person's employability. This capacity is determined to a large extent by the experience of an employee in previous jobs. Job-specific skills can imply serious handicaps, since this type of experience is only valuable in a limited number of places (see e.g. Booth & Snower, 1996). The willingness to participate in training is workers' willingness to invest time, money and energy in the development of their human capital. Becker (1962) pointed out that this willingness will depend on the expected return on this investment. This return consists of both a direct increase in earnings and an improved labor market position. The latter means an improvement of one's earnings potential (Rosen, 1975). This implies that workers that
are not willing to invest in their human capital run a double risk. Firstly, they do not develop themselves, which causes skills obsolescence (De Grip & Van Loo, 2002) what makes them less attractive for the labor market. Secondly, they give a negative signal to (future) employers, which may reduce their chances on the labor market when employers “screen” employees. (Thurow, 1975). Of course, the capacity to participate in training is at least as important. This capacity is particularly determined by workers’ basic knowledge (Cf. Bolhuis, 1995).

Functional flexibility can be either quantitative or qualitative (Bolweg & Van Beckhoven, 1995). Qualitative functional flexibility involves doing tasks or duties that are outside the job description of the current job of a worker while quantitative employability refers to flexibility concerning work hours (changing shifts, working overtime). Functional flexibility is a measure for someone’s flexibility in a job and is therefore a relevant indicator for individual employability. When someone is willing to be functionally flexible but lacks the capacity to do so, this willingness does not add much to someone’s employability. The capacity to be functionally flexible to a large extent results from actual functional flexibility in the past, which provides employees with a wide range of valuable experience. As was the case with the capacity to be mobile across jobs experience plays a central role here. The essential difference between the concepts, however, is that the capacity to be mobile across jobs refers to changing jobs, while the capacity to be functionally flexible is about performing tasks which are outside one’s job.

Stage 2: The Need for Employability: Developments in Society

In this section, the need for employability is discussed. It goes without saying that a sector of industry is, irrespectively of all other conditions, better off with optimally employable personnel. The need for employability is, however, dependent on the intensity of various developments in society. Four main developments can be distinguished (Riddell & Sweetman, 1997): Technological developments, organizational developments, economic developments (i.e. developments in competition and demographic developments.

Ongoing technological developments can cause job-specific skills obsolescence, which implies that skills learned in the past and gained experience are no longer sufficient for an adequate job performance (Neuman & Weiss, 1995). Due to the upgrading of the skill requirements in jobs, a gap arises between the human capital workers have and the required human capital (Borghans & De Grip, 2000). In order to bridge this gap, employability plays an important role. Technological developments can also cause jobs to disappear entirely. In the banking industry, for example, information technology has caused the disappearance of traditional teller jobs. When jobs disappear, a worker’s employability becomes crucial for continuing labor market participation. However, in this case employers also benefit from an employable workforce since they do not have to bear the cost of expensive outplacement procedures for workers who have to be reallocated.

Technological developments often take place simultaneously with organizational changes (see Bresnahan, Brynjolfsson, & Hitt, 2001). These organizational developments demand a lot from workers, in the sense that they must be able to continuously adapt to new circumstances. Modern organizations are set up with a need for flexibility. The more bureaucratic organizations of the past make room for less rigid ones, where employees often work in project teams and have a large degree of control over their own actions. Organizational developments demand a large degree of flexibility, which can be accomplished by being employable. When workers are used to changes in the content of their job due to the fact that they are regularly involved in task-and job-rotation programs or training, both the employee and the employer are more able to adapt to changes faster.

A third important development that several sectors of industry face is the increase in international competition. The firms in these sectors need to be able to adapt to changes in the international context faster. This increases their need for a flexible workforce. Moreover, there has been a global shift in the sense that labor intensive production processes have moved to low wage countries around the globe (Wood, 1994) and knowledge intensive production processes like R&D and innovation seem to be concentrated in Western Europe, Japan or the United States. Therefore, most western organizations have started to focus on competing on knowledge and innovative capacity (Porter, 1990). Since well-trained workers are generally better innovators, good training programs should be a key priority for all firms whose competitive power is highly related to the quality of their products or services (Bartel & Lichtenberg, 1987). The increasing international competition therefore demands both flexibility and training efforts from employees.

Finally, demographic developments (a greying workforce and a decreasing labor market inflow of youngsters) are important tendencies that require an employable workforce. In many western economies, the share of employees older then 55 will increase sharply in the immediate future. Due to the greying of the workforce, established channels of labor market exit (pre-pension etc) will become less common, because the costs will increase to an unsustainable level. Moreover, in many industrialized economies, an increasing shortage in the supply of younger
workers has been predicted which implies that employers will increasingly feel the need to retain their personnel longer.

Stage 3: Conditions of Effectuation

In the previous two sub-sections the various aspects relevant for the actual employability situation and the need for employability have been mentioned. When there are shortcomings in the available employability, it is profitable for both employees and firms to invest in personnel employability policies. In this third stage, we will identify the possibilities that currently exist within sectors of industry to effectuate or expand workers' employability. Following Thijssen (1998) these possibilities are labeled as 'conditions of effectuation' for workers' employability. Thijssen distinguishes between two types of conditions of effectuation. Contextual conditions of effectuation refer to e.g. the general situation on the labor market, the possibilities for career counseling and the provision of training courses. Personal conditions of effectuation refer to the willingness and the preferences of individual employees. Since this latter type of conditions of effectuation has already been dealt with in the part on individual employability, the conditions of effectuation we discuss in this paper are purely contextual in nature.

Stage 4: The Industry Employability Index

In the final stage of the model, the Industry Employability Index (IEI) is determined. It is based on all previously discussed indicators. Whenever a sector of industry has a high current employability, a moderate need for employability and favorable conditions of effectuation, the IEI-score will be relatively high. When a sector scores badly on one of these elements of the IEI, the value of the IEI will automatically be lower. The IEI may be calculated for the whole population of workers, but also for specific target groups, which are often considered to deserve special attention: Younger workers (16-29 years of age), older workers (50-64 years of age), lower educated workers and female workers.

Methodology

In this section, the proposed strategy to calculate an Industry Employability Index is applied to the Dutch economy. Not all required data are typically available in a single data source. Therefore, in the empirical part of this paper we use various Dutch data-sources: The labor supply and the labor demand surveys of the Organization for Strategic Labor Market Research (OSA) and the labor force survey of Statistics Netherlands (CBS). The various data sources more or less refer to the same point of reference at the mid nineteen nineties. The OSA supply survey data refer to 1996; The OSA demand survey data to 1997 and the CBS data to the bi-annual average 1996-1997. In order to make different quantities comparable, all data were indexed by converting them into standard normally distributed variables and re-scaling them such that the average score is 100. This implies that the resulting Employability Index is not an absolute measure, but a relative measure meant to compare the various sectors of industry according to their employability. In this section we describe and justify our choice of indicators.

Current Individual Employability

The current individual employability of the workforces of the various sectors of industry is measured by six indicators: three measure willingness and three are concerned with capacities. The six indicators are converted into an MTF-score (mobility, training and flexibility) in the way described above.

The willingness to be mobile is measured using data on workers' actual search behavior. When employees apply for new jobs on a regular basis they express their willingness to be mobile across jobs. However, not all search behavior can be considered relevant here. 'Forced' search behavior should not be seen as employability enhancing. For this reason we will focus on the job search of workers on their own initiative, as this implies a willingness to be mobile and this adds to their employability. In order to measure a worker's capacity to be mobile across jobs, we looked at the tenure of individual workers in their current job and divided this by the period individual workers participated in the labor market. This ratio is multiplied by workers' age, because older workers run a greater risk of 'concentration of experience', which decreases their capacity to be mobile.

The willingness to participate in training is measured using data on training participation. We here do not take into account whether or not an employee has successfully completed a training course, as this is not relevant for a worker's willingness to participate in training that was successfully completed. The capacity to participate in
training is measured by the total duration of initial education and previous (firm) training. This reflects Heckman's (1999) notion that "Learning begets learning. Skills acquired early on make learning easier."

Qualitative functional flexibility endows workers with a wide range of different experiences, which improves their employability. The willingness to be quantitatively flexible can, however, also indicate a weak position in the (secondary) labor market. Therefore, for the willingness to be functionally flexible we will focus exclusively on the qualitative dimension of functional flexibility. Finally, the capacity to be functionally flexible is measured by the experience from qualitative functional flexibility in the past. It is calculated by determining the frequency of performing tasks that are not part of one's job in the past.

**The Need for Employability**

Highly innovative sectors of industry have a high need for employable workers. Since *technological developments* in many sectors of industry are nowadays highly intertwined with improvements or changes in information and communication technology, the percentage of the workforce in a sector of industry that uses a computer regularly during work has been used as an indicator for technological developments. Two indicators combined into one, measure *organizational developments*. The first indicator is the percentage of employees that have experienced reorganizations. The second indicator is the percentage of people that works for a firm where a change in the position of the organization in the larger configuration (parent company, franchisee etc.) has taken place.

Sectors that are open to *international competition*, are expected to have a relatively high need for an employable workforce. The degree of international competition in sectors of industry is measured through the export shares of the industry’s production as a proxy of the degree of ‘openness’ of a sector. Last but not least sectors of industry with a greying workforce highly need employable workers, as their workforce may have old vintages of human capital (Neuman & Weiss, 1995). *Demographic developments* of personnel in the different sectors of industry have been measured by dividing the percentage of older employees (55+) by the percentage of youngsters (16-29 years of age). This indicator shows the severity of greying in the various sectors of industry.

**Conditions of Effectuation**

The conditions of effectuation of workers’ employability are determined by two indicators: (1) the intensity of training provision in the different sectors of industry and (2) the labor market situation (since a strong labor market offers workers more opportunities for further career steps and opportunities to switch to another job than a labor market with shrinking employment). The labor market situation by sector of industry is indicated by expected employment growth in the next five years (ROA, 1997).

**Results**

This section presents the empirical results obtained when the discussed framework is applied to the Dutch economy. In table 1, all indicators discussed above are presented. The current individual employability of the workforce by sector of industry is presented in the first seven columns. First the six separate employability indicators are presented. Then, in the seventh column all indicators are combined into a single unweighted index (MTF-score). Financial services and hotels/restaurants, repair and business services are the sectors with the most employable employees. In transport and communication, employees are on average the least employable.

In column 8 through 12 an overview is presented of the need for employability. Technological developments play an important role in the financial services industry, in the chemicals industry and in the energy and civil service, police, defense and education sectors. Organizational developments are most prominent in hotels/restaurants, repair and business services, as can be seen from the ninth column. The metal and electrical industry are also characterized by important organizational developments. Financial services and agriculture and fisheries are the organizationally most stable sectors of industry. The chemicals sector is the most open sector, as the tenth column shows. In this sector of industry, international competition plays an important role. The greying of the workforce is most prominent in the energy and civil service, police, defense and education sectors.

* WM=Willingness to be Mobile, CM=Capacity to be Mobile, WT=Willingness to be involved in Training, CT=Capacity to be involved in Training, WF=Willingness to be functionally Flexible, CF=Capacity to be functionally Flexible, MTF=Mobility, Training Flexibility Indicator, TD=Technological Developments, OD=Organisational Developments, ED=Economic Developments, DD=Demographic Developments, NEED=Combined Indicator for all developments, TI=Training Intensity, ED=Expansion Demand, CE=Conditions of Effectuation, IEI All=Industry Employability Index for all workers, IEI Yng=Industry Employability Index for younger workers, IEI Old=Industry Employability Index for older workers, IEI LE=Industry Employability Index for lower educated workers, IEI Fml=Industry Employability Index for female workers.

The combination of the four developments we discussed determines the overall need for employability and is shown in column 12. The need for employability is highest in the energy sector, due to the relatively strong effect of all individual developments. In the chemicals sector, three out of four developments distinguished are relevant, which results in a second position on the NEED-index for this sector of industry. On the third place on the NEED-index, we find the metal and electrical industry and the civil service, police, defense and education sector. In these sectors of industry, the organizational and the demographic developments are of key importance.

The “conditions of effectuation” of workers’ employability in the various sector of industry are presented in the columns 13-15. In the financial services and energy sector, training intensity is highest. Conversely, employees in agriculture and fisheries are least involved in training. Employment growth forecasts are favorable in the hotels/restaurants, repair and business services and commerce sectors. The employment forecasts are far less favorable in agriculture and fisheries and the energy sector.

Column 15 combines both contextual conditions of effectuation and reveals that the sectors of industry with the most favorable best conditions of effectuation are financial services, hotels/restaurants, repair and business services and chemicals. The agriculture and fisheries, food and beverage and civil service, police, defense and education sectors, however, score relatively low on the conditions of effectuation index.
In column 16, the IEI for all workers is presented. The financial services sector has the best score, which is mainly due to the favorable MTF-scores and the good conditions of effectuation. The construction and real estate sector has the second-highest IEI-score. This is due to a moderate MTF-score and to the fact that the need for employable personnel is lowest in this sector of industry. This combination implies that the available employability (MTF-score) at least partly offsets the demand for employable workers (NEED-score). Moreover, the conditions of effectuation are favorable in construction and real estate. The agriculture and fisheries sector scores worst on the IEI. The individual employability of workers in this sector of industry (MTF-score) is fairly low and although the need for employable workers is not that high, the relatively unfavorable conditions of effectuation (CE-score) give the sector the last position on the IEI-index.

The IEI for Specific Groups of Workers

In column 17-20 an overview is presented of the IEI for four specific groups of workers. For young workers (16-29 years old), conditions are most favorable in the financial services sector. The commerce and hotels/restaurants, repair and business services sectors take the second and third place. Current personnel employability (as expressed in the MTF-scores) of young workers in these sectors of industry lags somewhat behind. Agriculture and fisheries has the least favorable employability situation, due to the high need for employability combined with a low MTF-score and relatively unfavorable conditions of effectuation. The transport and communication and the metal- and electrical industry sectors show relatively unfavorable employability-conditions for younger workers as well. This is mainly due to the low current personnel employability (MTF) in these sectors of industry. Commerce, energy and the food and beverage industry are the sectors that have better employability conditions for young workers as compared to the scores for the whole population of workers.

Comparing the overall scores of older workers to the scores for young workers reveals that the IEI for workers aged over 50 is lower in virtually every sector of industry. For the of older workers the conditions are most favorable in the energy sector, due to a combination of a relatively high level of current personnel employability, a moderate need for employability and relatively favorable conditions of effectuation. The financial services and the construction and real estate sectors also show a relatively good employability situation for older workers. Older workers in transport and communication, civil service, police, defense and education, and the chemicals industry face the worst prospects when it concerns employability. In the first sector, the employability-situation is worst due to the unfavorable current individual employability of the older workforce. In the other sectors mentioned, the need for employability is fairly high. Moreover, civil service, police, defense and education scores badly due to the very limited conditions of effectuation.

The Industry Employability Index for lower educated workers refers to workers with an educational background equal to or less than lower vocational or general education. As was the case with the total population, commerce, construction and real estate, financial services and hotels/restaurants, repair and business services sectors have the best scores for lower educated workers, while agriculture and fisheries ranks last. Commerce beats the other sectors of industry due to the high current personnel employability in this sector of industry. The construction and real estate sectors are the only sectors where the current employability is higher than the need for employability. Since both sectors are characterized by relatively good conditions of effectuation, they end up with favorable IEI scores. In the agriculture and fisheries sector, the low individual employability of the lower educated is combined with a high need for employable personnel and relatively unfavorable conditions of effectuation. This causes this sector of industry to be the least favorable for lower educated workers.

The differences between female workers and the total working population are small. In a number of industries, the employability situation for female workers is better than it is for the population of workers as a whole. This may be largely due to the fact that the share of women that belong to the group of older workers is relatively small due to the very low labor participation of women above 50. As was the case with the total working population, the employability of female personnel is highest in the financial services and construction and real estate. The transport and communication sector also scores worst for female employees.

Conclusions and Recommendations

In this paper, we developed a conceptual framework for an industry employability index (IEI), which gives a quantitative indication of the relative performance of the various sectors of industry concerning the employability of their workforce. The model is applied to 13 sectors of industry in the Netherlands. The financial services sector scores highest on the Industry Employability Index. Other sectors with favorable IEI-scores are construction and real estate and hotels/restaurants, repair and business services. The agriculture and fisheries sector scores worst in terms of
employability. When we look at the IEI for four specific groups of workers, it becomes clear that the employability-situation for older workers is generally a lot worse than it is for their younger colleagues. In addition, lower educated workers are less employable than intermediate or higher-educated individuals. Differences between male and female employees are, however, considered to be rather small.

To obtain a more detailed picture of workers' employability, the collection of firm-specific data would be extremely helpful. Using this data on individual organizations would enable the construction of an employability index at the firm level. Such an index would make the labor market more transparent for employees wanting to gain a better understanding of their development opportunities and their employability in the various firms they intend to apply for a job. Moreover, the comparison of organization-specific employability-scores to the IEI of the sector of industry concerned would enable organizations to gain valuable insights in their own relative employability situation. Such a 'benchmark' would also make clear that employability is not only dependent upon the worker himself, but it is also affected by the organization and the sector of industry a worker is employed in. Another research opportunity would be to use the framework developed in this paper with data from other countries. This would enable comparisons between the employability-situation of sectors of industries in different countries.

Performance Improvement for Teacher Selection: A Holistic Approach to HRD Interventions

Kiyoe Harada
HRD Research

Jeffry S. Bowman
Bowling Green State University

Teacher selection is one of the most critical tasks for school personnel, to ensure the quality of education. This paper discussed several issues in teacher selection, based on person-job fit and person-organization fit, for a teacher selection model. A holistic approach was taken to propose a model of performance improvement interventions for personnel administrators. Practical and future research implications were also provided.

Keywords: Performance improvement, A model of teacher selection, HRD interventions model

Despite the efforts in improving education (e.g., using new teaching concepts and methods), the current state of education in the U.S. is a great concern, relative to the quality of the future workforce. For instance, American students have continued to perform at a lower level on proficiency tests, which results in increasing training costs among industries. In addition, 60% of newly graduated teachers failed a recent certification exam (Gross, 1999). In this regard, the quality of education is due, in part, to the quality of the people who teach and educate the future workforce. The selection and employment of highly qualified personnel in a school district is one of the most difficult of all administrative tasks (Harris & Monk, 1979).

Problem Statement

In teacher selection, the personnel administrators (e.g., superintendents and school principals) are most intimately involved in the process and in the decision-making. The selection literature has provided suggestions on the process, factors and criteria, errors, as well as other factors in an organizational context to make the best selection. However, hiring decisions are often made during the interview phase where the first impression is most frequently formed. More importantly, at times, personnel administrators tend to rely on their experiences and hunches, among other factors, to make the hiring decisions (Baron, 1993; Triandis & Triandis, 1967). If this is the case, hiring decisions might be interfered with by non-job related factors, misconceptions, and/or psychometric problems.

Training has been used to improve the selection and performance of personnel administrators. However, the effectiveness of such training has shown inconsistent results (Keenan, 1978). This might be because training is seen as a one-shot event without inclusion of other interventions, such as job aids and supports. However, there have not been sufficiently accumulated studies in selection practices, relative to performance improvement in school settings. Consequently, factors that might be related to and involved in the improvement of selection performance may not be well known yet.

The purpose of this paper is to provide a model of performance improvement interventions for teacher selection. Specifically, the study attempts to provide a model of teacher selection by applying the concept of “fit”, and it also provides a model of human resource development interventions for the advancement of performance improvement in teacher selection. The term, personnel administrators in this study, refers to superintendents and school principals who are responsible for the selection process and hiring decisions.

Selection Framework

Selection is an information-gathering and decision-making process to identify the best-qualified personnel for the job. It contains four phases: (a) recruitment, (b) screening, (c) interview, and (d) hiring decision-making. Studies of selection in school settings have looked at various aspects, such as: (a) the selection process, (b) job-related factors and non-job-related factors related to job qualifications and legal issues, (c) reliability and validity of the rating
A Model of Teacher Selection

The focus of discussions is on performance improvement of school personnel administrators. Prior to the hiring decision being made, all the information and data from the screening phases are gathered, analyzed, and integrated. The decision-making process is composed of a series of steps: (a) defining the problem (or kind of decision that has to be made), (b) the goal(s) of the decision, (c) identifying the alternatives to a given decision, (d) identifying the consequences of the decision, (e) the actual making of the decision, and (f) the implementation of the decision (Hoy & Miskel, 1996). Prior to the hiring decision being made, all the information and data from the applicants are rated categorically and listed as items for evaluation. The evaluation focuses on professional credentials used to compare the applicants against job requirements and specifications. These criteria must be measured objectively and consistently. However, impressions made of the candidates have been shown to influence the hiring decision. Furthermore, personnel administrators tend to use their experiences and sometimes hunches and intuition. Because of this, the best hiring choice may not be made. In this regard, there are opportunities for personnel administrators to improve their selection performance.

Theoretical Frameworks: A Model of Teacher Selection and Performance Improvement

Responding to needs for performance improvement in teacher selection, this section discusses a model of teacher selection applying the concept of fit and a model of performance improvement interventions for teacher selection.

To improve performance, a level of performance expectation must be defined in the work context and understood by performers. Because most performance issues lie in multiple layers within a work context, including work itself, performer, and workplace, performance problems are often multi-causal, caused by interactions of some problems and/or reasons concerning different issues, work units, performers, tools, motivations, and other factors (Rosenberg, 1996). In this regard, performance improvement in teacher selection should take a holistic approach. The focus of discussions is on performance improvement of school personnel administrators.

**A Model of Teacher Selection**

Selection is composed of two critical elements, information gathering and decision-making. For instance, job requirements and position specifications are determined, based on job information collected during recruitment, and a decision on who will be invited for interviews is made in the screening phase. During the interviews, while
information about applicants is gathered, decisions, including criteria to be used and candidates to be selected as finalists are made. The focus of decision-making is a balancing between selection criteria and applicants' qualifications relative to needs in a school. In this regard, the critical issue that personnel administrators are challenged with is whether they should take more consideration of job requirements or needs of the circumstances of a school.

The recent changes in the nature of work require employees to perform more knowledge work and a new type of work collaboration, such as within and outside networking and project teams. As a result, personnel administrators look for more than matching job requirements and applicants (Rynes & Gerhart, 1990). The concept of “fit” has gained increasing interest in selection research because it is concerned with balancing job requirements and organizational attributes, as they apply to individuals. Studies in fit have been shown to improve employee attitudes and job performance (Kristof-Brown, 2000). In this respect, the concept of fit can be applied to a model of teacher selection (Figure 1). There are two forms of fit; (1) Person-Job Fit (PJF), matching an applicant’s Knowledge, Skills, and Abilities (KSAs) and the requirements of a specific job, and (2) Person-Organization Fit (POF), matching an applicant’s personal factors and broader organizational attributes (Kristof-Brown, 2000; Rynes & Gerhart, 1990). Figure 1 describes factors used in hiring decisions and the two forms of fit in quadrants.

**PJF and JRFs.** Person-Job Fit (PJF) and Job-Related Factors (JRFs) focus on matching job demands and individual professional credentials. Therefore, PJF and JRFs are concerned with how well the applicants' professional credentials, such as Knowledge, Skills, Abilities, and Experiences (KSAEs) and other qualifications fit the job requirements. These factors are the most frequently used in selection and relate to job and specific task performance (Kristof-Brown, 2000). In this quadrant, potential problems relate to assessing and measuring KSAEs and frequently include the following psychometric errors: (1) halo error (a failure to distinguish among different aspects of performance, particularly exaggerating positive performance), (2) contrast error (comparing individuals to one another instead of against an objective standard), (3) leniency error (giving high ratings to all applicants), and (4) rater bias (consistency in rating among raters) (Noe et al, 1994).

To minimize these errors, training has been provided in industries. The focus of training programs is on interview technique and how to rate performance. Results show a positive relationship between training and reduction of errors as well as participants' confidence (Snodgrass & Wheeler, 1983). However, selection practices in schools as well as a relationship between training for personnel administrators and teacher selection has not been sufficiently looked into. Therefore, a small inquiry was completed for this study to get a feeling for selection practices in school districts, after the literature was reviewed. The sample in this inquiry was randomly selected and comprised 10% of the public school districts in a midwestern state. It was found that most building principals were not provided formal selection and interview training from the districts; instead, their knowledge about selection is from college courses, informally at administrator’s meetings, from experience, and by doing actual selection. Only a few districts provided training consultants for their special training needs. However, training fades within three to six months, sometimes before personnel administrators exercise it (Ivancevich, 1979). As a result, when selection time comes, they tend to go back to their experience and hands-on knowledge, and use their intuition and hunches. In this regard, other interventions should be taken into consideration, in regard to retaining gained knowledge and skills. The interventions include selection policies and procedures and job aids (e.g., selection manual, EEOC guidelines, rating handbook, evaluation matrices, etc.).

Support from supervisors and other colleagues has been recognized as fostering training transfer (Phye, 1989; Rouiller & Goldstein, 1993; Tracey, Tannenbaum, & Kavanagh, 1995). However, the work of a school principal and superintendent is upper level management in nature. Consequently, hiring decision-making is their responsibility. In this regard, forming a selection task team is an alternative intervention although the ultimate responsibility is personnel administrators. The task team include principals, assistant principals, superintendent and assistant superintendents, which could help to retain the learning intervention. Such a team can be thought of as a community of practice where apprentices can learn from masters.

**POF and JRFs.** Person-Organization Fit (POF) is concerned with how well individuals can fit into the organizational context, such as culture, the existing leadership structure, community, work groups, and the missions and policies of the school. Any kind of work requires collaboration with others. The nature of a teaching job is the same: the teachers work closely with colleagues, other school district personnel, parents, and members of the community. In this regard, focusing on only job-related factors may not be sufficient to select the best teacher. Therefore, factors relative to POF should not be overlooked.

The Job-related Factors (JRFs) and POF quadrant includes factors of personal characteristics and other non-job related factors (e.g., educational philosophy, work values, area of teaching interest, etc.) The critical issue is how to
minimize favorable perceptions of teacher applicants formed during the interview and decision-making phases. The favorable perceptions are the result of similar-to-me (similarity-attraction effects and social distance) and are also influenced by first impressions. Similar-to-me refers to a perception, developed by sharing common attributes between selection personnel and job applicants (Noe et al, 1994). If people share common teaching philosophies and personal characteristics, they are more comfortable in working together. If personnel administrators, influenced by first impressions, carry such misperceptions to hiring decisions, biases tend to be formed. Consequently, these perceptions also relate to psychometric errors and rating errors. Therefore, minimizing these perceptions is critical.

To improve selection performance, proper knowledge in communication, skills in perception checks, and knowledge in selection errors is important. Therefore, providing training in interpersonal communication, listening skills, and psychometric errors will help personnel administrators improve selection outcomes. At the same time, job aids, including an interview checklist sheet, rating manual and checklist, worksheet, and questioning manual, are also helpful for personnel administrators.

**NJRFs and PJF.** The Non-Job-Related Factors (NJRFs) and PJF quadrant is concerned with negligence and/or bias entering into the hiring decision. The Statutes clearly forbid the use of race, age, gender, disability, and religion in selection decisions. Most personnel administrators are aware of this; however, they should know how to use the statutes in practice, such as the kinds of questions that might relate to these factors. In this regard, possible interventions include setting up clear selection policies and guidelines, a school mission and policies, and a learning program in EEOC guidelines with legal implications. In addition, skill training, focusing on interview techniques, would also help administrators gain a good understanding of practices.

**NJRFs and POF.** The Non-Job-Related Factors and POF quadrant focuses on congruence between work context (school environment) and individual values. Factors include personal values, beliefs, interests, personal characteristics, bias, etc. Personnel administrators use PJF factors to eliminate applicants who do not meet job requirements, prior to taking consideration of POF factors. Furthermore, POF is addressed later in the interview phase to see how well the applicant can merge into the school environment. In this regard, personnel administrators may be influenced by their personal preferences, based on similar-to-me, personal characteristics, and individual beliefs and values. These preferences relate to psychometric errors, based on the theories of attraction-similarity and social distance and could lead to legal problems. Possible performance improvement interventions include leadership training programs, and job aids (e.g., policies and procedures, standard performance guidelines). In addition, taking a personal characteristics inventory could help the personnel administrators become aware of himself/herself and help to avoid personal bias and preference in selection.

**A Model of Performance Improvement Interventions**

The literature indicates that neither can experience without proper knowledge and skills be enough to perform selection, nor can knowledge without experiences be sufficient to bring the best qualified teachers in to schools.
Effective teacher selection comes from KSAEs taken together with scientific and systematic analysis of performance within the work context (Spitzer, 1992).

Human Performance Technology (HPT) is a systematized process for solving performance problems and identifying performance to be improved. It begins with systematic and systemic analyses of job performance, to define gaps between "what is" and "what should be." Performance gaps at the various levels in an organization (e.g., organization, process, individual, and work group) are analyzed to determine whether the gap should be filled or not. If there is a need for a performance gap to be filled, possible interventions are proposed to eliminate the gap (Langdon, Whiteside, & McKenna, 1999; Spitzer, 1992).

Performance improvement interventions are defined as means that are used to bring about changes in the performance of an individual, a work group, a business unit, a process, and a workplace, for the purpose of establishing, improving, maintaining, and/or distinguishing performance (Langdon et al, 1999). Therefore, holistic performance improvement interventions are recommended, based on both the cause and the context of job performance problems or performance improvement opportunities. Interventions can range from a relatively small change (a tool or procedure) to an entire organizational structure and system change. As such, the interventions can take various forms, such as learning programs, job aids, coaching and mentoring, performance standards, feedback, expert system, etc. Of these, the most promising interventions, based on systemic, results-focused, cost-effective, and comprehensive analyses, are used to improve target performance (Brandenburg & Binder, 1992; Spitzer, 1992).

Applying performance improvement technology to the improvement of teacher selection performance of personnel administrators, a model of performance interventions is proposed (Table 1). It describes each phase in the selection process, addressing selection issues in each phase, and discussions are based on integrating the teacher selection model and performance improvement interventions for teacher selection improvement.

Recruitment. One of the difficulties that personnel administrators face is the time allowed them to fill a vacant position. This problem might be due to any of several reasons, such as difficulty in predicting teacher vacancies, a lack of resources and/or administrative supports, and a lack of knowledge in recruitment procedures. Depending on the focus of performance level, potential interventions are: (a) setting up short-term and long-term human resource planning, which helps identify when and what vacant positions may appear, (b) appointing administrative staff to support recruitment, (c) establishing selection policies and standard procedures as guidance, and (d) identifying job and position requirements in the school. Training intervention is effective when personnel administrators lack proper KSAEs to do teacher selection. Personnel administrators often use informal learning opportunities, such as peer discussions, learning-by-doing, and OJT to know selection practices. Therefore, a formal training program, dealing with the overall selection process, practices, and methods, would be helpful.

Screening. Professional credentials of applicants are sent to school principals. To make sure all necessary applicant documents are gathered is sometimes a very tedious job for principals. Therefore, administrative support is critical to assure all required documents are ready for evaluation. At this stage, school principals should have a good understanding of job-related criteria for the teaching positions and clear ideas about what to ask and what not to ask, as well as what to look for in the teacher applicants. These concerns relate to their awareness of the pertinent legal issues and the consequences of not following them during screening and interview. Note that school principals tend to be influenced by errors, associated with first impressions and similar to me, through documents from applicants.

In this situation, intervention is designed to minimize such errors. For instance, job aids, could include: (a) a screening manual, (b) rating and interview manual, (c) guidebook for interview questions, (d) rating matrices (e.g., candidates x credentials and interview items x responses), and (e) EEOC guidelines. A formal learning intervention, such as training, is also important when the rating issue relates to psychometric errors.

Interview. Interviews are considered the focal point in the selection process because many personnel administrators tend to make hiring decisions at this stage. In addition, due to the popularity of the interview in selection, many personnel administrators rely on their experience in interview techniques. However, the literature shows that experience does not always provide proper knowledge. There is a difference in the effectiveness of ratings between those who use experience and those who have training. More importantly, those who do not have interview experience are eager to learn interview techniques and they transfer training into practice (Ford, Quinones, Sega, & Sorra, 1992). In this respect, training, (e.g., interview techniques and rating themes) is an appropriate intervention. The interview provides face-to-face communication, which requires skills in interpersonal communication and listening. Therefore, these skill-training programs are also helpful in performance improvement. Regarding job aids, an interview manual, a booklet for interview question items, and EEOC guidelines can be
helpful, particularly in retaining learning interventions in individuals. Another intervention could be a task team for selection and/or interviews. In this regard, while a principal is giving the interview, other personnel, such as an assistant principal, can provide assistance.

Decision. Hiring decisions should not be interfered with by any non-job-related factors; therefore, job and position requirements are heavily focused on. It is equally important to rate selection criteria against professional credentials. Making judgments on those credentials inherently contains psychometric errors, as discussed in the previous section. It is almost impossible to completely remove these psychometric errors from ratings. The issue is minimizing errors. In this regard, educational programs, focusing on not only psychometric errors, but also understanding factors behind the errors, are very important in designing interventions.

| Hiring Decision | Evaluating candidates' credentials | Analyzing & evaluating candidates' credentials, and interview ratings | Decision-making manual |
|                 | Decisions made, based on experience, intuition, hunches, & non-job-related items | Selecting the best qualified candidates, based on job-related and non-job-related factors | Decision-making chart |
|                 | Selecting the best-qualified candidates | Recognizing whether job fit or organization fit is emphasized | Hiring policies and standard procedures |
|                 |                                      | Performance standards for personnel administrators | |

In addition, skill training, such as interpersonal communication, listening, and decision making, is equally important to assure the effectiveness of selection performance. Possible job aids for personnel administrators include a decision-making manual and chart, and decision checklists. Because OJT and information learning have been commonly used among personnel administrators, coaching and mentoring from experienced and knowledgeable school principals and/or superintendents are also alternative interventions.
Feedback can be used as a performance improvement intervention. It is always helpful if personnel administrators evaluate newly hired teachers, by using 360-degree feedback. Such information should not be used for performance appraisal, but should be used to see how effective the selection criteria and the factors used for hiring decisions might be. In other words, this information should be used to improve teacher selection. In addition, personnel administrators can evaluate themselves against objective criteria of their performance in teacher selection. Objective criteria can include following up performance of newly hired teachers and getting feedback from peer teachers and parents.

Practical and Future Research Implications

A model of teacher selection and a proposed model of HRD performance improvement interventions for teacher selection have been discussed. Because a performance problem contains multi-facted causes within a work context, a holistic approach was taken into consideration in this paper to provide practical suggestions in selection practices and comprehensive performance improvement interventions for teacher selection.

For future research implications, there have not been adequate studies in teacher selection in school settings. After a literature review was completed, in order to get some information about selection practices, an inquiry was undertaken, by randomly selecting 10% of the public school districts in a midwestern state and conversations were held with central office personnel. The findings included: (a) the principals were either the sole or the major official responsible for the teacher selection process in their own buildings, (b) the principals did their own applicant screening (87%) while in the other districts, either the superintendent or the assistant superintendent did the screening, and (c) most principals took part in the interview process. However, in some districts, other personnel, such as the assistant superintendent or the personnel director were also present at the interviews.

These findings are a part of actual selection practices. Consequently, more questions and unknown factors remain unanswered. In this regard, a descriptive investigation of teacher selection practices should be undertaken to provide additional information. Furthermore, few studies have used theories and concepts (e.g., attraction-similarity theory, the theory of social distance, the theory of ratings, and the concept of fit) in selection research relative. These theoretical frameworks help identify relationships and cause-and-effect aspects of independent variables and dependent variables. Such research study will provide a theoretical contribution to the body of knowledge.

Regarding performance improvement, the effectiveness of selection training, focusing on interview and rating skills, as well as psychometric issues and ratings, has shown inconsistent results. HPT suggests that performance problems are composed of multiple causes, which indicate that training alone may not be as effective as expected. HRD interventions are designed to improve performance in various levels within an organization. Based on this notion, performance improvement interventions are provided. However, it is important to evaluate how well these interventions can bring about improvement. In addition, identifying independent variables and dependent variables will be another potential area for future research opportunity.

How the Research Contributes to New Knowledge in HRD

This paper is the first to provide an HRD intervention model for teacher selection. The framework focuses on the latest results in personnel research, particularly the concepts of person-job fit and person-organization fit, which are relatively new to in the workplace, and transfers the concepts to the public school system. This first attempt will increase a body of HRD knowledge and providing practical implications.

This paper focuses on the current state of teacher selection practices in schools for performance improvement of personnel administrators. A school, as an educational institution, is seen separately from any other organization. Therefore, it may not be considered as a type of organization with teachers as its human resources, where performance improvement of the organization and the individual can be expected. In this regard, this paper will contribute to increasing the body of teacher selection knowledge and practical implications for selection practices.

This discussion paper provides a comprehensive framework on selection improvement, bringing both theory and concepts into practice. Particularly, the interview, the most popular and the focal point of the selection process, is often used by school personnel administrators based on their experience, instead of being provided training with proper knowledge and skills. This may not always result in effective selection. In this regard, this paper provides insight into benefits of HRD interventions.

Employment Retention and Advancement Among Post-Welfare Participants in Wisconsin: Insights from W-2 Agency Representatives and Employers

Mary V. Alfred
Larry G. Martin
University of Wisconsin-Milwaukee

This study investigated the expert views of agency staff who provide case management services within the Wisconsin Works (W-2) program and of employers who hire Low Income Workers With Family Responsibilities (LIWWFRs). W2 staff assessed W2 employment retention and advancement services and employers assessed their own and W2 agency services for LIWWFRs. W2 agencies and employers provide these services as strategic initiatives to counter-balance the barriers faced by W-2 participants and LIWWFRs in their quest for employment retention and advancement.

Keywords: Welfare-to-work, Wisconsin-Works, W-2

In 1996, Congress passed the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA), taking a major step to change the culture of welfare from a system of dependency to one of personal responsibility and self-sufficiency. However, even before PRWORA, many states were experimenting with creative welfare systems that would move recipients from the welfare rolls and into the workplace. Wisconsin was one of the first states to undertake the challenge, and early in 1998, it completed its transition from Aid to Families with Dependent Children (AFDC) to Wisconsin Works (W-2). With its "work first" philosophy, W-2 was aligned with the welfare reform legislation of 1996. Both programs imposed strict time limits on recipients and required all who were capable to obtain immediate employment. The mandate to caseworkers, therefore, was to move recipients to the workforce as quickly as possible, so as to decrease dependency on cash assistance.

As a result of these changes in the welfare policy and the positive labor market conditions during the welfare reform era, welfare caseloads have substantially decreased (Swartz, 2001). According to Brauner and Loprest (1999), from March 1994, which was the peak of welfare caseloads, to September 1998, the national caseload of welfare recipients decreased by 43 percent. Wisconsin's cash assistance caseload during this period, however, decreased by 89 percent, the highest in the nation. With its success in reducing the case load and assisting many recipients to obtain employment, Wisconsin is widely acknowledged as one of the first states to move recipients from a dependency on cash assistance to a perception of self-sufficiency, resulting from employment. While the data suggest an increase in workplace participation among former welfare recipients, there is emerging evidence that suggests that employment retention and advancement among post welfare participants are issues that need immediate attention in order to fully evaluate the success of welfare reform.

Review of Related Literature

While retention and advancement have been identified as areas that need immediate attention, we have little empirical data on the extent of the problem in Wisconsin and the degree to which W-2 reform activities are successfully addressing the issues. Several studies have investigated the status of families who left welfare (Brauner & Loprest, 1999; Loprest, 1999); some evaluation studies have looked into education and training as vehicles for promoting economic self-sufficiency and human capital development (Bell, 2000; Cohen, 1998; Smith, 1999); and other studies have examined the low-wage job market and how welfare recipients are faring in such markets (Kelleen & Nightingale, 2000; Holzer & Stoll, 2000).

Studies that utilized data sources from Wisconsin have observed that as Wisconsin's economy has continued to expand, employers have found welfare recipients increasingly attractive as employees. Although most former recipients are concentrated in jobs in low-skilled and low-wage sectors, and nearly one-third of former recipients in Milwaukee work through temporary agencies (Corbett & Weber, 2000), employers have hired former recipients, who in years past would not have been considered for employment. A recent survey of 750 employers reported by Holzer (2000) compared Milwaukee to three other metropolitan areas: Los Angeles, Chicago, and Cleveland. The study found that the average duration of employment for newly hired recipients was 8 months, although significant percentages left after just 3-4 months. It also found that Milwaukee was at the high end of...
having jobs available and in the percent of jobs fielded by recipients. However, larger percentages reported problems with absenteeism, often related to child care and transportation problems. In addition, Holzer (2000) observed that Milwaukee experienced greater problems with turnover and job performance, which was interpreted as an indication that employers were digging deeper into the pool of welfare recipients in Milwaukee than elsewhere.

Post-welfare reform work-first policies have identified the issue of working poverty. The mean hourly wages for welfare recipients nationally range between $6.94 and $7.83, and the hours worked per week range from 34.0 to 35.2 (Holzer, 2000). In 1997 the average earnings was between $10,000 to $12,000.00; less than the poverty level for a family of three (Brauner and Loprest, 1999). The low wages, high turnover, and difficulty in finding and maintaining permanent jobs have translated into high levels of economic anxiety and worry among some former recipients (Kelleen & Nightingale, 2000). Rangarajan (1998) summarized the problems of employment retention and notes,

> While many welfare recipients who find jobs are able to keep them, a significant minority have a hard time holding onto jobs and lose them fairly quickly. . . . Many welfare recipients' reasons for losing a job are complicated. Most find low paying jobs but still have to deal with the standard costs associated with work (such as affordable child care and transportation). Many must cope with a reduction in other forms of social support (such as housing subsidies, and, perhaps, food stamps, and medical benefits). Nearly one in three work nonstandard hours, making childcare and transportation arrangements more complex. Because they have little work experience, many welfare recipients have unrealistic work expectations and walk out of their jobs when these expectations are not met. Many have little in the way of personal and social support and find the transition from welfare to work overwhelming and stressful. (p. 3)

Given the time-limited assistance and strict work participation requirements under W-2, Wisconsin policy makers and program administrators are realizing that a "work first" approach is not simply concerned with placing welfare recipients in entry-level jobs. It is also concerned with developing effective programs and strategies that will assist former working recipients to keep their jobs, avoid returning to welfare, and advance in the labor market. Therefore, Wisconsin has included elements of retention and advancement in the W-2 program since its inception, in the form of case management services to low-income working families. These efforts are primarily the domain of W-2 agencies and the staff, particularly Financial and Employment Planners (FEPs). For these unsubsidized participants, W-2 agency staff represent the lifeline of opportunities to state-supported services and programs that can potentially assist them to retain or advance in employment.

Another approach to retention and advancement services was added to Wisconsin's mix of TANF-funded programs in 2000 with the implementation of the Workforce Attachment and Advancement program (WAA). In addition to targeting families who are transitioning from W-2 to employment, WAA serves the general low-income working population, and it has an innovative employer services component. WAA providers have the flexibility to meet local employers' needs for skilled employees by developing and providing a broad range of job-specific training and skills development services, e.g., job skills training, mentoring, job coaching, and support services. The WAA program was implemented in late 2000, and is administered by both W-2 agencies and Workforce Development Boards (WDBs).

This study sought the perspectives of both NV-2 agency representatives and employers in identifying the problems faced by post welfare recipients in the workplace and the problems and services that are effective in addressing these problems. Integrating the perspectives of employers provided a two pronged approach to understanding the issues regarding employment retention and advancement among low income workers with family responsibilities (LIWWFRs).

**Purpose of the Study and Research Questions**

In order to fully evaluate the success of Wisconsin's W-2 program in placing large segments of welfare recipients into employment, state policy makers, W-2 agencies, employers, and other stakeholders are compelled to address the twin issues of employment retention and advancement faced by former recipients. Results from several research and investigative reports (Governor's Wisconsin Works (W-2) Education and Training Committee report, 1998; The Lewin Group, 1999; Mills & Kazis, 1999) have suggested that moving recipients into the workforce is just one part of the solution to self-sufficiency. The conclusion drawn from many of these reports indicate that attention must be paid to the issues and problems that participants encounter as they make the transition from welfare and that strategies, solutions, and services must be put in place to address these problems and help participants retain employment and advance in the workplace. Therefore, this research project sought to map the terrain of problems and barriers to retention and advancement experienced by both unsubsidized participants and low income workers.
with family responsibilities (LIWWFRs) and chart the array and effectiveness of services and programs provided to both populations by W-2 agencies and employers.

The following research questions were used to guide our investigation:

- How do W-2 agency and employer representatives describe the barriers that inhibit employment retention and advancement among W-2 participants (or low-income workers with family responsibilities)?
- To what extent do these barriers impair participants’ ability to retain employment and advance in the workplace?
- What employment retention and advancement services and programs are provided by W-2 agencies and employers?
- To what extent do W-2 agency staff and employers believe that services provided are effective in promoting job retention and advancement among unsubsidized employed participants?

Research Design

The project employed a survey design for the collection of data. Telephone surveys were administered to appropriate W-2 agency representatives and employers. A “selection with probabilities proportional to size” (Jaeger, 1984) random sampling process was used to select the 76 Wisconsin Works (W-2) agencies that had at least one unsubsidized participant the year prior to the study. The agencies were stratified into four groups: agencies with fewer than 10 cases, those with 11 to 80 cases, those with 81 to 500 cases, and those with over 500 cases. We took a 33 percent sample from each of these strata. From these agencies, the sample of 69 agency staff was identified. All of the agency staff responsible for placing or retaining unsubsidized employed participants from each selected site were targeted for interviews. In instances in which this responsibility was shared by the majority of case managers in an agency, about one-third of these individuals were asked to participate in the study. A total of 98 individuals were asked to participate in the study and 69 were interviewed, for a participation rate of seventy percent. Each interview ranged from fifteen to forty minutes.

Interviewees for the employer survey were identified via the contact persons from each W-2 agency. These individuals were asked to identify three employers with whom they had placed participants in the past year. A total of seventy-seven employers were contacted, and 41 (i.e., Human Resources Directors, Managers, or Representatives; Staff Supervisors; and Personnel Specialists) were interviewed. Therefore the participation rate for employers was 53.25 percent. Each interview averaged about twenty minutes, but ranged from fifteen to forty minutes.

The data collection instruments were developed from several sources: existing Wisconsin Department of Workforce Development (DWD) and W-2 agency services and programs; services, programs, problems/issues and barriers identified by discussions with DWD agency personnel; a multi-state group of other state and local officials via a teleconference involving members of the Welfare Peer Assistance Network (WELPAN); and existing instruments that have been used in previous W-2 studies of FEPs and employers. Both instruments were pilot tested with three agency staff and three employers before the final instruments were employed in the study. Data from all telephone interviews were entered onto blank copies of the instrument and later transferred to an SPSS-PC data file.

Findings

Profile of W-2 Agency Staff, Employing Organizations, and Working W-2 Participants

The demographic profile of the sample suggests that the typical W2 agency personnel responsible for sustaining participants in the workforce is an experienced, White female, with less than a BS degree. The sample was comprised of a broad range of small and large employers who have hired former welfare recipients and established a cooperative relationship with W-2 agencies. The typical employer in this sample employed between 100 and 249 workers (26 to 50 of these would be LIWWFRs); is located about a tenth of a mile from a transit stop; operates from multiple sites; recruits employees via newspaper ads and state W-2 agencies; screens applicants via personal interviews and takes these seriously in the hiring process; does not require applicants to take tests; and hired between 11 and 100 employees during the past twelve months. These employers did not consider a high school diploma or previous experience a necessary condition of employment, and only mildly preferred skills training or certification. They do require employees who have the ability to exercise personal initiative, use sound judgment, and demonstrate critical listening skills. They paid LIWWFRs a starting salary that ranged between $7.40 and $8.80 per hour. The majority of LIWWFRs hired by these employers were White women who work for forty or more hours per week and had some previous job experience. The majority of these employees work “fixed schedules,” in non-seasonal jobs, and do not receive tips, commissions, or participate in profit sharing to supplement...
their salaries. However, they do have access to company-sponsored health insurance. Qualitative data reveal that employees do not often participate in employer-sponsored health care programs because the high cost of these programs make them unaffordable to these low-income workers. The study also found that few of the low-income workers were promoted during the last two years, but most received raises in the past year.

The majority of W-2 agency staff indicated that either half or more than half of their unsubsidized participants had been separated from employment in the last year. Also, nearly two-thirds of them indicated that either half or more than half of their unsubsidized cases had been terminated from employment for "cause." The employers similarly experienced some turnover among LIWWFRs, with fewer than forty percent of employers retaining all or more than half of their LIWWFRs after two years. Employers indicated that about fifteen percent of those leaving their firms were terminated for cause. The high level of turnover among this group of workers suggests that there are serious barriers to their retention in the work place.

**Employment Retention and Advancement Barriers**

Unsubsidized participants face several significant barriers to their efforts to retain employment and advance in the workforce. The importance of barriers can be measured in the power of their inhibitory effect and in the number of participants affected. Each respondent rated (on a 5.0 point scale) the extent to which these barriers were problematic in participants' employment retention or advancement efforts and they rated (on a 5.0 point scale) the proportion of participants affected. These barriers were categorized as the following: Situational Barriers, Education and Learning Experience Barriers, Personal Issues, and Disabilities.

**Situational Barriers.** Of all four categories, situational barriers produced the highest collective mean score (4.00 on a 5.0 scale; indicating "quite problematic") in the order of their inhibitory effect. Situational barriers represented those survey items that addressed the extent to which participants experienced several possible situational problems that might inhibit their ability to maintain employment. These barriers include problems with child care, problems with transportation, housing instability, care for a child or adult with disabilities, and being victimized by crimes. In terms of the proportion of participants affected by these barriers, the items produced a collective mean score of 2.58 (on a 5.0 scale) which indicates that W-2 agency staff believed nearly one-half of the unsubsidized employed participants in their caseloads were affected by them.

**Education and Learning Experience Barriers.** Education and learning experience barriers represent the extent to which W-2 agency staff believed participants experienced employment barriers due to the absence of skills, attitudes and experiences assumed to be required in the workplace. This category received the second highest collective mean score of 3.69, on a 5.0 scale (indicating "quite problematic") in terms of inhibitory effect, and the highest mean score of 2.63 on a 5.0 scale, indicating about one-half of the participants are affected by these barriers. Verbal English language, written English language, math, and human interpersonal relationships skills, a lack of motivation to work, and being a non-English speaking immigrant were **Education and Learning Experience Barriers** that were found to inhibit retention and advancement in the workplace.

**Personal Issues.** The survey items categorized as personal issues represent those items which addressed participants' negative interpersonal interactions, behaviors, and actions that might pose impediments to their employment retention and advancement efforts. These items explored the issues of substance abuse, domestic abuse, and being charged with criminal behavior. Collectively, "personal issues" produced the third highest mean score of 3.63 on a 5.0 scale, indicating they were "quite problematic" in terms of inhibitory effect, and 2.45 on a 5.0 scale, indicating less than half of the participants are affected by these barriers. Of the personal barriers identified, **Substance Abuse** was rated the highest (4.26 on a five point scale) indicating it was thought to be "quite problematic" and was perceived to affect about one-half of the participants served (2.68 on a 5 point scale). **Domestic Abuse (violence)** was also found to be quite problematic (a rating of 3.88) and affected close to one-half of the participants (a rating of 2.49). Being charged with a crime was was found to be somewhat problematic (a rating of 3.37) and affected less than half of the people served (a rating of 2.25). About one-fourth of respondents indicated problems with personal issues affected either "about half or more than half" of their unsubsidized employed cases.

**Disabilities.** Three items explored the extent to which participants experienced the following types of disabilities: mental, learning, and physical. Problems with disabilities were found to affect less than one-half of unsubsidized employed participants (2.43 on a 5 point scale) and were found to produce the lowest collective mean score in terms of inhibitory effect (i.e., 3.55 on a 5.0 scale) indicating them to be somewhat to quite problematic. Agency staff perceived **Mental Disabilities** to be quite problematic (a rating of 3.86 on a five point scale) and were thought to affect about half of the participants served. Learning disabilities were also found to be quite problematic (a mean rating of 3.61) and affected over one-half of the caseload. **Physical Disabilities** were also found to be somewhat problematic (a rating of 3.25) and affected less than half of the employed participants.
Support Services. Support services comprised of eight services that form the core of the safety net provided directly by W-2 agencies and include child care assistance, job loans, placement services, food stamps, transportation assistance, Medicaid, emergency assistance, and job retention bonuses. All W-2 agencies are legally required to provide Child Care Assistance. Therefore, all (100%) of the staff interviewed indicated this service is available through their W-2 agencies. Similarly, nearly all of the respondents (i.e., 99%) indicated their agencies provided both Job Access Loans and Placement Services. An equal number of respondents (i.e., 96%) indicated their agencies provided Food Stamps, some form of Transportation Assistance, and health care assistance via Medicaid and/or BadgerCare. About ninety-three percent of respondents indicated that Emergency Assistance was provided, and fewer than half (46%) indicated that Job Retention Bonuses (or rewards) were provided to participants.

Collectively, these support services received the highest effectiveness ratings (i.e., 3.81 on a 5 point scale), indicating that they were quite effective in assisting unsubsidized employed participants to retain employment and advance in their jobs. They were also the highest rated (3.92 on a 5 point scale) in terms of the proportion of participants with whom staff members discussed the availability of these services. Child care assistance was rated the most effective (4.52 on a 5 point scale) indicating it was perceived as a valuable resource in employment retention and advancement among post-welfare employed recipients. Transportation assistance (with a rating of 4.14), Medicaid (with a rating of 4.12), placement services (with a rating of 3.64), and food stamps (with a rating of 3.55) were all perceived to be “quite effective.” The remaining support services, i.e., job loans (3.44), emergency assistance (3.32), and job retention rewards or bonuses (3.23), were perceived to be somewhat effective.

Educational and Learning Programs. This category was comprised of five types of educational programs that are provided directly by W-2 agencies or provided by contract agencies. These included Soft Skills Training, Employment Skills Training, Educational Programs (e.g., GED, basic skills, ESL, etc.), Financial Assistance for Postsecondary Education, and Mentoring Programs for participants. Soft Skills Training was rated as the most frequently offered (i.e., 94.2%) educational program provided by W-2 agencies. However, both Employment Skills Training and Educational Programs were rated as a tie for second by 81 percent of respondents. Financial Assistance for Postsecondary Education (FAPSE) was rated by 68 percent of respondents as being offered by their agencies, and fifty-five percent of the respondents indicated their W-2 agencies offer Mentoring Programs. Training Completion Bonuses were provided by the smallest number of providers, i.e., 8 (or 12%).

Collectively, these educational and learning programs and services received the second highest effectiveness ratings (i.e., 3.57 on a 5 point scale) indicating that they were quite effective in keeping post-welfare recipients in the workplace. They were also found to be discussed with at least one-half of the participants served. Employment skills training (with a mean rating of 3.91), educational programs (with a mean rating of 3.76), soft skills training (with a mean rating of 3.60), and financial assistance for postsecondary education (with a mean rating of 3.55) were all perceived to be “quite effective” in assisting employed unsubsidized participants to retain employment and advance in their jobs. In contrast, mentoring programs (with a mean rating of 3.19) and training bonuses to participants (with a mean rating of 3.00) were perceived to be somewhat effective.

Employer Intervention Services. This research queried eight types of employer intervention services and activities that are provided under the Workforce Attachment and Advancement (WAA) program and provided directly by W-2 agencies. These activities are directed at the employer, to provide on-site interventions with the employer on behalf of low-income workers and to facilitate the resolution of job retention and advancement barriers. Employers indicated the following intervention services and activities are provided by W-2 agencies: assistance with placement, assistance with work-site mentoring, training assistance, assistance with needs, outreach and marketing assistance, upward mobility programs, and payment for workshop attendance.

A total of 78 percent of the W-2 staff indicated Employer Assistance With Placement was provided by their W-2 agencies, and 71 percent indicated Employer Assistance With Work Site Mentoring and Coaching was provided.
Collectively, these services received the third highest effectiveness ratings (i.e., 3.50 on a 5 point scale) which suggest that they are quite effective in employment retention. These services included outreach and marketing (with a rating of 3.86), employer subsidized workshops (with a rating of 3.67), assistance with needs assessment (with a rating of 3.63), placement assistance (with a rating of 3.55), assistance with mentoring programs (with a rating of 3.55), and providing training assistance to employers (with a rating of 3.55) were all rated in the "quite effective" range. The remaining services, upward mobility programs (3.44) and training programs targeting employers (3.26) were rated in the "somewhat effective" range.

Employer Perceived Problems and Barriers of LIWWFRs

Collectively, these problems were identified by employers as being more likely or less likely to experience problems identified by the agency representatives: absenteeism or tardiness, illness, domestic abuse, charged with criminal behavior, and substance abuse. Collectively, this category of problems received the second highest mean rating from employers, i.e., 2.34 on a four point scale, indicating these problems were treated as being "somewhat more likely" to experience these problems than other workers. Poor interpersonal skills and work attitudes, and problems either not attending training or failure to apply training knowledge were rated in the range of 2.54 to 3.08 indicating LIWWFRs were "a little more likely" to experience these problems than other workers. Poor interpersonal skills and work attitudes, and problems either not attending training or failure to apply training knowledge were rated in the range of 1.65 to 2.36 indicating LIWWFRs were "a little likely" to experience such problems.

Personal Issues. This category is comprised of statements that deal with the perceived personal conduct of employees. Six items gauged the extent LIWWFRs experienced problems with personal issues: absenteeism or tardiness, illness, domestic abuse, charged with criminal behavior, and substance abuse. Collectively, this category received the second highest mean rating from employers, i.e., 2.34 on a four point scale, indicating these problems were "a little likely" to experience such problems.

Conclusions and recommendations

This study investigated the extent to which unsubsidized former welfare recipients who were still under case management with W-2 agencies experienced barriers in their efforts to retain employment and advance in the workforce. Additionally, we explored the types of services and programs W-2 agencies made available as strategic initiatives to counter-balance the barriers faced by participants. A third element of the study was to investigate the perspectives of employers regarding the workplace barriers and retention and advancement strategies they employed to promote the retention and advancement of Low Income Workers With Family Responsibilities (LIWWFRs). Several patterns emerged from the two data sources.

W-2 employed participants, a subset of LIWWFRs, face several significant barriers to their efforts to retain employment and advance in the workforce. W-2 staff and employers both felt that the barriers of child care and transportation problems and poor math and written English skills inhibit the ability of unsubsidized participants and
LIWWFRs to retain employment and advancement in the workforce. Because of the low academic skills requirement of employers for many of the jobs performed by this group of workers, it was found that many participants could qualify for low income, entry-level jobs. However, the skills requirement necessary for advancing in the workplace suggests that many of them could benefit from a variety of training and educational opportunities. The fixed schedules of many of the LIWWFRs would allow these individuals to schedule either employment-based or other continuing education programs that could improve their academic qualifications. W-2 agencies should try to develop more collaborative relationships with employers and other program providers in addressing these barriers. For example, a variety of context-based workplace literacy programs could be arranged via cooperative arrangements with individual employers, literacy program providers, and W-2 agencies.

Employers and W-2 agency staff have a high level of confidence in mentoring programs, especially worksite mentoring. Seventy-one percent of agency staff provide the service to employers and rated it as quite effective. Similarly, employers also rated that service to be quite effective. However, only 22 percent of employers participated in these programs. Given the level of confidence expressed by both employers and W-2 agency staff in the effectiveness of worksite mentoring and coaching, these programs should be expanded to a much broader range of employers. The prospect of making WAA programs more available to employers and assisting them with basic skills training should be pursued by W-2 agencies. Also, because of the confidence in the effectiveness of on-site child care and childcare subsidy in employment retention, we recommend that there should be an investigation to determine how these programs could be effectively expanded to increase numbers of employers.

This research is significant to the field of HRD as it provides employers and HRD professionals with insights into the barriers that inhibit employment retention and advancement of low-income workers with family responsibilities in the workplace and the services that are perceived to be effective in combating these problems. With this knowledge, organizational leaders and those responsible for training and development can plan and implement programs and services to increase the retention and advancement rate among this group of workers.

Multi-Source Feedback Appraisal In Two Types Of Organizational Structures: How Self, Supervisor and Other Ratings Differ

Karen K. Yarrish
Keystone College

Judith A. Kolb
Pennsylvania State University

The purpose of this study was to investigate the differences in a multi-source feedback appraisal between employee evaluation ratings of self, supervisor, and other in two different types of organizational structures. One hundred and eighteen nurse aides participated in the study. The findings indicate greater variability in the ratings of the group in which ratees work off-site.

Keywords: Performance Appraisal, Performance Feedback, Self-Evaluation

It has been clear for many years that performance appraisals don’t live up to expectations. They are not supported by top management, supervisors don’t like doing them, and employees don’t like having them done. Research suggests that supervisors don’t like doing performance evaluations because they find it distasteful to criticize subordinates, they aren’t trained to conduct performance evaluations, and they don’t trust the validity of the evaluation instrument (Beer & Ruh, 1990; McGregor 1990). Supervisors, in general, prefer to deliver positive performance ratings. (Herold & Parsons, 1985; Judge & Ferris, 1993).

Another factor in the continuing dissatisfaction with performance appraisal is the changing nature of jobs and organizations. In the past 10 years, there has been a decided shift in the structure of organizations (Waldman & Atwater, 1998). Greater emphasis is being placed on decentralization, downsizing, teams, and telecommuting. The current workforce is organized differently and is not always even located geographically together (Buhler, 1997). This change impacts the degree of close supervision and the development of the relationship between the ratee and the rater in the performance appraisal process. These differences in the U.S. workforce have created enormous challenges to management and to HR/HRD professionals who are responsible for developing, implementing, and assessing systems to measure performance and provide feedback to employees at all levels and locations.

These new types of working environments are referred to as "loosely coupled" (Weick, 1976). Such systems contain parts that are related to each other but still retain their individual identity and logical or physical separateness. A tightly coupled system is the traditional work situation in which a supervisor works closely with subordinates and supervises their work on a regular basis.

The traditional hierarchical performance appraisal system is not viewed as effective and does not favor the current work environment (Waldman & Atwater, 1998). Because of the continued level of dissatisfaction with performance appraisal and the fact that jobs have greater responsibility, more flexibility, and less direct supervision, organizations have moved toward using alternatives to the traditional, hierarchic, supervisor-controlled performance evaluation process. One such alternative is a multiple source or 360-degree performance appraisal process (Milliman, Zawacki, Norman, Powell, & Kirksey, 1994; Tornow, 1993). Whereas traditional performance evaluation systems provide feedback only from the employee’s supervisor, 360-degree systems also include feedback from peers, subordinates, and customers. Each of these sources provides relevant, and slightly different, information that is valuable to the employee (Borman, 1991; Hazucha, Hezlett, & Schneider, 1993).

Several researchers (Church & Bracken, 1997; Funderburg & Levy, 1997; Lawler, 1967; London & Smither 1995; London, Smither & Adsit, 1997; Salam, Cox, & Sims, 1997; Tornow, 1993; Waldman, 1997; Westerman & Rosse, 1997) have examined variables related to multi-source/360-degree feedback including such issues as accountability, perceptions, and rater attitudes. Additional studies have been conducted to examine ratee acceptance of various forms of performance appraisals (Albright & Levy, 1995; Bernardin & Buckley, 1979; Bernardin, Dahmus & Redmon 1993; Gosselin, Werner & Halle 1997; Robinson, Fink, & Allen, 1996). This focus on ratee acceptance has its genesis in the work of early motivational researchers such as Herzberg (1959) and Lickert (1967), who found that employee recognition, achievement, and employee satisfaction in decision making all led to increased levels of motivation and satisfaction in employees.

As organizations increasingly turn to multi-source or 360-degree performance evaluation processes as a means of improving the process, interest becomes focused on how the ratings among self, supervisor, and other may differ. With the exception of studies examining manager/subordinate agreement in leadership competency ratings (Atwater, Roush, & Fischthal, 1995; Smither, London, et al., 1995; Waldman & Atwater, 2001), little research has been conducted in this area.

Self-Appraisal

A number of studies have examined the self-appraisal piece of the multi-source or 360-degree performance appraisal process. These studies have concluded that self raters with higher self-esteem rated themselves with greater leniency than did those raters with low self-esteem (Farh & Dobbins, 1989), self rater appraisals are significantly related to appraisals from co-workers and are less influenced by the halo effect than appraisals from outside raters, (Fox & Dinur, 1988), self rater appraisals produce significantly lesser leniency error and more congruent ratings with supervisors when instructions referencing supervisory feedback are used (Steel & Ovalle, 1984), self raters differ significantly from others in their evaluation of communication behavior (Sypher & Sypher, 1984), and self raters in comparison to the other raters show greater leniency bias and less variability while exhibiting less of the halo effect (Thornton, 1980). There is a greater difference between ratings of supervisors and self than between ratings of co-workers and supervisors (Harris & Schaubroeck, 1988), and research continues to be conducted in the areas of biases and validity of self-appraisal of job performance and biases of self evaluation (Thornton, 1980).

Self-ratings of performance often differ from performance ratings by external evaluators (Fox & Dunur, 1988; Thornton, 1980). Self-appraisals of performance tend to be more lenient, more biased, and less variable than superior, peer, or subordinate appraisals (Thornton, 1980). Harris and Schaubroeck (1988) reported only moderate correlations between self-ratings by employees and ratings by others.

Self-assessments serve a variety of purposes. Participating in the appraisal process may make one more self-aware, more accepting of feedback, and more committed to goals and performance improvement. Also, an individual may be the only one who fully understands the forces operating to influence his or her behavior (Kolb, 1995, p.234).

However, little research has examined correlation between self and others in different types of organizational structures. Given the popularity of multi-source appraisal systems and the variety of ways in which today's organizations are organized, it seems important to collect data in different types of organizational structures. The study described here investigates the differences that exist between employee evaluation ratings of self, supervisor, and other in both tightly coupled and loosely coupled environments.

Research Question

What differences exist between employee evaluation ratings of self, supervisor, and other in tightly coupled environments and employee evaluation ratings of same in loosely coupled environments?

Methodology

Sample

Sixty-one home health care aides and 57 nurse aides from a 2200-person allied health facility located in northeastern Pennsylvania participated in this survey. The home health care aides, who are not closely supervised, represented the loosely coupled structure; the nurse aides, who receive direct supervision, represented the tightly coupled structure. The majority of the participants were in the 33 to 62 years of age category and had a high school/GED level of education. The participants had a mean of 7.46 years at their current position and a mean of 6.6 years employed by the allied health facility. There were no significant differences in demographic characteristics between the two groups.

Procedures

Raters' responses were compared to the evaluation of the ratee. Data were collected using a performance appraisal form that was developed by a focus group made up of the Vice President of Human Resources, the supervisors of both the tightly coupled and loosely coupled groups, a representative employee from each of the
groups, and the researcher. The two groups, loosely coupled and tightly coupled, participated in a multi-source performance appraisal process evaluating themselves and others in their department. The newly developed performance appraisal form used was developed by using a set of behavioral criteria developed specifically to meet the objectives and goals of the allied health facility. These behavioral criteria were directly linked to the individual's job description. Each employee participating in the research was trained on the procedures to use in providing and receiving feedback. Each ratee was evaluated by self, supervisor, and one other person familiar with his or her work. After participating, each ratee received feedback for each performance criteria evaluated. Ratees could not conduct reciprocal appraisals. This rule was established to rule out the bargaining of exchanging good evaluations between the two individuals.

Data were collected from the performance rating forms used by the participants in the study. The ratings from each of the various categories, self, supervisor, and other were sorted and analyzed.

Surveys

Data were collected using a Likert-style performance appraisal form. The behavioral criteria were directly linked to the individual's job description. Examples of sample criteria include: Demonstrates good judgment in all phases of work, Shows initiative by helping others when slow, Attends in-service education and reads reports, and Reports to work on time. Each employee participating in the research was trained on the procedures to use in providing and receiving feedback.

Focus groups

Information regarding the development of the performance appraisal instrument was collected in small focus groups. These focus groups were made up of the supervisors of both sets of employees being surveyed, the VP of Human Resources, one employee from each group, and the researcher. The purpose of the group was to develop an effective performance evaluation tool. Involving participants in the creation of a performance management system increases the likelihood of acceptance of the system (Mohrman, Resnick-West, & Lawler, 1990).

Limitations

The sample used in this study was representative of only one type of loosely coupled and one type of tightly coupled system in an allied health organization. Caution needs to be exercised in generalizing the results of this study to other organizations. Also, subjects in this study were in non-exempt or non-managerial positions. Data collected on managerial-level employees may yield different results.

Because the participants in this study worked in two different structures, their job titles and job duties were slightly different. This resulted in the use of different performance evaluation forms; however, both groups' forms were developed by the same focus group with input from supervisors and representatives from both the loosely coupled and the tightly coupled groups.

Results and Findings

Paired Test results for each of the headings-self/supervisor, self/other, supervisor/other-for the tightly coupled group are presented in Table 1.

**p< .01, *** p<.001

There were significant differences in a total of thirteen questions for the loosely coupled group: four in self/supervisor, one in self/other, and eight in supervisor/other.

Conclusions and Recommendations

There were no significant differences in the tightly coupled group in the categories of self/other and supervisor/other, indicating agreement between the ratings of the ratee and others and the supervisor and others. There was only one significant difference in the category of self/supervisor, indicating that overall the ratee agreed with the rating of his/her supervisor. This is somewhat surprising considering that self-ratings, in general, tend to be higher than ratings by others. This shared perception of employee performance in the tightly coupled group is encouraging and deserves further study.

There were thirteen significant differences in the loosely coupled group: four in self/supervisor, one in self/other, and eight in supervisor/other. These results suggest that, in loosely coupled groups, the physical distance between an employee and his/her supervisor might result in less supervisor awareness of employee performance. Multi-rater feedback might be particularly useful in situations in which employees work offsite.

Implications for HRD

Organizations are continually searching for improved methods of providing performance feedback. In addition, today’s rapidly changing organizational environment requires HRD professionals to develop systems that address the increased distance between supervisors and their direct reports. Because organizational structures have been changing so quickly, organizations have had a difficult time trying to provide accurate feedback to employees in a format that is accurate and helpful to the ratee. An important finding in this study was that individuals in a loosely coupled system did not always agree with the ratings of their supervisors and that supervisors ratings were not consistent with the other raters evaluating the performance of the ratee. This finding supports the use of multi-source or 360-degree performance evaluation systems in this type of organizational structure.
Another important finding in this study was that the tightly coupled group's results indicate a fairly consistent level of agreement with the ratings of the supervisor. Supervisors contemplating the use of multi-source feedback systems have expressed concerns about inconsistency of ratings. (Yarrish & Kolb, 2001). As this study reports, greater inconsistency was found among ratings in the loosely coupled group. Further studies are needed to determine whether this finding is replicated in other samples and, if so, implications for the use of multi-rater systems.

As more organizations continue to move away from the traditional hierarchical structure, more information is needed on finding cost-effective methods of providing valuable performance feedback to employees. Studies conducted in organizations regarding the effectiveness of various feedback processes would be useful for HRD professionals facing decisions on the choice and implementation of such systems. Continued empirical studies should provide information helpful to organizations facing important and expensive performance feedback systems decisions.

Career Related Competencies

Marinka A.C.T. Kuijpers
University of Twente, The Netherlands

This study will outline the changing nature of careers in the workplace, and trace the development of an instrument for identifying and measuring competencies for goal and value achievement. The relationship between competencies, personal factors, and career success has been studied amongst 1584 employees (51.5% response) in 16 Dutch companies. The outcome of this analysis will be presented.

Keywords: Career Development, Career Development Competencies, Career Actualization

In research and practice of Human Resource Development there is a growing emphasis on the personal responsibility of the employee for his or her career development. This is related to the idea that careers are becoming more unpredictable and boundary less (Defillippi. & Arthur, 1996). This results into the question which competencies are required to reach goals and values in the career. In this paper results are presented on the following research questions:

- Which competencies for career development can be distinguished?
- What is the relation between career development and the personal factors (gender, career phase and position)?
- What is the correlation between career development and career success?

This study is part of a PhD project about a career development model.

Career Development and its Competencies: Some Theoretical Foundations

It seems that you can not read an article, paper or dissertation on Human Resource Development which doesn’t elaborate on the changes of labor and labor market, and its consequences. These changes mark the transition from the industrial to the post-industrial society (Meijers, 1995) and have resulted in the knowledge economy, that can be characterized by increasing market forces, innovation, career mobility and competition for which fast and permanent learning is essential (Thijssen, 1995). Careers have become more unpredictable and boundary less (Defillippi. & Arthur, 1996). Because of this development, in the last decade the career of a person’s professional life has been emphasized. Hall & Mirvis (1995) state that in the past mainly the employers felt responsible for the career development of the employee, but that ‘career ownership’ defines a new meaning in the future, because organizations will not be able to meaningfully plan a person’s career due to developmental sequences. This means that the individual is on his own in career development.

Career development can be understood in two ways (dictionary on development):

- as the magnitude of achieved growth; development of the career in time (consecutive jobs and education), a career path;
- as a process to accomplish growth; in the way of exert influence on one’s career path.

This study about career related competencies aims at the process of career development by the individual employee. Career development in this way is not a onetime choice for a profession or job, but a continuing process to realize goals and values in work within the possibilities of and in dialogue with the environment. In this study the word career actualization is introduced. Career actualization results in taking initiatives for and acquisition of work experiences, learning experiences and network contacts based on present and developing capacities and motivation within the possibilities of the environment.

Obviously career paths are influenced by many external factors, like labor market opportunities and professional and private circumstances (Onstenk 1995; Kidd, 1996). Furthermore, personal factors like gender, previous education and age are proven to effect the way career paths develop (Nijhof, Mulder & Streumer, 1994; Woodd, 2000). Whether or not one’s career path and therefore career success can be influenced by competencies needs to be examined.

Although quite some research has been performed on (factor related to) de development of career paths (see Meijers, 1995), there is little empirical based insight on ability and behavior to exert influence on one’s career development.

Copyright © 2002 Marinka A. C. T Kuijpers
In literature three kinds of competencies are mentioned to be related to the development of employees' career paths:

- Working competencies: competencies to perform in a specific work situation or competencies for different work situations in different time periods (Onstenk, 1998; Thijssen 1997);
- Learning competencies: competencies to develop working competencies (Kessels, 1998; Thijssen, 1997; Min OC&W, 1997);
- Career related competencies: competencies to manage working and learning competencies within the personal career path. Career related competencies would be important for goal-centered career development. (Meijers, 1998; Thijssen, 1997; Carson, 1995; Hall & Mirvis 1995).

Working competencies, learning competencies as well as career related competencies affect the course of the career path. They act upon possibilities and impediments a person meets during his or her career. From the perspective that a certain extent of self control in the career is possible or even recommendable, work exceeding competencies could be of importance to develop and apply effective working competencies. These competencies are called career related competencies.

In this paper career related competencies will be interpreted as clusters of ability, behavior and motivation related to a specific subject of career actualization. Career related competencies can be distinguished from working competencies because they exceed the level of specific work, they are meta competencies. A 'boundary less career' requires according to Carson (1995) meta skills instead of job related competencies to select and accept in different settings. Meijers (1998) assumes that the core of the employability is not formed through specialized knowledge, but through the competency of getting insight of personal live values and work that fits these values.

Results of literature survey indicate that there are four career development competencies (process definition) (Kuijpers, 2000a, b):

- Self reflection: the competency to reflect upon personal capacities and motivations regarding the career.
- Work exploration: the competency to explore the labor market and specific work environment for suitable work activities and mobility prospect;
- Career control: the competency to plan and act upon one's own learning and working process;
- Self presentation: the competency to show and discuss one's capacities and values regarding work increasing the choices in career development.

Self Reflection
Self reflection, self research (Mensink, 1994) and self concept clarification (Taborsky & de Grauw, 1974) are central terms in research on career development and career services. Skills to reflect systematically on experiences are fundamental from the perspective of a changing labor market according to Kidd (1996). Career related research and practice, that focuses on matching persons with work requirements, puts emphasis on reflection on capacities. Meijers (1995) finds this cognitive method of approach too limited and pleads for emphasis on reflection on life values. Insight in one's motives and values in work are related to the meaning and identity of a person (Defilippi & Arthur, 1996) and is needed to be able to reach high performances.

Work Exploration
Acquire information on work related issues has been valued as being essential in career development. Gathering of information about work should be based on one's capacities and motivation. Information acquisition can take place on the different levels; information about work on the labor market, in a specific organization or on work activities. It handles content and development of work (Reynaert & Spijkerman, 1995; Meijers & Wijers, 1997). Another aspect of work exploration is orientation on mobility: the opportunities, procedures and relevant sources for transition on the labor market and in specific organizations, relevant for the capacities and motivation of a person. Crites (1984) describes the importance of using the right sources to gain information for career development.

Career Control
Based on self reflection and work exploration one can have to some extend control on his own career. Career planning is often valued as being essential; setting long and short term goals, determine activities to achieve one's goals and evaluate the results (Hall, 1987; Reynaert and Spijkerman, 1995; Kidd 1996). Besides career planning, control of the learning process is of importance for career control (Onstenk, 1998). Activities of learning process control are for example: define and analyze learning questions, evaluate and obtain appropriate training and development activities.

Thirdly control of one's work process seems to influence career development. This indicates activities that affect the content of work in a way that work makes a better fit with one's capacities and motivation. Part of control of the work process is the balance of work and private life (Meijers, 1995; Defilippi & Arthur, 1996).
Self Presentation.

Career actualization will not be achieved by evaluation of self and work only. One should make clear to relevant others what one wants and is able to fulfill: verbal career promotion. Based on outcome of empirical studies Kidd (1996) emphasizes that negotiation regarding one's career is important in career development. Important factors are assertion of capacities, motivation and future career planning, together with the ability to obtain appropriate training facilities and gain support necessary for future career development. Next to the ability to express verbally the capacities and motivation is the actual performance on the job. One should perform well on those specific tasks that signify future career wishes. Another important factor of career development in a dynamic job-market and a dynamic organization is one's networking skills, the so called 'knowing whom' competencies (Defilippi en Arthur, 1996) for extending ones career relevant network. A career relevant network is the source of career related information and increases one's position on the job-market.

These four competencies are used to study career actualization and its relation to the personal factors: gender, career phase and working position, and career success. In the next paragraph, the instrument development to measure career related competencies, the instrument and subjects involved in the main study, and the analyses will be outlined.

Methods

Instrument Development

The process of the development of an instrument for the measurement of career related competencies started with a study to clarify the important components. A literature survey combined with nine in-depth-interviews with experts on career development in The Netherlands was carried out. Experts are defined as either scientific workers who study on this subject or people who worked for a long time in the field of career development. The interviews were analyzed with Atlas ti, a program for qualitative analysis of textual data. The text was coded, dimensions and indicators were formulated. This resulted in the division of four competencies. Based on the indicators derived from the interview texts with experts items were formulated. The questionnaire was presented to employees, researchers, methodologists and linguistic experts for advise on improvement.

For content validation five experts on career development, who were interviewed before and four experts who were not involved in the study before, were asked to evaluate the questionnaire. All nine confirmed that in general the questions measured the construct career related competencies. Furthermore four in-depth-interviews were held with experts by experience about the applicability of the distinguished competencies to their career paths. The initial developed questionnaire included 131 items to measure career related competencies. To be able to diminish the number of items and to get an indication of the reliability and homogeneity of the questionnaire, a pilot study was carried out under 197 employees (response of 42 %) from the IT and Educational sector. Based on homogeneity and reliability analyses the number of items were reduced from 131 to 69. Twelve clusters of items were formed. The four competencies were each divided in three aspects: ability, behavior and motivation.

Instrument

The questionnaire that was used in the survey consisted of 104 items of which 69 items measure career related competencies. Four competencies were divided in ability, behavior and motivation items. With regards to the ability items, the respondents were asked to judge their own ability on a Likert scales ranging from 1 (very low ability) to 5 (very high ability). On behavior items the respondents were asked to indicate to which extent he or she agreed with the given statement or how often he or she performs activities with regard to career development. On motivation items the respondents were asked to indicate the importance of a statement. Other aspects of the questionnaire are amongst others: personal factors like gender, age and working position and career success which is subdivided in career success from own perspective (5 items) and career success from others' perspective (5 items).

Subjects

The questionnaire was sent to 3092 employees in 16 Dutch companies from March to July this year. These companies were selected from a national database from the Association of Chambers of Commerce. 1598 Employees (52 %) returned the questionnaire. The response rate by the companies varied from 35 % to 75 %. The questionnaire was sent to employees working on high professional and academic level, with minimal one year of working experience and a minimal 20 working hours per week. The choice for the educational level was made because of the ability for reflection on ability, activities and motivation. In The Netherlands reflection on ones own performance is one of the aspect taught in college and academic education.
The group that returned the questionnaire consist of 69 percent male and 31 percent female employees. The average age of the respondents is 39.5. 23 Percent fits in the career phase before 30 years of age, 44 percent in the phase from 30 to 45 years and 33 percent in the phase above 45 years. As for positions 49 percent works in operational positions, 22 percent in a management position and 18 percent in staff positions of which 3 percent HRD/HRM positions.

**Analyses**
Firstly homogeneity analysis by Homals were performed. Reliability, ‘independent samples T test’ and ‘one way anova test’ are performed of which the results are described in the next paragraphs.

**Results**

**Reliability of Scales**
Career actualization was operationalized into four competencies. These competencies were divided in ability, behavior and motivation. Cronbach’s alphas of the used scales and the number of items per scale are shown in the following table:

<table>
<thead>
<tr>
<th>Career actualization</th>
<th>Ability (A)</th>
<th>Behavior (B)</th>
<th>Motivation (M)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Self reflection (C1)</td>
<td>.83 (17)</td>
<td>AC1 .69 (7)</td>
<td>BC1 .80 (8)</td>
</tr>
<tr>
<td>Work exploration (C2)</td>
<td>.80 (16)</td>
<td>AC2 .71 (6)</td>
<td>BC2 .71 (8)</td>
</tr>
<tr>
<td>Career control (C3)</td>
<td>.83 (20)</td>
<td>AC3 .72 (9)</td>
<td>BC3 .73 (9)</td>
</tr>
<tr>
<td>Self presentation (C4)</td>
<td>.84 (16)</td>
<td>AC4 .71 (7)</td>
<td>BC4 .71 (7)</td>
</tr>
</tbody>
</table>

Scales of career actualization, competencies and modalities are reliable. Subscales of the combination of competencies and modalities regarding ability and behavior are satisfactory. The subscales regarding motivation are low, because the number of items are few.

The scale ‘career success’ consist of 10 items, Cronbach’s alpha .75. Career success is subdivided in career success from own perspective (α: .73) and career success from others’ perspective (α: .44).

**Competencies for Career Actualization**
To understand which competencies are relevant for career development one needs to know to what extend employees value their career actualization, or: ability, behavior and motivation on self reflection, work exploration, career control and self presentation. Table 2 shows means and standard deviations of the four competencies, the three modalities and the total: career actualization.

<table>
<thead>
<tr>
<th>Competencies for Career Actualisation (n=1580)</th>
<th>M</th>

<td>1.55</td>
<td>.49</td>
</tr>
<tr>
<td>Behaviour</td>
<td>1.46</td>
<td>.50</td>
</tr>
<tr>
<td>Motivation</td>
<td>1.70</td>
<td>.72</td>
</tr>
<tr>
<td>Career actualization</td>
<td>1.53</td>
<td>.45</td>
</tr>
</tbody>
</table>
Employees, participants of this research, seem to be very motivated regarding career actualization. They evaluate their ability for career actualization higher than their behavior. It seems that employees mainly aim at self reflection and less on career control. Reflection on capacities (mean 1.64) mainly contributes to the high mean for self reflection. The lower score for career control is due to low means on career planning (1.41) and control on the learning process (1.43) and can not be attributed to the mean on control of the working process (1.51).

T- test results indicate a distinction between all competencies and their modalities on a significance level of .000, except the distinction between the competencies 'work exploration' and 'self presentation'.

To get more insight on the question of relevance of career related competencies, the question on the extend of relationships with personal factors and career success is studied. Gender, career phase and working position are the personal factors of which the results are presented here.

Career Actualization and Gender

The question is: To what extend differ male and female from aspects of career actualization? A T-test was performed on the grouping variable gender. The test variables were career actualization, the four competencies, the three modalities and combination scales of the last two (see table 1). The significant differences between the groups are shown in table 3.

</table>

The above indicates that women are more motivated in career actualization together with self reflection. Besides that they more motivated in work exploration but they do not regard their ability and behavior more enhanced in comparison with the male population.

Career Actualization and Career Phase

In this section is analyzed to what extent the career phase determines the motivation, ability and behavior regarding the career related competencies. The first phase includes the period from the beginning of the career till 30 years of age, the second from 30 to 45 years of age, the third from 45 years and above.

The results of the test show that young employees estimate their self reflection to a higher degree compared to other competencies and compared to employees in the second or third career phase. Young employees have high scores specifically on ability and behavior on self reflection, not so much on motivation for self reflection. On the other hand do they value motivation for work exploration and career control significantly higher than employees above 30 years of age. Also their behavior on work exploration is more extended than behavior of employees in other career phases. This is not the case for behavior on career control.

In general employees below 30 years indicate that they are more motivated and do more on career actualization. Employees above 45 years value their ability for career actualization more than employees below 45, in particular ability for career control. Although not in every case significantly, the means of the middle career phase is in general lower than means of the other phases.

Career Actualization and Position

The third personal variables that is included in the study of career actualization is the position of the employee on the workplace. Three types of positions are distinguished: management position, operational position and staff.
position. Specifically was asked for HRM and HRD officers as part of staff positions, because career development can be part of their job.

</tbody>
</table>

The results above indicate that managers find themselves more competent and operational workers are less competent in self presentation. Managers value their ability for career actualization in general more than employees in other positions, specifically for self presentation. Operational workers estimate their ability for self presentation less, but they also seem to be less motivated for self presentation.

Staff workers, including HRM and HRD officers, don't indicate that they are more motivated, able or active regarding career actualization than other workers.

Career Actualization and Career Success

An essential question regarding career actualization is whether or not career actualization correlates with career success, and more specifically to which extend competencies and modalities of career actualization covariate with career success. Career success can be valued by others or by one self. Career success is valued by others through (un)employment, level of work position in comparison with education, salary, application success, promotions and social appreciation for the work. Career success can be valued by one self in the extend one can use his/her talents in his/her work, the evaluation of the importance of the work and the success of the career path up to now, and the satisfaction about development in salary, in career and about balance between work and private life.

* correlation is significant at the 0.01 level

Career actualization in general is more related to career success from one's own perspective than to career success from others perspective. The evaluated ability for career actualization is most correlated to career success. The competency 'self presentation' is related to career success from the perspectives from self and others, 'career
control' more to career success by own perspective. The competencies 'self reflection' and 'work exploration' are less related to career success.

Conclusion

The competencies that can be distinguished at this stage of the study are: self reflection, work exploration, career control and self presentation. These competencies, formulated based on interviews with experts and employees, were recognized in the results of the survey. Modalities of competencies that were distinguished are: ability, behavior and motivation. The (sub)scales which were developed to measure career actualization are in general reliable. The competencies and modalities distinguish themselves from each other statistically significant except for the competencies 'work exploration' an 'self presentation'.

Employees involved in this study are well motivated for career actualization. They evaluate their motivation higher than their ability, and their ability higher than their behavior. Focussing on the content aspect of competencies of career actualization the results show that self reflection is more and career control is less used for career actualization.

Personal factors which were described in this paper are: gender, career phase and work position. Female employees evaluate self reflection and motivation for career actualization higher than male employees. Younger employees (below 30 years of age) estimate their selfreflection, behavior an motivation to a higher degree than the employees in a later career phase. They also indicate that they act more upon work exploration. Employees in the career phase above 45 year estimate themselves in a higher degree regarding the ability for career actualization. Regarding the working position of employees it appears that managers value their self presentation higher than their other competencies and than employees on other positions. Employees on operational positions value self presentation lower. They are also less motivated for self presentation. Managers estimate their ability for career actualization in general higher than employees on other positions.

The personal factors that differ between groups on content and modalities of career related competencies are shown in the figure below.

In this figure is shown which competencies and its modalities are related (correlation more than .20 at .001 significance level) to career success. Career success in general is related to the competency 'self presentation' an the modality 'ability'. Career success from others perspective is only relevant related to 'self presentation'. Career success from own perspective is related to career actualization in general and to 'career control', 'self presentation' and 'ability'. The competencies 'self reflection' and 'work exploration', and the modalities 'behavior' and motivation are less related to career success.

The figure shows that the competencies and modalities, which are regarded to be relevant for career actualization, relate differently to personal factors and career success. This indicates a distinction between competencies and modalities. More advanced analyses are needed to expand on the concept of career actualization.
Contribution of the Study to the HRD Field

Little empirical studies are performed regarding career development as a process. The PhD. study, of which some results are presented in this paper, intend to give more insight on the relation between personal and situational factors and career related competencies, and between career related competencies and career success and HRD interventions.

Project Management Competencies Needed by HRD Professionals: A Literature Review

Charlotte M. Nitardy
Gary N. McLean
University of Minnesota

Project Management is internationally recognized as a management tool that is critical for success in the current work environment. It has grown into a core competency that is recognized widely. This paper reviews the literature on project management competencies, especially as it relates to Human Resource Development. We identify competencies and training needs required of project managers operating in HRD contexts, along with proposals for further research.

Key words: Project Management, Competencies

In 1987, the American Society for Training and Development (ASTD) commissioned a competency development study for human resource development professionals (Gray, 1999). The study explored the competencies requested of prospective HRD practitioners by employers in areas of personal, business, and intellectual competencies. Project management was at the top for Business Competencies and in the top five of competencies deemed critical to the success of an HRD practitioner. Our review of the literature on project management competencies needed by HRD professionals found that project management was key in all of the competency literature.

Research Problem

Project management is a large field that has the potential for significant impact on the field of Human Resource Development. However, no research was identified that explored empirically the specific project management competencies required of HRD professionals. This paper addresses the question, What project management competencies are required by HRD professionals? This paper is the first step in a larger research project. In this paper, the literature around this question is summarized, with implications for HRD. It is the intent of the authors to follow up on this paper with a survey of HRD professionals to determine the priority of project management competencies needed by them and ways in which such competencies have been and can be developed.

The results may be used for planning by individuals, organizations, and educational institutions. Individuals may use the findings of this study to evaluate their knowledge and skills in project management. Organizations seeking individuals for HRD positions may apply the findings to their candidate search criteria. Educational institutions preparing HRD professionals may consider these data in the design, development, and evaluation of curriculum.

Specifically, do HRD professionals need project management competencies? And if so:
1. What are the most important project management areas for practicing HRD professionals?
2. Why are the areas selected by the experts the most important for practicing HRD professionals?
3. What level of project management preparation do practicing HRD professionals need in order to succeed in the field?

History of Project Management

Most of the literature on project management suggests that 1957 was the date of its birth (Devaux, 1999). From its conception, project management has been perceived as a scheduling tool—The Critical Path Method (CPM) in the construction industry is documented to have started in 1957, and Program Evaluation and Review Technique (PERT) used in some consulting companies is documented to have started the following year. Devaux concluded that project management techniques have worked with differing degrees of success, in different industries, different companies, and on different projects. Project management has grown and is now internationally recognized as a management tool that is critical for success in the current work environment (Dilworth, 2001).

Although projects have been used extensively in the construction, space exploration, and engineering fields, their application has spread to a host of industries (Crawford, 1998). Organizations have recognized the efficacy of projects to create cross-functional teams and to achieve rapid results within time and budget constraints. This has made project management a critical and powerful tool for the modern organization (Pinto & Kharbanda, 1996).
Competencies

Competencies are commonly considered by organizations to help guide human resource development and in making human resource management decisions. Many definitions of competence exist. Frame (1999) described competence as consistently producing the desired results. A competency can also be considered a group of related knowledge, skills, and attitudes that influences performance (Parry, 1996). Ayer and Duncan (1998) expanded the definition of competency to refer to a specific, observable behavior or characteristic that leads to superior performance. There is a strong tradition of behavior-based competency research by Boyatzis (1982), and Spencer and Spencer (1993) that adds to the concept of competency by including the individual's motives, traits, and self-image or social role.

Project Management

According to Devaux (1999), every project, no matter what the industry or work type, is a compromise among three variables: scope, time, and cost. Scope is the total amount of work to be conducted or the sum of activities that will lead to the deliverable or product. The cost is the budget or the total resource usage required to accomplish the work scope. Time is the total elapsed time, from concept to completion, that it takes to perform the work scope. Thus, a competent project manager will be able to manage all three factors. According to Verzuh (1999), setting realistic expectations, fostering agreement among all parties, and then delivering the product is frequently challenging and always requires a wide array of techniques. Managing these techniques effectively is also necessary for a project manager.

Project Management Competencies

Understanding project management competence is important in job evaluations, staff development, recruitment and selection, training needs analysis and planning, job descriptions, and assessments and appraisals. According to Frame (1999), individuals and organizations have begun to see that what is needed is an internationally recognized approach to assessing the project management competencies of project managers since several project initiatives rely on these competencies. The creation of Project Management Institute’s (PMI) U.S.-based, certification examination in 1984 was an attempt to fill this need for a more professional approach to competency verification. Shortly after, APM, the U.K.-based Association for Project Management began to test whether people met their project management standards. APM developed its own Body of Knowledge and launched its certification program in the early 1990s. APM felt that the then PMI PMBOK Guide did not adequately reflect the knowledge base that project management professionals needed. As described later, there is a considerable difference between these associations' bodies of knowledge.

Some have suggested that certification does not guarantee project success (Sattler & Neights, 1998). There is need to develop these skills in the context of individual work environments. One context in which little has been written on project management competencies is HRD. Also, little is known as to which competencies are correlated with project success. It does appear that a project participant does not need to acquire all possible project management competencies. Ayer and Duncan (1998) suggested that one may be missing some competencies and still be considered competent. They said that competency balance and alignment with both contingency variables and organizational project management maturity are ideal state conditions. Also, all of the research evidence (Cooper, 1993; Crawford, 2000; Morris & Hough, 1987) has shown that, in order to deliver successful projects, managing scope, time, cost, resources, quality, risk, procurement, and so forth, the PM BOK factors alone are not enough. Dinsmore (1984) outlined the attributes of a good project manager as shown in Table 1, below.

Project management bodies of knowledge (PMBOK) have been published by professional project management associations for 10 to 15 years (Morris, 2001). Not only do they provide standards against which the associations' certification programs are run, many practitioners and companies use them as best practice guides to what the discipline comprises.

However, as seen above, the fact that there are at least two quite different versions of the BOK--PMI's and APM's (IPMA's)--implies confusion at the highest level on what the philosophy and content of the profession are. Basically, the two models reflect different views of the discipline. PMI's model essentially is focused on the generic processes required to accomplish a project: on time, in budget, to scope. APM's reflects a wider view of the discipline, addressing both the context of project management and the technological, commercial, and general management issues that it believes are important to successfully accomplishing projects (Morris, 2001).
Table 1. Attributes of a Good Project Manager (Dinsmore, 1984):

1. Leadership
   - Clear direction and leadership
   - Participating in technical problem solving and decision making.
   - Clearly delineating goals and objectives.
   - Unifying team toward project goals.
   - Delegating.
   - Sound decision-making.

2. Technical Expertise
   - Understand the technologies involved in the design, development, production, and fielding of the project.
   - Understanding of applications, markets, and customer requirements.
   - Managing technology.
   - Assessing risks and trade-off.
   - Predicting technological trends.
   - Assisting in the problem solving.
   - Communicating effectively with technical team.

3. Human Skills
   - Building multi-disciplinary teams.
   - Involving and stimulating personnel.
   - Managing conflict.
   - Communicating both orally and in writing with all levels of personnel.
   - Fostering a work environment conducive to teamwork.
   - Involving senior management.

4. Administrative Skills
   - Project planning.
   - Resource negotiations.
   - Securing commitments.
   - Assuming measurable milestones.
   - Establishing operating procedures.
   - Establishing and maintaining reporting and review systems.
   - Establishing and managing project records.
   - Effective use of program management tools and techniques.
   - Effective manpower planning.

5. Organizational Skills
   - Understand how the organization works and how to work with the organization effectively.
   - Building multi-functional work teams.
   - Working effectively with senior management.
   - Understand organizational interfaces.
   - Setting up an effective project organization.

6. Entrepreneurial Skills
   - General management perspective.
   - Managing a project as a business
   - Meeting profit objectives.
   - Developing new and follow-on business.

Project Management Institute (PMI) Model

PMI, as first in the field with this initiative (Cook, 1977), established its first project management body of knowledge (BOK) in 1976. It was not until the mid-1980s that PMI's became the basis of its standards and certification program. The certification examination developed by PMI was designed to measure the knowledge-based competencies of project professionals (Frame, 1999). PMI identified nine basic functional competencies that project professionals should master, as shown in Figure 1.

Association for Project Management Model

APM's model, as seen in Table 2, was influenced strongly by research on what it takes to deliver successful projects (Morris & Hough, 1987). This research addressed the question of what the professional ethos is in project management. Is it to deliver projects "on time, in budget, to scope," as the traditional view has had it (Archibald, 1997; Meredith & Mantel, 1995), or is it to deliver projects successfully to the project customer/sponsor? In essence
it has to be the latter, because if it is not, project management is a profession that, in the long-term, business and industry is not going to get very excited about (Morris & Hough, 1987).

HRD Professional and Project Management Competencies Findings

Developing HRD professionals requires a theory of competencies about what HRD professionals must know and do and a development experience based on those competencies. Many of the competencies required to be a good project manager are also required to be a good HRD professional. Table 2 shows some parallels between the first five steps in an OD intervention (Rothwell, Sullivan, & McLean, 1995) and the PM BOK. There are many similarities.

Recent research has shown that it is the project manager who emerges as the single overriding factor which decides a project's success or failure (Zimmerer & Yasin, 1998; Sattler & Neights, 1998). As more organizations
move towards a project-based approach, the demand for project managers has outstripped supply and there is a growing international interest in the selection, training and certification of project managers (Stewart, 1995;

Table 3. Steps in OD Intervention Paralleled with PM BOK Process Groups and Competencies.

<table>
<thead>
<tr>
<th>Steps in OD Intervention</th>
<th>Brief Description from Rothwell et al.</th>
<th>PM BOK Process groups and competencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Entry</td>
<td>The need for change in an organization becomes apparent. A problem is discovered. Someone or groups of people in the organization look for a person who is capable of examining the problem or facilitating change.</td>
<td>Business problem/limitation is identified from a strategic plan.</td>
</tr>
<tr>
<td>2. Start-Up</td>
<td>The change agent enters the picture, working to clarify issues surrounding the problem and to gain commitment to a change effort. <strong>Elements of Start-up</strong></td>
<td>Project Initiation</td>
</tr>
<tr>
<td></td>
<td>- Identify the client and the sponsor(s)</td>
<td>- Identify stakeholders who will be reviewing and approving project deliverables, make decisions and move the project along, remove business, technical or project roadblocks.</td>
</tr>
<tr>
<td></td>
<td>- Becoming oriented to the clients’ world;</td>
<td>- Build partnership/trust with stakeholders – develop good working relationships</td>
</tr>
<tr>
<td></td>
<td>- Establishing consultant’s competence and credibility</td>
<td>Procurement planning</td>

</tr>
<tr>
<td></td>
<td>- Understanding organization’s political system;</td>
<td>Solicitation</td>
</tr>
<tr>
<td></td>
<td>- Contracting the work to be done</td>
<td>Staff acquisition</td>
</tr>
<tr>
<td>3. Assessment and Feedback</td>
<td>The change agent gathers information about the problem and gives decision-makers and those having a stake in the change process feedback about the information.</td>
<td>This process is hopefully not necessary in project management because the assumption is that needs assessment has already been completed and the nature of the project determined before the recruitment of a project manager.</td>
</tr>
<tr>
<td>4. Action Planning</td>
<td>The change agent works with decision-makers and stakeholders to develop a corrective action plan. <strong>Action planning steps:</strong></td>
<td>Plan</td>
</tr>
<tr>
<td></td>
<td>- Determine the client’s degree of choice about change</td>
<td>Scope Statement</td>
</tr>
<tr>
<td></td>
<td>- Determine what needs to be changed;</td>
<td>- Includes a statement of business need/limitation/opportunities.</td>
</tr>
<tr>
<td></td>
<td>- Determine where to intervene;</td>
<td>- Describes what is required as an outcome/project deliverables – objectives.</td>
</tr>
<tr>
<td></td>
<td>- Choose intervention technologies</td>
<td>- It is a contact between the project manager/team and its stakeholders</td>
</tr>
<tr>
<td></td>
<td><strong>Processes for developing plan:</strong></td>
<td>- It sets expectations of the project</td>
</tr>
<tr>
<td></td>
<td>- Activities should be linked to goals</td>
<td>- It describes the project’s scope and cost – estimating and scheduling</td>
</tr>
<tr>
<td></td>
<td>- Activities should be clearly identified rather than broadly generalized;</td>
<td>- It provides an ROI</td>
</tr>
<tr>
<td></td>
<td>- Discrete activities should be linked;</td>
<td>- Project activity sequencing</td>
</tr>
<tr>
<td></td>
<td>- Activities should be time sequenced;</td>
<td>- Disclose risks and how you plan to manage them</td>
</tr>
<tr>
<td></td>
<td>- Contingent plans should exist in</td>
<td>- Include business, technical and project assumptions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Communication plan</td>
</tr>
<tr>

Crawford, 1998). In order to accomplish the above eight steps of an OD intervention on time, within budget, and according to specs, an HRD professional would need to construct a work breakdown structure. According to Frame (1999), each profession has its tools, and mastery of the tools is one of the key goals of the professional. Below are some of the tools outlined by Frame (1999) that could be used in conjunction with these steps (Table 4).

Table 4. Project Management Tools That Could Benefit HRD Professionals

Next Steps in Research

Based on this review, we propose that the following be undertaken as research projects:

1. Using the project management competencies identified in this review, determine the project management competencies that are adjudged to be necessary for HRD practitioners and assess the principal training needs in project management for HRD professionals by establishing the gap between the level of importance of each competency and the perceived level of expertise that exists for each one among practitioners through a survey of HRD professionals and managers.

2. Through a survey of HRD academics, collect data on the extent to which project management competencies are provided in academic programs.

3. Conduct a case study of companies currently using project management competencies within their human resource development areas.

Conclusion

Skills, knowledge, and attitudes form the foundation of competence. While there is little literature yet identified, it appears that HRD professionals require project management competencies. However, achieving competency is not an end to be achieved, rather it is a road to be traveled. To be effective, one needs to develop continually new competencies in an environment that is continually changing. Academic programs and HRD professionals both have
a responsibility to insure that HRD practitioners have such competencies. To do this effectively, much more information is needed. Thus, there is a need to determine the existing level of competency of HRD practitioners, the importance of the various project management competencies for HRD, the extent to which academic programs provide these competencies, and what more is yet needed in training and in academic programs.

Implications for HRD

It is not yet clear what the implications are for HRD. Much more research is needed before it is clear. Anecdotal information suggests that managers are concerned about deficiencies in project management possessed by HRD professionals. This anecdotal information, however, needs to be replaced with more evidence from the field as to the level of competency in project management that is needed by HRD professionals, the existing level of competence, and the role of academic programs in providing these competencies.

The Determination of Key Skills from an Economic Perspective

Jasper B. van Loo
Maastricht University, The Netherlands

Bert Toolsema
University of Twente, The Netherlands

We review the 'key skills' concept and design a methodology to determine which skills are key skills. Notwithstanding a large research tradition on key skills, there exists no clear criterion that is suitable to guide this decision. HRD might gain from such a criterion since an optimal investment in skills requires information on which skills are 'key' in production. Following the theoretical part, we determine key skills empirically using a dataset of vocational education graduates.

Keywords: Key Skills, Economics

Key (or 'core') skills play a significant role in the current debates on the importance of skills and lifelong learning. A large literature on key skills notwithstanding, there does not seem to be not much agreement on the exact definition of key skills. In the UK, for example, key or core skills have been defined in many different ways. Some have seen them as the way out of the over-specialized A-levels, or as a way to bridge academic and vocational tracks. For UK's Vocational Education and Training system some have argued that core skills are a means through which skills or qualifications can be transferred to multiple (vocational) contexts (Green, 1998).

To make it even more complicated, there seems to be an international linguistic confusion about the terms themselves. In the United States key skills are usually called "basic skills" (e.g. Bynner, 1997) or "generic skills" (Stasz, 1998), whereas in continental Europe (e.g. Germany or the Netherlands) one speaks of "key qualifications" or "key competencies" (Bunk, 1994; Nijhof, 1998; Onstenk, 1997; Rectz, 1989a, 1989b).

Typically, policy documents contain lists of key skills that seem plausible at first sight, but justification for which skills should be included are not given. Part of the confusion in the field of key skills has arisen due to the fact that skills have been studied from many different scientific backgrounds. Psychologists have treated skills as personal cognitive or physical fitness for task completion (Anderson, 1995; Gagné, Briggs, & Wager, 1988). In sociology, skills are perceived as means for workers to identify themselves with a certain vocational population. And for economists, especially those adopting the Human Capital theory, skills are personal attributes that are required in the process of value adding in the workplace (Attewell, 1990). In education skills are treated as trainable procedural personal proficiencies, which can be measured in performance tests.

One of the main issues in modern Human Resource Development (HRD) is keeping workers’ skills up to date. Due to the ongoing changes in the workplace, workforce flexibility has become an important asset in keeping organizations competitive (Watkins & Marsick, 1993). Investing in workers’ skills has therewith become part of company strategy in many organizations. An efficient investment in worker skills requires, however, that information is available on which skills are most important to invest in. Up until now, presumably, most organizations have relied on the current debate for deciding on which skills to invest in. Throughout the years, different key skills have been emphasized. With the emergence of new ways of organizing work, 'team working' skills have been stressed as key skills, while the diffusion of information technology in many workplaces has triggered the emphasis on ICT skills. Although there is a growing literature on key skills, both theoretical and empirical arguments for what skills are key skills and what skills are more 'key' then others, are lacking. In this paper, we attempt to bring some consistency in the debate on key skills by developing a methodology that enables the identification of key skills from an economic perspective. The central research question of this paper therefore is: How can we determine which skills are 'key' skills in a theoretically sound manner? The remainder of this paper is organized as follows: In the next two sections we review the key skill concept and develop a model for determining key skills. We then discuss the methodology used to determine key skills empirically. Using a dataset of working Dutch intermediate vocational education graduates, the results of this exercise are presented in the next section. The final section concludes and summarizes.

Theoretical Framework

Key skills: Some Insights From the Literature

One of the early American examples of the use of key skills in practice can be found in 1983 in the district of Lewisville, Texas. A Superintendent's Advisory Committee conducted a study in order to determine the desired key skills of students graduating from high School. They developed a questionnaire, which was sent to community members and officials from the business and professional community. Respondents were asked to rate the skills they found important. The 62 surveyed skills fell into nine categories. The skill categories rated "important" or "extremely important" by 80% or more of the members of the business and professional community were: Decision-making Skills; Future Plans; Life Coping Skills; Physical, Social, and Personal Health; and Computational Skills (Killian, 1983). In this example key skills refer to the most important or desired skills. These skills are different from the key skills found in the UK, where key skills are of a generic and transferable nature.

In the context of vocational education in Britain, key or core skills particularly refer to the core of functioning at work. Core skills reside in the training and vocational branch of education (Tribe, 1996). The basic ideas of the UK core skills movement can be linked to a list set up by the Further Education Unit in 1979. According to this document, core skills were supposed to:

- bring about an informed perspective as to the role and status of a young person in an adult society and the world of work;
- provide a basis from which the person can make an informed and realistic decision with respect to his or her immediate future;
- bring about continuing development of physical and manipulative skills;
- bring about an ability to develop satisfactory personal relationships with others;
- provide a basis on which the young person acquires a set of moral values applicable to issues in contemporary society;
- bring about a level of achievement in literacy, numeracy and graphicity appropriate to ability and adequate to meet the basic demands of contemporary society;
- bring about competence in variety of study skills;
- encourage the capacity to approach various kinds of problems methodically and effectively, and to plan and evaluate courses of action;
- bring about political and economic literacy;
- encourage an appreciation of the physical and technological environments and the relationship between these and the needs of man in general, and working life in particular;
- bring about a development of the coping skills necessary to promote self sufficiency in young people;
- bring about a flexibility of attitude and a willingness to learn, sufficient to manage future changes in technology and career.

(Tribe, 1996, p. 13-14)

Many lists of core skills have followed since then. Some aspects, however, come back in many lists. Core skills have been looked at as being skills that are generic and transferable, which means that they are applicable to a wide variety of occupations and transferable to many contexts. According to Tribe, most of the lists include: communications, numeracy, problem solving, teamwork, and technology skills. However, the question of which skills should be on the lists of key skills has not been approached using a scientific criterion. In practice, the skills on these lists tend to be those skills that are subjectively needed for education, everyday life and especially for work (QCA, 2000). Green (1998, p. 34-35) describes how core skills emerged in the UK:

"Core skills have emerged out of an historical absence in the UK. Alone amongst the major European nations in the 19th century, England developed a technical and vocational education that had no inherent connection with general education and schooling. Whilst on the Continent, and particularly in France and the German speaking states, the typical form of vocational training was the state-sponsored trade school, which combined workshop training with systematic instruction in vocational theory and general education, in England, with its voluntarist traditions, there were few such schools and vocational as opposed to skills training had to evolve in an ad hoc and relatively unsupported fashion [...]"
In reality in the UK, core skills refer to "just-enough" basic theoretical content. General academic education is brought into the vocational curriculum in an attempt to give vocational training a more profound general (theoretical) foundation (Tribe, 1996). Training in this sense becomes instrumental, especially to economic growth and prosperity. This has resulted in the criticism that core skills only represent the low level minimal standards of the academic content in UK's VET. General academic education is brought into the vocational curriculum as far as it underpins performance in expected work tasks and can be reduced to core skills (Green, 1998, pp. 28).

The core skills in the UK were renamed by the Qualifications and Curriculum Authority (formerly National Council for Vocational Qualifications (NCVQ) and the School Curriculum and Assessment Authority (SCAA)) into key skills. The QCA adopted a list from City and Guilds which consists of:

- Communication;
- Application of number;
- IT;
- Working with others;
- Improving own learning and performance; and
- Problem solving.

(QCA, 2000)

According to the QCA, key skills are widely applicable in work, education and everyday life. This does not help much in further defining the concept.

Across national boundaries, the literature reveals that reasons for including a skill as a list of key or core skills have usually been political or practical. The National Institute for Literacy has recently published a study that describes the identification of key skills (Merrifield, 2000). In this study, common activities and generative skills (which appear to be closely related to the key skills concept) were defined by using an iterative procedure by a number of working groups of experts. In another document, in the context of California community colleges, the definition of core skills is left to faculty, since they "...agree on a body of skills that most or all of our students should master before graduating" (Palomar College, 1999). The European Training Foundation (Shaw, 1998) has relied on a survey among experts in the EU-countries in order to determine key skills. There have also been changes over time regarding the definition of key skills. Typically, inspired by developments taking place in the work place, employers, politicians or other stakeholders have emphasized the importance of certain skills, which has resulted in many different lists of key/core skills.

The debate on key skills would greatly benefit from a common definition. Not claiming to have found the perfect one, this is our point of departure. Within the scope of this paper we define key skills from an economic perspective. As a starting point we consider skills to be personal and related to productivity, restricting its scope to work. Secondly, most skills can be developed or shaped by means of education and training or experience. Some skills, however, are difficult to develop. These are usually connected to attitudes or personality. Thirdly, literature on expertise has showed that skills are especially context-bound, since they are developed and applied in specific contexts of human activity (e.g. in a specific job, with specific restrictions, or in a specific organization) (Chi, Glaser, & Farr, 1988). We may define skills as:

Individual (developed or innate) attributes representing context-bound productivity.

Key skills, as we saw in the discussion above, have appeared due to the fact that some underpinning foundation of transferability is needed at the present labor market. Stasz (1998) argued that the modern workplace is changing because of technological innovations, flatter organizational hierarchies, and increasing globalization of markets. These changes have caused a higher demand on the flexibility of the workforce, which is reflected in hiring decisions of employers. Employers increasingly demand "generic skills" next to job-specific skills. Although research by (Bishop, 1997) showed that job-specific skills are still among the most wanted and productivity-related skills, he admits that the more general and underpinning skills are important as well. Bishop, focusing at the productivity effects of skills, reflected in wage and employer satisfaction, argues that skills like reading and mathematical skills "contribute to productivity by helping the individual learn the occupational and job specific skills that are directly productive. This implies that key skills impact productivity indirectly, rather than directly. If this is the essential characteristic of key skills, they may be defined as:

Skills that have stronger indirect effects than direct effects on productivity.
The remainder of this paper is devoted to finding skills that have this characteristic. This implies a better justification of developing a list of key skills. Rather than making political statements, those skills that have a larger indirect contribution to productivity than their direct contribution may be identified as key skills.

Identifying Key Skills: An Economic Framework

The contribution of skills to economic success, and in particular to productivity, can be measured in several ways. For example, one could determine the relative importance of skills to employers, for instance by studying selection criteria. One could also relate wage inequities of groups within a population to skills profiles. Usually the educational qualifications of groups earning higher wages are compared to the qualifications of those earning less.

Another methodology might be an ethnographic approach, in which one studies in detail which changes took place within production or service industry work and their consequences for skill requirements. A final example is to determine skills effects in a mathematical way by relating skills to wages (Levy & Murnane, 1999).

In economics the determination of skills that matter for wages has a rich history in the literature. In the well-known human capital literature (Becker, 1962; Mincer, 1974), skills are essentially divided into being either general or specific. Later, attention has been paid to skills that fall in between, so-called ‘transferable skills’ (Stevens, 1994).

The attention for skills as such, opposite to composites of human capital, has led to the development of research that addresses the contribution of different types of skills to productivity or wages. This literature has usually focused on a mathematical linear relation between skills and wages of the form:

\[ \ln W_j = \beta_0 + \beta_1 S_j + \ldots + \beta_N S_N + \epsilon_j. \]  

This approach has two drawbacks. Firstly, it does not focus on the relation between different skills, which seems essential when one tries to determine what skills are key skills. Secondly, the results of the regression analysis presented in (1) may be blurred by serious multicollinearity, since different skills tend to be strongly correlated.

In this paper, we present a different approach for determining key skills. In order to focus on the ‘key’ nature of the skills, we explicitly take into account the relations that exist between the different skills distinguished. We do this by finding the relationships between the different skills first, before performing any kind of wage regression. When key skills are considered to be skills that make other skills more productive, we may set up the following model:

\[ S_{in} = c_0 + \sum_{j=1}^{N} \beta_{jn} S_j + \epsilon_{in} \]  

For all skills \( S_{in}, n=1 \ldots N \) this equation relates \( S_0 \) to a constant and all other skills \( S_j, j=1 \ldots N \) and \( j \neq n \). Now, in order to find the indirect effect of a skill \( j \), we add up all the contributions of this skill to other skills, or in formal terms:

\[ \gamma_j = \sum_{j=1}^{N} \beta_{jn} \]  

In a second step, we set up a skill-wage equation:

\[ \ln w_i = \alpha + \beta_S S_i + \varphi_j \sum_{j=1}^{N} S_j + \epsilon_i \]  

This equation relates a skill \( n \) and the summation of all other skills to wages. We use (3) and (4) to determine the marginal effect of a change in the skills. The direct wage effect of a marginal change in \( S_{in} \) is \( \beta_n \). A change in \( S_{in} \), however, also has an indirect effect on all other skills, namely \( \gamma \) (equation 3). Since we are dealing with marginal changes, \( \gamma \) can also be considered as the total change in \( \sum_{j=1}^{N} S_j \), implying that the total indirect wage effect is \( \gamma \cdot \varphi \). In other words the skill-wage equation is composed of two skill effects: a direct effect of a certain skill to wages and a total indirect wage effect of the same skill. Now we can calculate both effects for each skill.
Research Questions

The research questions that evolve from the previous discussion are:

1) Which skills may be considered 'key skills', in the sense that their indirect effect on productivity is larger than their direct effect?
2) What are the direct and indirect productivity effects of these 'key skills'?

A key skill has been defined as a skill that has a larger cumulative indirect effect on other skills than on itself. In terms of equation (3) a skill is a key skill when $\gamma > 1$. The second research question is on the productivity effect of key skills. We calculate this productivity effect using equations (3) and (4), as explained above.

Methodology

In order to determine which skills are key skills, we use data from a graduate survey of Dutch intermediate vocational education graduates. The respondents where approached approximately 1 year after they graduated. During October-December 1999, 18,513 questionnaires were sent out, of which 9068 were returned. A little over 1,000 questionnaires were not suitable for data-entry, so that 7,889 cases remained. In order to focus on a group that is relatively similar in terms of activities, we selected those respondents who were working full-time (at least 35 hours) in an organization (we excluded self-employed graduates). This left us with 1702 cases for analysis.

The part of the questionnaire that is of particular interest for this paper is the list of skills. For fifteen different skills, respondents where asked to indicate on a 5 point Likert scale to what extent the listed aspects are required in their work. Using the data from these fifteen skill measures we approached skill by the so-called 'competence-in-use' concept (see Ellström, 1998), implying that skills are measured by the interaction between individual capacities and job requirements. Table 1 gives an overview of the skills investigated together with their average scores.

Results

In this section, we apply the model previously developed to the data. In order to find the indirect skill effects, we performed for each skill a separate regression on all the other skills. In table 2, we provide the regression estimates of the parameters of the explanatory skills in the regressions.

The results in the table reveal that from the 210 coefficients estimated, 78 are not significant and therefore not displayed. Twenty coefficients have a negative effect, while 112 coefficients have the expected positive effect. The final column shows that skills that have a cumulative effect on other skills, which is larger than 1 are: Problem-solving skills, independence, oral presentation/speaking skills, accuracy/carefulness, initiative/creativity and contactual skills. According to our criterion defined earlier, these six skills may be considered key skills. When these outcomes are compared to several lists of key skills published in the literature, we find a number of skills that are comparable. A notable exception to this are ICT-skills. While these are often cited as being key skills, our methodology fails to find evidence for this.

</tbody>
</table>

The table shows that writing skills, transfer of knowledge, planning/organizing/organizing activities and problem solving skills all have positive direct wage effects of around 2%. In contrast, co-operating/working in a team, independence, initiative/creativity, adaptability, and accuracy/carefulness all have negative direct effects on wages. Column 2 shows that of the 15 skills distinguished, 11 have significant and positive effects on wages in the range of 0.2 – 0.4%. The final column displays the total indirect wage effect from key skills. It reveals that these effects are largest for independence, accuracy/carefulness and initiative/creativity. Since problem-solving skills does not have a significant indirect effect on wages, the total indirect wage effect from this skill cannot be calculated.

Conclusions

This paper has tried to bring some consistency in the debate on key skills. Instead of making political statements by relying on ideas inspired by developments taking place in many workplaces, we have attempted to approach the key skill concept from a quantitative perspective. When key skills are defined as those skills having larger indirect effects on productivity than their direct effects, we may identify them using an economically inspired framework.

When we apply our theory to a sample of graduates, we find six key skills: problem-solving skills, independence, oral presentation-speaking skills, accuracy/carefulness, initiative/creativity and contactual skills. It is comforting that in many lists of key skills, similar aspects are included as being key skills. The often-cited IT skills, as being key in the modern workplace can, however, not be identified as a key skill using our methodology. A shortcoming of our analysis is that we cannot justify the choice of the fifteen skills we used in testing our methodology.

Although the empirical outcomes we obtained are intuitively appealing, our research methodology needs further investigation for adequacy, reliability and validity across countries, types of education and occupations in order to
improve on the methodology for defining and determining key skills. This would imply a significant advance in the usefulness of the debate on key skills and the application of this debate in educational curricula and continuing professional education. When key skills are those skills that make the difference in peoples’ careers, more research in this area is also something that HRD in general should be concerned with.

Critical Thinking in HRD—A Panel Led Discussion

Carole Elliott
Sharon Turnbull
Lancaster University, UK

The critical management studies (CMS) movement in organisational and management theory has gained momentum over the last 10 years. Through a panel discussion the aim of this session is to present what might be the theoretical and practical implications of a similar movement in HRD research and practice. The session will present challenges to the predominantly performative and learning-outcome focus of the HRD field, and will unpack some of the assumptions behind this orientation.

Keywords: Critical Management Studies, Research and Practice, HRD

What has come to be referred to as the critical management studies movement in organisational and management theory has seen a growth in activity over the last 10 years, but has hitherto not been acknowledged by the mainstream HRD community. It is by no means a unified theoretical movement, indeed its raison d'être might be characterised as a refusal to search for theoretical commensurability. Critical management studies (CMS) therefore attracts scholars from a variety of disciplinary and epistemological positions: post-modern, post-structuralist, labour process and post-Marxist schools, as well as feminist and post colonial researchers and those whose critiques are predominantly influenced by the Frankfurt school of critical theory. Ontological differences exist between researchers working within these traditions, but what they do have in common is a concern to challenge disciplines of management that "are generally understood to be devoted to the (scientific) improvement of managerial practice and the functioning of organizations" (Alvesson & Willmott, 1992: 1). CMS by contrast seeks to question "the wisdom of taking the neutrality or virtue of management as self-evident or unproblematical" (ibid). Those who locate themselves within the CMS field emphasise the necessity of questioning the received wisdom of traditional management knowledge and practices given the influence that managers as a social group exercise.

The increasing number of researchers aligning themselves to the CMS movement is demonstrated by the establishment of its own international conference (these took place in Manchester first in 1999, and again in 2001), in addition to specialist streams within the British Academy of Management, and American Academy of Management annual conferences. The ethos of CMS research now receives wider dispersal through a number of post-graduate and post-experience programmes within the management schools of UK universities. For example, for the past nine years, Lancaster University's Management School has run an Mphil/PhD programme in Critical Management.

We are proposing this innovative session for a number of reasons. We are concerned that the methodological traditions that guide the majority of HRD research do not allow researchers to engage in studies that challenge the predominantly performative and learning-outcome focus of the HRD field. We see evidence for this leading publications and journals as well as in the content of ARHD conference proceedings. We seek to unpick the assumptions behind the performative orientation that dominates much HRD research by exploring with researchers, working in a variety of traditions, whether this tradition is conducive to what we perceive is the greatest tension in HRD, the struggle to reconcile the needs of the individual with the needs of the employing organisation. For example, the emancipatory ideal sometimes touched upon by those interested in individuals’ aspirations to find spirituality and meaning at work (e.g. Chalofsky, 2001), challenges the performative view. If we indeed are witnessing a turn towards the sacralisation of work by organisations keen to co-opt the creativity and commitment of individual employees to an even greater degree, how does HRD respond to this?

The traditional methodological frameworks utilised by HRD scholars we argue, cannot adequately assess the impact of these moves upon the individual. We therefore perceive the need to open up HRD theory to a broader range of methodological and theoretical perspectives.

Session description

We propose a debate on the subject of what we will subsequently refer to as critical thinking, within HRD. A number of international panellists (7) chosen for their “critical” orientations will be invited to make a statement (5 minutes each) about what it means to them to think critically in HRD, and what forms of research this might lead to from their individual perspectives. Following this we will open the debate to the floor, where we hope to stimulate a debate from those holding similar or different perspectives. The two Chairs, who will summarise the debate at the end of the session, will manage the debate.

Chairs

Carole Elliott and Sharon Turnbull, Lancaster University, UK

Panellists

Monica Lee – Lancaster University, UK; Linda Perriton – University of York, UK; Sandra Watson – Napier University, Edinburgh, UK; Jim McGoldrick – University of Abertay, Dundee, UK; Jonathan Winterton – ESC Toulouse, France; John Truty - Technical Training Manager, M&M MARS INC, USA.; Dani Truty - Northern Illinois University, USA

Purpose

The purpose of the session is threefold:
• to explore what has hitherto largely been ignored in mainstream HRD research. That is the exploration of research questions through ‘critical’ research frameworks;
• to broaden the constituency of AHRD, so as to give space to the growing body of researchers in the critical tradition who are undertaking HRD research;
• to provide a forum for a healthy and lively debate on new opportunities for HRD research.

Goals

Our goals for the session are:
• to share knowledge, views, and beliefs about the relevance of critical management theory and research to the HRD community;
• to provide a forum for HRD researchers interested in undertaking research in the critical tradition to share ideas for current and future research;
• to set up a network of critical management researchers in the field of HRD;
• to provide a forum for additional levels of theoretical and methodological engagement within the Academy, and to encourage an inclusive spirit.

Content of the Session

The session Chairs will open the session by introducing the historical background and context of critical management studies, what it means to them, and how it has influenced their research in HRD.

This will be followed by personal contributions from each of the panellists about their own understanding of critical thinking and how they see it relating to their research in HRD.

The session Chairs will then open the debate to the floor where contributions from all perspectives will be encouraged. This discussion will be managed by the joint Chairs who will direct questions to the panellists to stimulate a lively debate which raises important issues.

The Chairs will each provide a summary at the conclusion of the debate, noting the issues that have emerged which will be important to consider and carry forward for future debate in the area.

Depending on the number of people attending the session, the session Chairs may decide to divide the audience into a number of smaller groups to ensure that contributions from as many participants as possible are heard, before reconvening for a plenary discussion.'
At the end of the session participants will be invited to join a network of critical scholars in HRD within the Academy.

Format and Style

To ensure the format and style is an inclusive one, the room will be arranged to allow the audience to see each other at all times and to engage with the panellists; e.g. in a Ushape formation or equivalent. The style will be constructive and encouraging of diversity, with efforts made by the Chairs to ensure the voices of as many participants as possible are heard. The tone of the session will be set by the diversity of views expressed by the panel, correspondingly we hope that this will encourage contributions from audience participants who hold a wide variety of perspectives that may not necessarily concur with those of the Panel or Chairs.

The debate will be intellectually stimulating, as it will take its cue from panellist’s contributions around ontology and epistemology, which we believe will stimulate the ongoing debate about the purpose and values of HRD. It will also recognise and accommodate the diverse views of those scholars from non-conventional and international academic backgrounds, and enable us to discuss the dominant prevailing assumptions in the Academy.

The values held by the Chairs of the session are that the Academy should be inclusive and accommodating of diverse ontological and epistemological perspectives. This means that all research perspectives should be recognised and judged according to their intrinsic value if the HRD community of researchers and practitioners is to grow in its reach and strength. Introducing the ‘critical’ voice into the Academy is not an attempt to subvert past or current research, but instead to broaden our understanding of the issues that face HRD, and to exchange our diverse views within an intellectually stimulating forum so that we continue to be open to learning from each other.

Implementing Management Standards in the UK

Jonathan Winterton
Groupe ESC Toulouse (Toulouse Business School), France

Ruth Winterton
Eldwick Research Associates, Bingley, UK

An increasing number of organisations in the UK are adopting competence and competency frameworks, including Management Standards, to structure management development. This paper reports on a study exploring the implementation of Standards in sixteen organisations, undertaken on behalf of the Inland Revenue and Customs and Excise, where Management Standards were subsequently embedded in those organisations' HRD systems and processes.

Keywords: Management Development, Management Standards, HRD Systems

The authors were commissioned by the Inland Revenue (IR) to undertake a series of case studies investigating the use of standards in management development within organisational contexts. During 2000, the IR and HM Customs & Excise (C&E) had piloted contextualised versions of the Management Standards developed by the Management Charter Initiative (MCI), with a view to their implementation throughout their organisations.

On the recommendation of the Handy Report (Handy et al, 1987), the MCI was established in 1988 as the operating arm of the National Forum for Management Education and Development (Constable, 1991). The MCI was recognised as the lead body for management and developed a generic set of occupational standards relating to areas of activity in managers need to be competent (Miller, 1991). Standards were developed for supervisory management (level 3), first line management (level 4) and middle management (level 5). The M3 standards for senior managers, first drafted by MCI in February 1995, focused on strategic issues. As with other occupational standards, functional analysis was used to produce a framework of management competences, from which the occupational standards for managers were developed. The Management Standards were mapped to VQ (NVQ and SVQ) criteria to fit the new framework of vocational qualifications, so the M3 Supervisory Management Standards equate to VQ level 3, while M2 Middle Management Standards equate to VQ level 5.

Like all occupational standards, the Management Standards were developed through functional analysis of management activities in a variety of contexts (Mansfield and Mitchell, 1996). The Standards defined key roles, and in the case of the M1 standards, for example, there were four key management roles:

- manage operations
- manage finance
- manage people
- manage information.

Each key role was broken down into a number of units of competence; the 'manage people' role, for example, comprised four units:

- contribute to the recruitment and selection of personnel
- develop teams, individuals and self to enhance performance
- plan, allocate and evaluate work carried out by teams, individuals and self
- create, maintain and enhance effective working relationships.

Each unit was in turn further sub-divided into elements of competence; the second of the above units, for example, was broken down into three elements:

- develop and improve teams through planning and activities
- identify, review and improve development activities for individuals
- develop oneself with the job role.

For each element of competence, performance criteria were defined which form the basis of assessment and range indicators were provided for guidance.

The Management Standards were reviewed in 1996 and as a result revised Standards were published in 1997.

Copyright © 2002 Jonathan and Ruth Winterton
Firstly, the Standards were re-written in a more appropriate and accessible language free from jargon. Secondly, the revision created two sets of Standards: the Vocational Qualifications Version relates to individuals as before, while the Business User Version relates to organizations. The two versions constitute an integrated whole in order to promote complementarity between individual and organizational needs for development. A system of core units and options was also introduced in order to make the Standards more flexible and easier to apply in different organizational contexts. Also, in place of the four key roles, there are now seven:

- manage activities
- manage resources
- manage people
- manage information
- manage energy
- manage quality
- manage projects.

Following the demise of MCI, the Institute of Management took over responsibility for maintaining the Management Standards, which are again under revision with a new version to be developed during 2002. While there has been criticism of using generic management standards (Collin, 1989; Otter, 1994) the benefits of using them as a framework for development have been widely acknowledged (Iles, 1993; Mabey and Iles, 1993).

The IR and C&E wished to learn from the good practice of other organizations that had adopted standards, whether the MCI Standards or others, as a framework for management development. Six objectives were agreed with the project management team:

- to analyse current practice in management development;
- to identify pertinent issues for organizations implementing the Management Standards;
- to investigate current trends in the delivery of management development;
- to develop a protocol for undertaking case studies in the use of the Standards;
- to lead the research in five of the organizations to be studied;
- to analyse and report on the findings from the case studies.

In connection with the first three objectives, a literature review was undertaken to identify the key issues relevant to the provision of effective management development and adoption of the Management Standards (Winterton and Winterton, 2000). This paper, based on the final report (Winterton and Winterton, 2001), deals with the final three objectives, so describes the methodology developed for the case studies and draws conclusions from analysing the case study findings.

Theoretical Framework

The literature review established the conceptual framework for the study in relation to both the competence frameworks adopted in organisations and the implementation issues associated with embedding the standards in HRD systems and processes.

While the MCI Standards have been shown to provide an effective structure for systematically developing managers' functional competences and personal competencies, in addition managers would need to acquire further competences and competencies. The competence framework proposed was one derived from the 'holistic model of professional competence' (Cheetham and Chivers, 1996; 1998), which had been used to structure an analysis of future management skills needs in an earlier project (Winterton, 2001). Underpinning the development of functional competence and personal competencies, managers need the opportunity to acquire new cognitive competences (knowledge and understanding) and over-riding meta-competencies, especially the ability to cope with uncertainty and learning to learn.

In terms of implementation, the literature suggests that a key rationale is the need to improve management performance in a context of profound and uncertain change. A changing environment (the IR is undergoing significant internal restructuring) requires more management development and necessitates that it is more closely focused on organizational strategy. Management development using standards has been shown to be clearly associated with improvements in performance at the levels of individuals, teams and the organization as a whole (Winterton and Winterton, 1999b). Learning processes associated with the development of individuals and teams differ and a learning organization approach was proposed as a means of providing structure to manage these processes and link them with organizational learning. Management standards were seen to offer a unifying framework for such an approach.

(Boutall, 1997).
Research Questions

The purpose of the cases studies was to explore a range of questions concerning the adoption of management standards in relation to the following four areas:

- **Rationale for adopting the Standards**: why did they do it? What existed before? When and why did they change? Were alternatives considered? What were the main debates? Is (how is) development linked to strategy? Is a competence framework used (in what, since when?) and how does it relate to the Standards?

- **Implementation issues**: how did they do it? How was it decided upon? Outline the planning and development process and the operational details, including design of competence framework. Main obstacles and how they were overcome, what had to be changed, how sceptics were addressed, who was responsible overall, and locally, how it was rolled out.

- **Human resource development issues**: implications of adopting the Standards. How training/development needs are established (and if that’s changed). Assessment and accreditation of competence, whether voluntary, take up rate etc. How identified needs are met and nature of support available for manager involved, including learning infrastructure, telematics, mentoring and coaching.

- **Post implementation**: how are the Standards viewed (by different parties)? Is their use mandatory (for what)? How is the impact of adopting the Standards being monitored? What performance measures? Who evaluates? What benefits have been identified (development, performance of individuals, teams, organization) and can these be attributed to Standards? Evidence? Overall assessment (was it worthwhile?) Key successes and failures, actual against expected outcomes. Hindsight (what would they do differently - would they do it at all?).

Methodology

The project steering team agreed with the researchers’ recommendation that a series of case studies should be undertaken to investigate the use of Standards in management development within organisational contexts. The methodology developed for this study was based on earlier research completed for the Department for Education and Employment and elaborated in Winterton and Winterton (1999). The case study approach adopted closely followed the replication approach to multiple case studies shown in Figure 1 (Yin, Bateman and Moore, 1982).

The design for the case study embodied the theoretical and conceptual underpinnings established from a review of the literature and the development stage was concerned with designing the case study protocol and identifying potential cases for study (Yin, 1984: 29-35). The case study protocol included an outline of sources of information to be addressed, the interview schedules and an outline structure for the case reports. Since a team of consultants from the IR and C&E, as well as the authors, undertook the case studies, it was important for all team members to adhere strictly to the protocol in order to facilitate cross-case analysis. Case reports were validated with the organisations and corrected before the cross-case Analysis was completed. In accordance with the terms on which access was agreed with the participating organisations, confidentiality was maintained with respect to individuals and anonymity preserved in relation to organisations.

Cases for study were selected on the basis of the apparent extent of adoption of the Management Standards and the likelihood that they would raise issues that would help inform implementation in the IR and C&E. A list of possible establishments for case study was drawn up following consultation with the IRTO project manager and staff from MCI. The number of cases to include in a multi-case design depends upon whether literal or theoretical replication is involved, the degree of confidence required in the results, and the resources available. For literal replication, the number of cases can range from 2 to 6 or more, the number increasing with the degree of certainty required and decreasing with the extent of difference between rival theories. For theoretical replication, the number of cases also depends upon the complexity of external factors anticipated to influence case study results. On this basis, it was decided that, ideally, a total of 20 establishments should be studied using the agreed protocol. Cases for study were selected on the basis of the apparent extent of adoption of the Management Standards and the likelihood that they would raise issues that would help inform implementation in the IR and C&E.

It was anticipated from earlier experience that the process of securing access would involve protracted negotiation before the organisation agreed to participate, but access proved much less problematic than in previous studies. Two factors probably explain this: the prestige of the IR/C&E as the client organisations and the fact that we were largely investigating implementation issues, rather than evaluating impact, which raises sensitive political issues within organisations. Access was achieved to 16 organisations within the time available for the study, and these represented a range of contexts and degrees of adoption of standards, including both the functional
competences embodied in the MCI Management Standards and personal competencies reflecting psychosocial characteristics.

Results and Findings

Findings from the case studies in sixteen organisations on the use of standards in management development are summarised below under the four areas of research questions established above.

Rationale

Respondents were asked a series of questions concerning the rationale within each organisation for introducing Standards and for embedding the Standards in HRD systems and processes.

Respondents in the sixteen organisations were first asked what were the main objectives in adopting the Management Standards. After eliciting unprompted responses from interviewees, a series of prompts was then offered, including such issues as increased management capability or competence; bringing about change; providing a structure for career management or qualifications and employability. The principal objectives in adopting Standards were to introduce statements of good practice using an existing competence framework; to establish a framework for management development; to offer a means of external audit to a national standard; and to support the organisation through a culture change.

Respondents were also asked about the relationship between management development and organisational strategy, the intervening role of appraisal and personal development reviews and the use of competence frameworks in HRD systems and processes. In relation to embedding the Standards, the key issues were developing competence in line with organisational strategy; incorporating competence statements in appraisal systems and personal development plans; and using a competence framework as a point of reference in HRD systems and processes, especially job profiles.

Implementation Issues

Respondents in the organisations were asked how the decision was taken to adopt an approach based on standards, and to outline the strategic planning and development process. The key strategic implementation issues were that senior management involvement and commitment was essential to successful implementation; external consultants were involved in some cases; and introducing competence-based qualifications was a stimulus to gaining commitment to Standards at all levels.

Respondents were also questioned on the operational aspects of implementation, including whether particular
Managers were targeted and if local 'champions' were used. They were also asked to explain how the competence framework or standards employed were selected or designed, including whether any research was undertaken into what other organisations were doing. The main operational implementation issues were that communicating the role of the Standards to all levels of the organisation was essential; few organisations had researched others’ experience with the Standards; pilot schemes and local champions had facilitated smoother adoption of the Standards within an organisation.

**Human Resource Development Issues**

In the sixteen organisations visited, interviewees were asked how the Management Standards (or other competence/competency frameworks employed) related to training and development initiatives. Individuals were asked to explain how training and development needs are established and how competence is assessed or accredited. With respect to competence needs and assessment, the case studies showed: performance and development reviews and training needs analysis are used to identify development needs; self-assessment and 360° feedback against the Standards provides a basis for personal development plans; and that competence assessment need not be linked to qualifications such as NVQs/SVQs.

Respondents in the case study organisations were also asked how development needs identified were met and what support is available for managers involved in training and development. In relation to delivering management development, the main findings were that learning resource centres employing multi-media are widely used to deliver development in the workplace, supported by mentoring. Face-to-face training with internal and external personnel is still widespread, often involving partnerships with Universities; individuals are taking responsibility for their own development through learning contracts and open and flexible learning.

**Post Implementation Issues**

Respondents in the organisations studied were asked about the use and evaluation of Standards, as well as the impact and benefits of their adoption.

The individuals interviewed were asked about the status of the Standards in the organisations visited, whether their use was mandatory and whether there was any monitoring of the effect of having implemented the Standards. The key issues in the use and evaluation of Standards were that Standards can be used to structure development irrespective of whether the competence-based qualifications are implemented; Standards can be embedded in the HRD systems and processes of organisations without managers being aware of their existence. MCI, and derivative, competence Standards are often combined with behavioural competencies in competence/competency frameworks. Formal evaluation of the use of Standards is very rare.

Respondents in the organisations studied were asked what benefits, if any, had been identified from adopting the Standards and their overall opinion as to their impact. The main successes and difficulties were explored and individuals were asked what they would do differently if starting again. The main impact and benefits of Standards on organisations is in providing a structure and focus for management training and development; the Standards offer a mechanism for establishing a transparent link between organisational strategy and management development. Better-targeted training and development improves management performance and staff retention. Managers are more qualified and flexible in dealing with the changing organisational environment; managers become more objective in reviewing the performance of their staff and in establishing development plans, including their own. Standards raise individual managers' self-confidence, motivation to accept wider responsibility and commitment to learning.

Difficulties encountered included integrating the Standards with existing initiatives and contextualising the Standards to make them appropriate to the specific organisational culture. Equally, there were problems in overcoming resistance to management development by managers who have specialist professional qualifications and in coping with the bureaucracy of competence-based qualifications. If starting again, those responsible would do some things differently, such as, take more time in building senior management commitment and in implementation, allowing individuals to adjust; communicate the objectives and successes more widely; allocate more resources to the programme, especially in support mechanisms.
Conclusions and Recommendations

There are inevitably limitations to the extent that lessons can be extrapolated from the diverse experience of a range of different organisations that can meet the specific needs of other organisations. Bearing in mind these limitations, the project team identified the following lessons as particularly relevant to the IR and C&E.

In relation to objectives, it is essential to ensure that the Standards are strategically aligned with business direction so that development supports strategy. The Standards can prepare the ground for cultural change provided they are focused on what the organisation needs for the future. Equally, contextualisation of the Standards is necessary to deliver the business benefits. We recommended that the Standards should be used to help focus and structure training and development within the IR and C&E. Managers should be encouraged to use the Standards in succession planning. The Standards also have implications for the management span, or area of responsibility, and for work organisation and job design.

The implementation strategy should build ‘ownership’ of the Standards within the organisation. It is essential to secure senior management support and involvement and to establish effective communication of the objectives and strategy throughout the organisation. There is value in using ‘champions’ to promote adoption and publicise good practice. Individuals who are professionally qualified may be reluctant to pursue management development, so must be convinced of the utility of the Standards for benchmarking relevant experience and developing necessary competence.

In operational terms, there is an optimum timetable for implementation, which is likely to be organisation-specific. If the process is taken too slowly, it will lose momentum, while if it is taken too fast, the majority will be lost in the process. At optimum speed, momentum is maintained, the majority of people are carried along, and the implementation process is completed within budgetary constraints. Qualifications are not a mandatory part of adopting the Standards for management development and this is an area in which to proceed with caution. Nevertheless, the Standards provide a mechanism and structure for linking the experiential acquisition of competence with further education and continuing professional development.

In delivering management development, individuals need support within the organisation to understand that learning will replace taught courses as the primary route for development. The infrastructure necessary for self-managed learning includes both learning resources available locally in the workplace and processes for delivering advice and guidance. Special attention should be applied to coaching (helping managers develop specific competences on-the-job) and mentoring (longer-term advice and guidance from a senior manager).

Evaluating the use of the Standards is important. The adoption of the Standards should not be seen as an ‘instant fix’ but as part of a journey of continuous improvement with milestones against which progress can be assessed. Nevertheless, there is value in establishing an evaluation strategy early in the process, identifying the evaluation criteria and measures, and adopting a methodology consistent with strategic objectives and within Better Quality Services.

The main impact and benefits of adopting Standards should be a greater clarity of role and consistency in standards to which managers work. In turn this clarity and consistency will increase the confidence of managers and of the organisations in their managers. The Standards can highlight the value of bringing in learning experience from elsewhere, helping to promote a broader view of development, without becoming bogged down on technical detail. As a result, managers should be encouraged to look outward and beyond the immediate context.

There will remain several questions to be resolved. It is important to address budgetary issues. The organisations need to commit real resources, time and money, to implementing and embedding the Standards in HRD systems and processes. The organisations will need to decide whether the Standards are to be mandatory for all managers, or to whom they will apply. There is considerable potential to link the Standards with the appraisal system, which raises the question of dealing with individuals who do not demonstrate the necessary competence.

Contribution to New Knowledge in HRD

The research was designed to meet the immediate needs of the client organisations, the IR and C&E, whose senior HR staff wished to be better informed about good practice in management development, especially the use of competence and competency frameworks. In so doing, the research contributed to new knowledge in HRD in relation to theory, methodology and substantive empirical knowledge of relevance to practitioners.

The main theoretical and conceptual contribution of the project is in integrating the apparently competing frameworks centred on functional competence (such as the occupational Management Standards developed by MCI) and psychosocial competency (such as the Hay competency framework). The empirical research showed that in practice, it is both possible and desirable to adopt a combination of competences and competencies, and
demonstrated the utility of the ‘holistic model of competence’ as a framework for achieving this.

The methodological contributions are threefold. First, the project demonstrates the benefit of using research to inform practice, since the IR and C&E adopted the recommendations in their entirety. Second, the way the research was conducted demonstrates the potential for building links between theory and practice through academics and practitioners working together in a research team. Third, the ease with which access was obtained for the case studies in comparison with previous projects shows the virtue of research being sponsored by prestigious state organisations like the IR and C&E.

So far as the authors are aware, no comparable study has been undertaken of contemporary Standards-based management development, so the results provide new empirically derived substantive knowledge. Moreover, as a checklist of good practice, the empirical findings are of considerable value to practitioners, as has been demonstrated by the adoption of our recommendations in their entirety by the IR and C&E.

The key themes with respect to the objectives in adopting Standards are as follows:

- introducing statements of good practice using an existing competence framework;
- establishing a framework for management development;
- offering a means of external audit to a national standard;
- supporting the organisation through a culture change.

The key issues with respect to embedding Standards are as follows:

- developing competence in line with organisational strategy;
- incorporating competence statements in appraisal systems and personal development plans;
- using a competence framework as a point of reference in HRD systems and processes, especially job profiles.

The key strategic issues in relation to implementation are:

- senior management involvement and commitment was essential to successful implementation;
- external consultants were involved in some cases;
- introducing competence-based qualifications was a stimulus to gaining commitment to Standards at all levels.

The key operational issues in relation to implementation are:

- communicating the role of the Standards to all levels of the organisation is essential;
- few organisations researched others’ experience with the Standards;
- pilot schemes and local champions facilitate smoother adoption of the Standards within an organisation.

The key themes in relation to competence needs and assessment are:

- performance and development reviews and training needs analysis are used to identify development needs;
- self-assessment and 360° feedback against the Standards provides a basis for personal development plans;
- competence assessment need not be linked to NVQs.

The major issues in delivering management development are:

- learning resource centres employing multi-media are widely used to deliver development in the workplace, supported by mentoring;
- face-to-face training with internal and external personnel is still widespread, often involving partnerships with Universities;
- individuals are taking responsibility for their own development through learning contracts and open and flexible learning.

The key themes with the use and evaluation of Standards are:

- Standards can be used to structure development irrespective of whether the competence-based qualifications are implemented;
- Standards can be embedded in the HRD systems and processes of organisations without managers being aware of their existence;
- MCI, and derivative, competence Standards are often combined with behavioural competencies in competence/competency frameworks;
- formal evaluation of the use of Standards is very rare.

The key themes in relation to the impact and benefits of Standards are:

- the main impact of Standards on organisations is in providing a structure and focus for management training and development;
- the Standards offer a mechanism for establishing a transparent link between organisational strategy and management development;
- better targeted training and development improves management performance and staff retention;
- managers are more qualified and flexible in dealing with the changing organisational environment;
managers become more objective in reviewing the performance of their staff and in establishing development plans, including their own;

- Standards raise individual managers' self-confidence, motivation to accept wider responsibility and commitment to learning.

The key difficulties encountered in adopting Standards included:

- integrating the Standards with existing initiatives;
- overcoming resistance to management development by managers who have specialist professional qualifications;
- contextualising the Standards to make them appropriate to the specific organisational culture;
- coping with the bureaucracy of competence-based qualifications.

Among the things that people would do differently if starting again were:

- take more time in building senior management commitment and in implementation, allowing individuals to adjust;
- communicate the objectives and successes more widely;
- allocate more resources to the programme, especially in support mechanisms.

The Applicability of AHRD Ethics Standards Internationally

Lisa A. Garrett  
Gary N. McLean  
University of Minnesota

This paper discusses some of the issues related to the applicability of the AHRD Ethics Standards internationally. It summarizes a review of literature on ethics standards and the applicability of those standards across countries. The authors conclude that there is no reason to assume that ethical standards that are applicable in one culture are necessarily applicable in another. From this, they identify issues for further research in the area.

Keywords: International HRD, AHRD Standards, Code of Ethics

The HRD field is becoming more established around the world (McLean & McLean, 2001). As HRD continues to grow and legitimize itself, greater attention has been given to the need for establishing standards for professional behavior. The Academy of Human Resource Development (AHRD) has produced its Standards on Ethics and Integrity (The Standards) (AHRD, 1999). The intent of these Standards has been to give HRD professionals a common set of values and principles upon which to build their work with integrity.

Although international business and society as a whole should expect ethical behaviors from HRD professionals (Hatcher & Aragon, 2000), is it reasonable to expect professionals from various countries to adhere to a common set of standards? But what are the ethical behaviors that international HRD professionals should practice? Can ethical standards be universally applied? Can the AHRD Standards be applied globally?

Purpose Statement

The purpose of this paper is to explore the research and theory-building literature to inform us about the global application of ethics codes. The concept of ethics in HRD, and the growing recognition of ethics as a developing research issue, demonstrates the importance of ethics in HRD. As businesses face many challenges in their efforts to participate in globalization, HRD will be called upon to use a variety of methods to support those efforts (McLean, 2001). As the HRD profession continues to expand globally, the issue of global ethics becomes one of increasing importance. The intended outcome of this literature review is to build a conceptual framework for further research regarding the extent to which standards developed in one country can be applicable in all other countries.

Theoretical Framework

There is no commonly agreed-upon ethical system or universally agreed-upon way to analyze ethical situations (Hatcher & Aragon, 2000). There are two generally acknowledged theories about ethics: teleological theory and deontological theory. Teleological theory, a consequentialist theory, focuses on the results of an act. The moral value of an action is a function of its consequence. Deontological theory, a nonconsequentialist theory, focuses on the act itself. A deontologist believes that the rightness of an action takes precedence over the consequences of the action. The results are not as important as the nature of the act in question (Burns, Russ-Eft, & Wright, 2001; Hatcher, 2000). We will look for common applications of these two theories in the literature.

Research Questions

This literature review sought to identify the research that has been conducted on the applicability of ethical standards across countries. Specifically, the review was guided by the following questions:

- What role does ethics play in the field of HRD?
- Can the AHRD Standards be applied globally by international HRD professionals?
- Should a separate code of ethics be developed for international HRD professionals?
Methodology

A literature review of research-based articles was conducted. HRD, psychology, international business, and ethics literature was reviewed. The following databases were searched: Educational Resources Information Center (ERIC), ABI Inform, and Business Source Premier. Keywords used in the literature search included: HRD and ethics, international business ethics, business and ethics, professional ethics, cross-cultural HRD, international HRD, and code of ethics. Reference lists of selected articles were examined for additional literature. Along with the AHRD Standards, ethical codes from the following professional organizations were also reviewed: American Psychological Association, Society for Human Resource Management, Organization Development Network, American Evaluation Association, and Organization Development Institute.

Results

The literature review revealed much that contributes to the research questions posed. The review presented here is organized according to the following categories: The AHRD Standards, professionalization of HRD, cultural differences in work-related values, cross-cultural HRD, international business ethics, and how other professional organizations utilize their ethics standards in an international setting.

The AHRD Standards

The Standards were developed by the Standards on Ethics and Integrity Committee in 1999. The committee consisted of six U.S. members, with Darlene Russ-Eft as chair. The standards were intended to provide guidance for HRD professionals engaged in practice, research, consulting, instruction, facilitation, or teaching. Aspirational in nature, they were intended to provide standards of conduct and set forth a common set of values for HRD professionals (AHRD, 1999).

The General Principles, the first category of the standards, include:

- Competence
- Integrity
- Professional responsibility
- Respect for people's rights and dignity
- Concern for others' welfare
- Social responsibility

A comprehensive list of the Standards is shown in Table 1. Each standards category includes a list of its specific standards:

Table 1. Academy of Human Resource Development Standards on Ethics and Integrity

<table>

</table>

Research and evaluation: Research and evaluation in professional context; data collection; responsibility; compliance with law and standards; institutional approval; informed consent; incentives to participants; deception in research; interpretation and explanation of research and evaluation results

Advertising and other public statements: Definition of public statements; statements by others; avoidance of false or deceptive statements; media presentations
Publication of work:
Reporting of research and evaluation results; plagiarism; publication credit; duplicate publication of data; release of data; professional reviewers; ownership of intellectual property

Privacy and confidentiality:
Discussions of the limits of confidentiality; protection of confidentiality; maintenance and ownership of records; disclosures; consultations; confidential information in databases; use of confidential information for didactic or other purposes

Teaching and facilitating:
Design, development, implementation, and evaluation of programs; descriptions of programs; accuracy, objectivity, and professionalism in programs; limitation on training and instruction; assessment of performance

Resolution of ethical issues and violations:
Familiarity with ethics; informal resolution of ethical violations; conflicting pressure with organizational demands; improper complaints; resolutions of ethical issues; cooperation with ethics committees

Along with the development of the Standards, the committee recognized the need to provide further guidance for researchers and practitioners. A casebook was developed that provided case studies in HRD ethics for further enhancement of the HRD profession. Further details on the cases can be found in Aragon and Hatcher (2001).

Several of the cases in the casebook described ethical issues in international settings. One case described a dilemma involving compensation practices in an organization in Tanzania (Bates, 2001). Other cases referred to illiteracy in Bangladesh and its impact on a research project (McLean, 2001) and the practice of quanxi in China (McLean, 2001).

Professionalization of HRD

The question is now being asked if an aspirational ethics document takes the profession far enough (Ruona & Rusaw, 2001). Aspirational ethical principles provide guidance to professionals for resolving dilemmas and conflicts, in contrast to an enforceable code that implies sanctions for specific acts based on formal judgements (Burns, Russ-Eft, & Wright, 2001). Ruona and Rusaw (2001) believed that the Standards play a critical role in helping HRD to develop necessary foundations for professionalization.

As the AHRD pursues professionalism, some have argued that consideration must be given to defining the construct of profession. Burns, Russ-Eft, and Wright (2001) used Wilensky’s (1964) five stages to describe the development of professions. Among these stages is: codes of ethics begin to appear (p. 214).

Ruona and Rusaw (2001) defined a profession as including, among others:

- Values
- Standards of Practice and Ethics
- Monitors the practice and its practitioners (p. 223)

Another definition of a profession comes from McConnell (1999). His definition of a profession, based on legal precedents, includes the following attributes:

- A code of ethics imposing standards higher than those normally tolerated in the marketplace
- A disciplinary system for professionals who breach the code
- A primary emphasis on social responsibility over strictly individual gain, and a corresponding duty of its members to behave as members of a disciplined and honorable profession
- A prerequisite of a license prior to admission to practice (p. 92)

Each of the three definitions of profession includes the concept of enforcement and control. Control could be through licensing, monitoring practitioners, or implementing a disciplinary system for those who breach the code. Whichever control method is used, an ethics code is to be used as a control mechanism. If the AHRD were to decide that an aspirational ethics document does not take the profession far enough, an enforceable code, though difficult to develop, would have implications for the practice of HRD, including international HRD.

There has been some focus on the application of the Standards in an international setting. Hatcher and Aragon (2000) presented the Standards as a generic document that is intended to provide both universal principles and limited decision rules to cover many situations encountered by international HRD professionals. The Standards
could be used by international HRD professionals but, according to the authors, not as a stand-alone or all-inclusive guide to ethical behaviors. Each international professional's personal experiences, individual values, and cultural values should be used to interpret, apply and supplement the principles set forth in the Standards. Hatcher and Aragon (2000) recognized the following:

We need more and better dialogue about what the international community of HRD professionals believes (values), what we want the profession to be in the future, and where we are now in regard to that quest. (p. 217)

Cultural Differences in Work-Related Values

A well-known model that illustrates the differences that can exist between cultures is Hofstede’s four value-based factors: Power Distance, Individualism, Masculinity, and Uncertainty Avoidance (Hofstede, 1984). He added a fifth factor, Long-Term Orientation, later. These factors have been used widely in analyzing culture, though the model has also received significant criticism because of the research used by Hofstede originally and the evidence that the framework is not valid in all circumstances (Kuchinke, 1999). Power Distance is the extent to which the less powerful members of a group or society accept and expect that power is and will be distributed unequally. Bureaucratic societies (such as Latin American countries) are typically higher in Power Distance, while more egalitarian societies (such as the United States) rank lower. Individualism is the degree to which group members expect that individuals orient their action for their own benefit rather than for the benefit of the group (Collectivism). The United States is ranked among the highly individualistic societies, while Asian countries are more strongly collectivistic. Masculinity is the distribution of gender-role stereotypical behavior. Masculine cultures (such as Mexico) honor assertiveness, aggression, and toughness among its male members while feminine cultures (such as Sweden) reinforce nurturing, caring, and modest behavior among both male and female members. Uncertainty Avoidance is the degree to which members of a group are uncomfortable with and avoid change, ambiguity, and uncertainty (Kuchinke, 1999). In countries with strong uncertainty avoidance (such as Germany) there tend to be more and more precise laws than in those with weak uncertainty avoidance (such as the United Kingdom) (Hofstede, 1997).

Jackson (2001) found that, in individualist cultures, ethical decision-making is based on concepts of universal principles of what is right and wrong while in collectivist cultures, it is likely that the decisions will be based on the contingencies of a situation and of maintaining face. In high uncertainty avoidance cultures, such as Germany and France, the level of economic and social regulation is likely to be high and internalized within the community. In low uncertainty avoidance cultures, such as Australia, this acceptance of regulation is likely to be low.

Another factor that can influence ethical practices in countries is the level of corruption that takes place. Transparency International (TI) is a non-government organization that is dedicated to increasing government accountability and curbing both international and national corruption. TI ranks countries each year by a Corruption Perceptions Index (CPI) score. The 2001 CPI shows that almost two-thirds of the countries ranked in the index score less than five out of a clean score of ten (TI, 2001). The CPI serves as an ethical barometer for different national economies. From the data that are gathered in the CPI, there is the assumption that there are ethical and unethical economies (Lee, 2000). The degree of integrity in these economies is measurable and comparable. Those economies that are more developed economically are more ethically developed.

Ethics is a growing concern in international business. The Caux Round Table of business leaders from Europe, Japan, and the United States was founded in 1986 and has established General Principles and Stakeholder Principles as a world standard against which business behavior can be measured (www.cauxroundtable.org).

Several examples of international ethical issues were identified in the literature. In a study of Korean and Japanese business executives, executives occasionally have to make unethical business decisions that conflict with their personal values, because of prevailing business practices (Lee & Yoshihara, 1997). Bribery is still a common practice in some countries (TI, 2001). According to Ryan (1994):

Presently in most of Central Europe, there is no framework for an ethical system. And whatever system exists or whatever basis for a system is on record, there is almost no system of enforcement. There is both a moral and a legal vacuum. (p. 68)

In a study based on respondents from 10 manufacturing companies in two Western countries and four countries of the former Soviet Union, nationality emerged as the most important predictor of the work-related values that were measured (Kuchinke & Ardichvili, 2001).

Multiculturalism and diversity offer difficult ethical challenges in the international evaluation arena (Bamberger, 1999). In many countries, gender issues do not have a high priority. The concept of stakeholder is seen
in some cultures as promoting conflict and challenging the traditional goal of consensus building. There is often resistance to the intervention of international agencies in what are considered religious or culturally sensitive areas.

**Cross-Cultural HRD and Ethics**

Although several sources were found regarding cross-cultural or international HRD, literature that dealt with the topic of international HRD and ethics was scarce. In reviewing a comprehensive annotated bibliography of over 150 articles related to international organization development (OD) appearing over the life of the *Organization Development Journal*, only two articles were about the specific topic of ethics (Str"aybreg, 2000). One article (Ryan, 1994) described the increasing attention given to business ethics in East Central Europe and Russia and in the former USSR Republics. The other article (Johnson & Wolfe, 1996) discussed global integrity ethics and the challenges for the field of organization development.

The literature reflected a recognition of cross-cultural differences in the practice of HRD but not in the specific area of ethics. HRD researchers and practitioners have some knowledge of international HRD but that knowledge is still in its infancy (Peterson, 1997). Hansen and Brooks (1994) recognized that organizations are increasingly operating within a global context and that HRD professionals are being challenged to examine the transferability of their efforts. In their review of cross-cultural HRD research, they found that HRD roles are interpreted differently in different cultures.

**International Business Ethics**

The topic of business ethics has received much attention in recent years. Academics and practitioners from the European community have also become more concerned with issues of business ethics (Buller & Kohls, 1997). Several articles in the literature dealt with the issue of addressing cross-cultural ethical conflicts in multinational corporations (Barker & Cobb, 2000; Kapstein, 2001; Payne, Raiborn, & Askvik, 1997). There has been a proliferation of MNCs since the end of World War II but an awareness of cultural and ethical differences has developed only recently. Barker and Cobb (2000) made the conclusion that consideration of ethical and cultural differences is necessary and MNC's must accommodate the differences when developing a code of ethical standards that will apply to business practices at home and abroad.

Establishing an ethical culture requires special effort. International agreements between companies are very difficult to establish and time-consuming. Once agreements are defined, international law makes noncompliance difficult to enforce (Payne, Raiborn, & Askvik, 1997). Those who wish to establish ethical codes need to reconcile their aspirations with the fact that most nations do not generally share common laws or regulations on labor rights and the environment (Kapstein, 2001). The vast differences in culture generate a host of managerial issues, including ethical ones, such as avoiding ethnocentrism and recognizing that no one culture is better as a matter of course than any other culture (Payne, Raiborn, & Askvik, 1997).

Several articles have argued in favor of building a code of ethics for international business. Wederspahn (1997) argued that having written ethical guidelines will help U.S. corporations walk the fine line between the requirements of the Foreign Corrupt Practices Act and the realities of local business culture. For a code to be applicable to any business and in any country or culture, it should consider ethical, cultural, and managerial issues (Payne, Raiborn, & Askvik, 1997). In general, a single set of ethics for a company is preferable, but it may be impossible to do. According to Smeltzer and Jennings (1998):

> A company with two sets of values, one for domestic business and another for international business, is a company headed for ethical crisis...It is not an issue of how a firm does business in each country, it is a question of whether a firm does business in each country. (p. 63)

Schwartz (2000) protested against the usage of ethical codes by business organizations. Business organizations should strive to create an environment where employees are comfortable and free to do what they believe is the right thing to do. If the task of business ethics is to facilitate a consensus as to what is right or wrong, one must question the validity of ethical codes since there is no evidence such a consensus exists.

**Professional Organizations and Codes of Ethics**

Having a code of professional conduct is one part of the self-regulatory efforts of professional organizations. Relatively little research has been done on professional codes of ethics (Wiley, 2000). In Wiley’s study of ethical standards for human resource management professionals, similar characteristics were found among the codes, which led to one conclusion that a unified code for the HR profession could be reasonably derived and would be beneficial. No discussion occurred regarding the application of these ethics in international settings.
Several professional organizations' ethical codes were reviewed to identify what considerations or statements were made in regards to international ethics and the applicability of the ethical codes. The organizations' codes examined were those of the Society for Human Resource Management (SHRM), American Evaluation Association (AEA), Organization Development Network (ODN), Organization Development Institute (ODI), and American Psychological Association (APA).

The SHRM Code of Ethical and Professional Standards in Human Resource Management (1989) is meant to be a useful tool applicable to the global HR profession as a whole, setting standards to which all members can aspire. Members of SHRM must abide by the code (SHRM, 1989). A statement is made that it is understood that the code is primarily U.S. centric, but the hope is that it is written in such a way that HR professionals anywhere will find it helpful in their daily professional lives. SHRM members are expected to adhere to the code.

In the AEA’s Guiding Principles for Evaluators (1994), the following statement is made:

These principles were developed in the context of Western cultures, particularly the United States, and so may reflect the experiences of that context. The relevance of these principles may vary across other cultures, and across subcultures within the United States. (p. 3)

The development of the Organization and Human Systems Development Credo of the Organization Development Network involved the participation of more than 600 people from 25 countries (OD Network, 1996). The credo is a working statement. One issue currently under discussion is whether or not it is appropriate to aspire to becoming a global professional community (p. 2).

The International Organization Development Code of Ethics (OD Institute, 1991) was supported unanimously by participants at the 1984 O.D. World Congress in Southampton, England. More than 200 people from over 15 countries participated in the process that produced the statement. A statement made in the notes of the document states:

By providing a common reference for O.D. professionals throughout the world, we seek to enhance our sense of identity as a global professional community. Because this statement was initially developed within the United States, adapting it to other cultures has been necessary. (p. 3)

The APA’s Ethical Principles of Psychologists and Code of Conduct does not refer to any international applicability (APA, 1992). Although the other organizations’ ethical codes are aspirational, the APA’s specific Ethical Standards set forth enforceable rules for psychologist conduct. Membership in the APA commits members to adhere to the APA Ethics Code. Psychologists and students who are not APA members are cautioned to be aware that the Ethics Code may be applied to them by state psychology boards, courts, or other public bodies.

Discussion and Recommendations

The results of this review support the need for more research in this area. Although applications of deontological theory were present in the various professional organization standards, we have been unable to identify any research that specifically looked at whether ethics standards developed in one country (U.S.A.) can be applicable in other countries. According to Peterson (1997), HRD researchers and practitioners have some knowledge of international HRD, but that knowledge is still in its infancy and is based on theories and interventions that may come from an ethnocentric U.S. base. Because organizations are increasingly operating within a global context, HRD professionals are challenged to examine the transferability of their efforts (Hanson & Brooks, 1994). It is our belief that this challenge extends to the transferability of ethical standards.

We propose to continue the research in this area by conducting a study on the applicability of the standards to international HRD practice. In this proposed study we will gather data from international AHRD members. This study will compliment the current work being done by the Standards on Ethics and Integrity Committee (communication with committee member Steven Aragon, 2001).

Contributions to HRD Knowledge

This literature review contributed to new knowledge in HRD by examining the applicability of the major research organization for HRD (AHRD) and its work on ethics in international settings. This study provides a deeper understanding of the issues surrounding ethical standards and their applicability in international settings. As globalization and the practice of ethical standards continues to influence the practice of HRD, this paper opens new avenues for research, particularly in the area of applicability of ethical standards.

Nature and Impact of ISO Certification on Training and Development Activities on Singapore Organizations

Hesan A. Quazi
Nanyang Technological University

Ronald L. Jacobs
The Ohio State University

Examined the impact of ISO 9001/9002 certification on training and development activities of organizations in Singapore. Nature and extent of HRD activities three years before and three years after ISO certification were requested. They were also asked to indicate whether the changes, if any, were due to the certification only or other reasons. Significant changes in HRD activities were reported in manufacturing organizations.

Keywords: ISO 9000, Training and Development, Singapore

The ISO 9000 family of international standards and guidelines has earned a global reputation as the basis for establishing quality management systems. The success of these standards is still growing and the number of countries where ISO 9000 is being implemented has increased. By the end of December 1999, it has been reported that at least 343,643 ISO 9000 certificates had been awarded in 150 countries (ISO, 1999). The trend of the number of organizations seeking certification has continued to increase from that time. By following the ISO 9000 standards, companies can discover what makes them successful and then they can document this information into formalized processes and procedures. Improved documentation, positive cultural impact, higher perceived quality and faster development time are some of the advantages of ISO 9000 certification. ISO certification has also been used as a marketing tool to open up new markets beyond the traditional sphere of influence. Some quality and productivity-related benefits of such certification include an improvement in on-time delivery and reduction in the cycle time, error rates and test/inspection procedures (Taormina, 1996).

One of the key elements in the ISO 9001/9002 (1994) standards is clause 4.18 – Training. The clause describes the minimum training and experience requirements of an organization. It requires that the organization train new employees and all personnel whose work affect quality. The aim is to continually improve training programs to enable employees to handle changes in the global marketplace and be updated with the latest technology advances (Taormina, 1996). The standard requires that the need for training of personnel should be identified and a method for providing that training should be established. Further, consideration should be given to providing training to all levels of personnel within the organization. The standard also emphasizes that particular attention should be given to the selection and training of recruited personnel and personnel transferred to the new assignments (ISO 9004).

In spite of the successes of ISO, however, there remain issues in regard to its implementation and use. For one thing, it has been argued that ISO 9000 breeds inflexibility in organizations (Taormina, 1996). In practice, whenever standards are commonly recognized across an organization, it makes whatever future revisions to the standards all the more difficult to accomplish. In a related sense, ISO might have the effect of stifling creativity among employees who are expected to take ownership of their own processes. Once the standards become institutionalised, employees may be uncertain of the wisdom of changing something that has been widely accepted. Finally, becoming certified and adhering to the ISO standards simply requires a high investment of organizational time, effort, and resources. Indeed, some organizations have balked at using ISO simply because of the expected expenses involved seemed greater than the expected benefits. In addition, ISO inevitably affects all aspects of the organization, including the training and human resource development activities, which may not be altogether anticipated. In this sense, ISO may have as much impact on its support activities as those considered to be primary to the organization’s reason for being in business.

The purpose of this study was to determine the extent to which ISO 9000 certification has impacted training and human resource development activities of organizations in Singapore. Specifically, the following research questions were addressed:

1. To what extent does ISO 9000 certification affect the conduct of training needs analysis?
2. To what extent does ISO 9000 certification affect the conduct of training design?
3. To what extent does ISO 9000 certification affect the conduct of training delivery methods?
4. To what extent does ISO 9000 certification affect the conduct of training evaluation?
5. To what extent does ISO 9000 certification affect the conduct of HRD activities in general?

Copyright © 2002 Hesan A. Quazi and Ronald L. Jacobs
These research questions were derived since they represent the basic phases of the systems approach of training design (O'Connor, Bronner, & Delaney 1996). For the study, training needs analysis was considered as determining what training subjects are essential and to help identify those employees who are in need of the training. Training design was defined as the creation of an intervention or training effort targeted at addressing the problem identified. Examples of such activities might include curriculum development, course design, computer-aided design and the development of learning aids or materials. Training delivery was defined as the means to communicate the training information to the employees, including the selection and deployment of the media, methods, and arrangement of the facilities. Training evaluation was defined as the systematic process of determining the effects of the training on learning and business performance.

**Literature Review**

In a study conducted by Elmuti and Kathawala (1997), in two manufacturing plants, one ISO 9000 certified and the other non-ISO 9000 certified, owned by a large corporation in the United States it was found that the ISO 9000 quality program improved the participants' quality of work life. In addition, there was a positive impact on employee productivity and export sales. A follow-up interview with the management of the corporation indicated that ISO 9000 supported the organisational objectives of productivity, quality of products, increased export sales, and quality of work life.

Chittenden, Poutziouris, and Muhktar (1998-99) investigated the differences between the characteristics of small firms in the United Kingdom which were ISO 9000 registered and unregistered, the motivation for and against registration and the experience of the costs, benefits, and value added of the ISO 9000. It was found that the firms, which adopted ISO 9000 tended to be large, multi-product and manufacturing based. These firms had customers that were larger than themselves or from government departments. These firms also had a formal management structure. On the other hand, the firms, that did not adopt ISO 9000, tended to be smaller businesses that dealt with domestic customers and serving the local market. They also had no formal management structure and were usually personalised by the business owner. The study concluded that a high majority of ISO 9000 users felt that the advantages of using ISO 9000 outweighed the disadvantages. Manufacturing firms that implemented ISO 9000 were primarily motivated by the desire to improve internal processes while small firms were motivated by marketing and competitive advantages.

Research on small businesses conducted by McAdam and McKeown (1999), in Northern Ireland showed that both ISO 9000 and Total Quality Management (TQM) resulted in benefits. The benefits derived from ISO 9000 were better control of business, increased sales/business, reduced costs, increased productivity and fewer customer complaints. TQM resulted in benefits such as increased sales/business, reduced scrap/waste, increased profits, fewer customer complaints, increased customer satisfaction, increased workforce morale/skills, increased productivity and cost reductions. The businesses that were gaining most from TQM had started with ISO 9000 and focused on external measures (e.g. customer satisfaction, etc.) as well as internal measures (scrap, efficiency, etc.). They also had full management commitment, high levels of employee participation and training.

Sun (1999) found that in Norwegian companies, implementation (or certification) of the ISO 9000 standards was significantly correlated with the results, especially the reduction of bad quality products and customer complaints, and business performance such as profitability and productivity. However, the ISO 9000 certification had little influence on market position and competitiveness, and no influence on employee satisfaction and environment protection. Anderson Anderson, Daly, and Johnson (1999) found that manufacturing firms in North America adopted ISO 9000 as a means to provide credible signals of quality assurance to external parties. ISO 9000 complements rather than substitutes Total Quality Management. In addition, ISO 9000 was adopted as a tool in a larger strategy of achieving competitive advantage through quality management and communicating quality results. For most firms, complying with customer or regulatory requirements appeared to be a secondary consideration.

In Singapore, Quazi and Padibjo (1998) identified the perceived benefits and barriers to the ISO 9000 quality system. The benefits that were identified by the ISO 9000 certified companies included - an increased customer preference, improved company quality image and competitiveness in the market, compliance to customer requirement, streamlined procedures and documentation, increased consciousness for preventive and corrective actions, and provision of a foundation in the pursuit of TQM. The study also found that ISO 9000 certification provided a stepping stone toward TQM practices.

Despite the benefits, there were numerous barriers that were faced by the SMEs which included high cost of implementation, lack of full commitment and participation of top management, lack of financial and human resources, employee resistance, no perceived advantage in certification of the service industry, and that proper training and education of employees could not be ensured (Quazi and Padibjo: 1998). Simons and White (1999) conducted a study in North America on 63 ISO 9000 certified and 63 non-ISO 9000 certified companies in the electronics industry. The study did not support the claims that ISO certified companies help realise the
advantages in operational performance over non-ISO certified companies. An empirical study in New Zealand on manufacturing companies found that smaller companies (with fewer than 100 employees), when compared to the larger companies, are more likely to implement ISO 9000 because of external factors rather than internal factors. They also showed less understanding of the relationship between ISO 9000 and TQM, which resulted in implementing ISO 9000 only, and had little intention of extending their quality programs further. They found the small companies to be less likely to implement a TQM program compared to large ones and were likely to stop after implementing one ISO program. Further, large companies appeared to be more likely to use ISO 9000 as a precursor to TQM, whereas small companies were satisfied with ISO 9000 accreditation (Lee & Palmer, 1999). Wiele and Brown (1997-1998) in a study of organizations with less than 250 employees in Australia found that most SMEs seemingly felt forced to go for ISO 9000 certification and did not move further down the quality path. One of the driving forces for a company to move forward to develop a quality management system comes from customers and they might force the SMEs to go for ISO 9000 certification and only a very few of them will be converted into quality believers and will move forward on the TQM journey. Goh and Ridgway (1994) reported a very similar finding on SMEs in the UK. The study revealed that the ISO 9000 certification was the end-point in the quality journey of the sample companies.

In summary, it has been reported that ISO 9000 certification has resulted in both positive and negative impacts on organizational performance. Specific benefits that have been reported through various studies are—improved quality of work life, increased customer preference, improved company quality image and competitiveness in the marketplace, higher productivity and export sales, better control of business, reduced costs, fewer customer complaints, streamlined procedures and documentation, increased consciousness for preventive & corrective actions and the like. On the other hand, some studies indicated that ISO 9000 certified companies did not realize advantages in operational performance and foreign sales over non-certified companies. Clause 4.18 of ISO 9001 requires that the certifying companies establish and maintain documented procedures for identifying training needs and provide for training of all personnel performing activities affecting quality.

Although requirements of all the ISO 9000 clauses are important for the quality management system, it can be argued that employee training is critical for the achievement of the benefits discussed above. In support, a number of studies have shown the relationship between training and business performance (Jacobs, 1994; Jacobs, Jones, & Neil, 1992; Robinson and Robinson, 1989). McAdam and McKeown (1999) found that for the achievement of customer satisfaction, scrap reduction and improvement of efficiency, full management commitment and high level of employee participation & training were present. Quazi and Padibjo (1998) also reported that lack of proper training and education of employees was one of the barriers to the achievement of ISO 9000 certification.

However, from the literature review presented above it is noted that no study has yet investigated into the nature, extent and impact of training on the benefits accrued through ISO 9000 certification. The objective of the present study is to explore the impact of ISO 9000 certification on the nature and extent of training activities of the certified companies.

Methodology

A survey research methodology was used for the study. A questionnaire was developed to address the questions. Primarily a 5-point Likert type scale was used to capture the HRD related information on "before" and "after" the ISO 9000 certification. The companies were asked to indicate the nature and extent of their training and human resource development activities three years prior to certification and three years after the certification.

They were also asked to indicate the possible reasons for such changes. The questionnaire was pre-tested with three ISO 9000 certified organizations and two researchers knowledgeable in the field. These respondents were requested to comment on the content as well as the clarity of the questionnaire. The questionnaire items were amended as per the comments received during the pre-test.

The final version of the questionnaire was mailed or faxed to 177 ISO 9000 certified companies in Singapore and was addressed to the Management Representative of ISO 9000 program, HR manager, or other executive that senior management deemed suitable to respond. To improve the response rate follow-up calls were made two weeks after the questionnaires were sent out.

Results

One hundred seventy seven (177) questionnaires were sent out and 33 (18.6%) valid responses were received back. Of these responses, 28 were useable for the data analysis. The final sample consists of 19 companies from the manufacturing sector and nine from the non-manufacturing sector. In all, manufacturing companies make up 68 percent of the sample. Among them, 17 were privately owned (89.5 percent), while foreign
companies wholly owned the remaining two companies. A majority of the manufacturing companies (52.6 percent) had a turnover of between S$10.0 million to less than S$50.0 million in 1997, as compared to 11.1 percent for non-manufacturing companies in the sample. Four manufacturing companies reported having turnover over of S$100.0 million (21.1 percent). No non-manufacturing company reported the same level of turnover for that period. About 53 percent of the manufacturing companies and 56 percent of non-manufacturing companies reported having less than S$15 million in total fixed assets in 1997.

Among the 19 manufacturing companies, 17 (89.5 percent) were certified in the ISO 9002 standard. The percentage of non-manufacturing companies certified in the ISO 9002 standard was nearly the same (88.9 percent). The remainder of the sample companies were ISO 9001 certified. About 63 percent of the manufacturing companies and 78 percent of the non-manufacturing companies had hired a consultant to assist them in getting certified. About 21 percent of the manufacturing companies and 44 percent of non-manufacturing companies took about six months to receive certification, and 47 percent of the manufacturing companies and 66 percent of the non-manufacturing companies took about one year. In the non-manufacturing companies, the largest proportion (56%) of the employees reported to have secondary level education followed by tertiary level (18%). However, in the manufacturing companies about 38% of the employees have primary level education followed by secondary (32%) and then tertiary level (16%).

Impact Of ISO 9000 Certification On Training Needs Analysis

From the result of the t-test on the total sample it could be concluded that there was a significant increase in TNA after ISO 9000 certification (p= .00). Similar significant findings were found in the manufacturing sector (p=.001). The non-manufacturing sector was not significant (p=.247).

Impact of ISO certification on Training Design

The result of the paired t-test on the total sample indicated that that there was a significant increase in Training Design activities after ISO 9000 certification (p=.00). A similar significant impact was found in the case of the manufacturing sector (p=.00). However, the result indicated otherwise in the case of non-manufacturing sector (p=.53).

Impact Of ISO Certification On Training Delivery Methods

Seven indicators were used to measure the impact of ISO 9000 certification on Training Delivery Methods. When t-tests were conducted on the total sample, it was found that the ISO 9000 certification did have significant impact on each of the training delivery indicators (the p values ranged from .00 to .017) and therefore, the null hypothesis was rejected. Similar result was obtained in the case of the manufacturing sector (the p values ranged from .00 to .004). However, as in the earlier cases, no significant differences were found in the case of the non-manufacturing companies (the p values ranged from .104 to .622).

Impact Of ISO 9000 Certification On Training Evaluation

Four indicators were used to measure the impact of ISO 9000 certification on training evaluation. When t-tests were conducted on the total sample, they were found to have significant positive impact on training (p- values ranging from 0.000 to 0.002). Similar result was obtained in the case of the manufacturing sector (p values ranged from .00 to .006). However, as in the earlier cases, no significant differences were found in the case of the non-manufacturing companies (p values ranged from .104 to .447).

Impact Of ISO 9000 Certification On Human Resource Development Activities

Five indicators were used to measure the impact of ISO 9000 certification on human resource development:

- Average number of training hours per employee per year
- Average training hours per employee per year for different types of training
- Average percentage of payroll dollar spent on training
- Types of training provided in organizations
- Perceived benefits of ISO 9000 certification

When t-tests were conducted on the sample, the ISO 9000 certification showed significant impact on overall HRD activities (the p values ranged from .00 to .003). A similar result was obtained in the case of the
manufacturing sector (the \( p \) values ranged from .0 to .003). However, as in the earlier cases, no significant differences were found in the case of the non-manufacturing companies.

The sample companies reported an increase in the total training hours per employee per year at all levels of employees (that is, executives, mid-level managers, supervisors and front-line employees). Middle level managers and executives had the largest increase with 80.6 percent and 77.7 percent respectively. The aggregate change for manufacturing companies showed an increase of 67.7 percent. In case of non-manufacturing companies the results were different from those of the manufacturing sector. Training hours increased by 31 percent and three percent respectively in case of the front-line employees and mid-level managers. The hours declined in case of the executives and the supervisors. The combined sample however, showed increase in all levels of employees ranging between 27 percent and 50 percent. When the respondents were asked to indicate the possible reasons for such changes, about 43 percent of them indicated that the change was due to the implementation of ISO 9000 standard only. However, 39 percent said that the change was due to the shift of company policy other than ISO 9000 certification. The opinion varied between manufacturing and non-manufacturing.

In the manufacturing sector, average training hours per employee per year for different types of training increased for most categories of employees and for most types of training except for Technical Training and Production & Engineering. In both of these instances, the hours decreased for the supervisory staff and the front line employees. In the case of non-manufacturing, average training hours increased for most categories of employees and for most types of training except for technical training and product and quality training. In these two categories the hours either decreased or remained unchanged except for technical training for middle level managers, which went up by ten percent. Mixed result is observed when all the samples were considered together.

When the respondents were asked to indicate the reasons for the change in average training hours per employee per year for different types of training, 61 percent of the total sample indicated the change was due to the implementation of ISO 9000 Standard only whereas, another 25 percent stated that the changes were due to change of company policy other than ISO 9000 certification. Only seven percent indicated that the change in PSB/SDF incentive programs were the reason for such outcome. The opinion of the respondents varied between the manufacturing and service sector.

In the manufacturing sector, there was slight increase in average percentage payroll amount spent on training in the case of mid-level managers (0.1 percent) and the supervisors (0.4 percent). However, the amount spent declined in the case of the executives by about two percent but there was no change for the front-line employees. The picture in the non-manufacturing sector was however different from that of the manufacturing where the average percentage payroll amount spent on training increased for all categories of employees by between 2.5 percent to 3 percent.

When the respondents were asked to indicate the reasons for change in the percentage of payroll spent for training, 57 percent of the total sample indicated the change was due to the implementation of ISO 9000 Standard only whereas, another 18 percent stated that the changes were due to change of company policy other than ISO 9000 certification. The opinion of the respondents varied between the manufacturing and service sector. For example, 47 and 78 percent of the manufacturing and service organizations respectively indicated that the reason for the change was due to ISO 9000 certification.

During the implementation of the standard 95 percent of the manufacturing companies provided some form of ISO 9000 training for their executives. For non-manufacturing, 89 percent of the companies provided such training. All the responding companies did provide such training for their middle level managers. More than 90 percent (manufacturing 95 percent, non-manufacturing 100 percent) of the sample companies provided awareness training for their supervisory level employees. In case of the front line employees, 68 percent of the manufacturing and 100 percent of the non-manufacturing companies provided such training. Less than two-thirds of manufacturing companies (63.2 percent) and 100 percent of the non-manufacturing companies reported having their employees trained as 'Lead Auditor'. About 95 percent of the manufacturing companies and 89 percent of the non-manufacturing companies provided Internal Auditor training to its employees.

The respondents were asked to rate a number of statements regarding the possible advantages of ISO 9000 certification on a 5-point Likert-type scale (1= strongly disagree and 5=strongly agree). The statements were on training and development, competitive position, customer relationship, quality of products and services, training related record management, and on-the-job-training. The summary of the findings is reported below:

**Training And Development.** Based on the overall sample, 50 percent either agreed or strongly agreed that ISO certification helped improve their training and development processes. About 32 percent were undecided and the rest 18 percent disagreed with the statement. About 53 percent of the manufacturing and 44 percent of service organizations either agreed or strongly agreed with the statement. About 11 percent and 33 percent of the manufacturing and non-manufacturing respectively disagreed.
Competitive Position. Majority of the overall sample (83 percent) agreed or strongly agreed that ISO 9000 certification improved their competitive position, 14 percent were undecided and 2 percent disagreed. About 95 percent of the manufacturing and 56 percent of the non-manufacturing organizations agreed with the statement.

Relationship With Customers. More than 90 percent of the respondents either agreed or strongly agreed that ISO 9000 certification improved relationship with their customers and only 7 percent were undecided. About 79 percent of the manufacturing and 100 percent of the non-manufacturing organizations agreed with the statement.

Quality Of Products And Services. Ninety-five percent of the sample organizations either agreed or strongly agreed that the ISO 9000 certification helped improve the quality of their products & services and the rest were undecided. All the manufacturing companies and about 78 percent of the non-manufacturing companies agreed with the statement.

Training-Related Records Management. About 75 percent of the sample either agreed or strongly agreed that ISO 9000 certification improved training-related records management, 21 percent were undecided and the rest four percent disagreed. About 79 percent of the manufacturing and 66 percent of non-manufacturing companies agreed with the statement.

On-The-Job Training. Only 65% of the organizations felt that ISO 9000 certification improved on-the-job-training program and the rest 40 percent were undecided. About 69 percent of the manufacturing and 44 percent non-manufacturing companies agreed with the statement.

Summary and Discussion

In summary, from the results presented, a consistent pattern emerged. For all the five research questions significant improvements in training needs analysis, training design, training delivery, training evaluation, and human resource development activities were reported by the manufacturing organization but not in the case of the service organizations. In case of the manufacturing organizations, average training hours had increased for all types of employees whereas, for the service organizations the result was mixed. Slightly less than 50 percent of the respondents agreed or strongly agreed that the increase was due to the ISO 9000 certification. When probed into the different types of training, it was found that the average training hours for various types of training had gone up for both manufacturing and service sectors. About 60 percent of the respondents agreed or strongly agreed that the improvements were due to ISO certification.

Average percent of payroll amount spent also increased in both manufacturing and service sectors with the exception in the case of executives in the manufacturing. More than fifty percent (57 percent) of the respondents agreed or strongly agreed that the increase was attributable to the ISO certification.

Most of the sample organizations provided awareness training for all levels of their employees. ‘Lead Auditor’ training was provided by majority of these organizations. However, there was relatively less proportion of organizations (63 percent) in the manufacturing sector that provided ‘Lead Auditor’ training compared to the service sector (100%).

More than 75 percent of the respondents agreed or strongly agreed that ISO certification resulted in improved competitiveness, improved relationship with customers, improvement of quality of products and services and improvement in training related records. However, only 50 percent of the respondents agreed or strongly agreed that the certification helped improve the training and development process.

Significant improvements in training needs analysis, training design and delivery, training evaluation and HRD activities were reported in the manufacturing organizations. However, no such improvements were found in the service sector. Also there is some degree of agreement among the respondents that the improvements in the average training hours per employee and average percentage of payroll amount spent for training in the sample organizations were the outcome of ISO 9000 certification. Besides training related activities, the respondents also indicated that ISO 9000 certification helped their organizations derive benefits in a number of aspects i.e., improved competitiveness, improved relationship with customers, improved quality of products and services and improved management of training records.

McAdam and McKeown (1999), Sun (1999) and Quazi and Padibjo (1998) reported that ISO 9000 certification helped improve relationship with customers, comply to customer requirements and reduce customer complaints which are in line with the finding of this study where 90 percent of the respondents agreed that such certification help improve relationship with customers. Findings of this study regarding the positive impact of ISO 9000 certification on competitive position correspond with those of Anderson et al. (1999) and Quazi and Padibjo (1998). However, this finding is in contradiction with that of Sun (1999) who argues that ISO 9000 certification has little influence on market position and competitiveness.
Finding of Quazi and Padibjo (1998) on improved training related records is similar to that of the present study. This is to be noted that improved management of quality records is one of the primary benefits of ISO 9000 certification and therefore, the finding is in consonance with the objective of the certification. Although McAdam and McKeown (1999) reported that the ISO 9000 certified companies had high levels of training activities but that does not necessarily mean that such activities have gone up as a result of ISO 9000 certification. Quazi and Padibjo (1998) on the other hand reported that lack of training of the employees was one of the barriers to ISO 9000 certification. However, findings of this study clearly indicate that such certification did help improve the training and human resource development activities of the responding organizations. Furthermore, between 40-60 percent respondents agreed that the average hours of training per employee per year and average percentage payroll amount spent on training had increased due to the ISO 9000 certification.

The finding of this study indicate that ISO certification help improve the quality of the products and services. Although ISO 9000 standard does not directly address the quality of the products and services, quality improvement may be the outcome of a well-managed system. According to Dalfonso (1995) the ISO 9000 standard is to produce a quality system within an organization which enables it to improve the way it currently does business, focus resources, document its processes, improve its customer relationship and satisfy customers and be involved in quality improvement. The quality system induces the management and employees to consciously trying to improve the quality of its products and services. Therefore, the finding of this study is consistent with the objective of the standard.

The manufacturing organizations showed significant improvements in all five phases of the systems approach when compared the levels of such activities between three years prior to and three years after the certification. In the case of service organizations, no significant differences were found. As no earlier studies reported any findings on this particular issue, it is not possible to specifically comment on the reasons for such result. The only possible reason that could explain the findings is that the sample size of the service organization in the sample was very small (N=9) and as such it may have affected the outcome of the statistical tests performed. Furthermore, the size of the organizations may have played a role in the kind of results obtained. A good discussion on the impact of ISO 9000 and organizational size could be found in Lee and Palmer (1999), Wiele and Brown (197-1998), Goh and Ridgway (1994) and Quazi et al. (in press). Due to the small sample size in this study no analysis using the organizational size and other related variables was attempted. Further studies in different countries with larger samples are suggested for the purpose of generalization of the results reported in this research.

Applying Client and Consultant Generated Metaphors in HRD: Lessons from Psychotherapy

Darren Short
Perspectives, UK

The metaphors we use shine a torch on how we perceive situations. For decades, some psychotherapists have used their own metaphors and the metaphoric language of their clients as part of a process to understand and transform behavior. This paper provides an overview of some of those techniques and an initial reaction to how they could be transferred to the helping relationship role of HRD consultants in organizations. The paper highlights the need for further research.

Keywords: Metaphor, Psychotherapy, Consultancy

Dedication: Much of this paper was written during September 11-15, 2001. It is dedicated to the volunteers from the Holy Heart of Mary High School, St Johns, Newfoundland, who looked after me, and the hundreds like me, stranded many miles from home.

As Schein (1999) described within the concept of appreciative inquiry, “our mental models and the metaphors we use for deciphering and labeling reality structure what we see and how we think about it” (p. 56). Situations will therefore be perceived differently by two individuals to the extent that the metaphoric structure, with which conceive reality, is similar or different. These structures can be grouped together to help summarize the ways in which many individuals perceive a set of situations, for example, Kuchinke’s (2000) three theoretical approaches to HRD and examples of metaphoric language for each. Others of particular relevance to HRD include Marshak’s (1993) grouping of metaphors for change and Morgan’s eight metaphors for organizations.

Metaphors are always present in our language, and therefore offer a potential insight to how we conceive situations and responses. That is certainly the case within organizations, and there are many documented examples of metaphors being used by employees and leaders. There is also evidence of this metaphoric language being used in HRD work within organizations. Short (2000) highlighted examples covering: how perceptive organizational consultants notice the rich metaphorical language of clients and other stakeholders as they describe their work environment; and using metaphors to facilitate transformations in organizations, for example by identifying gaps between current and desired metaphors as catalysts of change or by facilitating change in organizations that is either incremental (within a metaphor) or fundamental (from one metaphor to another).

These cited examples describe the application of metaphor at a group or organizational level, where change is required by a group or across an organization. What is less clear from existing work is how to analyze and transform metaphor at an individual level. For example, imagine the situation where an HRD consultant is working one-to-one with a client: how does the consultant use metaphors introduced by the client, and how does the consultant introduce his/her own metaphors to aid understanding and transformation? Some of this work has been described within Neuro-Linguistic Programming texts, although has not been considered from an HRD research perspective nor linked into the recent work on metaphor in HRD published by HRD researchers (for example: Short, 2000; Ardichvili, 2001; Daley, 2001).

Contribution and Structure of This Paper

Many fields and disciplines have acted on the importance of studying metaphor, including psychology, information systems, psychotherapy, organization development, organizational change, teaching, and research; and suggestions have been made that HRD can learn from that study and can translate those lessons into the HRD context (Short, 2000). This paper focuses on application in HRD, and specifically on the way in which HRD consultants can apply metaphor in their one-to-one work. It does that by considering the potential lessons from the experiences of those applying metaphor in a field where equivalent one-to-one conversations are held between a ‘consultant’ and a ‘client,’ that of psychotherapy. There are, without doubt, other lessons to be learned from other fields and disciplines, but space dictates that this paper focuses on one.

This paper should be considered within the broader context of the recent developments in the study of metaphor in HRD. For example, the 2001 Advances in Developing Human Resources journal issue dedicated to metaphor in HRD closed some of the gap between metaphor study in HRD and those in other disciplines by

40-1
illustrating metaphor in HRD research, practice, and education. Lessons for HRD from the application of metaphor in psychotherapy were touched upon briefly in the Advances issue. For example, Short (2001a) stated that, "consultants could adapt methods already being applied in psychotherapy to explore clients' metaphors" (p. 387). This paper picks up that hook and considers the methods applied in psychotherapeutic practices. It addresses the three questions: How are metaphors applied in psychotherapy? What can HRD learn from the application of metaphor in psychotherapy? What are the implications for HRD professionals?

The paper is structured to first describe metaphor theory; then the application of metaphor in psychotherapy; followed by a discussion section exploring the suitability of transferring the application techniques to HRD practice; and finally, an implications and conclusions section describing the need for further research and reflection on the application of metaphor in HRD practice.

Theoretical Framework on Metaphor

Metaphor is derived from the Greek meta, meaning 'above or over,' and phorein, meaning 'to carry or bear from one place to another.' Metaphors therefore carry meaning over from one domain to another (Kopp, 1995). To be a little more specific, a metaphor presents a way of seeing something as if it were something else and, by transferring meaning from one domain into another, it enriches and enhances both domains (Barrett & Cooperrider, 1990).

By presenting something as if it were something else, metaphors seek to generate new meaning for an existing entity or to fill gaps in our language. To use an example from HRD, the term 'brainstorming' fills a lexical gap by providing a powerful image of the activity rather than a longer literal description (Short, 2001b). That new meaning is typically generated by structuring inherently vague items in terms of something more concrete (Tsoukas, 1991), with the creative potential of metaphor depending on the tension between the two. People therefore conceive of something uncertain or unknown, such as an organization, by associating it with something they know a lot more about, such as a machine (Morgan, 1997). The generation of new meaning results from the partial nature of metaphors, and that partial nature implies that several metaphors are needed to provide a more rounded coverage of an entity. A good example is Morgan's (1997) use of eight metaphors to capture the different features of organizations: machine, organism, brain, culture, political system, psychic prison, flux and transformation, and instruments of domination.

Many theories have been offered to describe and explain different aspects of metaphorical language and metaphor processing (Cameron, 1999; Gibbs, 1999) but, more than any other, cognitive theories of metaphor have had the greatest impact on metaphor research and thinking over the past thirty years. Lakoff and Johnson (1980) proposed that metaphor is not just a matter of language, and that human thought processes are largely metaphorical; and this led an increasing agreement that metaphor is an indispensable basis of both language and thought (Goatly, 1997).

Lakoff and Johnson (1980) argued that such expressions as 'is that the foundation of your theory?' and 'the theory needs more support' do not exist individually as random clichés but instead reflect how we conceive of theories and arguments as kinds of buildings through the conceptual metaphor THEORIES (AND ARGUMENTS) ARE BUILDINGS. Many other mappings exist between language and conceptual metaphors, leading Lakoff (1993) to conclude that, "metaphor is not just a matter of language, but of thought and reason. The language is secondary. The mapping is primary, in that it sanctions the use of source domain language and inference patterns for target domain concepts" (p.208). Metaphors therefore operate as filters that screen some details and emphasize others, and in so doing they organize our view of the world (Barrett & Cooperrider, 1990). Lakoff and Johnson (1980) argued that if a person values those factors highlighted or emphasized by a particular metaphor, then that metaphor can acquire the status of truth, and then guide future actions, justify inferences, and help set goals. Associating metaphor with action raises the potential for influencing future behavior through changes to metaphors, perhaps through the introduction of new and imaginative metaphors to change conceptual systems. This is not to suggest that language alone changes reality, but that changes in conceptual systems alter what is real for us and affect how we perceive the world and act upon those perceptions (Lakoff & Johnson, 1980).

Many examples have been documented of how behavior change resulted from the introduction of new metaphors. Short (2001b) listed a few of these and their references, including: helping a dysfunctional group to liberate aspirations, decrease interpersonal conflict, build strategic consensus, and renew the collective will to act; reframing problems to produce innovative ways of tackling social policy problems; pictorial metaphors in computer-generated displays used in the development of professionals to guide future skilled action; 'unfreezing' organizations prior to change; and the reframing of client-generated metaphors in psychotherapy.
Metaphors in Psychotherapy

There are many different definitions and types of psychotherapy, although a central feature is that of the relationship between the therapist and the patient, which seeks to produce changes in cognition, feeling, and behavior (Holmes & Lindley, 1989). The therapy situation comprises three main elements: a healing agent (the therapist), a sufferer who is seeking relief, and a healing relationship that includes a structured series of contacts between the healer and sufferer (Frank & Frank, 1991). According to Lankton and Lankton (1983), the majority of clients enter psychotherapy as a ‘last ditch effort’ to gain relief from problems that are immediately threatening, where their perceptions about change may be locked or obscured and altering those perceptions is the foundation of change in psychotherapy.

Watzalawick (1978) identified two languages present in psychotherapy: the one was objective, definitional, cerebral, logical, and analytical – the language of reason, or science, of explanation and interpretation; the other was the language of imagery, metaphor, and symbols, which according to Lankton and Lankton (1983), engages normal comprehension-making mechanisms of the mind more effectively than logical speech. Watzalawick (1978) argued this was due in part to the way the brain processes metaphorical language. The left hemisphere of the brain tends to process information sequentially, building realities one piece at a time in terms of hierarchies, dealing with the logical and rational (Close, 1998). Consequently, when problems are tackled using the left hemisphere, it is possible that clients believe the soundness of the advice given to them but remain unable to make the needed changes in their behaviors and feelings (Barker, 1996). The right brain functions by grasping things in their entirety; it is the world of spatial awareness, visualization, music, art, drama, feelings, intuition, and spirituality (Close, 1998). Where a series of logical, rational treatment plans have failed, metaphors can bypass (or outflank) the left-brain, opening up potentials for creating new patterns and connections (Close, 1998), and so offering creative approaches to perception and behavior change (Barker, 1996).

The basis of metaphor in psychotherapy is the belief that new experiences and ideas can result from evoking and transforming metaphorical images. There are many examples of how metaphors, in the form of stories, have influenced the behaviors of many people, including religious parables and children’s fables (Lankton & Lankton, 1983); and the application of metaphor in psychotherapy builds on the power of metaphor to affect behavior. Not that the application of metaphor in psychotherapy forms a new ‘school’ of therapy, but instead emphasizes the therapeutic interventions possible because of the metaphorical communication within existing methods (Kopp, 1995).

There are two broad classes of metaphor application in psychotherapy: client-generated, and therapist-generated (Kopp, 1995); and the literature review in this section provide an overview of each. The vast majority of accounts of metaphorical interventions in psychotherapy involves the use of therapist-generated metaphors, rather than client-generated (Kopp, 1995).

Therapist-Generated Metaphors in Psychotherapy

The general approach to using metaphors in psychotherapy, through stories and anecdotes, was pioneered by Milton Erickson, specifically within the context of Ericksonian hypnotherapy (Lankton & Lankton, 1983). Several features typified Erickson’s approach, including the use of metaphor as part of an indirect strategy, and the use of embedded metaphors (introducing new metaphors within other metaphors) as part of a conscious/unconscious dissociation. Whereas Erickson’s application of metaphor was generally with clients in a state of hypnotic trance, others have documented the more general application of therapist-generated metaphors, including Barker (1996) who described eight types of metaphor introduced by therapists (also see Close, 1998, for examples of applications):

- Major stories – carefully constructed, often quite long, stories tailored to the specific needs of a clinical situation.
- Anecdotes and short stories – used with limited goals to make specific points in a concise and focused way.
- Analogies, similes, and brief metaphorical statements – have similar aims to anecdotes and are commonplace devices used in everyday conversation.
- Relationship metaphors - where one relationship is used as a metaphor for another.
- Tasks and rituals – valuable at transition points, such as the transition from one situation to another, or at the termination of therapy.
- Metaphorical objects – where one object is used in therapy to represent another.
- Artistic metaphors – allowing people to express their feelings and ideas through drawing, painting, sculpture, etc.
- Cartoon therapy – linked to artistic metaphors, this is used particularly with children.
Barker (1996) stated that all the different types have the same aim: of reframing (changing the meaning of something), by offering different understandings of situations, of people’s views of themselves or others, of relationships, of how problems can be solved, of past experiences, and of what the future holds. This is achieved by using metaphors to make or illustrate points, suggest solutions, help people to recognize themselves, seed ideas, increase motivation, embed directives, decrease resistance, model a way of communication, etc., (Barker, 1996, citing from Zeig).

Client-Generated Metaphors in Psychotherapy

Kopp (1995) believed that, “a client’s metaphoric language lies closer to the client’s unconscious than any theory’s metaphoric language. Thus, it is the metaphoric imagery created by the person that most directly represents that person’s unconscious process” (p. 115). Kopp (1995) therefore described client-generated metaphors as “allowing both the therapist and the client [to] expand and deepen their understanding of the client’s belief system reflected in the client’s metaphoric speech and early childhood memory metaphors” (p. xvii). Kopp (1995) argued that there are six dimensions of client-generated metaphors that illustrate individual reality (he called there metaphorms). The six are, about the: self, one (either an individual or a group), life, self-other (the client’s connection with others), self-life (the client’s connection with themselves), self-life (the client’s connection with life).

Emphasis on clients’ metaphors requires that the therapy shifts into the domain of metaphoric imagery, with attention being paid less to the logical meaning associated with the communication content and more to the metaphoric image. This is achieved by the therapist facilitating the client’s exploration of his or her own metaphoric imagery, avoiding external interpretations or frames of reference, as would be introduced if the therapist used his or her own metaphors. As Kopp stated (1995), through the therapy, “the client is freed by changing the metaphor, which can result in a change in the client’s perception of reality. The changed metaphor is expanded to include a new possibility of relationship with self, others, and the world” (p. 107).

Kopp (1995) offered a six-step process for working with these client-generated metaphors as they appear in psychotherapy:

1. Step 1: The therapist notices metaphors present in the client’s communication.
2. Step 2a: The therapist invites the client to explore his or her own metaphoric images.
3. Step 2b: If the client does not understand or respond, the therapist prompts for descriptions, potentially by offering their own images.
4. Step 3: The therapist invites the client to explore the metaphor as a sensory image (building on the description of the image, who is involved, what is happening, etc).
5. Step 4: The therapist invites the client to describe the feelings and experiences associated with the image.
6. Step 5: The therapist invites the client to transform the metaphor whether by changing the metaphoric image or by inviting the client to consider a change suggested by the therapist.
7. Step 6: The therapist invites the client to build a bridge back to the original situation.

Exploring the Similarities Between Psychotherapy Metaphor and Applications in HRD

HRD and Psychotherapy: Overview

There are clear links between HRD and psychology (Swanson, 1992), with psychology being described as one of the root disciplines of HRD; however, specific associations with psychotherapy have been explored less thoroughly. Nevertheless, there are similarities between the descriptions of psychotherapy offered earlier in the paper by Frank and Frank (1991) and by Holmes and Lindley (1989) and descriptions of organizational consultancy and the helping relationship role of consultants described by Schein (1999).

Many descriptions have been offered for the stages involved in training and OD, and these tend to stress the importance of HRD professionals understanding the situation, designing or working with clients to design interventions, and supporting clients through implementation of interventions (amongst other key stages). The main intended outcome for such interventions is behavior change, usually described in terms of performance improvement. Where such interventions involve one-to-one work with clients, HRD professionals and psychotherapists are involved in equivalent activities in supporting clients, understanding problem situations and their root causes, tackling beliefs and unchallenged assumptions that underpin current behaviors, tackling those causes, and encouraging behavior change. The practice remit of most HRD professionals goes beyond this, for
example to deal more frequently with group and organizational levels, but this paper concentrates on the similarities between psychotherapy and HRD at an individual level. The implications will be considered in terms of client-generated and therapist-generated (the term 'consultant-generated' will be used when referring to application by HRD professionals).

**A process for Using Client-generated Metaphors in HRD**

Some work has already been completed on using client-generated metaphors in HRD practice, at least in terms of understanding the current situation. Basten (2001), for example, used an adapted learning history instrument to analyze interviews with employees, and so to highlight metaphors employees used to describe their organization's culture. She identified a dominant metaphor of the organization as a pioneer, with at least three themes of the organization on a journey, as a building, and in a battle. These were then contrasted with metaphors identified from key documents from the organization. The method was offered as a means of deriving an agreed history of the problem or situation, of tracking changes in metaphor over time, and of raising levels of awareness on dominant metaphors and their impact on employee behavior.

However, Kopp's (1995) work on client-generated metaphors in psychotherapy went much further by illustrating applications to changing client behaviors. He offered both six metaphorms (six dimensions of metaphoric structure) and six steps for using client-generated metaphors. His six metaphorms can be translated into the context of HRD as being:

- **Self** – e.g. I am trapped in this job and ready to explode.
- **Other** – e.g. my boss is a baboon, my work team is a bunch of circus clowns.
- **Life** – e.g. work is a maze with snipers hidden in the bushes.
- **Self-self** – e.g. I keep banging my head against a wall.
- **Self-other** – e.g. I am trying to transform my team into superheroes.
- **Self-life** – e.g. my career is sinking into the quicksand.

Being aware of these six metaphorms helps HRD professionals to develop a more holistic understanding of how clients structure their reality. For example, through several discussions and careful analysis of the metaphorms used, HRD professionals can gain a picture of how reality is perceived by the client relative to themselves, those they work with, their work life, and their relation to others and their work. As part of that process, or as a separate process, HRD professionals can adapt Kopp’s six stages into seven steps for facilitating behavior change in clients using the reframing of metaphorms. Those seven steps are:

- **Step 1:** The HRD professional notices metaphors present in the client’s communication. To illustrate possible examples, Basten’s (2001) case study included: we are trying to keep our heads above water; it is like fighting windmills constantly; the idea has been shot at twice already but keeps coming back. This requires that the HRD professional tunes into metaphoric language, although without tuning out literal descriptions (and so listening with both hemispheres of the brain).
- **Step 2:** The HRD professional invites the client to explore his or her own metaphoric images (if needed, prompting the client using the professional’s own examples). This step involves developing the metaphor from a short statement and into a mental image, for example by asking, “what does fighting windmills look like?” or “when you say the idea has been shot at twice, what image occurs to you?” Note the importance of using the language of the client, and inviting him or her to generate a mental image.
- **Step 3:** The HRD professional invites the client to explore the metaphor as a sensory image (building on the description of the image, who is involved, what is happening, etc). This involves exploring a few of the sensory aspects of the image, such as what else the client sees or hears in the image, by asking: “Who is in the image, and what are they doing?” “What is happening in the image, and what happened before this point?” “What happens next?”
- **Step 4:** Once the client has finished exploring the imagery, the HRD professional invites him or her to describe the feelings and experiences associated with the image. Again, the HRD professional stays within the metaphoric image, avoiding introducing new content, by asking such questions as: “What’s it like to be fighting windmills?” or “What are you feeling as you try to keep your head above water?”
- **Step 5:** When exploring the metaphoric image seems complete, the HRD professional invites the client to transform the metaphoric image. The ideal is for the client to change the metaphoric image, however in some case it may be necessary to invite clients to consider suggested changes. The rationale behind this step is that the metaphoric image represents the original situation as described using metaphoric terms, and so changing the image can produce changes to the metaphoric terms and how the original situation is.
perceived. Changing the metaphoric image requires that the client considers how he or she needs or wants to feel or experience, and what the sensory image should be.

- Step 6: After facilitating a change in the image, the HRD professional then invites the client to build a bridge back to the original situation using a two-stage approach. First, the HRD professional asks, “What parallels do you see between your original image and the current situation you face,” and invites discussion of the similarities. Second, the HRD professional asks, “How might the way you changed the image apply to your current situation?”

- Step 7: As the changed image produces new insights on the current situation, the HRD professional encourages the client to identify specific actions he or she can take within the current situation and in the direction suggested by the changed metaphoric image.

**Figure 1: Diagram of the steps for applying client-generated metaphor in one-to-one HRD practice**

---

**Applying the Client-generated Metaphor Process in HRD Practice**

This seven-stage process is not intended as a replacement for existing conversations between HRD professionals and their clients, nor should it be viewed as an HRD professional’s primary means of approaching behavior change in one-to-one consulting or counseling situations. However, it does offer HRD professionals an additional technique for applying in particular situations, and best practice will need to be determined through research (in terms of when and how to use metaphors in one-to-one HRD situations). More work is also needed to determine how the above steps can be applied to different situations, for example, whether there is a shortened version of the process that can be applied in certain situations without the need to work through all seven.

In the meantime, experience from application in psychotherapy offers some insights to the ‘when’ and ‘how’ of client-generated metaphor application in HRD, including:

- Certain clients will be more open than others to exploring metaphor in conversations with HRD professionals. It is possible that some already make deliberate use of metaphor, for example as a tool to describe situations to their employees or to the HRD professional. Such individuals are likely to be more open to exploring the metaphoric images, and potential changes to those images, that flow from their metaphoric language. Others are likely to be more reluctant. HRD professionals need to use their judgment when deciding how to introduce metaphor into their one-to-one work with a specific client, if at all.

- Part of the decision on timing may involve the degree of rapport developed between the HRD professional and the client. Where there is a long-term trusting relationship, HRD professionals are likely to find it easier to introduce metaphor into their one-to-one work with that client. Earlier attempts, without the
Developing Human Resources

A process for Using Consultant-generated Metaphors in HRD

Several books are already available that offer HRD professionals a source of metaphor, in the form of stories, that can be introduced as consultant-generated either in a one-to-one or group setting. Berman and Brown (2000), for example, offer stories to help with: overcoming barriers to learning, promoting self-esteem, successes and failures in the learning process, differentiating between wants and needs, leaving the past behind, dealing with conflict, etc. When used in group-settings, Berman and Brown (2000) provide HRD professionals with guidance on using guided visualization techniques to accompany the stories.

As with therapist-generated metaphor in psychotherapy, it is likely that metaphors generated by HRD professionals are used explicitly in behavior change far more than those generated by clients, in part because of the relative ease with which they can be introduced into dialogue. Using client-generated metaphors requires a deliberate, systematic process whereby the HRD professional pays attention to client metaphor, then works with the client to explore them and draw parallels between current and desired situations. On the other hand, consultant-generated metaphors, particularly in the form of stories or anecdotes, can just be slotted into dialogues (for example, to emphasize the need for change), and it is likely that this happens on a regular basis without drawing attention to the role of metaphor in the change process.

Whereas the use of client-generated metaphor requires adopting a specific process, using consultant-generated metaphors may mean that the HRD professional can apply the process that he or she would normally adopt when working with clients to understand situations or identify possible actions. This would, of course, depending on the type of metaphor used. Although building metaphor into existing processes is possible, experience from the application in psychotherapy illustrates the importance of paying careful attention to selecting the best metaphor, to help clients may need to understand the parallels between their situation and the messages in the metaphor, and to the potential for returning back to the metaphor during long dialogues or a series of them.

Some of the metaphor options available to HRD professionals include those identified by Barker (1996) for psychotherapy: major stories; anecdotes and short stories; analogies, similes, and brief metaphorical statements; relationship metaphors; tasks and rituals; metaphorical objects; artistic metaphors; cartoon therapy; and artistic metaphors. Each offers the potential for application in HRD one-to-one work with clients, and research is needed to determine how each is currently used and best practice in their application.

Conclusions and Implications for HRD

This paper set out to build on the recent work on metaphor in HRD and, in particular, on the journal Advances in Developing Human Resources dedicated to metaphor in HRD research, practice, and education. In the Advances, Short (2001a) identified that there was still much for HRD to learn from exploring the application of metaphor in other disciplines, and that was particularly the case for HRD practitioners who could further extend their use of metaphor in working with clients. Although a number of disciplines could have been selected for study, this paper concentrated on psychotherapy, where metaphor application is well documented. The paper therefore explored how metaphors are applied in psychotherapy, what HRD can learn from that application, and the implications for HRD.

As the literature review in the paper demonstrated, psychotherapy has recognized the potential for metaphors to assist in changing perceptions and behaviors both in terms of client- and therapist-generated metaphors. There are potential advantages for HRD from considering the lesson from both types, although the space available in this paper meant that it could only scratch the surface. In doing that, it highlighted the potential from exploring the Kopp (1995) six-metaphor structure for understanding reality as perceived by the client, and also the potential from adapting Kopp's process for using client-generated metaphor during HRD consultancy. Lessons from adapting the Ericksonian approach of therapist-generated metaphors were explored in less detail in this paper, although there is a need for that work. As well as such specific work, this paper has also demonstrated the potential gains from continuing the journey through further research and scholarly practice by examining such questions as:

- Which HRD problems lend themselves most readily to the application of metaphor?
- Which HRD clients lend themselves most readily to the application of metaphor?
• What context is required for introducing metaphor application (for example, in terms of the relationship between the HRD professional and the client)?
• What training or professional development do HRD professionals need in preparation for building metaphor into their work?

In terms of scholarly practice, this paper calls for increased sharing of practitioner accounts of using metaphor, where HRD professionals are working to support changes in how situations are perceived and to facilitate behavior changes. Through the sharing of case studies, answers will gradually emerge to the above questions.

Emotional intelligence is now being referred to as the panacea for all organizational performance ills. It is these types of broad generalizations that move this area of interest dangerously close to a corporate fad. A more limited perspective of emotional intelligence, however, may provide an avenue for further research. The purpose of this paper is to review the current state of research in emotional intelligence and to explore the applicability of this phenomenon to HRD.

Keywords: Emotional Intelligence, Organizational Performance

The field of organizational behavior consists of the systematic study of the actions and attitudes that members exhibit. Those actions and attitudes are displayed through the activity of lived emotion, through workday frustrations and passions, which are deeply woven into organizational roles and characterize and inform organizational processes (Fineman, 2000a). These organizations and their processes are a network of feedback systems. This systemic activity is a foundation of an organization. The effectiveness of this systemic activity, through the actions of its organizational members can drive individual and organizational performance.

There has been a surge of interest in Emotional Intelligence through the 1990’s, especially with the popular publication of Goleman’s (1995) book entitled Emotional Intelligence. The study of areas to improve individual and organizational performance exists within the field of Human Resource Development (HRD). Looking to the framework of emotional intelligence may provide an additional pathway for research for HRD scholars. Emotional Intelligence as defined by Mayer and Salovey (1997) is:

...the ability to perceive accurately, appraise, and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth (p. 10).

The purpose of this paper is to review the current state of research in emotional intelligence and to explore the applicability of this phenomenon to HRD. The basis of emotional intelligence first comes with an understanding of the role of emotion at work and the respective research in that area. From this basis, additional details into research in emotional intelligence will be identified along with its applicability to HRD. This literature review will be limited to those primary contributors in the respective areas.

Study of Emotion

The study of emotional intelligence has emerged out of the psychological domain within the overall study of emotion. Emotion research itself has been driven primarily from a sociological and psychological perspective. Various research interests exist within each domain of study.

Sociological Perspective

Much of the sociological emotion at work research is based on the groundbreaking research of Hochschild (1979). In her essay, she proposed that a perspective of emotion management provides a lens through which one can inspect the self, interactions and structure. She identified “feeling rules” which were guidelines within the organization that governed how people try or do not try to feel in ways “appropriate to the situation”. Emotion management is the type of work that is required to deal with the organizational “feeling rules”. Hochschild (1983) furthered this work and defined emotion management as the “management of feeling to create a publicly observable facial and bodily display” (p. 7).

Emotions can be indicators of well-being and happiness. Prior to Hochschild, Goffman (1969) considered that many of the emotions conveyed by employees could be thought of as control moves. These control moves are the “intentional effort of an informant to produce expressions he thinks will improve his situation if they are gleaned

by an observer” (p. 12). Rafaeli and Sutton (1987) followed the spirit of Goffman’s writings in their paper where they considered work settings in which employees display emotions in order to fulfill role expectations.

Emotion is a component of communication, and for it to convey meaning the message must be encoded by a source and decoded by a receiver (Osgood, Suci & Tannebaum, 1957). These emotional messages or displays can be taught to employees through operant conditioning, socialization, informal organization, selection and even rewards. These rewards are used to encourage or discourage the display of certain emotions (Rafaeli & Sutton, 1987). But it is the organizational context that has the strongest influence over feelings conveyed at the outset of an emotional transaction. Because of this, Rafaeli and Sutton proposed, “emotion work can bring about immediate, encore and contagion gains (or losses) for the organization” (p. 29). This emotional contagion is the ability to have a heightened potential to infect others on an emotional plane through facial and vocal expressions and posture (Domagalski, 1999).

Callahan and McCollum (2001), Short (2001) and Turnbull (2001) are currently completing emotion work in the field of HRD. Callahan and McCollum describe a framework for conceptualizing emotional behavior in an organizational context. Short looks to analyzing training from an emotion perspective and Turnbull looks at the role of emotions in a corporate change program. These HRD scholars, as well as Hochshild, Goffman and Rafaeli & Sutton are looking into the role of emotion work from a sociological perspective, but of what interest would the construct of emotional intelligence be from a psychological perspective?

**Psychological Perspective**

The definition of HRD has evolved and still today, numerous definitions exist (Weinberger, 1998). HRD defined as “a process of developing and or unleashing human expertise through organization development and personnel training and development for the purpose of improving performance” (Swanson, 1995, p. 208) has the greatest utility from an organizational performance perspective. Various definitions of emotional intelligence also exist. The Mayer and Salovey (1997) definition of emotional intelligence however, has a narrower, more focused perspective as opposed to the multitude of broad-based definitions put forward by Goleman (1995, 1998) and others. The development of unleashing human expertise is a critical component for HRD. In general, expertise is defined as “displayed behavior within a specialized domain and/or related domain in the form of consistently demonstrated actions of an individual that are both optimally efficient in their execution and effective in their results” (Herling, 2000, p. 20). Emotional intelligence and its relationship to various forms of expertise provide the applicability of this construct to HRD.

**Current State of Emotional Intelligence**

In order to more effectively understand the emotional intelligence framework, a brief review into historical roots provides the foundation. Beginning with the roots of the words “intelligence” and “emotion”.

**Historical Roots**

Detterman (1986) defines intelligence as a “finite set of independent abilities operating as a complex system”(p. 57). He describes success in understanding this system of intelligence as directly related to our ability to obtain independent measures of the various parts of the system. Emotional intelligence is proposed to be one of those parts of the larger construct of intelligence. Weschler (1958) defines intelligence as “the aggregate or global capacity of the individual to act purposefully, to think rationally, and to deal effectively with his environment” (p. 10). So, intelligence could be described as the umbrella, with various components or dimensions of intelligence underneath.

Emotion is defined as a “mental state of readiness that arises from cognitive appraisal of events or thoughts; has a phenomenological tone; is accompanied by physiological processes; is often expressed physically (e.g., in gestures, posture, facial features); and may result in specific actions to affirm or cope with the emotion, depending on its nature and meaning for the person having it” (Bagozzi, Gopinath & Nyer, 1999, p. 186). Emotions are organized responses that include physiological, cognitive, motivational and experiential systems (Salovey & Mayer, 1990). A few basic examples of such emotions are happiness, fear, surprise, anger, and disgust. When discussing emotions, we’re not only referring to those extreme emotions, such as intense anger, but the everyday emotions of living and communicating. Expressed emotion is therefore part of the work role.

The roots of emotional intelligence are found in the concept of social intelligence. Thorndike (1920) defined social intelligence as “the ability to understand and manage men and women, boys and girls – to act wisely in human relations” (p. 228). Sternberg (1985) views social intelligence also within a general theory of intelligence as “the
mental processes and structures used to attain contextual success" (p. 330). Ford and Tisak (1983) further refine the definition to "one's ability to accomplish relevant objectives in specific social settings" (p. 197). This third operational definition is focusing on specific real-life social interactions and the ways that individuals have learned to deal with these specific situations and includes some self-assessment of one's social skills and interests (Brown & Anthony, 1990).

Beyond social intelligence, Gardner (1983) proposed his theory of multiple intelligences, which included both inter and intra personal intelligences. Both of these domains constitute social intelligence according to Gardner. He defines them as:

- Interpersonal intelligence is the ability to understand other people: what motivates them, how they work, how to work cooperatively with them. Interpersonal intelligence...is a correlative ability turned inward. It is a capacity to form an accurate, veridical model of oneself and to be able to use that model to operate effectively in life. (p. 25).

With the components of intelligence, social intelligence and emotion, Salovey and Mayer (1990) proposed that emotional intelligence is a subset of social intelligence and is part of Gardner's view of the personal intelligences. They described emotional intelligence abilities that may be categorized into five domains: a) self-awareness; b) managing emotions; c) motivating oneself; d) empathy; and e) handling relationships. Emotional intelligence includes a set of conceptually related mental processes involving emotional information which include a) appraising and expressing emotions in self and others; b) regulating emotions in the self and others, and; c) using emotions in adaptive ways. The key here is that they are mental processes. Emotional intelligence includes the "recognition and use of one's own and other's emotional states to solve problems and regulate behavior" (Salovey & Mayer, 1990, p. 189). Emotional intelligence is a combination of the idea that emotion makes thinking more intelligent and that one thinks more intelligently about emotions. Salovey and Mayer (1990) were the first to design a framework of emotional intelligence, and defined it as a "type of social intelligence that involves the ability to monitor one's own and others emotions, to discriminate among them, and to use the information to guide one's thinking and actions" (p. 189).

Models of Emotional Intelligence

Salovey and Mayer were one of the early pioneers in the area of emotional intelligence and throughout the 1990's have continued to publish many studies in this area. Goleman (1995) popularized the notion of emotional intelligence through his book Emotional Intelligence and followed in 1998 with Working with Emotional Intelligence. The writings in emotional intelligence have taken two different approaches. Mayer, Caruso and Salovey (2000) describe the first approach as a 'mixed model', which is a socio-emotional approach that includes not only abilities but is inclusive of many personality characteristics. This first model is a broad perspective and definition of emotional intelligence. The second approach is described as an 'ability model'. This approach defines emotional intelligence much narrower, and is exclusive of many of the personality characteristics that are included in the 'mixed model'. Following is a brief outline of the difference and the respective contributions.

Mixed Model Approach. Goleman (1995; 1998) is one of the earlier proponents of the "mixed model" of emotional intelligence. Goleman used neuroscience and psychological theories to form the basis for his descriptions of emotional intelligence. He defined emotional intelligence as one's ability to "motivate oneself and persist in the face of frustrations; to control impulses and delay gratification; to regulate one's moods and keep distress from swamping the ability to think; to empathize and to hope" (Goleman, 1995, p. 34). He further described it as a set of traits that could be referred to as one's "character". Bar-On (1995) also looked at emotional intelligence from a mixed model perspective. He defined emotional intelligence as "an array of capabilities, competencies and skills which influence one's ability to succeed in coping with environmental demands and pressures" (1995, p.5).

Mayer and Salovey (1997) have said that their first 1990 (Salovey and Mayer) definition of emotional intelligence would also fall more under the "mixed model" definition. Other mixed model authors such as Cooper (1997) and Cooper and Salwaf (1997) in their book Executive EQ, tried to take the emotional intelligence construct and apply it to executives in an organizational context. They developed their four-cornerstone model of emotional intelligence, which includes: a) Emotional literacy; b) Emotional fitness; c) Emotional depth; and d) Emotional alchemy (Cooper, 1997). The authors describe each cornerstone, or aspect of emotional intelligences as a tributary. Trust is a key component for emotional fitness, whereas character and integrity are critical for emotional depth. The blending of all the forces is called emotional alchemy.

The difficulty with these various mixed model definitions of emotional intelligence is that they take a rather broad stroke at the construct of emotional intelligence. The broader the perspective, the more difficult it is to
measure and attribute to key outcomes. In addition, these broader definitions within the “mixed model” framework results in a series of descriptions of pro-social behaviors and personality traits and not a more restrictive definition of emotional intelligence (Bryant, 2001). This tends to be the direction of most popular press writing in this area as well. The more focused, limited, definition of the “ability model” of emotional intelligence provides a greater research avenue, as these components are not already accounted for by existing personality theories and measures.

Abilty Model Approach. Mayer and Salovey modified their definition in 1997 to clarify some potential holes and misunderstandings and further delimit their perspective to an ability focus (see page 1 for definition). The key assumption underlying this definition is the connection between emotions and intelligence. It is the ability to think intelligently about emotions as well as the ability to use emotions to think intelligently that is critical to the perspective of Mayer and Salovey (Graves, 1999). The authors Mayer, Salovey and Caruso are the only researchers to put forward a more limited view of emotional intelligence, within the “ability model” framework. With this foundation of Emotional Intelligence, what are some possible implications for the field of study of HRD?

Emotional Intelligence in the Organization

Much of the popular press espoused the benefits of emotional intelligence as the key foundation to an organizations success. These key benefits were supported through a great deal of anecdotal evidence. There were, however, several research studies that looked at the role of emotional intelligence in the workplace. Abraham (1999) conceptualized emotional intelligence within the framework of the organization. The purpose of this conceptualization was to provide a framework for future empirical research. The authors' framework consisted of nine propositions of emotional intelligence ranging from is relationship to work group cohesion, to performance, organizational commitment and organizational citizenship.

Abraham (2000) looked at the role of emotional intelligence and its impact with job control. The author proposed that job control might affect the consequences of emotional intelligence through the ability of emotionally intelligent individuals to present themselves favorably and to relate problems to internal emotional experience. This author found that emotional intelligence was significantly associated with organizational commitment and that it predicted a large amount of the variance in both job satisfaction and organizational commitment. A better understanding of organizational life however could occur through the exploration of the emotional interactions of top management, through the role of leadership.

Leadership

Emotions are an integral part of organizational life and they have applications to leadership (Ashforth & Humphrey, 1995). There exist today many different organizational theories of leadership (Yuki & VanFleet, 1992). Many of the theories of leadership today have charisma as their core concept (as cited in Kuchinke, 1999). Weber (1968) initially defined charisma as a “quality of an individual personality, by virtue of which he is set apart from ordinary men and treated as endowed with supernatural, superhuman, or at least specifically exceptional qualities” (p. 48).

From the foundation of Weber, Bass (1985) developed a theory of transformational leadership, which distinguished it from transactional leadership. Transformational leadership occurred through the motivation of subordinates to perform at a higher level, offering intellectual challenges, paying attention to individual development needs and leading followers to a higher collective purpose, mission or vision. Transactional leadership occurred through a process of negotiation, rewards in exchange for attainment of specific goals and agreed upon tasks (Bass, Kuchinke). Transformational leadership, with its development out of charisma, has emotions as its base (Wasielewski, 1985).

Sosik and Megerian (1999) studied the relationship between aspects of emotional intelligence and transformational leadership behavior. They found that correlations between emotional intelligence predictors of leadership and leadership behavior differed based on categorizations of self-awareness. Those managers who maintained self-awareness, possessed more aspects of emotional intelligence and were rated as more effective by both their superiors and subordinates than those who were not as self-aware. This study provides some additional groundwork for developing and or improving emotional intelligence in organizational leaders.

Caruso, Mayer and Salovey (in press) look to addressing the role of emotional intelligence in leadership effectiveness. These authors describe that one of the goals of effective leadership is to “create and enhance individual and group relationships” (p. 6). Kahn (1993) cited by Caruso, Mayer and Salovey studied relationship formation as an emotional attachment. The ability of leaders to manage emotions effectively (a component of
emotional intelligence), has been supposed to foster this attachment. Through Caruso and Mayer's (in press) case studies, they provide another potential area of research for HRD scholars. Research questions in the areas of emotional intelligence and its relationship to different domains of leadership effectiveness looks to the expertise of leaders and whether emotional intelligence is significant to that expertise.

Management

In addition to leadership, the role of emotional intelligence to management development is another area of research interest to the field of HRD. Langley (2000) makes an argument for the importance of using emotional intelligence as a form of evaluating the competencies of various levels of management and providing the foundation for management development. Carson, Carson and Birkenmeier (2000) also management scholars, developed and validated an instrument for measuring emotional intelligence. Langley and Carson, Carson and Birkenmeier used the Goleman (1988) construct of emotional intelligence as the basis for their papers. As identified earlier, that construct is very broad, consequently, an exploration into the area of emotional intelligence from an ability model perspective and its relationship to management development would be an additional area of interest to HRD scholars.

Jordan (2000) recently reviewed emotional intelligence based on its contribution to the practice of management in organizations. This author looked to the Mayer and Salovey (1997) emotional intelligence framework as the most appropriate to evaluate the linkage between emotion and cognitive interactions and the resulting contributions to organizational performance.

Individual and Team Performance

Graves (1999) evaluated the relationship between emotional intelligence and cognitive ability and its ability to predict performance in job-simulated activities. Using the Mayer and Salovey (1997) framework and the MEIS instrument, Graves found that the emotional intelligence measures were not redundant with cognitive measures. And stated that “emotional intelligence and cognitive ability play equally important roles in explaining differences in people’s ability to (a) influence and (b) demonstrate interpersonal competence” (p. 187). He found support for emotional intelligence as a predictor in adding value to an organization’s selection processes. Graves (1999) concludes that if further results show that “emotional intelligence can be trained and it predicts job performance, the implications for selection, employee development, and performance evaluation could be staggering” (p. 195). These are all areas of research interest to HRD and its impact on performance.

Bryant (2001) is currently researching the relationship between emotional intelligence and sales performance. He specifically is looking to those factors that contribute to high performance in sales and their relationships to emotional intelligence. Additionally, his study is positioned to add to the normative data of the MSCEIT. Bryant is conducting his research within the HRD umbrella and his results will provide some of the first studies in HRD specifically associated with emotional intelligence.

Caruso and Wolfe (in press) explore the role of emotional intelligence in the workplace. Through their case study writings, they lay the foundation for empirical studies into the relationship between emotional intelligence and: a) career development; b) selection; c) training; and d) management development. From an HRD perspective, answers to these relationships would provide additional groundwork for their work in improving organizational performance.

Finally, Rice (1999) looked to the role of emotional intelligence and its impact on team performance. This work provides an initial inquiry into this area of study. HRD scholars interested in teams, team expertise and their resulting performance could look to the emotional intelligence framework for an additional area of study. All of these areas, organizational commitment, leadership effectiveness, management development, training and development and team performance remain fruitful areas of research for the HRD scholar. Using the emotional intelligence framework provides these researchers another perspective to evaluate these areas and their resulting impact on improving organizational performance.

Conclusion

Any new body of research interest provides researchers the opportunity to view, study and test it from a variety of perspectives. The area of emotional intelligence is no different. Unfortunately, the popular perception of this phenomenon is far ahead of its researched support. The domain of emotional intelligence study falls into two key categories. The first category defined by Goleman (1995,1998) and many others in the popular press, has been
described as the ‘mixed model’ approach. This model and its respective proponents continue to publish many articles, and it is the most well known within the business community. The continued proliferation of these tests, in multiple mediums through books, and internet on-line “quick tests” and the consultants using them with little scientific support, push this area of study dangerously close to the precipice of another corporate fad.

The second category is defined by the academic scholars Mayer and Salovey (1997) and has been described as the ability model approach. This approach more narrowly defines emotional intelligence from a cognitive ability perspective and minimizes the cross over into personality characteristics that convolute the “mixed perspective”. This approach emerged through the research efforts of Mayer, Salovey and others through the 1990’s. These authors have followed a more cautious path and have been more concerned with first appropriately defining emotional intelligence and creating an appropriate instrument to measure it than pushing forward into hypothetical outcomes and predictive power that has been the calling card of the Goleman camp.

The ability model perspective also provides a more appropriate avenue for researching the application of emotional intelligence to the field of HRD. The study of emotional intelligence and its relationship to leadership, management, teamwork and team performance are areas ripe for further research in HRD. Several research agenda's in the area of emotional intelligence to consider are:

- What is the relationship between emotional intelligence and leadership style?
- Does an emotionally intelligent leader produce better results?
- Can emotional intelligence be trained?
- Does ones emotional intelligence impact their performance?
- What is the role of emotional intelligence in team performance?
- Do emotionally intelligent individuals provide better service (customer service, technical support, sales support, etc.)?

Though these research agenda's are not all encompassing, they provide the initial connections to HRD theory and practice. The study of emotional intelligence from a more limited perspective and its connections to HRD theory will provide a more scholarly basis of work from which the HRD practitioner can pull from. Only when these theoretical connections and the resulting impact on organizational, process and individual performance are confirmed through solid research, can the HRD practitioner begin to utilize this information. It is this research that is required, in order to ensure that emotional intelligence is not pushed into another “corporate fad”.

Toward A More Harmonized View of Emotion Management: 
The Influence of Identity Salience

C. Leanne Wells  
Virginia Tech

Jamie L. Callahan  
Texas A&M University

Research on emotions in organizational life has increased substantially in the last decade. A number of models and theories have been proposed to help better understand the nature of this phenomenon. This paper reviews the control distinctions model of emotion management proposed by Callahan and McCollum (2000). We suggest that the concept of identity plays a useful role in further understanding the application and implications of emotion management in organizations.

Keywords: Identity, Emotion Management, Emotional Labor

Emotion management, specifically emotional labor, has become a popular topic in exploring the work of organizations. It is over two decades since Hochschild (1979) introduced her emotion systems theory. Volumes of literature and research have been devoted to exploring and testing this theory. A recent model introduced by Callahan and McCollum (2000) distinguishes the two terms of “emotion work” and “emotional labor” associated with emotion management. A key component of that model is the locus of control in the management of emotion; in other words, they explore who decides when and how an individual should manage emotion. The present paper looks at the nature of this control as it relates to emotion management and suggests that the incorporation of concepts of identity would help harmonize the various types of emotion management.

Our purpose is to explore how we can extend our understanding of emotion management in such a way that the interests of both the individual and the organization are honored. We specifically want to forge a path toward a more integrative perspective of emotion management efforts in order to appreciate more fully how this perspective may “speak” to us in terms of intervention efforts – both by the organization and by the individual – for future research opportunities. We believe that the literature on identity, with accompanying constructs such as self and identity salience, opens that path for us. In the present paper, we explore the literature on emotion management and then describe how the concepts of identity can be used to create greater harmony between individual and organization with regard to emotion management actions. We conclude with some implications of our present thinking for research and practice.

Emotion Management

Emotion management theory stems from Hochschild’s (1979, 1983) work addressing the individual’s attempts “to change in degree or quality an emotion or feeling” (1979, p. 561) based on social guidelines. She differentiates from earlier concepts posed by Goffman and Freud, seeing emotion management as a means of evoking, shaping, or suppressing emotions. Hochschild (1979) equates emotion management to deep acting – the management of the feelings underlying expression – a premise beyond Goffman’s surface acting, which is management of expression alone. She also migrates from Freudian limitations of emotions as unconscious and involuntary to envisioning emotion management as an active process enacted “by self upon the self, by self upon others, and by others upon oneself” (1979, p. 562).

As an active, conscious, and voluntary process, emotion management often occurs when an individual perceives a discrepancy – Hochschild (1979) terms it a “misfit” or “pinch” – between what is felt and what should be felt as determined by social feeling rules. Serving as “baseline[s] in social exchanges” (Hochschild, p. 553), feeling rules not only govern an individual’s feelings but also influence how that individual reacts to (thinks) and acts (behaves) upon those feelings. For example, when an individual receives a compliment, social feeling rules commonly dictate a feeling of gratitude. Beyond gratitude, feeling rules typically influence a cognitive reaction, such as “I like what she said and I should acknowledge it in an appreciative way,” as well as behavioral reactions in the form of a smile, words of thanks, or a returned compliment.

1033
Beyond the “what” of these emotions, social feeling rules also define the “how much” and “how long” parameters of affective experiences (Hochschild, 1979). Continuing with the previous example, feeling rules would not only dictate appreciation but also determine the degree of appreciation you felt—perhaps as compared to how much appreciation you would feel if complimented on a different attribute or accomplishment, if the compliment had come from a different person, or if the compliment had been received in another social setting.

Display rules differ from feeling rules in that they characterize the behavior associated with emotions. While it was noted earlier that feeling rules influence actions, display rules have more power in predicting behavior. Ashforth and Humphrey (1993) note display rules as norms, which can be defined on multiple social levels. For example, the behavior dictated by receiving a compliment might vary with the social setting or the social group. We might acknowledge an accepted societal display rule, which could differ from the norm defined by a subculture, an occupation, a family unit, or a specific organization. This difference does not have to be contradictory, although it is possible that it is. Each of us may agree that the general social norm for receiving a compliment is to display a smile and express verbal thanks. However, my subculture might dictate that I also display a blush with lowered eyes and verbally credit others who influenced or enabled my “success.” Your organization may expect you to also extend a handshake and return a similar compliment.

Differentiating between display rules and feeling rules returns us to the concepts of surface acting and deep acting. Surface acting is a form of impression management in which the individual displays an emotion different from the felt emotion (Ashforth and Humphrey, 1993). With deep acting, the individual attempts to feel the displayed emotion. Through cognitive, bodily, or expressive techniques—singly or combined—these deep-acting efforts aim at a “tripartite consistency” (Hochschild, 1979, p. 563) between the situation, the feeling, and the conventional frame. The individual receiving a compliment may actually feel embarrassment but display gratitude as expected within the social situation and the conventional frame. Using deep-acting techniques, that same individual works toward genuine feelings of gratitude, perhaps initially co-existing with but later replacing embarrassment.

In fact, the desire to reduce or eliminate inconsistency is so powerful, it is not uncommon for the individual to endeavor to change the situation when it is too much to change the emotion within a conventional frame (Francis, 1997). In this scenario, it is easy to envision the individual incapable of feeling genuine gratitude—and perhaps struggling unsuccessfully to surface the appropriate display of emotions—either quickly removing himself from the situation or redirecting the conversation and, in effect, ignoring the compliment. It is conceivable to believe that the individual may seek to remove future inconsistencies by avoiding similar situations or the person offering the compliment.

Some argue “society can regulate expressive behavior but not the individual’s expressive experience” (Ashforth and Humphrey, 1993, p. 97). But when “pinched,” an individual using emotion management to reduce gaps and to create a fit between the “is” and “should” feelings is in reality regulating that expressive experience. As a social creature, the individual is unlikely to engage in any emotion management effort in a vacuum—exclusive of societal influence, if not societal regulation. To say this in a different way, the individual who successfully replaces the feeling of embarrassment with gratitude may at first have been influenced to do so. If emotion management—deep acting—is enduring, it can also be argued that society (or the social group) has indeed regulated the desired feeling or expressive experience.

**Emotion Work versus Emotional Labor**

In her original work, Hochschild (1979) used emotion management synonymously with emotion work. Later, she distinguished emotion work from emotional labor using the Marxian differentiation between use value and exchange value (Hochschild, 1983). Here she conceived emotion work as “the management of feelings... in a private context where they have use value,” while positing emotional labor in a public context where feelings are “sold for a wage and therefore have exchange value” in an effort to produce “the proper state of mind in others” (1983, p. 7). Thus, the key to discriminating between emotion work and emotional labor is seemingly the purpose for which the emotion management is performed (Callahan and McCollum, 2000). As Callahan and McCollum (2000) observe, the literature following Hochschild’s 1983 work provides a number of interpretations regarding the terms emotion work and emotional labor— at times using them interchangeably, periodically failing to distinguish them from one another, and sometimes even confusing and contradicting the terms. In her study of emotional contagion among health-care employees, Strazdins observes “Hochschild’s definitions of emotional labor and emotion management refer to the management of emotion in the self in order to display emotion, whereas emotional work refers to behaviors that alter other people’s emotions” (2000, p. 3). In another comparison, she defines emotion management as how an individual impacts his own emotions, with
emotional contagion being how others' emotions impact the individual. Seeking to uncover "hidden workloads" in her study of university personnel, Pugliesi (1999) equates emotion management with emotion work, then distinguishes emotional labor as wage-compensated efforts, further denoting these efforts as regulated by the organization. Copp (1998) fails to make any distinction between emotion work and emotional labor, simply terming the efforts "emotion management" in her study of floor supervisors working with developmentally disabled staff. Similarly, Konradi (1999) makes no mention of the two terms, using the umbrella of "emotion management," in her examination of courtroom strategies of rape survivors. Thoits (1996) aligns with Hochschild's definitions but limits emotional labor as self-controlled efforts, labeling other-controlled strategies as interpersonal emotion management.

Citing a number of additional works, Callahan and McCollum contend "that distinction between emotion work and emotional labor is important not only to advance theory development but also to advance practical interventions in organizations" (2000, p. 18). They elect to use emotion management as an overarching term inclusive of both emotion work and emotional labor. As an advancement of Hochschild's (1979, 1983) emotion systems theory and spurred by Tolich's proposition that emotional labor "is not always under the control of the organization" (Callahan and McCollum, p. 9), they use dichotomies of exchange value/use value and of internally controlled/externally controlled to explain the type and power influence of emotion management, respectively. Their model is presented in Figure 1, with synthesized definitions of each quadrant provided by the present authors.

The model provides clarity regarding the natures of exchange value and use value. Equally important is its addressing of control so often cited by other researchers as an important element of consideration when engaging in emotion management work. Their theory advancement allows not only for more targeted intervention strategies, which is the subject of their work, but also for keener insights into the nature of the individual engaging in emotion management efforts. How are the concepts of self and identity linked to emotion management, especially emotional labor? Which links – already observed and noted – can be further pursued, perhaps strengthened or enhanced? How might identification be an additional tool in harmonizing the control of emotion management efforts?
Identity theory “explains social behavior in terms of the reciprocal relations between self and society” (Hogg, Terry & White, 1995, p. 256). Baumeister and Muraven (1996) see this as an adaptive process between the individual and the societal context. Mead (1934) asserts that the self emerges from social experience and develops according to its interactions and relationships with that experience and with other individuals. Indeed, he maintains that there is no self separate from the community and that it is only through “relationship to others … through superiority to others, and inferiorities in comparison to others” (p. 204) that we realize self. Advancing this premise, the self is further defined by others’ valuing and respect, and a sense of self is realized not only through personal actions but also through others’ collaboration and influence, which if contested compromise that sense of self (Campbell, 1997). In essence, the self is a social collective, both complex and dynamic – learning, defining, maintaining, and appreciating itself through interaction with others.

A variety of social roles allows for multiple components of self or multiple identities (Terry, Hogg & White, 1999). Through Mead’s (1934) eyes, we are a compilation of different selves, which uniquely and individually react to and interact with others and with social experiences. It is the reactions of others and society that determines which self we choose to be. As Mead alleges “the complete self is thus a reflection of the complete social process (p. 143). Thus, self and identity are each social constructs, emerging in part from the societal roles the individual assumes.

Mead (1934) identifies the unified self as consisting of separate “me’s” and “I’s.” The “I” is an historical self, representing “the response … to the attitudes of the others” or response to the social situation itself – a naïve source of “freedom, of initiative” (pp. 175, 177). In contrast, the “me” is more of a present self composed of all the historical “I’s,” representing “the organized set of attitudes” and “values of the social group” – a sophisticated, “conventional, habitual individual” (pp. 175, 197, 214). In other words, the “I” is a genuine, instinctive self, while the “me” – arguably no less genuine – is a more learned, developed self.

With the introduction of the “I” and “me,” Mead (1934) infuses the self with an element of time. This element of time denotes a process of development, a “psychological unfolding of personality” piece by piece until the whole is formed (Robbins, Chatterjee, & Canda, 1998, p. 197). As Campbell avers, a sense of self requires “opportunities to understand the self in relation to the past” and is dependent “on some of a person’s experiences becoming memories” (1997, p. 55). As such memory, self, and person become inseparable, “braided concepts” and identity becomes linked “to sameness of memory over time” (Campbell, pp. 53, 63).

Essentially, the individual considers both past and future selves and strives for an integrated self, as well as a “defined personality within a social reality which one understands” (Robbins, Chatterjee & Canda, 1998, p. 198). To achieve such a synthesis, each individual responds to the social environment with distinct aptitudes. Kroger and Green credit Erikson with qualifying this phenomenon as “different capacities use different opportunities to become full-grown components of the ever-new configuration that is the growing personality” (1996, p. 477). Successful ego development leaves the individual with not only a strong sense of identity but also of individuality. As suggested, identity remains impressionable, susceptible to crisis and role confusion at any point during the lifespan.

Returning more fully to the concept of social role, Simon defines a role as a “set of expectations prescribing behavior that is considered appropriate by others” (Hogg, Terry & White, 1995, p. 257). Thus, an individual’s sense of self is linked directly to behavior. As social creatures, the more closely that behavior aligns with the expectations and satisfaction of others, the greater the individual’s sense of self and self-esteem. Misalignment often results in feelings of distress and self-doubt. The degree to which behavior is reflective of role expectations depends on the identity salience. The various identities forming the self are organized hierarchically with those nearer the top becoming more significant, whether in defining self (Hoelter, 1983) or in influencing behavior (Stryker, 1980). This identity salience explains why individuals “with the same role identities may behave differently in a given context” (p. 257).

In addition, identity is a means of making life meaningful and is connected to the individual’s basic values (Baumeister & Muraven, 1996). They present a more modern – suggestive of more evolved – self where the individual “look[s] inside [herself] to find the sources of value and the answers to moral dilemmas (p. 410). This positions the self as a value base on its own merit and aligns the self with morality, contradicting historical moral mandates of self-restraint and self-deprivation in deference to others. With this freedom, the individual perhaps relies less on the social sanctioning of others (or society at large) for the development and approval of self than did his ancestors. With this evolution we recognize a more independent – although not separate – self. The old adage that “no man is an island” remains true, even in this modern world.

In an empirical study exploring the nature of role-identity salience, Callero (1985) supports the link between role-identity salience and behavior. Sustaining the concept of a more independent self, the study asserts that role
behavior is not significantly linked to the expectations of others. It does, however, reinforce the independent effects of the individual's self-definition of role, as well as the individual's identity salience with the role, in influencing behavior. As such, behavior in an identity-salient role is driven more by the expectations of individual rather than the expectations of others.

It is important to appreciate the complexity of identity salience. While the Callero study indicates a greater influence on identity salience by the individual, it does not negate the influence of others. It is more appropriate to consider the full realm of influence on identity salience. Hoelter's (1983) study intimates that identity salience increases with greater commitment to the identified role, as well as more positive evaluation of role performance. Commitment is directly related to the "cost of giving up meaningful relationships" (Stryker, 1968, p. 560), while role evaluation is attributed to the individual's self-reflexivity. Self-reflection is influenced by how others view and appraise the individual and how the individual compares self to others (Hoelter, 1983).

In a subsequent effort, Hoelter proposed a theory of personal consistency in which he notes identity salience as a product of the individual's "perceived power, activity and personal well-being" (1985, p. 118). Basically, Hoelter is addressing the individual's flexibility in responding to (i.e., behaving in) diverse social situations and social demands. The smaller the number of identities that are salient to the individual, the more likely he is to respond consistently, denoting a decreased sense of personal control within the given social setting. Not only must an individual have a high degree of identity salience, but also he must possess this salience across identities in order to perceive personal control and behave inconsistently (i.e., flexibly based on the uniqueness of the situation).

In summary, the self is a composite of identities largely defined through social interactions with others. Identity requires a past, a present, and a future. The individual, as an active agent within a social environment, taps into capacities and memories to take advantage of social opportunities that inform both current identity and the direction and development of future identity. One's sense of self predicts behavior, which is also reflective of social roles and the expectations of others. The degree to which an individual strives to align behaviors with these roles and social expectations depends on identity salience. As a social construct, the self does not strive to distinguish itself from these roles and social expectations or to relinquish ties to them. However, modern society has evolved to recognize the self as a moral agent, representative of the individual's basic values. This evolution gives the individual social permission to act and behave in ways that are protective of identity, self, and needs. When the needs of others and the needs of self misalign or conflict, the individual may choose options historically "unavailable.” Even in instances where significant social others disagree or disapprove of the choices, the larger society provides empathy and sanction for these individual decisions. When examining or anticipating behavior, it is critical to appreciate locus of control in the role of the self, as well as the role of social others.

Emotion Management And Identity

Hochschild (1983) herself connects emotion management, specifically emotional labor, with the concepts of self and role identity. She notes that emotional labor “calls for a coordination of mind and feeling, and it sometimes draws on a source of self that we honor as deep and integral to our individuality” (p. 7). In highlighting the culture's celebration of the unmanaged heart, Hochschild depicts the managed heart as an apparent antithesis of the authentic, natural, or spontaneous self. Further, she claims “emotional labor poses a challenge to a person's sense of self,” as it becomes an issue of “estrangement between what a person senses as her ‘true self’ and her inner and outer acting” (p. 136). A lack of authenticity arises when the individual fails to perform deep acting and must rely on surface acting for job performance. When deep acting is required but unachievable, “the only way to salvage a sense of self esteem ... is to define the job as ‘illusion making’ and to remove the self from the job, to take it lightly, un seriously. Less of the job reflects on the self; the self is ‘smaller’” (Hochschild, 1983, p. 135). In removing the “real” self from the job, the individual creates a false self, a “disbelieved, unclaimed self, a part of ‘me’ that is not ‘really me’” (p. 194). Hochschild emphasizes a danger in “overdeveloping the false self and losing track of its boundaries” (p. 195).

And while she admits that this separation between a real and false self is sometimes wise, sometimes saving, Hochschild equally acknowledges this fissure as problematic: “For in dividing up our sense of self, in order to save the ‘real’ self from unwelcome intrusions, we necessarily relinquish a healthy sense of wholeness. We come to accept as normal the tension we feel between our ‘real’ and our ‘on-stage’ selves” (1983, p. 183-184). We may begin to “act to please others at the expense of our own needs and desires” (p. 194). The cost to the self — “real” and collective — can be costly. As Hochschild sees it “the essential problem is how to adjust one’s self to the role in a way that allows some flow of self into the role but minimizes the stress the role puts on the self” (1983, p. 188). For Hochschild, emotional labor seems to require a separation between self and role, specifically work role. In comparison, Ashforth and Humphrey expand the definition of emotional labor and,
drawing on social identity theory, surmise "the greater the identity with role, the weaker the negative effects of emotional labor and the stronger the positive effects on well-being" (1993, p. 89). As such, they acknowledge the risk to self from emotional labor efforts, while offering identity as a means of moderating these potentially negative effects. They also allow for the display of genuine emotion as inclusive of emotional labor itself.

As mentioned earlier, the degree of identity salience directly associates with the individual's sense of authenticity. Stated another way, the less discrepancy I feel between my role and my identity, the stronger my sense of self value or self worth. Using Thoits' terms, Ashforth and Humphrey (1993) categorize the possibilities as follows. Emotional labor provides the individual an opportunity for either an "identity-relevant" experience – one that is meaningful to the salient identity – or an "identity-irrelevant" experience – one that holds little if any meaning for the salient identity. An "identity relevant" experience proves to be "identity enhancing" if the emotional labor strongly associates with the salient identity. In contrast, when the emotional labor strongly opposes the salient identity, the "identity relevant" experience becomes "identity threatening." As noted earlier, Hochschild (1979) maintained that the aim of deep acting is to achieve "tripartite consistency" between the situation, the feeling, and the conventional frame. For emotion management efforts to be healthy (i.e., identity enhancing rather than identity threatening), it seems a similar relationship is needed between role, self, and identity. Otherwise, it is reasonable to assume the individual will experience some degree of emotional dissonance and self-alienation.

Insights and Implications

In further clarifying emotion work and emotional labor and in acknowledging the control base of these efforts (i.e., internal self and external others), Callahan and McCollum (2000) advocate for supplemental lenses for considering emotion management activities, especially when selecting and implementing organizational intervention strategies. Their control continuum invites additional regard for the individual managing emotions. The element of identity salience seems a particularly compelling consideration.

It seems self-evident that individuals with high-salient work identities are more invested in the organization. The emotion management experiences of these individuals are more likely to be identity relevant and identity enhancing. They are perhaps more receptive to organizationally-controlled emotion management interventions. They are more likely to engage – readily and successfully – in self-controlled emotion management interventions. These individuals may exhibit a more balanced reliance between self and the organization when engaging in emotion management strategies, for their efforts aim not only for a fit within the organization but also for affirmation of self.

Figure 2. The Identity Overlay
An overlay of identity salience onto the Callahan-McCollum model might be represented as in Figure 2. Identity salience is strongest at the center of the diagram. The smaller concentric circles reflect the balanced reliance between self and organization. The smaller the circle, the greater the focus on harmonization between the four basic modes of emotion management. As identity salience increases, the focus of control over emotion management becomes more balanced in any given organizational role. In other words, because high identity salience incorporates components of both individual and organizational, actions of emotion management would be guided by relatively equal amounts of internal and external control.

It is important to note the assumptions for this adapted model. First, just as Callahan and McCollum (2000) noted a systems perspective in identifying intervention strategies, we expect an individual to engage in organizational emotion management efforts across the four quadrants. Second, as it is commonly recognized that an individual identifies with multiple social roles, this same multiplicity is expected within an organizational context, meaning that a single individual will likely recognize and identify with numerous work roles. Third, each unique role may have a distinctive identity salience—it is neither necessary nor expected for an individual to have equivalent salience across roles. This stems from Ashforth and Humphrey’s reflection on within-role calibrations “whereby one oscillates between personal engagement and personal disengagement” (1993, p. 101). A similar phenomenon is anticipated across roles. Finally, based on value (e.g., exchange or use) and control (e.g., internally or externally), an individual’s salience may vary within a single role from quadrant to quadrant. For example, an individual may have greater identity salience with role responsibilities more closely aligned with autonomous emotional labor than responsibilities within the same role that are associated with indirect emotional labor.

What is the usefulness of the identity salience overlay? Of necessity, organizational interventions frequently are generalized by nature, aiming to reach far and wide within the organization. Yet because these interventions target people, the organization is wise to anticipate and consider the reaction to and receptiveness of these efforts through a lens of self and identity. Use of this lens positions the organization to consider and select interventions with greater flexibility, increasing the likelihood that the organization will provide multiple options and avoid single-approach strategies.

Returning briefly to the interventions outlined by Callahan and McCollum (2000), an organization might choose to implement emotional labor interventions of work design, employee wellness plans, and goal setting. While research supports the appropriateness of these types of interventions, the original model does not account for the varied employee responses and reactions to these efforts. The overlay of identity salience offers a deeper perspective. While it may prove unfeasible to individualize interventions for each single employee, the organization can increase intervention success through consideration of identity salience by subgroup population or empowering managers to adapt intervention strategies with identifiable individuals.

Additional exploration of this model adaptation should include a more in-depth application of identity salience to emotion management efforts. What else can identity salience tell us about the individual engaging in emotion management? Based on identity salience, can we anticipate differing reactions to emotion management efforts within each of the four quadrants? How might strategizing organizational interventions using this perspective influence the degree of identity salience among individuals and over time? Beyond identity salience, what additional factors may assist with a greater individual perspective regarding emotion management?

Conclusion

As a theory or model is considered for practical and research application, it is natural to view it from assorted perspectives to more fully explore and appreciate its contributions. A practitioner or researcher hoping to benefit from the theory or model surveys existing information and studies to help inform his current understanding and to build additional insight and awareness. He may endeavor to answer such questions as “How is this meaningful to me?” or “How can I make this more meaningful—to me and/or to others?”

This paper presented an overview of literature addressing self, identity, and emotion management. It outlined some key areas of overlap in these fields of study and research. In addition, it suggested a meaning-making adaptation of an existing emotion management model for the practitioner or researcher desiring a more individualized perspective on emotion management strategies. Identity salience is one approach for achieving a more targeted view of the individual involved in emotion management. Such a targeted perspective positions the organization for greater success. The individual can also expect to benefit from reduced emotional dissonance, as well as an increased sense of self-authenticity.

An Instructional Strategy Framework for Online Learning Environments

Scott D. Johnson
Steven R. Aragon
University of Illinois

The rapid growth of web-based instruction has raised many questions about the quality of online courses. It appears that many online courses are simply modeled after traditional forms of instruction instead of incorporating a design that takes advantage of the unique capabilities of web-based learning environments. The authors present a conceptual framework that can guide the development of online courses. Specific examples of instructional strategies that fit the framework are described in detail.

Keywords: Online Instruction, Web-Based Instruction, Instructional Strategies

Distance education is an instructional delivery system that allows students to participate in an educational opportunity without being physically present in the same location as the instructor. Although print-based correspondence study is the traditional method of distance education, more contemporary approaches rely heavily on various forms of instructional technology (Garrison, 1987). The reason for much of the growth in distance education programs in recent years is due to the development of the Internet and improvement of technologies that support online learning environments. For example, among higher education institutions offering distance education, use of two-way interactive video and one-way prerecorded video was essentially the same in 1997–98 as in 1995 while the use of asynchronous Internet-based technologies nearly tripled in that same time period (Lewis, Snow, Farris, Levin, & Greene, 1999). This change is not new to the distance education community, which has seen technology-based educational innovations come and go with much fanfare. The instructional films of the 1940’s were expected to radically change the educational delivery system, as were instructional radio and television. While each of these technology innovations had some impact on educational programs, they did little to change the fundamental nature of education. The Internet and computer technology, as the next generation of technological innovation to impact distance education, appears to have the power to significantly alter the education landscape.

In spite of this rapid growth, there is considerable concern about the effectiveness of this educational innovation. Numerous studies comparing traditional classroom-based instruction with technology-supported instruction have found no significant differences on critical educational variables such as learning outcomes and student satisfaction (Clarke, 1999; Johnson, Aragon, Shaik, & Palma-Rivas, 2000; Navarro & Shoemaker, 1999; Smeaton & Keogh, 1999). A very popular web site (http://teleeducation.nb.ca/nosignificantdifference) contains a listing of over 300 research reports on technology for distance education (Russell, 1999). This comprehensive bibliography spans seven decades and highlights studies that found little or no significant impact of instructional technology on various educational variables.

The obvious conclusion is that the technology used to support instruction has little impact on students’ attainment of educational outcomes. The primary factor in any instructional initiative, irregardless of format or venue, is the quality of the instructional design that is ultimately implemented. Based on the lack of evidence that technology significantly influences the learning process, scholars in the field of instructional technology now conclude that the technology used in an online program is not as important as other instructional factors, such as pedagogy and course design (Phipps & Merisotis, 1999). This is not a new idea however, as stated by Schramm in 1977, “learning seems to be affected more by what is delivered than by the delivery medium” (p. 273).

This paper describes a research and development effort that evolved during the creation of an HRD graduate program (HRE Online) that was taught entirely online. The learning environment that was created to support HRE Online was based on the assumption that learning is a complex event that cannot be explained with a single theory of learning. Instead, we hypothesized that quality learning environments should be based on instructional principles that are derived from multiple learning theories. Through an analysis of existing literature and experienced-based practices throughout the development of HRE Online, we sought to answer the following questions:

1. What instructional principles for online learning environments can be derived from a fusion of multiple theories of learning?
2. Based on those principles, what specific instructional strategies or techniques can be applied in an online learning environment?

Copyright © 2002 Scott D. Johnson and Steven R. Aragon
The purpose of this paper is to present a perspective of online teaching and learning that looks beyond the traditional paradigm of instruction. Once such a perspective is adopted, instructional designers can incorporate the key elements that are needed in quality online learning environments.

Instructional Challenges for Online Course Designers

Innovations in instructional technology are often implemented in very traditional ways. For example, while the television had the potential to significantly alter the way people were educated, its use as an instructional tool built on an existing instructional paradigm by providing a "talking head" that merely passed information to the student. Using this innovation in this way lacked creativity and ignored the power of the technology. The same problem now seems to be occurring in online instruction. Instructional designers are creating online courses that are simple conversions of their equivalent face-to-face counterparts. Online courses tend to build on traditional views of learning where the primary goal is to transfer information from the instructor to the student. This is accomplished by providing students with access to information and expecting them to demonstrate their learning on an exam. Examples of how face-to-face instruction has been converted for online delivery include recorded lectures, online readings, homework assignments, and online tests.

The growth of online instructional programs raises an interesting question for online course developers. Should we model our online course designs after formal models of instruction or should we incorporate innovative approaches into our online programs? If we hope to develop powerful learning environments via the web, the answer should be clear. Instructional designers need to look for innovative ways to support quality teaching and learning without succumbing to the temptation to have online instruction become direct instantiations of traditional forms of instruction. The challenge for instructional designers is to devise ways to create pedagogically sound content for delivery over the Internet. Online courses need to address variability in student learning styles and provide external forms of motivation for the isolated student. The challenge is also to facilitate active learning in online courses while avoiding the tendency to provide too much information. The most difficult challenge may be to devise ways to promote high levels of interactivity among students and instructors. Such interactivity can result in community building, collaboration among learners, and enhanced communication.

Instructional Principles for Online Learning Environments

In order to confront these challenges, instructional designers must examine their traditional perspectives and adopt a new philosophy of teaching and learning that is appropriate for online instruction. This does not imply that traditional theories such as behavioralism should be tossed aside in favor of the more contemporary social-constructionist theories. Instructional designers need to match their desired learning goals and instructional methods to the appropriate learning theories. We argue that this new philosophy should build on a combination of learning theories rather than being confined to one preferred perspective (Johnson, 1997). For example, quality online learning environments should be comprised of elements of behavioral learning theory (e.g., positive reinforcement and repetition), cognitive learning theory (e.g., address multiple senses, present new information in motivating ways, limit the amount of information presented, and connect new information to prior knowledge), and social learning theory (e.g., encourage group interaction, peer assessment, and personal feedback). Adopting a synthesized theory of learning can have a synergistic result by integrating the most positive and powerful aspects of each individual learning theory into an online learning environment.

The pedagogical model used to develop the HRE Online master's degree program was created by building on specific aspects of adult learning theory (Bandura, 1971; Skinner, 1968; Thorndike, Bregman, Tilton, & Woodyard, 1928; Vygotsky, 1978). Two conceptual models that were developed from an extensive study of the literature were reviewed. These two models were then synthesized into seven general principles that appear to be critical for quality learning environments (Johnson & Thomas, 1992; Johnson, 1997). We contend that powerful online learning environments need to contain a combination of these principles: (1) address individual differences, (2) motivate the student, (3) avoid information overload, (4) create a real-life context, (5) encourage social interaction, (6) provide hands-on activities, and (7) encourage student reflection (see Figure 1). This pedagogical model for online instruction was used to create the design template that is followed for each course in the HRE Online program. The following section provides specific examples of instructional strategies that have been used in the HRE Online program. Each of these strategies highlights the importance and practical application of the seven principles of quality online learning environments.
Using the Framework to Create Instructional Strategies for Online Courses

**Individual Differences**

Within a learning context, differences can be found in the areas of general skills, aptitudes, information processing, and application of information to new situations. In addition, all learners differ in their ability to perform various education-based and real-world learning tasks. Consequently, the general abilities or preferences of the learner will affect his or her ability to accomplish different learning outcomes. Individual differences specific to learning and instruction can be found within intelligence, cognitive controls, cognitive styles, learning styles, personality types, and prior knowledge (Jonassen & Grabowski, 1993). Each dimension helps us understand 1) patterns of thinking and reasoning about information, 2) how individuals process information to make sense of the world, 3) preferences for information processing, and 4) how past knowledge, skills, or ability influence the learning process. Each of these dimensions, collectively, helps to describe one’s personality.

Recognition of individual differences has, for the most part, been taken into account and promoted through the instructional design template used in HRE Online. The following techniques and strategies have been used in our online courses to address individual differences.

1. **Provide content in multiple formats.** This is done through the use of various communication technologies. Lectures are audio streamed and synchronized with the applicable PowerPoint presentation. These lectures are additionally transcribed and posted in the course website. This is quite beneficial for students who travel and want to take the transcribed lecture with them to read. Content is also presented through WebBoard discussion groups where students are required to share and discuss information with each other. Each course also has links to outside web sites that provide supplemental material on the current topic.

2. **Allow for individual locus of control.** All courses provide various means of navigation within the online course. Content can be accessed through links or a graphical organizer. An individual can be as systematic or random in his or her access of course material as they desire. Although the course is built and presented in a hierarchical sequence, it does not have to be accessed in the same way. While it is not necessarily encouraged, students are also not discouraged from moving through the course in a random order.

3. **Encourage active and collaborative interaction.** Recognizing that “the whole is greater than the sum of the parts,” each course is designed with activities that are both individual and group based. Working within “virtual teams,” students work together to solve problems, analyze cases, and develop group deliverables. These assignments allow individual ideas, perspectives, and experiences to be heard and collectively considered. The idea of “agreeing to disagree” is taught through these experiences.
Motivation

At its most basic level, human motivation is controlled by the drive to satisfy a range of human needs (Maslow, 1970). According to Maslow's hierarchy of needs, if people lack basic needs or security, those needs must be addressed before higher level needs such as social status and self-worth can be attended to. While this model is certainly an influencing factor in human behavior, it may be more appropriate to examine motivation in terms of its complex interaction with cognitive, emotional, and behavioral factors.

The ARCS Model of Motivation is a practical way for instructors to address the issue of student motivation (Kellar & Suzuki, 1988). This model is based on a review of psychological literature on motivation and breaks motivation into four major concepts; (1) Attention, (2), Relevance, (3), Confidence, and (4) Satisfaction. Instructors must be able to gain and maintain students' attention by providing an environment that is interactive and participative. While keeping the students' attention is critical, it cannot be maintained unless the students feel that the course material is relevant. In other words, the course content, activities, and assignments must be related to their personal and professional goals. Students must also feel confident that they can achieve the expected outcomes of the course; therefore instruction should be flexible to compensate for individual student needs. The final component of the ARCS Model is satisfaction, which corresponds to whether or not students derive satisfaction from the instruction. For example, students will not perform as well if they feel dissatisfied with the instruction because it does not present enough of a challenge.

Strategies for enhancing student motivation in a web-based environment can best be characterized as either novel and entertaining approaches or attempts to personalize the instruction. We have successfully used the following techniques to enhance the motivation of our online students.

1. Incorporate games into the online environment. An example of a successful game for an online course is the popular television show called “Who Wants To Be A Millionaire.” We have used this game during live synchronous sessions to summarize course content covered previously and to provide a sense of community among the students. The instructor plays the role of Regis Philbin, the game show host, and reads a question that requires the students to put a sequence of answers in the correct order. The students then type the correct order (e.g., B, C, D, A) as quickly as they can into a WebBoard chat window. The student who first answers correctly becomes the contestant who calls a toll free number so their voice can be patched through to the class. This provides live dialogue when the instructor asks a student the first of several multiple-choice questions. The student has the option of answering the question directly or, if they are not sure of the answer, they can use one of two “lifelines.” The lifeline “Ask the Audience” involves asking all students to post what they think is the correct answer in the chat space. The contestant can then use their colleagues' responses to select the correct answer. The contestant can also “Phone a Friend” by asking one particular student for help, to which they respond by typing their answers in the chat space. The game continues until the student answers a predetermined number of questions correctly or responds with an incorrect answer. When this happen another sequencing question is asked so another contestant can be selected.

2. Simulate a radio talk show with multiple DJs and “call-in” guests. In many online courses the students spend much of the “class time” listening to the instructor through streaming audio or video technologies or during a live “web cast” during a synchronous class session. As we all know, it can be both boring and difficult to listen to one voice for any length of time, especially when there are few visual cues to accompany the audio. To provide variety and a livelier online atmosphere, we have been successful having multiple speakers interact during these broadcasts to liven up the synchronous sessions.

3. Use multimedia when appropriate. Online courses tend to be primarily textual-based forms of instruction. While this may be preferable to some students, we must recognize that the students of today are different from those of the past. The MTV generation seems to desire visual over verbal stimulation and there is no excuse for not incorporating multimedia into technology-based learning systems. We have found that graphic images, photographs, and videos enhance student motivation. For example, in several of our courses we have created short QuickTime clips from popular movies and television shows that can be streamed over the web. These clips provide entertaining examples that support the concepts and procedures being discussed in class and provide a nice break from the textual format that dominates current online environments.

Information Overload

Providing too much information in a short period of time contributes to memory overload, which makes learning difficult and leads to confusion and poor retention. Psychological studies show that most people can manage about seven “pieces” of information at one time without too much difficulty (Miller, 1956). Providing more
than that amount of information at one time overloads short-term memory. Instructional designers need to follow the Rule of Seven, which suggests that the amount of information presented at one time should be limited to no more than seven pieces of content (Clement, 1985). The Rule of Seven suggests that instructional designers “chunk” instructional content into small groups and give students the opportunity to learn each “chunk” thoroughly before being presented with new information. Using this strategy will result in better understanding. The following strategies have been used successfully in our online program.

1. **Limit the amount of content and activities.** By following the Rule of Seven, we help avoid memory overload by purposely limiting the amount of information and activities we provide in a course. For example, we ask instructors to break their lectures into 10-12 minute “chunks” or segments. These short lectures are recorded and converted into streaming media for delivery to students. These short lectures make it easier for students to complete in one setting and it forces the instructor to concentrate on only a few main concepts in each “mini” lecture. This approach also fits ideally with the concept of a learning cycle.

2. **Organize instruction around learning cycles.** The instructional design model used in the HRE Online program utilizes learning cycles at the core of its modular approach. Each course has a hierarchical structure containing sections, modules, and learning cycles. This approach allows for easy updating of courses over time and the development of custom courses to meet different client group needs. More importantly, this instructional design approach builds on theories of adult learning. Each learning cycle is comprised of three components. The first component provides the student with access to new content through a streamed audio or video file or by reading an online article. The last component of the learning cycle involves evaluating the learning outcomes through an activity involving self-assessment, peer-assessment, or formal instructor assessment and feedback. Once the learning cycle is completed, a new cycle begins with the presentation of a new “chunk” of content, followed by new application and assessment activities.

3. **Provide a graphic organizer for the course.** It is very easy for students to get lost in any hypertext environment as they navigate through online courses that contain extensive layers of content distributed over multiple locations. To avoid the frustration and memory overload that can occur in a web-based environment, we provide a visual representation of the course structure. This graphic organizer serves as a map for students as they navigate through various portions of the course. The graphic is also hyperlinked so students can quickly move to a desired location in the course by clicking directly on the image.

**Contextual Learning**

Context is an essential central element in learning because knowledge is a product of the activity, context, and culture in which it is developed and used (Brown, Collins, & Duguid, 1989). Wilson (1993) identifies three major premises of context and how these affect knowing and learning. The first is the idea that learning and thinking are social activities that are structured by constant interpersonal interaction. Second, the available tools within the particular situation significantly structure an individual’s ability to think and learn. Finally, “human thinking is profoundly structured by interaction with the setting” (p. 72). We offer the following recommendations to online instructors to promote contextual learning in the virtual classroom.

1. **Create virtual learning teams.** At the start of each new course, students are placed in a virtual learning team consisting of three to four other classmates. This allows the instructor to replicate the group experience found in face-to-face settings. Students work together on weekly assignments and projects via conferencing systems, conference calls, e-mail, and Instant Messenger. This initiative provides a group context that is similar to what would be experienced in the face-to-face classroom.

2. **Simulate reality using appropriate case studies.** Regardless of the delivery format, the more “real-life” examples that can be utilized, the better students will learn. Case studies are an excellent way to provide the context through which new learning can be developed. As with any situation where a case study is used, it is critical to choose cases that relate to the content of the course. In our online evaluation course, students are provided with a case describing a program within an organization that needs to be evaluated for effectiveness. Throughout the duration of the course, students are asked to design an evaluation around this case using the concepts, ideas, and procedures taken from the course materials. Students are provided with feedback through WebBoard discussions and weekly synchronous chat sessions.

3. **Require collaborative projects with schools, businesses, or other organizations.** Students are encouraged, where possible and appropriate, to develop course projects within the context of their work environment. This provides a real-life context in which to imbed application of the material. For example, in the online instructional design course, students develop a training package that represents 68 hours of training time. The majority of the students choose to develop a training package that addresses a performance issue within their organization.
Social Learning

Social learning theory combines elements from both behaviorist and cognitive theories and posits that we learn best by interacting with others in social settings (Merriam & Caffarella, 1999). Behavioral learning theory contributes to social learning because people do not learn from observation alone but through imitation and reinforcement of what they observed. Cognitive theory focuses on the cognitive processes involved in the observation over the resulting behavior with the idea that individuals can regulate their own behavior by recognizing consequences. Social learning is manifested through socialization, social roles, mentoring, and locus of learning.

For the social learning theorist, the purpose of education is for the learners to have new roles and behaviors modeled for them. Instructors and peers serve as a model for new roles and behaviors within an educational context. The following strategies have been successfully used by online faculty to promote this perspective.

1. **Create a personal connection with students.** The goal is for instructors to be perceived as a real person in mediated communication. This is promoted several ways. Each course has an audio-streamed welcome message from the faculty member. This helps the student to put a face with the voice. Additionally, actions such as humor, vocal variety, personalizing examples, addressing students by name, questioning, praising, initiating discussion, and encouraging feedback all help make this connection. Personal connection can also be made through the use of “relational icons” or “emoticons” made by combinations of punctuation marks.

2. **Peer review and feedback.** Feedback from fellow students is as important as instructor feedback. Therefore, students in many online classes are asked to provide a meta-evaluation of another student’s work. The purpose of the activity is to help their peers by providing comments that help the person understand the areas that are clear and well done and the parts that need further development. This activity also models appropriate format for the particular assignment being developed.

3. **Require and facilitate interaction.** This may not seem like a new approach, however, in the online environment, it is much easier for students to be passive both in weekly assignments involving the group as well as during synchronous chat sessions. In addition to basing a percentage of the course grade on participation, other initiatives can be taken as well. One is to post an agenda of the upcoming week’s synchronous session. This serves as an advanced organizer and allows students to come to class better prepared for interaction. Another technique is to post discussion questions prior to a synchronous session so students can think about the topic and be ready for a discussion. Throughout the week, students are required to review comments and ideas that have been posted by other students and respond to them in a virtual class discussion. Two things that are important to keep in mind. First, while the quantity of interaction is important (measured by hits on the WebBoard), the quality of interaction is what should be stressed. If not, it becomes too easy for students to fall into the trap of providing comments that add little or no value to the discussion. Second, it is important that the instructor model the expected type of interaction by providing quality comments to the discussion as well.

Active Learning

There seems to be an assumed separation between knowing and doing in education (Brown et al., 1989) where knowing is valued over doing and mental activity is valued over physical activity. However, cognitive theorists have challenged this perspective because the activities through which learning occurs are inseparable from cognition. In order for formal online instruction to be successful, some form of learner activity must be included.

Active learning can occur in many forms in an online environment. Discovery learning, project-based learning, and cooperative learning are common techniques for engaging students in activities that involve considerable amounts of creativity, decision-making, and problem solving. Each of these instructional approaches emphasizes the importance of learning from experience that is goal driven and activity-based. Since these activities usually take more time to complete, they provide for sustained thinking about specific problems over long periods of time. The following are specific examples of how active learning can be applied in an online environment.

1. **Organize online courses around projects.** Since HRD is a constantly evolving applied field of study, it is reasonable to design an online HRD course with a heavy emphasis on the application of the skills and procedures needed by the HRD professional. The best way to accomplish this in an online environment this is through a project-based approach. Application-rich courses can be designed around major projects and specific activities to be completed in order to create a final product. For example, in the instructional design course where students are expected to create a complete training module, they need to complete many specific tasks such as conducting a needs assessment, developing training plans, and creating instructional media. By adopting a project-based approach, the online instructor can easily incorporate the concept of active learning into a virtual environment instead of providing the typical “read and write” online course.
2. **Think-Pair-Share in a virtual environment.** Having online students work in groups of two or three within a virtual environment is a great way to keep students active and focused on their learning. Think-pair-share is an active learning technique used in many face-to-face classes but is rarely used in a virtual environment. The goal is to help students organize prior knowledge, brainstorm questions, or summarize, integrate, and apply new information. This strategy can be used in both synchronous and asynchronous situations.

3. **Use small group discussions during synchronous sessions.** Although few online programs seem to rely on synchronous class sessions, they can provide powerful opportunities for student interaction. We conduct weekly synchronous sessions in our program where the instructor performs a live audio broadcast to the students over the web while the students interact with the instructor and other students in a group chat space. While this in itself encourages active learning, incorporating small group interactions into the large group discussions further enhances it. This is accomplished by having the instructor describe a discussion activity to the class and then asking them to enter their private "virtual team" chat space to discuss and complete the assignment. A specific time is given when the students are expected to return to the class chat space and share the major points of their discussion with the rest of the class. Although this technique is commonly used in many face-to-face classes, it is a unique, yet underutilized, strategy in an online learning environment.

**Reflective Learning**

Mezirow defines learning as "the process of making a new or revised interpretation of the meaning of an experience, which guides subsequent understanding, appreciation, and action" (1990, p. 1). Reflection allows individuals to correct distortions in their beliefs and critique "the presuppositions on which our beliefs have been built" (Mezirow, 1990, p. 1). Argyris and Schon refer to critical reflection as double-loop learning "that results in a change in the values of theory-in-use, as well as in its strategies and assumptions" (1996, p. 21). The process of reflection enables the ideas, understandings, and experiences of individuals and groups to be reviewed (Preskill & Torres, 1999). Values, beliefs and assumptions of team members are explored through reflection. Through better understanding of individuals' mental models, we can better understand how two or more people can view the same event so differently. Watkins and Marsick (1993) see reflection as a key to continuous learning. The following three strategies can be used to promote reflective learning.

1. **Provide extensive and timely feedback.** While this is something most instructors already know, it is important to remember that the online environment removes some of the human "checks and balances" that face-to-face students have with the instructor. While the opportunity to ask questions and have interaction with the instructor is relatively equal, feedback received through physical distance, eye contact, facial expressions and personal topics of conversation is not present for these individuals. Therefore, it becomes even more important that the instructor take time to provide feedback that is detailed enough to paint a complete evaluative picture. This includes addressing not only the areas that were weak or need improvement, but providing praise for the areas that were done well. Instructors are encouraged to get this feedback to the students no later than a week after the assignment is turned in.

2. **Incorporate "One Minute Papers" and "Muddiest Point" into class.** "One Minute Papers" are short writing exercises in which students are asked to reflect on a particular topic as a form of knowledge assessment activity. Students are asked to post a quick list of the new knowledge they gained through a particular session. The "Muddiest Point" activity allows students to identify the areas of confusion or uncertainty and/or to raise additional questions around the content of the session. Both of these activities benefit the students and instructor by providing feedback on what was clear and what may need further attention through the use of reflection.

3. **Online diaries or reflective journals.** Diaries and journals promote continuous reflection throughout the course. Entries can be self-directed or promoted by an issue, question, or experience posed by the instructor. Journals allow students to reflectively interact with various course topics and experiences and, as noted earlier, critically examine how their values, beliefs and attitudes fit with the material. This is a way that promotes growth beyond what regular instructor and student interactions provide.

**Concluding Thoughts**

The instructional strategy framework discussed in this paper is clearly a work in progress. Although the framework is based on well-recognized theories of learning and represents a synthesis of ideas from multiple perspectives, it is not fully developed, nor is it all-inclusive. Additional principles will be added as the online program continues to develop and evolve. The specific techniques for applying the instructional principles highlighted in this paper are currently in use in the HRE Online courses and continue to be enhanced each time they are implemented. The
possibilities for application of the instructional strategy framework are only limited by the creativity and energy of the instructional designers and course instructors.

Formalized research efforts need to be conducted to validate and improve the strategy framework and the instructional techniques that evolve from it. Studies that examine the effectiveness of instructional strategies in online courses are lacking in the educational technology literature. Most literature provides anecdotal comments on experiences with online courses and empirical research that compares face-to-face and online delivery methods. Instead of comparing two dissimilar learning environments, future studies should empirically test the effectiveness of different instructional techniques in maximizing learning opportunities and achievement in online environments.

Using Online Learning to Meet Workforce Demand: A Case Study of Stakeholder Influence

Angela Benson
University of Illinois at Urbana-Champaign

The purpose of this initial phase of inquiry was to investigate how stakeholder interests influenced one state's efforts to provide online, undergraduate degree programs to meet workforce needs. The investigation employed an embedded qualitative case study design. The findings showed that the negotiation of opposing and conflicting stakeholder group interests resulted in the prevailing of the interests of some stakeholder group at the expense of the interests of other stakeholder groups.

Keywords: Online learning, Program Planning, Distance Education

Traditional education and older forms of distance learning have presented difficulties for non-traditional learners. These learners include busy professionals who travel extensively and unskilled laborers employed in jobs with inflexible hours that make a traditional school schedule unworkable. Many business organizations and academic institutions have turned to online learning using the Internet and other web-based technologies in order to provide the needed learning experiences for these under-served learners. Over the past decade, online learning has evolved into a growing vehicle for providing adults with new skills, updated information, and new knowledge, often through degree programs. While online degree programs are primarily concentrated at the graduate, professional level, there are an increasing number of programs being developed at the undergraduate level (Davis, 1999). Unfortunately, a recent Institute for Higher Education Policy analysis of the distance education research literature indicates that distance education research has not kept pace with distance education use (Phipps & Merisotis, 1999). A review of the current literature related to distance education program planning, with a specific focus on online technologies, revealed the same lack of related literature (Benson, 2001).

Because of the number and types of stakeholders typically associated with online degree programs, this study sought to unravel the complexity of online degree program planning by examining the roles of the stakeholder groups involved in one state's efforts to meet workforce demands through online degree programming. In doing so, this research makes a much needed contribution to the literature base related to the planning and implementing of online degree programs, and provides practical insight to HRD professionals who are among the stakeholders of such programs.

Theoretical Framework

For the most part, online degree program development efforts have been approached using existing models from instructional design, adult education, and distance education. The models from these areas can be classified using the taxonomy that Cervero and Wilson (1994a) use for adult education program planning models: classical, naturalistic and critical. Classical models have their roots in systems theory as reflected in Tyler's (1949) curriculum development model. These models take a strict, systematic approach and require the completion of a stepwise process that usually begins with defining objectives and continues through evaluation. Naturalistic models were developed because researchers and practitioners wanted models that were more reflective of the environments in which planning, designing, and learning is actually accomplished. Instead of requiring a stepwise process as in the classical models, naturalistic models accommodate the value judgments of planners, designers and developers. Critical models were developed to focus attention beyond content knowledge and skill development to emancipatory action on the part of learners and instructors. Table 1 summarizes the model categories and provides example models from each of the three disciplines.

Cervero and Wilson (1994a) identified key problems with models in each of the categories. Classical models do not "account for the dimensions and variability of planning contexts, the nature of practical judgments, or the values that influence how judgments are made" (p.17). Naturalistic models fail to provide "any standards, either technical

41-2
or ethical, for knowing whether the planner has made the "best" judgment" (p. 20) and do not address the unequal
power relationships of the people involved in planning. Critical models fall "short in exploring the ways [political
and ethical] insights might be worked out in the everyday world faced by program planners" (p. 24). Cervero and
Wilson (1994a) provide an alternative to the classical, naturalistic and critical models with their negotiation of
power and interests model. According to Cervero and Wilson, "Planning programs is a social activity in which
people negotiate personal and organizational interests " (p. 4). They contend that programs are not created by
following a series of steps, or by making a set of best judgments, or by identifying power inequities; rather they are
created through the social negotiation of the interests of the involved stakeholders (Cervero & Wilson, 1994b).

Purpose and Research Questions

The purpose of this initial phase of inquiry was to investigate how stakeholder interests influenced one state's efforts
to provide online, undergraduate degree programs to meet workforce needs. This study is significant because it
sought to investigate the online degree program planning process from the social and political perspectives, rather
than the technical perspective that is the focus of most related lines of inquiry. The research questions that guided
this inquiry are:

1. What interests did the affected stakeholder groups bring to the planning and implementation process?
2. What influence did those interests have on the resulting online degree programs?

Methodology

The study employed an embedded qualitative case study design (Yin, 1994). Strauss and Corbin (1998) identified
three types of problems that are appropriate for qualitative research: 1) attempts to understand the meaning and
nature of the experience of persons with problems, 2) explorations into areas about which little is known, and 3)
inquiries into feelings, thought processes, and emotions that are difficult to extract or learn about through more
conventional research methods. This investigation met all three criteria. This study sought to make meaning of the
social and political processes in operation during the planning and implementation of online degree programs. The
focus on the socio-political aspect of planning was a new one for the online education environment, and required
experiential data that could not be collected through quantitative means.

Case study research is distinguished from the other types of qualitative research in that it is "an intensive
description of a single unit or bounded system, such as an individual, program, event, group, intervention,
community" (Merriam, 1998, p. 19). Case study design can take many forms. In a single-case design, the unit of
analysis is the case itself (Yin, 1994). In an embedded case designs, “attention is also given to units or subunits” of
the case (p. 41). The case in this embedded case study was NetEd, a statewide, online, undergraduate degree
program initiative undertaken by the university system of a large southeastern state. The embedded cases were the
six NetEd stakeholder groups: NetMan, University System Office of Academic Affairs (University System OAA),
University NetEd Oversight Committee (University NOC), DevelopInc, Online Faculty, and Online Students.

Qualitative research typically focuses in depth on relatively small samples that are selected purposefully. The
case study usually requires two levels of purposeful sample selection: the case level and the participant level
(Merriam, 1998). The case level selection of NetEd was done using intensity sampling, a form of purposeful
sampling (Patton, 1990). With intensity sampling, the researcher seeks “information-rich cases that manifest the
phenomenon of interest intensely (but not extremely)" (p. 171). NetEd's planning and implementation processes
manifested the technical and socio-political aspects of planning and implementing online degree programs that were
of interest in this study.

Overall, participant level selection was done using the maximum variation form of purposeful sampling. The
goal of maximum variation sampling is to “capture and describe the central themes or principal outcomes that cut
across a great deal of participant or program variation” (Patton, 1990, p. 172). For maximum variation, participants
were taken from each of the six defined stakeholder groups. Within the participant groups, participants were selected using snowball, or chain, sampling. In snowball sampling, the researcher "identifies cases of interest from people who know what cases are information-rich" (p. 182). Table 2 lists the stakeholder groups included in the study, the number of participants in each group, and each group's function.

Qualitative methods consist of three types of data collection: (1) interviews; (2) direct observation; and (3) documents. The power of the methods is not in their individual use, but in the triangulation resulting from their collective use (Merriam, 1998; Patton, 1990; Yin, 1994). Therefore, this study used all three forms of data collection. Semi-structured, one-on-one interviews of 1.5 to 2 hours were conducted with each of the 13 participants and follow-up e-mail interviews were conducted with six participants. Observations were conducted of seven 3–4 hour meetings in which NetEd stakeholders participated. In addition, over 50 NetEd planning documents including meeting agendas, committee reports, commissioned studies, program objectives, mission statements, and marketing materials were collected and analyzed along with the researcher's journal.

Data analysis is the "process of making sense of the data" (Merriam, 1998, p. 178). Data analysis for this case study had descriptive and explanatory components. The descriptive component provided detailed descriptions of the case, the embedded cases, the planning process, and the stakeholder interests. In the explanatory component, the stakeholder interests and the planning process were viewed from the perspective of the negotiation of power and interests model (Cervero & Wilson, 1994a).

Merriam's (1998) version of the constant comparative method was used for the descriptive component. According to Merriam (1998), the researcher using the constant comparative method begins with a particular incident from a data set (interview, document, or observation) and compares it with another incident in the same data set or in another data set. The comparisons lead to the creation of tentative categories that are then compared to each other. Comparisons among categories are constantly made until all the incidents have been categorized and there is no ambiguity in the categorizations. The analysis of the observations and documents, including the researcher's journal, was conducted concurrently with the analysis of the interviews.

A modified form of Yin's (1994) explanation building was used in the explanatory component of data analysis. In explanation building, the researcher brings a theoretical framework to the analysis and uses the case and embedded cases to verify, fail to verify, or further develop the framework. For this study, the researcher began the explanatory analysis after completing the descriptive analysis. During the explanatory phase of analysis, the researcher compared the case, NetEd, to the theoretical framework to determine how the negotiation of stakeholder interests and the planning process shaped the resulting NetEd online degree programs. For this analysis, the researcher identified instances of negotiation when a) the researcher observed the negotiations, b) stakeholders explicitly discussed the negotiations, c) consensual or conflicting interests within or across stakeholder groups impacted the power relationships among the stakeholders, d) consensual or conflicting interests within or across stakeholder groups impacted the frames defining the NetEd initiative, or e) consensual or conflicting interests within or across stakeholder groups impacted NetEd's purpose, audience, content, and format.

Validity and reliability take on slightly different meanings in qualitative research. Internal validity refers to how well the data collected capture the reality of the phenomenon under study; external validity, to the transferability of the research findings, or the readers' ability to generalize the findings of the study to their specific situations; and, reliability, to the consistency of the findings, or whether the results are consistent with the data collected. The researcher enhanced the validity and reliability of this study by using triangulation, member checks, and peer debriefings, and by providing a stated theoretical framework and a rich, thick description of the findings that allow
readers to draw their own conclusions about the transferability of the findings to their environments, and by maintaining an audit trail of research activities through memo writing and reflective journaling.

Study Limitations

Previous research using the negotiation of power and interests model as the theoretical framework has focused narrowly on a single educational program, the size and scope equivalent to a short-term course. This study took a broader view and focused on a degree program consisting of multiple semester-length courses. The difference in scope of the studies is reflected in the level of analysis conducted. Previous studies explored the depths of the interpersonal interactions and negotiations between individual stakeholders. This study, because of its broader focus, explored the macro-level interactions and negotiations between stakeholder groups, rather than between individual stakeholders. Taking the broader approach allowed the researcher to investigate the negotiation of power and interests within a large-scale project. In order to accomplish this broader approach, the researcher had to relinquish the ability to simultaneously investigate the micro perspectives within each of the stakeholder groups. As a result, the analysis reflects a macro-level view of stakeholder negotiations rather than the micro-level view provided in previous studies.

Program Description

The case under investigation was NetEd, a statewide, online undergraduate degree program initiative undertaken by the university system of a large southeastern state. NetEd's goal was to provide online degrees in areas of critical shortage as defined by the state's workforce needs. NetEd consisted of two projects, NetMan and NetCore. NetMan provided a web portal to online degrees offered by institutions within the state's university system. NetCore was the online core curriculum development project within NetEd. NetCore courses formed the first two years of coursework (i.e., the core curriculum) for the online degrees offered through the NetMan portal. The final two years of online coursework were to be provided by various academic departments at the system institutions.

Figure 1 shows the organizational reporting structure of NetEd. NetMan resides in the NetMan organization and reports directly to the University System Board. NetCore resides in the University System OAA. Though Figure 1 shows the NetCore project residing in the University System OAA organization, the project spanned multiple organizations in the university system. The relationships of the six stakeholder groups are described in Table 1.

Figure 1. NetEd Organizational Reporting Structure.

Findings

Stakeholder Interests

Cervero and Wilson (1994a) described three types of stakeholder interests: expressed interests, which are the stated, or revealed, preferences of individuals involved in the planning process; ideal interests, which refer to "what is really in the interest or good of a person, whether she or he thinks so or not" (p. 124); and, real interests, which are the "norms, values, and purposes implicit in what planners do" (p. 125). The findings of this investigation suggest a second taxonomy: overarching interests and operating interests. An operating interest is a perspective of an overarching interest held by one or more stakeholder groups. Table 3 shows the overarching interests and operating interests identified for the NetEd stakeholder groups. Each overarching interest has at least one associated operating
interest. For example, the Quality overarching interest has four operating interests and the Policy overarching interest has three.

| System Change         | • Limiting change to course modality for accreditation purposes  
                        | • Effecting system-wide change |

Table 4 shows a mapping of overarching interests to the stakeholder groups who held those interests. As shown in the table, multiple stakeholder groups shared each of the overarching interests. For example, the NetMan, University System OAA, and Online Student stakeholder groups shared the Student Lifestyle Accommodations overarching interest. In addition, all stakeholder groups held multiple overarching interests. For example, the Online Faculty stakeholder group had four overarching interests: Quality, Development, Process, and Marketing categories.

The data indicate that while stakeholders shared overarching interests, the operating interests within those overarching interests were often in conflict. For example, within the Process overarching interest, the DevelopInc stakeholders' operating interest in process control conflicted with the Online Faculty stakeholders' operating interest in process flexibility. Likewise, the University NOC's operating interest in meeting accreditation standards conflicted with NetMan's operating interest in overcoming the stigma associated with online learning.

This finding suggests that stakeholders of online degree programs must go beyond surface level discussions of consensual overarching interests and uncover those potentially conflicting operating issues early in the planning process. If conflicting operating interests are identified early, they can be addressed reasonably without causing any unnecessary stress on the process and the stakeholders. Uncovering conflicting operating interests late in the planning and implementation process can undermine the effectiveness of the process and the stakeholders.

Stakeholder Influence

Cervero and Wilson (1994a) posit that programs are shaped through the negotiations of the interests the stakeholders bring to the planning process. The ability of a stakeholder to influence the negotiations, and thus the resulting program, is determined by the power relationships among the stakeholders. This stakeholder capacity to act may be “socially systematic,” derived from the organizational and political structures within which they act; or “socially ad hoc,” derived from their role or position with respect to the planning task at hand (p. 128).

Table 5 shows the complexity of stakeholder negotiations involved in NetEd’s planning. Consistent with the Cervero and Wilson (1994a) model, the table shows that the negotiations of overarching interests shaped NetEd’s audience, content, and format. For example, negotiations around the Quality overarching interest shaped NetEd’s content, format, and process. The table also shows that the negotiations of multiple interests contribute to the shaping of a single program component. For example, NetEd’s audience was shaped by negotiations around the Buy-In, Student Lifestyle Accommodations, Programming, and Marketing overarching interests.

Cervero and Wilson (1994a) posit that an ethical planning process is one in which the interests of all affected stakeholders are substantively represented, regardless of their place in the power hierarchy. The NetEd initiative did not display this characteristic. Influence amongst the NetEd stakeholders stemmed from two seats of power: NetMan and the University NOC. NetMan did planning for NetEd online degree programs and for the NetMan portal, while the University NOC focused more narrowly on planning for NetCore. The influence of each of the six stakeholder groups is discussed in this section.

University NOC Stakeholders. The University NOC consisted of representatives, primarily chief academic officers, from institutions that ultimately would have to approve the NetCore online core curriculum. Each system institution, with the exception of the three research universities and the medical school, elected to place representatives on the University NOC. These institutional representatives had the opportunity to shape policy that governed NetCore course development and implementation. Decisions on the University NOC were made by consensus, rather than by voting, since it was imperative that all institutions agree with all NetCore policy.

The University NOC model of including representatives from system institutions in NetCore planning activities extended to the NetCore course development teams. Each team had six faculty members representing six system
institutions. Using a team approach to NetCore course development allowed individual system institutions to participate in defining an online core curriculum that would be acceptable to all system institutions.

Unlike the University NOC planning team, which was made up of representatives from system institutions, the NetMan planning team was comprised of the NetMan staff with no institutional representation. As a result, NetMan had to "go on the road" to get "buy-in" from system institutions. In these road shows, the NetMan stakeholders presented the findings from their market research and tried to position the NetEd initiative and the NetMan project within that initiative as providing value to the university system and to the individual institutions.

Given the composition of the planning teams of the two projects, it should not be surprising that the University NOC exerted more influence over NetEd planning processes than NetMan. The University NOC planning team included the affected stakeholders while NetMan planning included none of the affected stakeholders. These University NOC representatives were decision-makers at their respective institutions and could make commitments that their institutions were bound to honor, while NetMan had to rely on the "good-will" of system institutions.

NetMan Stakeholders. NetMan's market research indicated student interest in "anywhere, anytime learning." In fact, NetMan's initial press releases and web portal used the phrase, "anywhere, anytime learning." Unfortunately, NetMan stakeholders were unable to exert the influence necessary to see "anywhere, anytime learning" realized within the NetCore courses, which were class-paced over the length of a semester. Neither NetMan's position in the university system organizational structure ("socially systemic power"), nor its functional role on the NetEd project ("ad hoc power") provided the power base the organization needed to ensure that NetCore course development proceeded as the market research dictated. As "facilitators," NetMan stakeholders were forced to rely on the "good will" of other stakeholder groups.

In general, any time a NetMan interest conflicted with a University NOC interest, the University NOC interest prevailed. Unfortunately, it is not clear that the prevailing of the University NOC was in the best interest of the NetEd initiative. One of NetMan's most fundamental interests, to effect system change, was in direct conflict with the University NOC's interest of limiting the educational change impact of NetCore to changing delivery media. The University NOC stakeholders prevailed because their interest in meeting accreditation standards outweighed NetMan's interest in system change.

Online Student Stakeholders. The Online Student stakeholders appeared to exert very little influence on NetEd planning. Students expressed interest in "anywhere, anytime learning," but all the NetCore courses were class-paced over the length of a semester.

Online Faculty Stakeholders. The Online Faculty and University OAA stakeholders brought their historical power relationships to the NetCore project. Historically, faculty members were clients that the University System OAA sought to serve and satisfy. During the NetCore course development process, the relationship gradually changed to one in which the University System OAA became more directive with faculty. Faculty did retain power based on their status as subject matter experts and content providers, and as representatives of institutions who ultimately had to approve or reject the course offerings. Not surprisingly, online faculty stakeholders exerted their strongest influence over the content of the individual courses.

University OAA and DevelopInc Stakeholders. The ability of the University OAA stakeholders and the DevelopInc stakeholders to influence NetEd planning decisions was limited by their organizational relationship to each other and to the University NOC. Since the University OAA hired DevelopInc, DevelopInc stakeholders treated University System OAA stakeholders as clients to be served and satisfied. The University OAA, on the other hand, operated at the direction of the University NOC and treated them with deference.

Implications for Future Research
While research has been conducted to identify strategies for managing power relationships among stakeholders (e.g., Mabry & Wilson, 2001), no research has been conducted to identify strategies to uncover and clarify the overarching and operational interests of stakeholders as identified in this study. Future research should pursue this line inquiry.
In addition, many studies have examined success factors for students in online courses, but few, if any, have focused on student perspectives on program and course planning and design. Such research would be a step in the right direction towards including student perspectives, which were discounted in the NetEd project, in the planning and design process. Future research also should consider the possible integration of the social and political focus of Cervero and Wilson's model with the technical focus of traditional instructional design and program planning models. An integrated model might better capture the environment in which planners and designers do their work. This future research should include program models with stakeholders from the business community.

**Contribution to HRD Practice and Theory**

Many HRD professionals perform the role of program planners in their daily work. As such, many rely heavily on traditional instructional design and program planning models to direct their efforts. The findings of this study suggest that the negotiation of power and interests model may provide a new perspective and a new set of tools with which to address the challenges inherent in managing planning and design processes that involve multiple stakeholder groups and a myriad of stakeholder interests. By suggesting a new perspective from which to view old problems, this research adds new knowledge to HRD theory and opens the door to future investigations that could yield models and theories of practice that are specific to the HRD environment.

**References**

Distance learning programs in higher education have grown rapidly in recent years due to the popularity of "online" or "web-based" instruction. However, little research has been conducted on effective online program models within the field of human resource development (HRD). The purpose of this study was to identify and describe program models for online HRD course delivery.

Keywords: Online Programs, Online Models, Web-Based Distance Learning

Advancements in computer technology have had tremendous effects on the world--how we communicate, conduct business, perform research, and even go shopping. By a simple click of a button, transactions can be made in minutes between people thousands of miles apart. Business and industry are using the Internet as a vehicle for advertising their products, offering their services, and broadening their clientele. In the same respect, higher education institutions are now using the Internet to offer courses to students who are located anywhere in the world. Many refer to this form of distance learning as online or web-based education.

The concept of distance learning has been in existence for many years. Through the use of audiotapes, videos, and correspondence, educational institutions have offered courses to students who could not physically attend their classes. Most students who enroll in distance learning courses are over 25 years of age and are characterized as highly motivated, disciplined, and committed (University Continuing Education Association, 1998). Through distance learning, students may take courses to obtain professional certification, continuing education units, or associate, baccalaureate, and graduate degrees.

Current statistics highlight the unprecedented escalation in the number of instructional programs offered through distance learning. For example, both the number of courses taught at a distance by postsecondary institutions and their enrollments nearly doubled between 1994-95 and 1997-98. In just one year, between 1997 and 1998, the growth of distance learning programs in higher education was well over 70% (Lewis, Snow, Farris, Levin, & Greene, 1999). Future projections suggest that this increase will continue because of the popularity of online instruction. The growth in online instructional programs for adults is not confined to higher education. The market for web-based corporate learning is expected to reach $11.4 billion by 2003, up from $550 million in 1998 (Moe & Blodgett, 2000).

Distance Learning Models

Distance learning is represented in a variety of educational models. These models are built around the instructional process; presentation of content; interaction with faculty, peers, and resources; practical application, and assessment (Institute for Distance Education, 1997). The most common types of distance learning models are distributed classroom, independent learning, and open learning + class model.

In the distributed classroom model, interactive telecommunications technologies extend a classroom-based course from one location to groups of students at one or more other locations. Educational institutions can broadcast face-to-face lectures to "satellite" sites that are strategically located near their students. Learning is synchronous or real-time. Since the satellite sites are equipped to receive and transmit both audio and video, "remote" students are able to participate in the lectures as if they were physically present. The technologies used to support the class sessions include two-way interactive video, one-way video with two-way audio, audio conferencing, or audiographic conferencing. The telephone, postal mail, fax, and a computer (for e-mail and conferencing, access to online resources, and submission of assignments) are used to support out-of-class communication.

The independent learning model does not require students to be in a particular place at a particular time. Instead, students are able to access course information, interact and collaborate with faculty and classmates, and submit course assignments from anywhere in the world. Students are given detailed course syllabi and access to faculty. Since there are no face-to-face class sessions, in-class technologies are not required. Technologies to support out-of-class communication include postal mail, voice mail, electronic mail, computer conferencing, and telephone. This model is used by most educational institutions to deliver online instruction.
The open learning + class model is a combination of the distributed classroom and independent learning models. Students use printed class materials and media, such as videotapes and CDs while learning at their own pace. There's also occasional use of interactive telecommunication technologies for group meetings among all enrolled students. This model uses the same communications technologies as the distributed classroom model.

**Purpose of the Study**

Given the extraordinary growth of online instructional programs in higher education, it is essential to know what online strategies or models are most effective in delivering Internet-based programs, in particular HRD programs. This is a new area of program development, and little is known about these types of models. Just as educational institutions use distance learning models to offer courses at a distance, what types of online models do they use to deliver Internet-based HRD courses? The goal of this study was to identify and describe existing program models for online HRD course delivery. The research questions that were used to focus this study were:

1. What services and technologies are used to deliver online HRD courses?
2. What program models are used to support HRD online programs?

**Methodology**

A status study was conducted to obtain information about online HRD programs in higher education institutions and the types of online models they use to deliver their courses. Because of the exploratory nature of the study and the need for timely, cost effective, and easily quantifiable data, a survey design was used to address each research question. A questionnaire was placed on a web site for participants to access. After 2 weeks, non-respondents were sent a follow-up e-mail message reminding them to complete the questionnaire. Telephone calls were made to those who did not respond to the e-mail reminder.

**Population**

The population selected for this study was higher education institutions in the United States that are associated with the Academy of Human Resource Development (AHRD). AHRD is an international organization comprised of researchers and graduate students who are interested in various aspects of HRD. The 1999-2000 AHRD membership roster, which consisted of 650 members, was used to identify institutions that have HRD courses and programs. From this membership list, the researchers identified a total of 128 educational institutions with connections to AHRD, and 107 of these were U.S. based.

The researchers then visited the department web sites of each institution to determine if they offered web-based HRD courses. A keyword search using terms such as “Internet-based courses”, “online”, “distance education”, and “distance learning” was also performed. If the institution offered Internet-based courses, the researchers performed another query to determine if they offered HRD courses that were 100% online. Results from this search identified 19 AHRD institutions that appeared to offer Internet-based HRD courses. To validate this list of institutions, the 1999, 2000, and 2001 AHRD conference proceedings were also searched using keywords. This search revealed no additional institutions that offered 100% Internet-based courses. Although several strategies were used to identify appropriate institutions, it is still possible that some institutions that offered HRD online programs were overlooked because various search engines were used to browse the university websites.

A contact person (i.e., faculty member or program coordinator) was then identified from the web site for each institution that offered some type of HRD online course. Each of these individuals was then contacted to invite them to participate in the study.

**Instrumentation**

A web-based questionnaire was used to collect the program data. Prior to developing the questionnaire, the researchers conducted a literature review to determine if any distance learning surveys had been developed that could be adapted to the HRD online status study. From this search, the Survey of Distance Learning Programs in Higher Education was identified (Primary Research Group, 1997). Although the survey displayed face validity, it appeared to lack content validity. Several of the items had to be rephrased, while others were deleted due to lack of applicability. After numerous revisions, the questionnaire used for this study bore little resemblance to the original instrument. The final instrument contained 33 questions addressing issues of financing and marketing online
courses, online faculty and staff support, online faculty training and compensation, online student support and resources, course development, and technologies used to deliver online courses.

To ensure content validity and clarity, a group of HRD faculty and graduate students participated in a pilot test of the questionnaire. Based on the pilot test results, the questions were revised and the final instrument was placed on a web server for participants to access and complete. Sampling was not required since all North American AHRD institutions with online courses and degree programs were asked to complete the questionnaire.

Data Collection and Analysis

All data were collected online via the Internet. Participants received an e-mail inviting them to participate in the online survey. The response rate was 68.4%. Of the 13 responding institutions, 6 did not offer HRD courses that were 100% web-based and one institution elected not to participate. The six institutions that agreed to participate were then sent an Internet address so they could access the questionnaire. Participants responded to questions by clicking on the appropriate answers or inputting short responses. Once the questionnaire was complete, participants submitted the form and the items were transferred to a database.

Microsoft Access and Excel were used to organize the questionnaire data. The researchers looked for patterns in the data and calculated frequencies and percentages for each response category. An extensive web-site analysis was also conducted for each program that had online HRD courses. This analysis consisted of an examination of the web site for each program and a review of various program characteristics related to the research questions.

Results

Respondents were asked to provide general information about their online HRD programs such as types of programs offered, number of students receiving degrees online, student profiles, typical class size, available faculty and student support services, and technologies used to deliver online instruction. Table 1 provides a listing of the institutions that offer 100% web-based HRD courses and online degrees.

Bowling Green State University

Bowling Green State University offers core courses toward a Doctor of Philosophy in Technology Management via the Internet. The Ph.D. program uses a consortium of institutions to offer core courses to support the online doctorate in technology management. The consortium is comprised of Central Missouri State University, East Carolina University, Texas Southern University, University of Wisconsin-Stout, North Carolina A&T, and Indiana State University, which serves as the lead school.

The program is designed to prepare specialists who have extensive knowledge of scientific and engineering developments, knowledge of the economic and political organizations of the global community, and sensitivity to the ethical and moral issues surrounding technology. Requirements for the Ph.D. include: 15 semester hours of general technology core courses, 12 hours of a major specialization area, 12-18 semester hours of cognate studies, 27-33 semester hours of research, and 6 hours of internship. Courses are designed to provide experiences that address topics in contemporary and future trends of technology. Philosophical dimensions influencing decision making, historical perspective, and implications for technological development, and technical systems are included. HRD online tuition ranges between $500 and $599 per course.

Indiana State University (ISU)
Indiana State University offers an online Master's of Science degree in Human Resource Development for Higher Education and Industry degree and core courses toward a Ph.D. in Technology Management. The master's program is designed to prepare professionals for higher education, industry, business, government, and other agencies. It requires a total of 33-36 hours. Upon completion of the program, participants are able to plan, conduct, and manage education, training, and other human resource development activities. The core courses offered for the online Ph.D. program are the same ones offered through the consortium with Bowling Green State University. Currently, over 125 students have completed their degree online, with tuition costs under $500 per course.

University of Illinois at Urbana-Champaign (UIUC)

The University of Illinois offers an online Master's degree in Global Human Resource Development. The program is designed for individuals currently working in or aspiring to HRD positions in either the private or public sector. It is focused on employee training and development, organization development, and the use of information and technology to improve individual and organizational performance. Emphasis is placed on HRD leadership in both domestic and international settings. Upon completion of 9 units (36 semester hours) of coursework, students are awarded a Master’s of Education (Ed. M.) degree. To date, 13 students have completed their degrees and 59 are currently enrolled online. Tuition costs is currently $1008 per course.

University of Louisville

The Department of Leadership, Foundations, and Human Resource Education at the University of Louisville offers an Internet-based Master's of Education (M.Ed.). This pilot program was developed with a grant from the United States Army. The M.Ed. program focuses on human performance improvement, instructional design, and human resource management. Currently, the only course offered over the Internet is Organizational Analysis. This course examines the processes and techniques used to (1) conduct organizational task and person analyses and (2) identify training needs in a non-school environment. They plan to expand their program to offer the entire degree program online. Students who are enrolled in the online HRE program and are located in the Louisville area are given the option to take the same courses on-campus. The program requires a minimum of 30 credits for completion with a core curriculum of 27 credits. The University of Louisville began offering their HRD course online in the summer of 2001. Tuition costs per course are below $500.

University of Minnesota

The University of Minnesota’s HRD program is one of six faculty groups within the Department of Work, Community, and Family Education. Their HRD program prepares students to become work, community, and family education professionals. Although they do not offer any online degrees or certificates, they have several Internet-based courses. Tuition costs are variable and dependent on whether students reside in state or out-of-state and whether they are part-time or full-time.

Western Carolina University

The Department of Human Resources is part of Western Carolina University’s College of Education and Allied Professions. The department’s goal is to meet the needs of aspiring and experienced human resource professionals. They offer a Master’s degree in Human Resources, where students may specialize in e-learning, organization performance, or interdisciplinary human resource studies. A few of the graduate level courses are available over the Internet. Western Carolina University has been offering HRD online courses for more than 3 years. Tuition costs per course are under $500.

Status of HRD Online Programs

The average online class size at the participating institutions ranged from 7 to 35. Their typical online students were part-time, graduate, and career/professional. When asked to rank the importance of various reasons for offering courses online, the highest ranked reasons were to provide alternatives to traditional and non-traditional students, stay competitive, and serve new markets. One institution’s main reason for offering online courses was to model e-learning while another’s main reason was “because admin said so.” The least likely reason they offered online courses was to reduce impact on college facilities. The primary strategies that participating institutions used to
market their HRD online programs were e-mail, listserves, and websites. Persons responsible for marketing their HRD online programs were HRD faculty, directors of graduate studies, and program directors.

Support for Online Faculty and Students

The level of faculty support, faculty incentives, teaching load, and percent of full-time and adjunct faculty varied at each institution. Bowling Green State University does not offer incentives or support services to their faculty; their teaching load for their online courses is the same as their face-to-face courses, and only their full-time faculty teach online. Indiana State University supports faculty with instructional designers, graphic artists, computer assistance, web page development, and online faculty training. Faculty receive additional funding for course development and assessment. The teaching load for online courses is generally lower than the traditional classroom. Of their online faculty, 90% are full-time while 10% are adjunct.

The University of Illinois provides their faculty with instructional designers, programming, and multimedia assistance as needed. Only one of their online instructors is adjunct. Online and face-to-face courses are considered equivalent when determining teaching load. Illinois faculty are given a one-course release during the semester they develop a new online course, and they are provided with a half-time teaching assistant each semester the course is offered.

The University of Louisville has a teaching and learning center that provides faculty support for their online program. They also provide their online faculty with training in the use of Blackboard™ software. The teaching load for their online courses is higher than the traditional face-to-face courses. However, both online and face-to-face courses are considered the same when determining teaching load. As an incentive, faculty are given a semester of release time to develop their courses. Their entire online faculty are full-time.

Western Carolina University does not offer incentives nor support services to their faculty, and new online faculty are not required to undergo formal training prior to teaching their online course. The teaching load for their HRD online courses is equivalent to a face-to-face course. In the same respect, an online course counts the same as a face-to-face course in determining teaching load.

Unlike the other institutions, online courses at the University of Minnesota are developed by outside contractors with minimal input from their faculty. Faculty receive no incentives for teaching online. Since course development is outsourced, the teaching load for online courses is generally lower than the face-to-face courses. As a result, the online and face-to-face courses do not count the same when determining teaching load. Their entire online faculty are adjunct.

The types of student support and services varied for each institution. With the exception of Bowling Green State University and the University of Minnesota, each participating institution offered some type of orientation to acclimate students to their online system. Indiana State University sends their online students a CD that contains instructions and a self-guided tour. The University of Illinois offers online training that requires students to practice using the course technologies by installing software, submitting documents, and verifying that they can receive streamed audio and video. The University of Louisville’s student orientation consists of a review of technical requirements. Western Carolina University offers to their online students software training and tutoring on how to be an online student.

The Internet services that the institutions provide to their students also varied. All participating schools provided their students with an online library database and catalog. Most schools also provided online advising, course catalogs, e-mail access requests, grades, and registration. Table 2 gives a summary of all Internet services offered by each institution.

Online Course Development and Technologies

With the exception of the University of Minnesota, regular faculty design online HRD courses. Courses at the University of Minnesota are developed by outside contractors with minimal input from their faculty. At the University of Illinois, graduate students are also involved in course development. When asked how much of the total online program costs are attributed to course development, both Bowling Green State University and Indiana State University indicated less than 10%. Western Carolina University attributed 11% to 30% of their HRD online program costs to course development. The University of Illinois indicated that 31% to 50% of their costs are attributed to course development. Development costs were reported to be greater than 50% at the University of Louisville and the University of Minnesota.

The variety of technologies used to deliver online HRD courses includes audio conferencing, audio lectures (asynchronous and synchronous), chat rooms, e-mail correspondence, discussion conferencing (e.g., Web Board), video conferencing (synchronous), and video lectures (asynchronous). All participating institutions utilize chat rooms, e-mail, and discussion conferencing. Asynchronous audio lectures are used by half of the institutions. Table 3 details the technologies used by each institution.

Bowling Green State University anticipates an increase in the use of audio conferencing and discussion board technologies. Indiana State University plans to use more audio lectures, chat rooms, video conferencing, and video lectures. The University of Illinois intends to make greater use of video conferencing and video lectures. The University of Louisville indicated that they plan to make greater use of all available technologies. The University of Minnesota and Western Carolina University do not anticipate changing the technologies they are currently using to deliver online instruction.

Online Models

Three models, the contractor model, the consortium model, and the independent program model, best characterize the HRD online programs presented in this paper. In the contractor model, courses are designed and developed by an outside contractor. This model is ideal for institutions that may not have the expertise to develop and deliver the online courses, technical support to maintain the courses, or the time to convert their face-to-face material to an online format. The University of Minnesota uses this model to deliver their online courses.

The consortium model involves a collaboration of universities where faculty from participating institutions deliver one or more online courses rather than an entire degree program. This model is useful for institutions that may not have enough faculty to teach online. The Ph.D. program offered at Bowling Green State University and Indiana State University is part of a consortium degree program, where Indiana State University serves as the home school. Other consortium members include Central Missouri State University, East Carolina University, Texas Southern University, University of Wisconsin-Stout, and North Carolina A&T.

Within the independent program model, institutions take full responsibility for the development and implementation of their online program. This model is ideal for institutions that want to have full control over the online program's structure, policies, and technologies. This model is also ideal for academic units that have the technological capacity to develop and support technical solutions for course development and delivery. For example, this model works well for the University of Illinois because its many doctoral students who are specializing in the field of instructional technologies are able to support the program and develop their technology skills through graduate teaching and research assistantships. The University of Illinois and the University of Louisville used the independent program model to develop their online program.

Discussion

This study introduced three models that can be used to deliver Internet-based HRD programs—the contractor model, consortium model, and independent course model. The contractor model includes courses that are offered by educational institutions but designed and developed by an outside contractor. The consortium model involves a collaboration of universities that are responsible for teaching one or more courses within a degree or certification program. Within the independent program model, the department assumes full responsibility for the entire online program.

At the onset of this study, over 107 North American AHRD institutions were identified as potentially offering HRD courses online. Of these 107 institutions, only 6 are offering web-based courses that are 100% online. Why are so few institutions offering HRD courses online? There are several plausible reasons for this; however, some main issues could be (1) the need for considerable technical support and expertise, (2) the initial startup cost, (3) the need to train faculty to teach online effectively, and (4) the enormous time commitment that is needed by the developers of online courses.

With these concerns, the authors offer some recommendations. For institutions lacking the technical support and expertise to develop online courses, one plausible solution is to outsource these services. This is the direction the University of Minnesota took by offering their online courses through outside contractors. Another solution might be for institutions to develop one online course per semester using the most basic, cost-effective, and easy-to-use technologies. These technologies could include chat rooms, email, discussion conferencing, and asynchronous audio lectures. The University of Louisville is an example of an institution that has taken this approach when they began offering one course during the summer of 2001. The idea behind this strategy is for institutions to start small until they gain more online experience.

If funding is a concern, organizations such as the Alfred P. Sloan Foundation (www.sloan.org) provide program development grants to universities to develop new online courses. These awards are intended to cover the one-time costs of converting existing course materials to a pedagogically sound online format. The Department of Human Resource Education at the University of Illinois converted their regular courses to an online format with financial support from the Sloan Foundation.

Institutions that do not have the faculty or staff to teach online courses may consider joining a teaching consortium as was done by Bowling Green State University and Indiana State University. Within the consortium, faculty from participating institutions deliver one or more online courses rather than an entire degree program. This arrangement "lifts the burden" off one institution so that it can be shared among many.

Time commitment is another barrier that may prevent institutions from offering online courses. Institutions may not have the time to develop the courses and at the same time may not have sufficient faculty to teach the courses. There are several solutions to this problem, many of which have already been addressed. Institutions could
outsource course development (University of Minnesota), they could become part of a consortium (Bowling Green State University and Indiana State University), or they could bring in adjunct faculty from other related departments to teach the online courses (Indiana State University, University of Illinois, University of Minnesota).

Rather than focusing on disadvantages to offering online courses, it is essential that institutions consider the benefits of offering Internet-based courses. One main advantage to offering Internet-based courses is that it allows institutions to reach other markets they would not have been able to reach otherwise. This includes the international population, working professionals, and single heads of households. Another advantage is that it increases institutional prestige. By offering online courses, institutions can serve as models for others seeking to offer similar Internet-based courses. As a result, popularity increases and ultimately the student population increases (online as well as face-to-face).

**Future Research Implications**

Technology is rapidly changing and is impacting the way institutions deliver Internet-based courses. Online technologies used today differ from the technologies used five or more years ago. Moreover, institutions that have offered online programs for a while are familiar with the various technologies and are able to offer more "online amenities" to their students. For example, the University of Louisville, who recently began offering Internet-based HRD courses, provides their online students with a limited number of online services. In contrast, Indiana State University, where over 125 students have completed their degree online, provides their students with numerous services online. A research study could be conducted to compare HRD online programs that have been offered less than a year, 3 years, and 5 or more years. An interesting research question would be: How does the structure and format of an online program change over time?

The results of this study also indicate that institutions vary in their use of online course technologies. Future studies should investigate the reasons why some online course technologies were chosen over others (i.e., the advantages and disadvantages of using various online technologies). Some possible research questions could be:

1. How do training requirements differ for each course technology?
2. Which technologies promote greater student-to-faculty and student-to-student interaction?
3. Which technologies best enhance student learning?

The University of Illinois utilizes synchronous audio lectures in their online courses. Another interesting research study could determine if synchronous sessions are worthwhile. Factors such as student questioning, student-student interaction, and student-faculty interaction could be compared between synchronous and non-synchronous audio modules. Some possible research questions would include:

1. How satisfied are faculty and students with the synchronous lectures?
2. Do student-faculty and student-to-student interactions increase in the synchronous lectures?
3. What factors promote quality synchronous interaction?

This paper provides information on the innovative session in the form of a brief theoretical framework, a set of session objectives, and a description of the process. It is intended to inform conference participants as they make the decision about whether to attend the session, and to provide them with background reading prior to the session.

Keywords: Metaphor, Research Design, HRD Practice

"... metaphors are capable of giving us a new understanding of our experience. Thus they can give new meaning to our pasts, to our daily activity, and to what we know and believe" (Lakoff & Johnson, 1980, p. 139).

Volume 3, issue 3 of the series Advances in Developing Human Resources (ADHR) was dedicated to Metaphor in Human Resource Development. It brought together articles written by some of the HRD scholars who have been at the forefront of exploring the current, and potential, use of metaphor in HRD research, practice, and education. Part of the history of that issue can be traced back to an innovative session on metaphor held during the 2000 AHRD conference in Raleigh-Durham. This session will further the work by providing a vehicle for facilitating dialogue between the authors and readers on the content of the ADHR issue with the view to clarifying understanding, exploring the application of metaphor in HRD research and practice, and highlighting options for collaborative research. The session will give equal weight to application of metaphor in HRD research and practice, as well as to theoretical aspects of metaphor.

This brief paper provides a theoretical framework for the session, and outlines the session objectives and design. Conference attendees are also invited to read other papers on metaphor elsewhere in the conference proceedings.

Theoretical Framework

Despite there being well over 125 documented definitions of metaphor (Leary, 1990), there is a clear tradition that views them as central to the task of accounting for our perspectives on the world (Cameron, 1999). This cognitive stance argues that people not only use metaphorical language, but the way they view the world is structured using metaphor that frame realities. Metaphors are therefore considered to not only influence language but also behavior. As such, the metaphors used in HRD (as elsewhere) influence how reality is framed by those in the field, how
problems are conceptualized, how solutions are designed, and how efforts are evaluated (Tsoukas, 1991). That nature of that influence could benefit or hinder the field but, without an explicit analysis of the impact of metaphor on HRD, those in the field will be unaware of the benefits, the hindrances, and how to change the situation. This gives rise to discussions on how perspectives, language, and behavior of those in HRD can be influenced by changing the metaphors-in-use.

Metaphor analyses have been completed for several fields of study, for example: psychology (Leary, 1990), human resource management (Dunn, 1990), information systems (Kendall & Kendall, 1993), organizations (Morgan, 1997), and teaching (Cortazzi & Jin, 1999). The ADHR issue on metaphor made a major contribution in closing the gap between HRD and other disciplines in the level of attention paid to metaphor. It did that in the areas of:

- Understanding metaphor theory: Summarizing metaphor theory and research from the disciplines of applied linguistics and cognitive-psychology, and in so doing highlighting the importance of further research into HRD metaphor.
- Learning about HRD from current metaphors-in-use: Research was reported that studied metaphors in the language of HRD, with analyses of what those metaphors may tell us of how we conceive of HRD, what values underpin our language and behaviors, and how aware HRD professionals are of the metaphors they use and their potential implications.
- Metaphors in HRD research, practice, and education: Examples were provided of how metaphors were collected and analyzed in HRD research, of how metaphors could be (and were being) used by HRD practitioners both in training and in organizational change, and of how metaphors could be used in the education of HRD academics and practitioners.
- Critical analysis of metaphor in HRD: Dominant metaphors were highlighted, as was the need to challenge such metaphors and generate new metaphors that could influence how situations were perceived and actions were designed. Examples were offered of how different surface metaphors could influence conceptual metaphors and behaviors in HRD.
- Strategies for metaphor in HRD: Cross-cutting analysis of the content of the issue, when combined with work of other scholars, led to the first steps in understanding the concept of best practice in HRD research, practice, and education.

Short (2001), when reflecting on the content of the ADHR issue, highlighted six main implications for HRD, and five of those six form the basis of this innovative session. The five are:

- HRD researchers should increase their understanding of the application of metaphor in data collection, analysis, and reporting; paying attention to the options, benefits, and risks. They would be helped by the development of agreed best practice in the use of metaphor in HRD research.
- HRD practitioners need to reflect critically on the metaphors that drive their work within organizations, including the dominant metaphors they use for conceiving of organizations and their role in them. That process would be supported greatly by the sharing of practices, for example through conference papers and journal articles.
- Metaphor should be considered for inclusion in the education of HRD professionals, both in terms of theory and its application to HRD. For example, the development of HRD practitioners could usefully cover methods for applying metaphor in organizational diagnosis, intervention design, and communication during planned change.
- HRD professionals should continue to explore the application of metaphor in other disciplines and consider its suitability for transferring into HRD, as demonstrated through the application of metaphor in psychotherapy and the potential for its use in HRD consultancy, coaching, and counseling.
- Systematic research is needed to fully understand the impact of metaphor on HRD. In completing that, the discipline would benefit from challenging dominant metaphors and questioning how those lead to practices and beliefs that are currently taken for granted.

Session Objectives

The innovative session is designed with the over-arching objectives of:
Facilitating a dialogue between those who wrote for, and those who read, the ADHR issue on metaphor in HRD, to allow questions to be raised, and provide further clarification on the application of metaphor in HRD.

Extending the dialogue beyond the ADHR issue by exploring the application of metaphor in HRD research and practice using case studies (linked to a symposium paper on the use of client- and consultant-generated metaphor in HRD practice).

Identifying new opportunities for research into HRD metaphor and a network of interested researchers.

Within those overarching objectives, the session will provide a forum where:

- Researchers can discuss the application of metaphor in data collection, analysis, and reporting; paying attention to the options, benefits, and risks. Research described in the ADHR issue will act as the introduction to metaphor application in HRD research, and a case study will then be used to provide the basis for small group discussions of application options, methods, and issues.
- Practitioners can reflect critically on their use of client metaphors to analyze situations and identify potential interventions. Again, the case study will provide the broad context for the discussion on application by HRD practitioners.
- All participants have the opportunity to explore the theoretical foundations on metaphor, and the links between metaphor, cognition, behavior, and behavior change.

Session Content and Structure

The session will be designed in four parts:

- **Introduction** – Participants will hear an overview of the session, and be introduced to the facilitators. This part will also include definitions of metaphor, introductions to the language of metaphor (e.g. labels), illustrations of the various forms of metaphor, and descriptions of the theoretical links between metaphor, behavior, and behavior change. Speakers will also illustrate the use of metaphor in HRD research and practice, and in so doing to provide participants with an understanding of methods and issues for use later in the session.

- **Group discussions on metaphor in HRD research and practice** – In small groups, participants will utilize a case study to apply basic metaphor techniques, both from the context of the researcher and the practitioner. This will allow for discussion, thus increasing the opportunity for participants to raise examples, ideas, issues, and concerns. Participants will also have the opportunity to dialogue with ADHR authors over the application of metaphor in HRD research and practice.

- **Group discussion debriefing** – Each small group will share a summary of its discussions and conclusions; and facilitators will identify cross-cutting agreements, concerns, and questions about metaphor application in HRD research and practice.

- **Summarizing learning** – main learning points will be identified and summarized.

**Is this New and Innovative?**

The session is innovative in several ways:

- It uses a session at an AHRD conference to maintain the momentum from an ADHR issue, in part by facilitating dialogue between authors and readers, and in part by supporting application of ADHR learning points through case studies discussed in small groups.
- It furthers work on five of the six ‘main implications’ identified by the ADHR, thus moving forward a small step on a lot of fronts.
- It provides participants with the opportunity to discuss and apply material from a symposium paper on the application of metaphor in psychotherapy and lessons for HRD.
- It allows for levels of participation and interaction not possible from symposia sessions.
- It provides a forum for identifying new examples of metaphor application in HRD research and practice, as part of continuing work to describe best practice. These will be used in the design of future research.
What this Session Contributes to HRD

With reference to the session's stated objectives, its contribution to HRD includes the following:

- Facilitating a dialogue between those who wrote for, and those who read, the ADHR issue on metaphor in HRD – this will allow for questions about the issue to be raised, provide further clarification on the application of metaphor in HRD, elicit new examples and viewpoints on metaphor in HRD, further clarify current knowledge on best practice, and identify new opportunities for research into HRD metaphor.
- Providing conference attendees with the opportunity to apply metaphor in small groups case study discussions, thus increasing their understanding of application techniques.
- The session content will be summarized and used in writings on best practice in applying metaphor in HRD.

Managing Culture in the E-Workplace: The Practitioners’ Perspectives

Catherine Marie Sleezer  
Oklahoma State University

Cathy Bolton McCullough  
Francis Tuttle Technology Center

Roger L. Cude  
McLeod USA

This session engages human resource development (HRD) practitioners in analyzing organization cultures in their e-workplaces. Participants will consider how the cultures of their organizations are changing in response to information technology (IT). Exercises will focus on the four levels of systems thinking reflected in Senge’s Iceberg Model: Events, Patterns of Events, Structures, and Mental Models. Participants will share resources for improving the culture in e-workplaces and identify research and resources that are needed.

Keywords: Culture, Information Technology, Needs Analysis

Session Purpose

As organizations grasp for alignment using the new information technology (IT) tools of business, many leaders find themselves adjusting to new ways of working. Kanter (2001) identifies the following essential questions for today’s organizations: How should organizations change in order to succeed in a digital world? What should an organization’s new ways of working look like for maximum impact on profitability, employee satisfaction, quality, innovation, etc.? This session will explore answers to these questions. The goals of this session are to

1. bring cultural patterns of the e-workplace to the forefront,
2. discuss the impact of culture on performance improvement in the e-workplace, and
3. share resources for stimulating change in the way people within e-organizations work.

Content of Session

In this session, participants will practice using Senge’s (2000) Iceberg Model as a lens for viewing culture in their own organizations. Participants will also engage in reflection and dialogue about the responses to the IT challenges in their various organizations, about resources for addressing the challenges more effectively, and about needed research in this area.

Theoretical Framework

HRD professionals, who are responsible for managing and facilitating culture change in organizations, are increasingly challenged to help position their organizations within the new Internet Age economy. They interact with two important influences in the Internet Age: information technology (IT) and people. People create IT uses, and they also create the pathways for exchanging information within organizations. The way people interact with IT and other factors in accomplishing their tasks influences how the organization’s work gets done and the outputs that result (Lawson & Sleezer, 2001; Van Buren, 2001). For example, organizations today are using new IT applications to move beyond providing stakeholders with information, to automate processes, and finally to transform them (Christie, 2001).

Many organizations initially viewed IT strategies as golden rings for repositioning their organizations. However, for many the initial challenge of getting hold of a golden ring proved easy when compared to the challenges of managing IT use for improving performance. “Taking full advantage of the potential of the Internet Age requires leaders to lead differently and people to work together in new configurations” (Kanter, 2001, p. 7). Because an organization’s culture facilitates or constrains actions and interactions, culture change provides important leverage for performance improvement.

Copyright © 2002 Catherine Sleezer, Cathy Bolton McCullough and Roger L. Cude
Researchers, scholars, and business authors have been enthralled with the concept of business culture (Clark, 1972; Deal & Kennedy, 1982; Ouchi, 1981, Pettigrew, 1973, Sathe, 1983, 1985; Schein, 1985, 1989, 1990). Culture is a construct that has been viewed in various ways. It has been viewed as a manifestation of a leader's style of management (Petty, Beadles, Chapman, Lowery, & Connell, 1995). In addition, linkages have been drawn between various cultural dimensions and bottom-line performance (Denison, 1984, 1990, 1996). Culture appears to have deep roots in the mental models (i.e., in the assumptions and beliefs regarding expectations) that are held by organizational members about all organizational operations. Employees tend to build expectations based on their personal experiences, peer pressure, myth, gossip, and wishful thinking. In all likelihood, that will not change. But what can change is what people do with the result (Weick, 1995).

Denison believes that the mental models of organizational members are not totally transparent, but, instead, are manifest in expressed behaviors. Furthermore, they are expressed as behaviors and are, therefore, quantifiable. According to Schein (1999), culture matters because decisions that are made without awareness of the underlying cultural forces may have unexpected and undesirable consequences.

As technology provides new pathways for doing work, it also challenges “tried and true” management practices. How will organizations adapt? What will successful e-organizations look like? Today, some routines have begun to look different (e.g., on-line ordering, customer service, project management). However, the effectiveness of organization change initiatives has been estimated at only 10-20% at best (Ashkenas, 1995). Furthermore, Ardichvili (2001) stated that the primary reasons for failing to accept new patterns of work provided by IT are an overemphasis on technology-based solutions and a lack of attention to the human component of the equation. The rate of failure in strategic change initiatives indicates that success variables have yet to be explicitly defined and/or internalized by leaders and employees (Boyett, 1995).

To be most effective IT changes must be integrated with an organization's core beliefs, processes, and practices. In essence, organizations are on the verge of needing a massive culture change—a change in the way work is done, performance is measured, and employees are recruited and retained (Meeder & Cude, 2001). Of course, while these changes are occurring, successful organizations must continue to operate as financially sound, innovative, and quality-driven business enterprises.

The shift required of leaders today is from looking at skills and process behavior to examining mental models (i.e., values, attitudes, and beliefs) of the organization and its employees (Lee & Zemke, 1993). This shift must begin with an organization's greatest asset: its people. Leaders are quick to talk about rapid change, but research suggests that less than 10% of companies desiring to creatively and productively implement new technology into their ways of work are successful (Boyett, 1995). Morrison & Schmid (1994) noted that implementing new ways of work requires education, people skills, clear communication, and incentives. In other words, culture change is a requirement for organizations that want to compete most effectively in the Internet Age economy.

Debates continue about how to leverage an organization's culture for success, how to develop it, and how to change it. Indeed, culture might be the most important variable for creating, supporting, and sustaining bottom-line results in today's new economy (Fisher and Alford, 2000).

Systems Theory

Systems theory is foundational to the HRD profession. Integrating systems with the researched-based knowledge of culture's impact on organizational performance (Denison, 1990; 1996), can help HRD practitioners consider effective organizational change strategies relative to IT's impact on the current mental models of work and performance.

IT provides a relatively new influence on organizational performance. Leaders value IT because it provides 1) many new options for action and 2) links among individual employees and among organization functions. However, the more variables and the greater the interdependence of variables, the greater the systemic complexity (Dörner, 1996). Humans often do a poor job of understanding complex systems (Dawes, 1988; Dörner, 1996).

Tools for understanding how variables interact to produce results can be found in the literature of systems thinking. One such tool is the Iceberg Model (Senge, 2000). Senge shows the frozen ice that is visible above water and the larger ice mass that is invisible below the water. The ice below the water supports the visible portion of the iceberg. In the Iceberg Model, visible events are like the portion of the iceberg that is above water. The patterns of events are just below the water. The systemic structure that supports the patterns of events can be found at a deeper level, and the mental models that support the structures are found at the deepest level.
Because organizational cultures include aspects that are visible as well as deeper aspects that are not visible, the Iceberg Model is a useful tool for exploring this construct. According to Denison (1996), beliefs drive behaviors. In turn, behaviors drive results. Therefore, it is practical to approach organization culture via its most direct dimension: how people act as captured in organizational events. Systematic reflection on such events can reveal patterns of events and the systemic structures and mental models that support them.

In summary, IT offers a new set of solutions that can help organizations function more strategically, while also employing the flexibility necessary to improve innovation, quality, employee satisfaction, and positive bottom-line results. Using IT to effectively produce business results requires changing to the technology that best enables organizations to do their work. This may be the easier change to make. Changing the internal processes of the organization to maximize the contribution of IT and human resources may be a harder goal to reach. "The narrow question: How do we structure our e-business unit? The broader question: How do we change our whole organization? The first is oriented toward presenting the best face to outside audiences. The second recognizes that the biggest challenge is inside" (Kanter, 2001, p. 169).

Most organizations literally have decades “of history baked into their cultures and processes. Technology and the Internet are not coded into their organizational DNA—at least not yet” (Christie, 2001, p. 45). HRD professionals who help guide organizations in culture change efforts can benefit from using a systems lens to reflect on the culture of their organizations. They can also benefit from discovering how culture changes in the e-workplace vary across organizations. Finally, they can benefit from knowing the available and needed resources and research.

Description of Format

Participants will form small groups of six. This session begins with a brief introduction of the topic and the Iceberg Model. Organization culture will be discussed, and questions of interest relative to the e-patterns of work will be posed to the group.

In the second phase, participants apply the Iceberg Model to identify events and patterns of events. After working individually to reflect on an organization’s IT events and then patterns of events, participants then interact in small groups to discover the commonalities among events and patterns of events across organizations. We will compare the participant’s responses to the events and patterns of typical organizations from Lawson and Sleezer’s 2001 study.

The third phase will replicate the process of phase 2 but will focus on systemic structures and mental models. We will compare the participant’s responses to the structures and mental models of typical organizations from Lawson and Sleezer’s 2001 study.

The fourth phase will be an all-group discussion about insights gained from the first three phases (15 minutes). The discussion will also include the resources and research that are available and those that are needed.

Investigating the Association Between Productivity and Quality Performance in Two Manufacturing Settings

Constantine Kontoghiorghes
Oakland University

Robert Gudgel
Pennsylvania College of Technology

The main purpose of this study was to examine the relationship between productivity and quality performance in two manufacturing settings. In all, the results of this study have ascertained the close association between quality and productivity performance and suggested that investments in quality should indeed result in productivity gains. The quality management variables that were found to be the strongest predictors of productivity performance were those pertaining to internal process satisfaction, external customer satisfaction, and consistent delivery of work output in a complete fashion.

Keywords: Productivity, Quality, Performance

As highlighted by ASTD's "Human Resource Wheel" (McLagan, 1989), the ultimate desired outcome of HRD interventions is improvements in productivity, quality, innovation, human resource fulfillment, or readiness for change. It is also widely known that in today's very competitive and customer driven markets both productivity and quality have become a very important strategic priority for most organizations. Yet, despite their importance, HRD research in the area of productivity and quality performance has been almost non-existent. The main purpose of this empirical study is to address this limitation of HRD research and thus examine the relationship between productivity and quality performance in two manufacturing organizations.

Perhaps the lack of research in the productivity and quality improvement area can be attributed to the conflicting points of view pertaining to the compatibility of the productivity and quality improvement approaches. Manufacturing managers in the U.S. and Western Europe have traditionally argued that improvements in product quality are costly and do not result in commensurate improvements in productivity (Womack, Jones, & Roos, 1990; Mohanty, 1998). This belief has been challenged since the mid twentieth century by quality experts who have suggested that improvements in quality also result in productivity increases. One of the earliest experts to suggest a link between productivity and quality was Feigenbaum (1961) who stated that "productivity is increased by emphasizing the positive control of quality rather than after-the-fact detection and rework of failures" (p. 20). Deming (1982, 1986) argued that improvements in quality do create corresponding improvements in productivity by reducing costs, errors, rework, and delays. Feigenbaum (1961) indicated that "with the balanced manufacturing capability for quality production in place, productivity rises as costs per unit decrease" (p. 20).

Quality has been described as satisfying customers (Spencer, 1994), conformance of a product to established standards (Crosby, 1979, Garvin, 1984, Lindsay & Petrick, 1997), and desired characteristics and value of a product as defined by the customer (Womack and Jones, 1996). Womack and Jones (1996) further suggest that "value can only be defined by the ultimate customer and it is only meaningful when expressed in terms of a specific product (a good or a service, and often both at once) which meets the customer's needs at a specific price at a specific time" (p. 16). Quality of services has been described as timeliness of providing services when requested by customers, completeness of services provided, courtesy to customers, consistent service quality and responsiveness to customer needs (Lindsay & Petrick, 1997). Finally, Japanese quality expert Masaaki Imai (1986) suggested that "in its broadest sense, quality is anything that can be improved" (p. 9).

Productivity is commonly defined in terms of output to input ratios (Sumanth, 1981a, 1981b), the number of processes a worker can handle during the time necessary for producing one unit (Monden, 1993; Womack & Jones, 1996). Productivity has also been described by various performance measures such as machine utilization, schedule performance, and cost variances (Huge, 1990). Another description of productivity is output divided by an organization's total headcount (Huge, 1990). By any of these definitions, productivity is viewed as an outcome which is measured against resources expended to create that outcome.

Organizations that have succeeded in improving productivity and quality have typically used approaches such as total quality management (TQM), continuous improvement (also called kaizen), or lean manufacturing principles (also called the Toyota production system). TQM has been defined as a customer focused strategy involving all employees in continuous improvement of processes, products, and services (Herron, Bohan, & Meyer, 1997). TQM
has also been described as "a group of methods and techniques for enhancing competitive performance by improving the quality of products and services (Grant, Shani, & Krisn, 1994, p. 26). Relative to service industries, the TQM concept has been called total quality service (TQS) and defined as "a true commitment to operationalizing the concept of customer focus, establishing service performance standards, measuring performance against benchmarks, recognizing and rewarding exemplary behavior so as to increase sales and market share" (Stamatis, 1996, p. 43).

Relative to creating and maintaining effective work areas, a process called 5 S's has been used as part of lean manufacturing practices (Monden, 1993). 5 S principles require employees within their work areas to eliminate unnecessary equipment and clutter (sort), organize work areas for ease of using tools and equipment (set in place), maintain cleanliness of work areas (shine), use standard procedures and visual aids to process work (standardize), and comply with the first four S's (Sustain). Womack and Jones (1996) suggest that use of 5 S principles is an important step towards creating and maintaining work areas which promote better quality and productivity.

Related to TQM and lean manufacturing are the concepts of Kaizen or Continuous Improvement (Monden, Shibakawa, Takayanagi, & Nagao, 1985; Imai, 1986). Kaizen means continuous incremental improvement of quality and productivity processes to help meet organizational goals (Imai, 1986). Kaizen also means using employee ideas and participation to accomplish these quality and productivity improvements (Imai, 1986).

In all, the concepts of TQM, lean manufacturing, and kaizen seem to incorporate many common characteristics that help organizations improve quality and productivity. These common elements can be summarized as process improvement, employee involvement, reduction of waste, performance measurement, benchmarking against competitors and the best organizations, focus on customer needs, control of product and service quality, control of costs, a learning culture, and mutual help to provide quality inputs in a timely manner.

A five year worldwide study of the automotive industry by Massachusetts Institute of Technology revealed that certain assembly plants had concurrently achieved high quality and high productivity (Womack et al., 1990). These plants were managed using lean manufacturing (Womack et al., 1990) or the Toyota production system (Monden, 1993). Lean manufacturing is characterized by prevention of errors and defects, simple and synchronized manufacturing processes, speed in changing from production of one product to another, and a major focus on elimination of various forms of waste such as unneeded inventory and unnecessary movement of products. Lean Manufacturing includes employee control of quality decisions, employee involvement to improve processes, error-proofing of work output, and use of 5S principles. (Womack et al., 1990; Monden, 1993).

A case study by Gudgel and Feitler (2000) documented a quality management intervention in a manufacturing firm that resulted in concurrent improvements of 57% in quality and 81% in productivity. A single quality management intervention was able to produce a dramatic and simultaneous improve in both quality and productivity. The documentation of these improvements support Deming's concept of better quality resulting in better productivity and the link between quality and productivity variables proposed in this study.

An empirical study by Kontoghiorghes and Bryant (2001) examined the link between quality and productivity in a service non-profit organization in the health care insurance industry. Positive and strong correlations were found between the investigated quality and productivity indicators. The Kontoghiorghes and Bryant study further identified the quality indicator "work output by peers is consistently delivered in a complete fashion" to be the strongest predictor of two of the three productivity indicators investigated (work output by peers exceeds expectations; inputs from peers are received in a timely fashion). This study also found satisfaction with internal processes, to be the strongest predictor of the productivity indicator of "cost effective production". Other quality indicators and variables that were found to be strong predictors of the investigated productivity indicators were: satisfaction with quality of peer work output; emphasis on doing things right the first time; measurement of product or service quality at every step of the process; organization focus on process improvement; and, decision making involvement. In all, the results of this study highlighted the close association between quality and productivity performance in a service environment and suggested that investments in quality should indeed result in productivity gains.

Despite some anecdotal evidence that suggests a strong association between quality and productivity performance, still many today consider the two as antithetical approaches. As Deming (1986) put it, "folklore has it in America that quality and production are incompatible: that you can not have both. A plant manager will tell you that it is either or. In his experience, if he pushes quality, he falls behind in production. If he pushes production, his quality suffers" (p. 1). According to Mohanty (1998), however, "it is productivity (value addition) and quality (value enhancement) that determine competitiveness. To remain competitive, organizations need to integrate and synergize both productivity and quality" (p. 759). Despite the need to integrate and synthesize the quality and productivity approaches, very little empirical research has been conducted to examine the commonality between the two (Mohanty, 1998).
Purpose of the Study

As it was stated in the introduction, the main purpose of this study was to examine the relationship between productivity and quality performance in two manufacturing organizations. In doing so, the relationship between distinct quality and productivity indicators was assessed and described. Further, this study attempted to identify and describe organizational variables that are commonly important for quality and productivity performance. Lastly, this study attempted to determine the extent to which the findings of the Kontoghiorghes and Bryant (2001) study in a service non-profit organization could be validated in a manufacturing setting as well.

The organizational dimensions that were assessed in this study were: continuous improvement practices, quality management, the learning culture of the organization, management practices, employee involvement, organizational structure, reward systems, job design, innovation practices, technology management, knowledge management, and teamwork. The quality indicators considered in this study were: external customer satisfaction; customer loyalty, satisfaction with quality of work output by peers; work output by peers is consistently delivered accurately; internal process satisfaction; the extent to which all products or services produced meet established specifications; on-time delivery of products or services; the extent to which employees react quickly to resolve unexpected problems; the extent to which no further changes or rework is needed after the final products or services are produced; and, the extent to which no scrap is produced.

Productivity in this study was measured in terms of the following indicators: the extent to which the amount of work output by peers exceeds expectations; the extent to which products or services are produced in a cost effective manner; and, the extent to which inputs are received from others in a timely fashion.

Research Questions

The main research questions for this study were:
1. What is the relationship between the identified productivity and quality indicators?
2. Which of the quality management variables incorporated in the study can also serve as predictors for productivity performance?
3. To what extent do the results of this study, which was conducted in the manufacturing domain, validate those of the Kontoghiorghes and Bryant study, which was conducted in a service non-profit organization?

Methodology

Instrument. The instrument of this study consisted of a 108 Likert item questionnaire, which was designed to assess the organization in terms of the earlier described dimensions and indicators. Many of the dimensions and indicators were assessed with scales that were used or described in previous literature or research (Buckingham & Coffman, 1999; Hackman & Oldham, 1980; Kontoghiorghes, 2001a; Kontoghiorghes, 2001b; Kontoghiorghes & Dembeck, 2001; Lindsay & Petrick, 1997; Macy & Izumi, 1993; Pasmage, 1988; Whitney & Pavett, 1998), while several were custom-designed specifically for this and other studies. In all, the questionnaire attempts to determine the extent to which the organization is functioning as a high performance system and according to TQM and sociotechnical systems theory principles. Further, the instrument assesses the extent to which the organizational environment is conducive to training transfer and a continuous learning culture.

The instrument utilized a six-point scale that ranged from “strongly disagree” to “strongly agree”. The first version of the questionnaire, which consisted of 99 Likert items, was originally pilot-tested on a group of 15 participants for clarity. Furthermore, a group of seven experts in the organization development, human resource development, or quality management areas reviewed the instrument for content validity. Upon revision, the instrument was then administered to a group of 323 members of five different organizations. Reliability tests were conducted and the instrument was further refined and expanded. As stated earlier, in its final format the instrument consisted of 108 Likert items. The reliability of the instrument was measured in terms of coefficient alpha and was found to be 0.98.

Subjects. The sampling frame of this study consisted of 179 employees of a manufacturing facility in Texas and 60 employees of manufacturing facility of a different organization in Michigan. Both facilities manufactured products used in the auto industry. The surveys were administered internally by an Organization Development manager in the Texas facility and a Human Resource manager in Michigan. The surveys were given to all members of both facilities. In all, 134 of the employees of the Texas facility (74.8%) and 55 of the Michigan one (91.6%) returned the surveys. Collectively, 189 of the possible 239 participants returned the surveys and thus the overall response rate is calculated at 79.08%. In short, 81.1% of all respondents were hourly employees, 1.8%
administrative personnel, 7.7% salaried professional, 4.7% supervisors, 4.1% middle management, and 0.6% senior
management. 75.9% of all respondents were male and 24.1% female. In terms of education, 64.3% of the
respondents had a high school degree, 19.1% an associates, 7.6% a bachelors, 3.2% a masters, and 1.5% a Ph.D.

**Data Analysis.** The research questions of this study were answered through the use of correlational and
regression analyses. In particular, through Pearson correlations the relationship between the identified productivity
and quality indicators was described. Further, through stepwise regression analyses the most important quality
management variables for productivity performance were identified and described.

**Results and Findings**

**Correlational Analysis.** The Pearson correlations between the productivity and quality indicators are displayed in
Table 1. Table 1 further depicts the average correlation of each quality indicator with the respective productivity
indicators as well as the average correlation between each productivity indicator and the respective quality ones. As
shown, all quality indicators were found to be positively and significantly correlated with every one of the
productivity indicators. The correlations ranged from 0.292 to 0.739 and were significant at the 0.01 level. In sum,
the correlational data in Table 1 indicates that each productivity indicator exhibited an average correlation of 0.46 or
higher with the corresponding quality indicators. This result indeed confirms the close association between
productivity and quality performance. The quality indicator that was found to exhibit the highest correlations with
the respective productivity indicators was internal process satisfaction (Avg r = 0.603; p < 0.01). The especially
high correlation between internal process satisfaction and cost effective production (r = 0.739; p < 0.01) demonstrates that an emphasis on continuous process improvement, which is one of the cornerstones of total quality
management, will ultimately result in more cost effective production and thus improved productivity and
profitability.

The quality indicator that exhibited the second highest average correlation with the productivity measures was the
extent to which work output by peers is consistently delivered accurately (Avg r = 0.532; p < 0.01). This finding
suggests that an emphasis on the quality of work output by everybody in the organization will result in more
efficient and timely operations which in turn positively affect productivity. External customer satisfaction was the
third quality indicator that was found to be highly associated with the productivity (Avg r = 0.519; p < 0.01). This
finding in essence validates the main hypothesis of this study and Deming’s assertion that a quality driven culture
which makes external customer satisfaction a number one priority will ultimately function in productive ways as
well. It is widely known that external customers demand timely services as well as reliable and functional products
at a reasonable price. Thus, organizations that are truly customer driven are the ones that are characterized by(streamlined, timely, and efficient processes as well as a special focus on product quality. Given that streamlined,
timely, and efficient processes as well as product quality result in speed, less waste and rework, it is not surprising
that external customer satisfaction was found to be highly associated with all productivity indicators.

The other three quality indicators that were found to exhibit an average correlation of 0.5 or higher with the
productivity ones were the extent to which work output by peers is consistently delivered complete (Avg r = 0.513;
The extent to which employees are satisfied with the quality of work output they receive from their peers (\(\overline{r} = 0.511; p < 0.01\)), and the extent to which no change or rework is needed after the final products are produced (\(\overline{r} = 0.503; p < 0.01\)). Again these three correlations together empirically validate the strong association between productivity and quality performance and the importance of making quality a top priority. In terms of the remaining correlations displayed in Table 1, the quality indicators below were found to exhibit the following correlations: produced products or services meet specifications (\(\overline{r} = 0.485; p < 0.01\)); on-time delivery of products or services (\(\overline{r} = 0.481; p < 0.01\)); external customer loyalty (\(\overline{r} = 0.433; p < 0.01\)); employees react quickly to resolve unexpected problems (\(\overline{r} = 0.402; p < 0.01\)); and, no scrap produced (\(\overline{r} = 0.318; p < 0.01\)). In all, the results of the correlational matrix displayed in Table 1 indicate a high association between quality and productivity performance and the compatibility of the quality management and productivity improvement interventions. In sum, the correlational data in Table 1 empirically validates Deming’s assertion that as quality improves, costs decrease because of less rework, fewer mistakes, and fewer delays.

Regression Analyses. As shown in Table 2, the three stepwise regression models identified the stronger predictors of each one of the productivity indicators. Interestingly enough, the strongest predictor for each productivity indicator pertained to a quality indicator, which once again demonstrates the strong association between productivity and quality performance.

With regard to the first productivity indicator, “amount of work output by peers exceeds expectations”, the five predictors selected by the stepwise regression model accounted for 50.4% of its total variance. Accounting for 35.5% of the total variance, external customer satisfaction was found to be by far the strongest predictor of work output exceeding expectations. This finding in essence confirms the importance of having an organizational culture that is customer driven and highlights that quality and productivity are not antithetical constructs. Quality does indeed yield productivity gains. The second predictor selected by the regression model was the extent to which employees in the organization receive rewards based on their performance. In a way this finding validates expectancy theory and demonstrates that when an employee believes that his or her performance will result in desired outcomes then he or she will be more motivated to perform. The third predictor into the model was the extent to which the organization does not have turnover problems. This result is important in the sense in today’s constantly downsizing and restructuring corporate world employee commitment has become a secondary concern. Yet, as the results of this regression model show, employee turnover problems can be detrimental to productivity and hence organizational competitiveness.

Turnover causes disruptions to operations, especially when key and talented people leave the organization. It takes a while and often considerable training before newcomers reach the same proficiency level. Thus, building organizational systems capable of attracting and retaining employees can be considered very important when employee output is of prime concern.

The last two variables selected by the stepwise regression model were the extent to which no change or rework is needed after the final products are produced as well as the extent to which the employee is motivated to transfer the newly learned skills and knowledge back to the job. With regard to the former variable, it is clear that the less the organization invests its energies and manpower to redoing defective work the more productive it will be. Further, this finding once again validates Deming’s philosophy—i.e. a focus on quality will ultimately result in productivity gains and cost reduction due to less rework, fewer mistakes, and fewer delays—and thus reinforces the notion there is a strong association between quality and productivity performance. In terms of motivation to transfer, its inclusion in the regression model exemplifies the importance of training transfer and why the organizational environment should be designed to facilitate it. Simply put, the more employees transfer what they learn back to the job, the more productive they will be.

The second stepwise regression model in Table 2 pertains to the productivity indicator of “cost effective production”. In all, the five predictors selected by this regression model accounted for 65.4% of the total variance of this productivity indicator. The strongest predictor by far was internal process satisfaction, which accounted for 54.7% of the total variance of cost effective production. Taking also into consideration the fact that internal process satisfaction was found to exhibit the highest average correlation with all productivity indicators (\(\overline{r} = 0.603; p < 0.01\)), it is safe to conclude that interventions, such as TQM, lean manufacturing, Kaizen, or 5S practices, that are designed to improve the processes in the organization will be the most likely to yield the biggest productivity gains. The remaining independent variables selected by the regression model were: the extent to which the employee has influence on the performance ratings his or her peers receive; produced product or services meet established specifications; the employee has learning and growth opportunities in the organization; and, product or service quality is measured at every step of the process. Collectively the five predictors reveal that an organization will be more likely to operate in a cost effective manner if there is a great emphasis on process improvement, quality measurement, a high performance team environment that allows peers to evaluate the performance of each other,
and plenty of learning and growth opportunities. In short, all these predictors reflect characteristics of a quality driven culture and thus once again demonstrate the strong association between quality and productivity.

The last regression model incorporated in Table 2 belongs to the productivity indicator "inputs are received from others in a timely fashion". The nine predictors included in the model accounted for 65.4% of the total variance of the dependent variable. Once again, the strongest predictor in the model pertained to a quality indicator—the extent to which work output by peers is consistently delivered in a complete fashion—which in turn accounted for 43.1% of the total variance. In total, four of the nine independent variables selected by the regression model were quality management (QM) variables, which again demonstrates the strong association between productivity and quality. In particular, aside from the extent to which work outputs by peers are consistently delivered in a complete fashion, satisfaction with quality of peer work output, quick employee reaction to resolve unexpected problems, and quality measurement were the other QM variables that were found to be significant predictors of the dependent variable. Together, these QM variables reflect an organizational culture that emphasizes the key TQM components of measurement, speed, and quality work.

<table>
<thead>
<tr>
<th>Amount of work output by peers exceeds expectations</th>
<th>Cost effective production</th>
<th>Inputs are received from others in a timely fashion</th>
</tr>
</thead>
</table>
| External customer satisfaction  
$R^2 = 0.355$ | Internal process satisfaction  
$R^2 = 0.547$ | Work output by peers is consistently delivered in a complete fashion  
$R^2 = 0.431$ |
| Rewards are based on performance  
$\Delta R^2 = 0.067$ | Have influence on performance ratings peers receive  
$\Delta R^2 = 0.049$ | Receive praise and recognition when doing good work  
$\Delta R^2 = 0.066$ |
| No turnover  
$\Delta R^2 = 0.042$ | Produced products/services meet specifications  
$\Delta R^2 = 0.032$ | Knowledge of expectations  
$\Delta R^2 = 0.031$ |
| No change or rework needed after final products are produced  
$\Delta R^2 = 0.019$ | Learning and growth opportunities  
$\Delta R^2 = 0.012$ | Satisfied with quality of peer work output  
$\Delta R^2 = 0.029$ |
| Motivated to transfer newly learned skills and knowledge back to the job  
$\Delta R^2 = 0.022$ | Product or service quality is measured at every step of the process  
$\Delta R^2 = 0.014$ | Multiskill work environment  
$\Delta R^2 = 0.027$ |
| | Receive supervisory feedback about performance  
$\Delta R^2 = 0.020$ |Someone at work has talked to me about my progress

$\Delta R^2 = 0.013$ | |
| $R^2 = 0.504$ | Adjusted $R^2 = 0.484$  
$F = 25.61$  
$N = 131$ | $R^2 = 0.654$  
Adjusted $R^2 = 0.640$  
$F = 47.55$  
$N = 131$ | $R^2 = 0.654$  
Adjusted $R^2 = 0.629$  
$F = 25.67$  
$N = 131$ |

The remaining five variables in the regression model pertained to the extent to which the employee: a) receives praise and recognition when doing good work; b) knows of what is expected of him or her at work; c) functions in a multiskill work environment; d) receives supervisory feedback about his or her performance; and, e) has discussed his or her progress with someone in the organization. In all, these five variables together suggest that inputs from others will be received in a timely manner if performance takes place in a multiskill work environment within which...
job expectations are made clear and the employee receives frequent feedback and recognition for his or her performance and progress. Special attention should be given to the importance of a multiskill work environment, since it affects performance in at least two ways. First, research has shown that a multiskill work environment facilitates job motivation, which in turn positively affects job performance (Hackman & Oldham, 1980; Pasmore, 1988). It should also be noted however, that a multiskill work environment is especially important in a manufacturing setting because it assists in alleviating absenteeism and delay related problems. It is no secret that nowadays most facilities function with a very lean workforce and thus the speed of their operations can be severely undermined by absenteeism problems. A strategy many manufacturing organizations use is to train their employees on multiple skills so that if an employee is absent a colleague can quickly step in and assume his or her role. That way any operational delays are avoided and the system is still able to conduct its operations in a timely manner. Thus, it should not be considered a surprise that this study has found the variable pertaining to a multiskill work environment to be a predictor of timely operations. In short, this result follows and validates existing manufacturing practices.

Summary and Conclusions

The results of this study provide empirical evidence of a strong link between quality and productivity. Both the correlation and regression analyses indicated positive and significant relationships between quality and productivity indicators. In particular, the correlational data in Table I indicated that each of the three productivity indicators exhibited an average correlation of 0.46 or higher with the eleven quality indicators included in the study. The quality indicators that were found to exhibit the highest correlations with the corresponding productivity indicators were: internal process satisfaction; work output by peers is consistently delivered in an accurate fashion; external customer satisfaction; work output by peers is consistently delivered in a complete fashion; satisfaction with quality of peer work output; and, no change or rework needed after the final products or services are produced. In terms of the regression analyses, the results in Table 2 show that the quality indicators of external customer satisfaction, internal process satisfaction, and work output by peers is consistently delivered in a complete fashion were proven to be the strongest predictors of productivity performance.

Another important conclusion that stems from the results of this study is that organizational emphasis on continual improvement of processes and quality will ultimately result in more cost-effective production, which in turn improves both productivity and profitability. A practical example that pertains to this approach is the latest achievement of Toyota Motor Corporation. Due to heavy reliance on continuous process improvement, which is a cornerstone of TQM and Lean Manufacturing principles, Toyota has been able to reduce its production costs to such an extent that it will be able to manufacture a more advanced and improved vehicle at 3-7% less than last year’s model (Toyota information seminar, 2001). What is most interesting about Toyota’s achievement is that other major competitors face higher costs and shrinking market shares and profits at this time.

In all, ten of nineteen variables that most strongly predicted productivity outcomes were quality management variables. Overall these ten quality management variables accounted for the majority of the variance of the corresponding productivity regression models. Based on this finding one can thus conclude that quality and productivity performance are indeed closely interrelated and one should not consider them as antithetical phenomena. Rather, investments in quality should be perceived as a means to higher customer satisfaction, greater market share, and ultimately productivity gains.

The importance of organizational variables such as performance rating of peers, performance based rewards, praise and recognition for good work, and knowledge of expectations are also seen in this study. All of these had a positive impact on productivity indicators as demonstrated in the regression analysis. These organizational variables represent classic TQM and STS social system activities, which underscore the importance of employee motivation and satisfaction for organizational success.

In terms of previous research, the results of this study are consistent with the results of the Kontoghiorghes and Bryant (2001) study. In short, both studies have found all productivity and quality indicators to be positively and significantly correlated. Further, both studies identified the quality indicators of “internal process satisfaction” and “work output by peers is consistently delivered in a complete fashion” to be the strongest predictors of “cost effective production” and “inputs are received from others in a timely fashion” respectively. Therefore, despite the fact both studies were conducted in very different work environments, one may conclude that they both ascertain the strong association between productivity and quality performance and support the assertion by quality experts such as Deming, Feigenbaum, and Imai that improvements in quality do also create improvements in productivity. Lastly, both studies identify “internal process satisfaction” and “work outputs by peers is consistently delivered in a complete fashion” as the most important quality indicators for productivity performance.
Implications for HRD practice, Limitations, and Future Research

An important implication for HRD practice is the empirical evidence this study provides that Deming's concept is valid that quality improvement also improves productivity. This means HRD practitioners must draw upon TQM and related concepts that support quality improvement in order to assist their organizations to be competitive and productive. The results and conclusions of this study are limited, however, to this sample of manufacturing facilities in the automotive parts industry. Further research is suggested to gather additional empirical evidence about the relationships between quality and productivity in other organizational settings and industries.

Tri-Dimensional Social Support from Supervisor and Multilevel Performance in Governmental Units in Thailand

Duchduen Bhanthumnavin
National Institute of Development Administration

This study examined the relationship between supervisory social support and performance of subordinates and groups. Usable data of 355 pairs of supervisor-subordinates working in health centers in Thailand were used. The results revealed that gender was associated with support receiving in effecting subordinate performance. Dimensions of supervisory social support also predicted performance in subordinate and group levels. Self-efficacy was an important predictor of group performance. Discussion, implications for HRD in Thailand, limitations, and recommendations for future research are presented.

Key words: Supervisory Social Support, Subordinate Performance, Group Performance

Performance is a key (Swanson, 1994) for organizational survival and effectiveness. Scholars and researchers have been searching for determining factors that influence performance. Research on performance, especially in individual level has been received considerable and sustained attention in many fields of study including organizational psychology and human resource development (HRD). The findings from research studies in these fields found many possible factors that affect performance. Supervisor has been suggested as one of them.

During the last two decades, research in organizational context in Thailand and other countries has generally revealed positive consequences of support from supervisors. It was positively related to subordinate’s work motivation, such as job satisfaction (e.g., Sorod & Wongwattanamongkol, 1996), commitment to work (e.g., Littrell, Billingsley, & Cross, 1994), and quality of work life (Bhanthumnavin, Vanintananda, & et al., 1997). Support from supervisors was also found to reduce job stress (e.g., Etzion & Westman, 1994), burnout (e.g., Eastburg, Williamson, Gorsuch, & Ridley, 1994), health problem related to work (e.g., Blau, 1981), and health care cost (e.g., Manning, Jackson, & Fusilier, 1996). Furthermore, supervisory support was also found to enhance subordinate’s transfer of training (e.g., Gregoire, Propp, & Poertner, 1998). These variables are associated with performance.

Supervisory Social Support and Performance in Group Context

The need for improving performance demands scholars and researchers to devote their efforts in searching for factors that influence the performance. Since Thailand has been affected by economic crisis, it is suggested that one of the most direct ways for improving performance of working groups in organization is to developing human resources. Such efforts should be emphasized on supervisors (Bhanthumnavin, 2000) which can be more beneficial to both supervisors, as well as to the subordinates. This is because supervisors are not only motivating subordinates to work, but also controlling and managing the immediate resources of the workgroup. Their behaviors, thus, can also greatly impact subordinates in both direct and indirect ways, as well as in both positive and negative directions.

Since 1981, a new approach for assessing supervisor’s behaviors at work, so-called “supervisory social support” (SSS), has been introduced (House, 1981). SSS, generally consisted of at least three major dimensions: emotional support, informational support, and material support (Cohen & Wills, 1985; House, 1981), was associated to subordinate performance in many Thai studies. For example, a study employing 403 Thai teachers was conducted by Nirunthawee (1989). The part of study examined social support including from supervisors on subordinate performance. The researcher found that teachers’ performance in terms of self-reported work effectiveness was positively related to social support. The similar result was found in other Thai studies using similar group of samples (e.g., Iedbar, 1991; Koonprasert, 1992), and in nurses (Phorsrihong, 1993), executive officers (Sorod & Wongwattanamongkol, 1996), and police officers (Pinipradit, in press).

The results from Nirunthawee’s study, moreover, revealed the positive relationship between social support including from supervisors and performance in terms of supervisory rating. Other Thai studies also found the similar result (e.g., Na Wanjun, 1993). However, it should be pointed out that these above studies assessed many sources of social support (supervisors, coworkers, family and friends) at the same time in one measure. Thus, SSS was not fully studied in terms of its multi-dimensions in different work situations.
Furthermore, there is little evidence of the relationship of SSS and group performance. The assumption being made in Thailand is that SSS should lead to performance in both subordinate and group levels. The empirical results in this area are much in need.

Other Factors that Affect Performance in Group Context

Besides SSS, there are other factors affecting performance in workgroups. Perceived organizational support (POS) was suggested to impact on subordinate performance through subordinate’s commitment to work (e.g., Eisenberger, Fasolo, & Davis-LaMastro, 1990), prosocial behavior in terms of in-role and extra-role behaviors (e.g., Lee, 1995; Settoon, Bennett, & Liden, 1996), and organizational citizenship behavior (e.g., Lynch, Eisenberger, & Armeli, 1999). Many researchers would argue that subordinate’s psychological characteristics which affect work motivation can also play important role on their performance, such as self-efficacy (Bandura, 1986; 2000), and work overload (e.g., Chiles, 1982). Self-efficacy and work overload were also found together with SSS or social support in having interaction effect on individual performance (e.g., Ballentine & Nunn, 1998; Glaser, Tatum, Nebeker, Sorenson, & Aiello, 1999). Studies on the relationship of these variables were rarely found in Thailand. Thus, there is the need to examine their effects on performance of subordinates and groups.

Purpose of The Study

A key problem in HRD is to determine factors that influence the performance of subordinates and groups. One strong possible factor is SSS. The main purpose of this study is to investigate the relationship between SSS and performance of subordinates and groups. The second purpose is to examine the effect of other potential factors on the performance in these two levels. Furthermore, this study compared and contrasted these effects in different types of subordinates. There were three research hypotheses in this study.

Hypothesis 1: Subordinates reporting high degree of emotional support, informational support, and material support will get higher supervisory rating than those reporting low degree on all of these support dimensions. This result will be found in female subordinates rather than in male subordinates.

Hypothesis 2: Emotional support, or informational support, or material support, will be positively related to work effectiveness, or supervisory rating, or group performance.

Hypothesis 3: Self-efficacy will be associated with group performance.

Methodology

Sample

The respondents were 972 matched pairs of supervisor-subordinates working in health centers in six provinces in Thailand. Without follow up, 542 supervisors and 517 subordinates returned usable questionnaires which yielded response rate of 56% and 53%, respectively. Of these numbers, data from only 355 pairs were used. The subordinate participants consisted of 150 males, and 204 females with one unidentified on gender. Their age ranged between 18-58 with the average of 30.48 years old ($\overline{X} = 5.93$). The supervisor participants were 148 males and 203 females with four unidentified on gender.

Measure

All measures were written in Thai language. Most of them were summated rating measures, with 6-point Likert scale ranging from “very true” to “not at all true”. The details of each measure are as below.

Supervisory social support (SSS). This measure was constructed by the researcher based on literature (e.g., House, 1981) and existing measures (e.g., Niruthawee, 1989). This measure assessed perception of subordinate on supervisor’s behaviors in three dimensions: emotional support (e.g., showing respect and appreciation), informational support (e.g., giving advice or guidance related to work), and material (e.g., providing needed resources, services, and goods). It consisted of 10 items for each dimension with the total of 30 items. Reliability in terms of alpha coefficient show satisfactory results in emotional dimension ($\alpha = .9413$), informational dimension ($\alpha = .9168$), material dimension ($\alpha = .9168$), and total measure ($\alpha = .9702$).
Perceived organizational support (POS). This measure was constructed by the researcher based on Eisenberger, Huntington, Hutchinson, & Sowa, (1986)'s concept. The measure consisted of 15 items assessing subordinate’s perception on supports from organization in terms of being valued, being cared about, and working in flexible environment. Alpha coefficient was .8670.

Self-efficacy. The researcher constructed the measure based on Bandura's (1982; 1986; 2000) concept. It is consisted of 15 items assessing the belief of subordinate that he or she has capability to perform a task. Alpha coefficient was .8117.

Work overload. Base on literature and interview results, the researcher constructed this measure, consisting of 10 items. The items assessed work overload from view point of subordinate in terms of being in the work conditions that require beyond his or her normal role. Alpha coefficient was .8487.

Work effectiveness. The researcher constructed this measure based on literature and interview results. This measure consisted of 10 items. The subordinates were asked how well they can perform the jobs in terms of quality, quantity, and time. Alpha coefficient was .7212.

Supervisory rating. Supervisors were asked to rate a subordinates regarding his or her performance in terms of quality, quantity, and time within the past six months. Constructed by the researcher, it consisted of 15 items. Alpha coefficient was .9206.

Group performance. Group performance, related to organizational missions, was rated by supervisors in terms of quality, quantity, and time. This measure, total of 15 items, was constructed by the researcher with alpha coefficient of .8660.

Location of workplace. Subordinates were asked to identify the distance between their health center and provincial capital (urban area) in terms of kilometers.

Descriptive data and correlation among measures are displayed in Table 1.

Results

Hypothesis 1 was tested by 3-way ANOVA to find the interaction effect of emotional support, informational support, and material support on supervisory rating in female subordinates and male subordinates. As expected, this interaction was found only in female subordinates (see Table 2). Results from post hoc test in terms of Scheffe indicated that female subordinates reporting high degree of all three support dimensions got higher supervisory rating than those reporting low degree of all three dimensions. Thus, the hypothesis 1 was supported.
Furthermore, the results in male subordinates revealed only a main effect of informational support. The result surprisingly indicated that male subordinates reporting low informational support ($\bar{x} = 66.29$) were rated by their supervisor as more effective than those reporting high informational support ($\bar{x} = 58.49$).

In order to test hypothesis 2 and 3 concerning the contribution of variables, multiple regressions were performed on work effectiveness, supervisory rating, and group performance. Data were analyzed in total sample and in four subgroups. In the first step, subordinate’s personal background variables were entered in the equations. Results from Table 3-5 indicated that gender made a significant contribution only to work effectiveness in total sample and in young subordinates. Age was found to be a significant predictor of supervisory rating in total sample and in female subordinates, as well as, of group performance in total sample. Education did also make a significant contribution only to group performance, especially in old subordinates.

Subordinate’s psychological characteristics and situational factors were entered in the second step in all equations. In addition, work effectiveness and supervisory rating were added in this step only for the equation of group performance. It was found that self-efficacy made a significant contribution to work effectiveness in all groups, as well as to group performance in total sample and especially in female subordinates and in young subordinates. The results suggested that high self-efficacy subordinates rated themselves as more effective and were in centers with higher performance than relatively low self-efficacy ones. POS was found to be a significant predictor of work effectiveness, especially in old subordinates. Old subordinates with high POS reported higher work effectiveness than those with relatively low POS. Location of workplace also made a significant contribution to work effectiveness and group performance in male subordinates, and to supervisory rating in old subordinates. The results suggested that these subordinates who reported that their centers were not located near urban area (provincial capital) also reported higher work effectiveness, got higher supervisory rating, and/or their groups were more effective than their counterparts.

After partialing out the effects of subordinate’s personal background, psychological characteristics, and situational factors, two of the three dimensions of SSS were significantly related to performance. First, emotional support made a significant contribution only to subordinates performance in terms of work effectiveness and supervisory rating. The results of both types of performance were found in total sample, female subordinates and young subordinates (see Table 3 and 4). The findings suggested that subordinates reporting higher emotional support got higher supervisory rating than those with relatively low emotional support. On the contrary, high emotional support subordinates, instead, rated themselves as less effective than the relatively less emotional support ones.

Secondly, material support was also found to make a great contribution to performance in both subordinate and group levels (see Table 3-5). The results suggested that subordinates reporting higher material support also reported higher work effectiveness (total sample, female subordinates, and young subordinates), got higher supervisory rating (total sample), and were in the centers with higher performance (young subordinates only).

Thus, the results on work effectiveness and supervisory rating in total sample and two subgroups with the result on group performance in young subordinates supported the hypothesis 2. The hypothesis 3 was supported from the results on group performance in total sample, and two subgroups.

Discussion

This study examined the relationship between three dimensions of SSS and performance of subordinates and groups. The current data collaborated earlier findings (e.g., Vaux, 1985) concerning the association between gender and support receiving. The results revealed that female subordinates perceived more support than male subordinates. Furthermore, among female subordinates, the ones with high degree of all three-support dimensions got higher supervisory rating than those reporting low degree of all three-support dimensions. Regarding male subordinates, it was unexpectedly found that male subordinates reporting high informational support got lower supervisory rating than those reporting low informational support. Male subordinates may not need much informational support to improve their performance.

Note: \(\beta\) (Education), KM (Location of workplace), POS (Perceived organizational support), SE (Self-efficacy), WO (Work overload), WE (Work effectiveness), SR (Supervisory rating), Emo (Emotional support), Info (Informational support), Mat (Material support)

The major contribution of the present study involves the evidences that dimensions of SSS predicted performance of subordinates and groups. In more details, emotional support was one of significant predictors of subordinate performance in terms of work effectiveness and supervisory rating. These results were found in total sample, and especially in female subordinates and in young subordinates. However, the direction of magnitude of emotional support in predicting these two types of performance was in the opposite. It was surprisingly found the negative direction in predicting work effectiveness. Further analyses revealed that this negative direction was found when subordinates reported high work overload, or high self-efficacy. Previous studies also suggested that receiving support can be hurt rather than help (Jung, 1987; Rook, 1984) when recipients are in high work overload because of increasing stress (e.g., Kaufman & Beehr, 1986). Supervisory support was also found to inhibit performance of subordinates with high self-efficacy in a recent study (Ballentine & Nunns, 1998).

Material support was also found to make a great contribution to performance in both subordinate and group levels. The results suggested that subordinates with high material support reported higher work effectiveness, got higher supervisory rating and were in the centers with higher performance than those with low material support. These results were found especially in young subordinates. Young subordinates who were new to their works might have perceived the importance of material or equipment related to their works, rather than old subordinates whose works became routinely. Thus, perceiving high material support increased their individual as well as their group performances.

Information support was not found to make contribution to performance in this study. This could be because supervisors in health centers may not be the important source of information. As directly assigned from the Ministry of Public Health or administration in provincial level to be trained by the job title, supervisors sent their subordinates to participate in meetings and training related that works. Thus, the subordinates received information directly rather than via their supervisors.

The relationship between self-efficacy and group performance is rarely studied. Many researchers suggested that, instead of self-efficacy, collective efficacy is more likely to be associated with group performance (e.g., Seijts, Latham, & Whyte, 2000). It is evident in this study that self-efficacy was one of the important predictors of group performance in total sample and in other two subgroups. The possible explanation is that health center is generally a very small work unit, consisting of one supervisor and 2-4 subordinates. Thus, in such a small group, the effect of employee's self-efficacy could be found in group performance.

Implications for HRD in Thailand
Training should be given to Thai supervisors in health centers to provide appropriate amount and types of support in terms of emotional support, informational support, and material support in order to produce positive impact to performance in both levels in different types of subordinates. Supervisors should also be taught to identify and train to provide support to subordinates with varying levels of work overload and self-efficacy. Regarding the subordinates in health centers, training to improve their self-efficacy is recommended in general, and especially for female subordinates and young subordinates. Supervisors can also enhance these subordinates' self-efficacy in many ways, such as, being a good exemplar, and verbal persuasiveness.

Limitations

The first limitation of this study is that it is nonexperimental. It should be caution to make statements of causality and generalization based on the results of this study. Furthermore, self-report data were used. It should be pointed out that this method might have the effect of artificially inflating relationship among variables. The researcher was also aware of the strong correlation among the three dimensions of perceived supervisory social support. However, the high correlation may not be avoided because these dimensions are suggested to be interrelated in nature (Fenlason & Beehr, 1994; Sarason, Sarason, & Pierce, 1990). The final limitation is that this study employed cross-sectional study.

Recommendations for future study

This study should be replicated in both private and government organizations in Thailand. Furthermore, experimental studies in creating and testing a social support training module for Thai supervisors should be done. Longitudinal studies in this topic are encouraged to assess supervisory social support in both providing and receiving overtime. Such studies should also take psychological characteristics and situational factors into account in order to get complete picture of the phenomenon. Condition seeking approach is also recommended by analyzing data in subgroups. This is because different subordinates or groups of subordinates may seek, perceive, and interpret social support from supervisors in different ways.

Continuous Improvement through TQM – A Case Study in Rhetoric

John Stuart Walton
Prabhjot Kaur Basra
London Guildhall University

This paper discusses the relationship between TQM, organisational wide change initiatives and continuous improvement through a case study analysis of eight large UK organisations over a fifteen-year period. It develops and tests out an explanatory conceptual framework to inform the analysis. It explores the use and significance of rhetorical devices in the case study organisations to persuade people of the need to change continuously.

Keywords: Continuous Improvement, Organisational Change, TQM

This paper originates from a case study review of Total Quality Programmes (TQPs) – defined as a suite of organisation wide change initiatives with a continuous improvement orientation - within seven large privatised (plus a candidate for privatisation) organisations in the UK between the period 1983-1997 (Basra 2001). Four of them operate in the service sector, four are manufacturing or production oriented. The smallest organisation employed between 7,500 and 8,000 staff, the largest between 125,000 and 240,000 staff over the period covered by the study. All of them experienced competition without governmental protection and seven of them were subjected to major downsizing. Nevertheless each of them meet the requirement of survival that as Hackman and Wageman (1995 p310) point out is the primary goal of TQM from the perspective of the movement's founders. For the purposes of the research a privatised organisation is defined as having involved a transfer from government ownership to private ownership since 1979, with many of the general public holding shares. An initial survey established provisional information on change in staff attitudes and behaviours over the period following privatisation. For example 71% said that their working practices and organisation understanding had been greatly enhanced, 61% had become actively involved in improving the quality of their work, 95% said they needed to fit in with the way their customers worked. Following this initial survey, for each of the case study organisations an audit trail was conducted, by means of company documentation and other sources, on quality in general and TQPs in particular. This resulted in a chronological account of the evolution of TQPs in each organisation from 1983-1997. The initial survey and the chronological accounts surfaced a number of common themes and approaches associated with TQPs as well as a mean average of 25 TQ related programmes per organisation with over 200 different names being used. Key themes and key words across the programmes were isolated and looked at in turn to identify origins of, inspiration behind and objectives of TQPs. The concept of change through continuous improvement, or associated terminology, was common across each case study organisation. Of particular interest was the identification of persuasive terminology used to convey the quality message and convince people of the need to change.

Problem Statement

Walton (1999 p355) argued that 'it is no longer appropriate to treat HRD as a synonym for Training and Development.... Perhaps more than anything what epitomises this transformation has been the development starting in the 1980s of Total Quality management (TQM) initiatives in large organisations, often linked to cultural change programmes'. However the relationship between TQM and corporate change programmes maintains a problematic status in the literature. Hackman and Wageman (op cit.) comment that virtually every intervention ever tried by an organisation development consultant has somewhere or other been attributed to TQM. Continuous improvement is a term that is central to TQM thinking and by definition implies ongoing change. Harris (1995), accepts that 'continuous improvement efforts and TQM are often linked' but recognises that the connection between the two efforts is not clear. 'Efforts to bring a continuous improvement philosophy to organisations have been labelled both subsets of TQM programmes and as encompassing TQM' (Harris ibid. p 97). This paper seeks to provide a conceptual framework to clarify the relationship between TQM and macro corporate change initiatives, with particular reference to continuous improvement.

There have been a number of self-conscious attempts to use rhetorical imagery in populist literature dealing with organisational change. Naisbitt and Aburdene (1985.) state (p3) that 'the aim of this book is not just to inform but to inspire'. Peters and Waterman move from 'In Search of Excellence' to a 'Passion for Excellence' in their
well known publications of the 1980s. Hackman and Wageman (op cit.) comment that 'the rhetoric of TQM is engaging, attractive and consistent with...the managerial Zeitgeist in the United States' (p 338). Pithy phrases and slogans from the quality gurus include: 'drive out fear', 'work smarter not harder' and 'it will not suffice to have customers that are merely satisfied' (Deming 1986); 'fitness for use' and 'managerial breakthrough' (Juran 1988); 'it is always cheaper to 'do the job right first time' and 'zero defects' (Crosby 1979). Rust et al (2000) pursue the implications of 'delighting the customer', which they note has became a term used in 'executive exhortations' in the marketing trade press since about 1990. Hackman and Wageman (op cit. p338) conclude that 'rhetoric is winning out over substance', restricting their observations to the US. In focusing on the actual terminology used over a period of fifteen years to propagate the message of 'continuous improvement', this paper explores this claim and its significance for change theory in a UK context.

Theoretical Framework

The concepts of quality and TQM have been subjected to significant academic scrutiny in recent years. Reeves and Bednar (1994), building on Garvin (1988), identify four separate roots of quality definitions – quality is excellence, quality is value, quality is conformance to specifications, quality is meeting and/or exceeding customer's expectations. A number of writers have tried to establish common content features of TQM programmes (Chang 1993, Waldman (1994) in which change and continuous improvement is emphasised. Reed et al (1996) have developed a framework for analysing the relationship between firm orientation and TQM content from a contingency perspective. Their model indicates that some organisations have a greater customer orientation focusing upon market advantage and increased revenue, whereas others have more of an operations orientation focusing upon process efficiency and reduced costs. They restrict it to the manufacturing sector but suggest that it could apply to firms in service industries. This paper builds on and extends the Reed et al framework, incorporating culture shift, employee involvement and continuous improvement, three factors mentioned by both Chang and Waldman above and figuring in the case study organisations. (Figure 1 below)

Research Questions

The first question asks about the relationship between TQM and macro culture change through investigating the concept of continuous improvement. The second question relates to identifying any differences in the terminology used to refer to continuous improvement between the case study organisations and, if so, could these be related to factors such as an operations orientation v a customer orientation? The third question addresses the issue of why should people accept exhortations to continuously improve and the nature of the persuasive terminology used? Has it changed over time and if so how? Is there any evidence in the UK that 'rhetoric is winning out over substance'?
Methodology

A case study approach was adopted, described by Bogdan and Biklen (1992) as 'a detailed examination of one setting, or one single subject, or one single depository of documents, or one particular event'. In this instance it was one particular subject across a range of organisations. The study involves a retrospective analysis of phenomena occurring over the period 1983-1997 but goes beyond mere 'historical research'. Yin (1994 p8) argues that 'the case study relies on many of the same techniques as a history, but it adds two sources of evidence not usually covered in the historian's repertoire: direct observation and systematic interviewing. Again, although case studies and histories can overlap, the case study's unique strength is its ability to deal with a full variety of evidence - documents, artefacts, interviews and observations - beyond what might be available in the conventional historical study.' Archival research to establish key initiatives and supporting terminology over a given period was undertaken. Interviews were conducted with selected managers across each of the case study organisations, chosen because of their organisational knowledge, enabling rich sources of data to be obtained based on their experience, opinions, aspirations and feelings. Although its detailed analysis does not fall within the ambit of this paper, a questionnaire was circulated at the outset of the research to a cross section of 200 employees from 20 privatised organisations. This was designed to test out a series of propositions including that TQPs have been used across the privatised sector as a key tool towards achieving continuous improvement; and that communication and training are key to the introduction of any TQP.

This paper incorporates a rhetorical analysis of organisational texts to analyse key stylistic and other devices used in the case study organisations to try to convince people of the need to change. Summarising the excellent analysis provided by Leach (2000) rhetorical analysis can be defined as the analysis of persuasion attempts in oral performances or written texts. Politicians, for example, perform 'acts of persuasion' in their speeches. Trainers perform 'acts of persuasion' in their presentations. Top managers perform 'acts of persuasion' in their communications to staff and external stakeholders. This rhetoric is directed at a discrete audience that is expected to give some sign that it is persuaded by the arguments presented, classically through a change in behaviour or opinion. There are three persuasive genres or stases: forensic, epideictic and deliberative (Gross 1990, Fahnstock 1986). Forensic theory is the rhetoric of the law courts. Epideictic rhetoric is centred on contemporary issues, and on whether a certain individual deserves praise, blame or censure as in funeral orations and award ceremonies. Deliberative rhetoric is found in the arena of policy, where debate centres on outlining and eliciting commitment to courses of future action. The mode of persuasion is frequently speculative. The texts used in the case study organisations to propagate the change message can be described as deliberative. They included company annual reports, newsletters, magazines and videos.

The next stage of analysis draws upon the five 'canons' of rhetoric used by Cicero in classical Roman times. These canons are: -Invention - how arguments are 'invented' to achieve particular purposes through 'ethos' - the credibility of the author or speaker; 'pathos' - the appeal to emotion, and 'logos' - how logical arguments are used to convince us of their validity; Disposition - by what structural logic does the text or speech support its ultimate aims; Style - the relationship between the form of the discourse and the content. Style includes rhetorical tropes or 'figures of speech' such as metaphor and analogy; Memory - how a text or speech stays in the memory; how particular discourses call upon cultural memories shared by authors and their audiences, (Lipsitz 1990); Delivery - the relationship between the dissemination of a work and its content.

The Emergence of TQM

Most authorities on TQM locate the concept in the work of the so-called quality gurus, namely Feigenbaum, Crosby, Juran, Deming and Ishikawa and there have been a number of studies comparing some or all of their perspectives (eg Oakland 1989, Harris op cit.). Harris in tracing the evolution of TQM identifies the emergence of a customer focus and the development of traditional quality control techniques for use outside the production area where they originated, which made TQM applicable to other sectors such as service industries. He contends that as the need for a focus on the customer and the important role of employee involvement in successful quality management became clear, the term TQM began to replace the term Total Quality Control (TQC), first coined by Feigenbaum (1957) in the 1950s. TQC in turn was an attempt to move quality concerns from a narrow focus on statistical control within a production department to a wider, more systems thinking arena, albeit still from a manufacturing perspective. A number of the case study organisations specifically used the term TQM at some stage of their TQP life cycle. The first TQM programme in BT was launched in 1986 as an umbrella term to cover a range of Quality Improvement
initiatives. There was a strong customer orientation — quality was defined in 1987 as ‘meeting the customer’s (agreed) requirements at lowest cost…first time every time’.

Continuous Improvement in the Literature

It is unclear when the term ‘continuous improvement’ was first used. The concept underlies the Deming management method as defined by the Delphi panel in the 1950s (Anderson et. al (1994)). Deming (1986), in his ‘14 points for management to abide by when considering quality’, referred to ‘improving constantly and forever the system of production and service’ to improve quality and productivity and to decrease costs. Juran first uses the term in 1988, in the 4th edition of his Quality control Handbook. Reed et al (op cit.) analyse ‘continuous improvement’ in terms of process improvement of operations in manufacturing. They argue that in TQM terms, the concept of continuous (process) improvement is considered as an efficiency tool, with strong affinities to Kaizen — ‘the never ending attention to detail that reduces the effort and time that it takes to conduct operations’ (Schmidt and Finnigan 1992). They recognise, however, a trend to move away from the earlier ‘continuous process improvement orientation to the broader ‘continuous improvement with a focus on the customer and market. Hunt (1993: 46) states that ‘continuous improvement depends on both innovative and small incremental changes’. He quotes a report emanating from the Logistics Management Institute which states ‘that no process, product or service ever attains perfection and that neither the customer’s expectations nor the quality of service remains static.’

Continuous improvement is featured within the assessment criteria of some prestigious quality awards. It is specifically referred to in the European Quality Award (Business Excellence) model launched in 1992, under two headings. The first is ‘People Management’ — ‘how the company releases the full potential of its people to improve its business continuously’ - and the second is ‘Processes’ — ‘how processes are identified, reviewed and, if necessary, revised to ensure continuous improvements of the company’s business’.

Results and Findings

Continuous Improvement in the Case Study Organisations

There are references to continuous improvement in each of the case study organisations, often in association with other TQ concepts, as can be seen in the following extracts. BT (Service Sector): “We will constantly improve the quality and capability of our products and services” (The Leadership Guide 1987). “We are committed to continuous improvement” —part of revised BT values which also included ‘we put our customers first; we are professional; we respect each other; we work as one team’ (1991). “Continuously improving levels of service” —one of aims of BT Customers First strategy which stated by way of introduction ‘we are committed to providing our customers with a helpful, polite and world-class service’ (1992). BAE (Manufacturing Sector): “To maintain exceptional customer satisfaction through continuous improvement whilst maintaining national and international Quality Systems Standards Approvals” from Quality Strategy (1995). Rover (Manufacturing Sector): “TQ requires continuous improvements in everything we do, using and investing our resources effectively at all times to minimise total costs” (1985). ‘Continuous improvement, total flexibility….and participation in quality action teams’ - measures included within the New Deal programme (1992). “What has really changed at Rover as a result of our total quality programme is the company culture - the commitment to continuous improvement both as individuals
and in the contribution we make to the success of the business” (Rover Group CEO – 1994). BA (Service Sector): ‘Maintaining constantly improving targets as a good employer as well as manifesting concerns for social and community opportunities and environmental standards wherever the company operates’ (Vision statement 1986).

BAA (Service Sector): “Achieving continuous improvements in the cost and quality of all process and services” (1992). “CI is all about customer service. CI needs staff involvement at every level. CI is a process of providing improvement, continuously” (1992). "Our continuous improvement philosophy seeks to enhance customer satisfaction cost-effectively and increase profits by meeting the evolving needs of our airline customers and their passengers” (1993). “Never ignore a problem - always look for a way of overcoming that problem. The best person to improve the company is YOU - because you are at the sharp end. You know what will work and you know what won't work so never be afraid to voice your opinion or your views. By working together and adopting CI as a daily philosophy we can ensure that BAA offers its customers the best service possible. CI - Making a Better Future today and every day" (BAA CI literature 1991). BP (Production Sector): Continuous improvement listed as one purpose of the initiative called ‘Benchmarking Process’. Others listed; achieve 'Best in Class' cost structure; ensure cost competitiveness to attract investment; provide competitive advantage for each product: i.e. customer satisfaction and quality, reliability, delivery and cost; and survival (1992). BS (Manufacturing Sector): Our aim is to provide all customers, internal and external, with quality products and services and to strive for continuous improvement—(from Teeside Works Mission Statement 1992). RM (Service Sector): Customer driven strategy that moves RM to an "environment where a steady and continuous improvement of every thing RM do is a way of life" (1988). ‘Continuous Improvement' - Key principle of Customer First programme- (1993- 1995). ” We in RM have made great strides to quality improvement. We have set tough targets but these are necessary if we are to maintain and improve our position in the market place ... Quality improvement is a continuing path and we cannot afford to rest. Our reputation depends on everybody making a contribution and becoming involved” (Assistant MD 1994)

A textual analysis of the above continuous improvement statements identified other associated concepts/themes. The main themes were Customers (including service) - 6 companies made connections (4 from the service sector, 2 from manufacturing/production). Employee involvement – 4 (3,1). Costs – 4 (1, 3). Business results – 3 (0, 3). Services – 3 (2, 1). Products – 2 (1, 1). Processes – 2(1, 1). Targets – 2 (2, 0). Kite-mark (Award) – 1 (0, 1). To be the best – 2 (2, 0). Culture – 1 (0, 1). Survival - 1 (0, 1). There was some indication from this that the manufacturing/production organisations were more interested in costs and business results than those operating in the service sector. But further analysis of other texts showed how all of the above themes interconnected.

Customer Orientation. The case study organisations show evidence of a customer orientation through trying to achieve continuous improvement in the area of customer satisfaction. The BAA quotations above specifically connect the two themes. There is a change in emphasis over the period from understanding customer requirements to meeting customer requirements to exceeding customer requirements to providing extraordinary customer service to ‘delighting and thrilling’ customers. Recurrent keywords and phrases (with dates when first used where available) associated with programmes and activities include: Customer care (BA 1984, BT 1985); understand our customers (Rover 1986, BT 1987, RM 1988, BS 1992); customer satisfaction (BAe 1990, BP 1992), enhance customer satisfaction (BA 1993) exceptional customer satisfaction (BAe 1994); extraordinary customer satisfaction (Rover 1989); meeting customer requirements ((Rover 1986, BT 1987, BAA 1993, BAe 1994 ); exceeding customer expectations (RM 1995); customer focus (BA 1983, Rover 1989, BT 1988, RM 1990, BAA 1993, BS 1994); highest levels of customer service (BA 1987); excellence in customer service (BT 1990, BAe 1996); putting customers first (BA 1986, RM 1988, BT 1990, BS 1990); delighting customers (BAe 1996, BS 1996); DELIGHT and THRILL customers (BT 1992). ); inspire lifetime (customer) relationships ( Rover 1995)

Employee Involvement / Participation / Teamwork. They were a strong feature across the organisations often associated with continuous improvement. For example: BT: "We will make sure we understand and meet the requirements of our colleagues, to enable us to operate as an effective team" (1987) ; Bae: "We are dedicated to working together, and with our partners” (1995); Rover: “continuous improvement; total flexibility ... and participation in quality action teams”; BA: ‘It All Depends On Me’ – (Programme for ground staff 1987) ‘Everyone makes a difference’ (Marshall, CEO 1989); BAA: "CI needs staff involvement at every level" (1992); BP : "Openness, care, teamwork, empowerment and trust” (1990). BS: "I believe strongly that the growth of workforce participation in team activities is vital to maintain our progress towards Total Quality aimed at delighting the customer” [Vicars, MD Tinplate BS 1996]; RM: Employee participation via Continuous Improvement -1991-94. Our reputation depends on everyone making a contribution and becoming involved (1994).
To be the Best. Underpinning the notion of continuous improvement was a desire to 'be the best' (BA 1983) or 'best in class' (BP 1992) or to be a world-wide leader e.g. BT's aspiration "to become the most successful world-wide telecommunications group" (1990). BAA made a specific connection. "The route to a world class company is customer satisfaction, continuous improvement and committed people able to give of their best" (1995)

Culture Shift. Culture shift was seen as significant in all companies. BT: "We are committed to far reaching changes in our culture", [Graeme Odgers 1989]; Bae: "I want to create a British Aerospace culture ... we must benefit from learning from each other ... Our People Value underpins all that we do in our change programme" [Evans CEO 1996]; Rover: "What has really changed at Rover as a result of our total quality programme is the company culture", [Towers, CEO 1994]; BA. "To change the image of the company. To change the culture of the company. To increase profits" from the Putting Customer First initiative [1983]; BP "... we senior managers at BP want a nimble, new culture for our company. New culture - new behaviours and new motivation" [David Simon, senior executive 1990]; BS: Culture change through team-working [1994]; RM: "Since 1988 virtually all change in RM has been closely linked to the TQ approach" [Delafield 1993]. "Commitment to quality in all we do, striving to provide a service that at least meets our customers' requirements, has been central to our strategy. This has involved a transformation from being an inward, product-oriented organisation to an outward market-led and customer-focused one ... Our horizons need to expand still further, to establish new, more radical ways of looking at business strategy" [Cockburn 1993]

Rhetorical Analysis of Terminology Used in the Case Study Organisations

Invention. Ethos; Credibility of author or speaker – All of the statements listed emanate from CEOs or senior directors or are taken from company policy statements. Pathos; Appeal to emotion - The case study analysis threw up a number of rhetorical flourishes in each of the companies in question to support a commitment or ownership orientation. Examples include; Working with pride (Rover). Inspire lifetime relationships (Rover). We will foster pride and integrity in the organisation (BT) Every BT employee is an ambassador for the company. BA will have a corporate charisma such that everyone working for it will take pride in the company (1986 Mission statement). Our reputation depends on everyone making a contribution and becoming involved (RM). Logos: A range of logical arguments was drawn upon. There is a strong theme throughout the case studies about responding to competition “Times are tough. Competition is not just a bogeyman for us to frighten our people. It is very real and it is hurting” [BT Group Managing Director, 1992]. “To me the situation is close to crisis. Competition is really biting us, as competitors are hungry for BT share of the market” [MD, Development and procurement, 1992]. “To become the best airport in the world we must have the best people in the industry and equip them to compete effectively” [BAA Take Off 1996]. “All parts of the company are involved in programmes to increase productivity to ensure we are competitive” [Horton, CEO BP, 1990]. Responding to change is also a key theme. “It is not for us to inflict change, but for us to engage in a dialogue with our customers to determine their true needs and then to look at what we are doing and see if there is scope for change” [CEO RM, mid 1980s]. “We need to recognise change as a way of life as we enter the 1990s. We need to be prepared to manage actively the surprises of an uncertain, complex, volatile and rapidly changing world” [CEO BP Company Video 1990].

Disposition. Overall, the structure to achieve the aims is exhortative, sentences or clauses on many occasions prefaced by phrases such as 'we need to' or 'we must' or 'we want'. There is also a growing tendency towards hyperbole – it is not good enough to satisfy, we have to delight and thrill, be exceptional, be number one, be the best without any sense of irony. At a more technical level, where problem solving techniques are explained for example, there is frequent use of simple explanatory diagrams, to show how logical and obvious the approach is.

Style. There are an abundance of examples above of figurative language, which is the stylistic device most associated with rhetoric. “Our horizons need to expand still further” (RM); “competition is really biting us” (BT); ‘we want a nimble new culture” (BP); “the unwieldy telephonic dinosaur that came blinking into the light 10 years ago has evolved into a streamlined world class player” [BT 1994] - the list is endless. The words ‘mission’ and ‘vision’ featured throughout the study, are figures of speech, imported from a religious context.

Memory. Throughout the case study analysis, and implicit in many of the quotations above, were appeals to change based on reminding people of problems with the old, pre-privatised culture; its lack of responsiveness, its hierarchical nature, its inappropriateness to deal with new commercial demands such as competition and the need to retain customers. The ongoing swell of new programmes kept the perceived need for behavioural change in people's minds and enabled them to recall previous initiatives. Phrases were chosen to stick in the memory, many originating
from the quality gurus. Variants of ‘Do it right first time’ and ‘zero defects’ figured in seven of the case study organisation, ie. BP’s ‘Get it right first time and better the next’ in 1996. Other interesting slogans were; ‘vital few and useful many’ (BT 1988); ‘the 5 rights to do the right job’ [BAe 1990]. Programme titles were chosen with great care: ‘Putting People First’ (BA); ‘For all our tomorrow’s’ [BP 1989]; ‘The New Deal programme’ [Rover 1992]; ‘Continuous Improvement’ [BAA 1991].

Delivery. In addition, there were a series of strategies to reinforce messages by repetition through a range of media. High profile ‘roadshows’ run by CEOs, tapes, and videos buttressed the policy documents, line managers were trained in how to cascade the messages through their chain of command.

Conclusions

Over the period covered by the case study analysis ‘continuous improvement’ provided an overarching reference point for the TQPs in each of the organisations. The analytical framework outlined in figure 1 proved to be a valuable vehicle for comparing and contrasting the TQPs in the case study organisations from a continuous improvement perspective, but linked to the other TQM features incorporated. There was no significant evidence to differentiate between organisations on the basis of customer/process orientations, both of which were shared concerns. But throughout the period of study there was a focus on aspirational and inspirational vocabulary that led to a heightening of rhetorical imagery across all the organisations.

The language emanated from CEOs and other senior managers, supported by authoritative documents, videos and roadshows. The message was reinforced by a heavy investment in training. There is strong evidence that the case study organisations adopted an incremental ‘transformational change’ methodology. Steps (Nadler 1983, Kotter 1995) include establishing a sense of urgency of the need for change by examining market and competitive realities; creating a vision to help direct the change effort; communicating the vision throughout the organisation using every
vehicle possible; consolidating improvements and producing even more change. To persuade others of their position top management drew upon a range of rhetorical devices through a variety of communication modes.

There was abundant evidence of TQM rhetorical language being imported from the US and being added to. Did it get in the way of substance? The survey that accompanied this study indicated that 75% of those sampled were satisfied with the outcomes of the TQP initiatives. On the other hand, others complained of initiative overload, and two of the CEOs were dismissed over the period as they lost the support of their management team and staff.

An Analysis of Factors Associated With Research Productivity of Human Resource Development Faculty

Heather A. Williams
Louisiana State University

James E. Bartlett II
University of Illinois

Joe W. Kotrlik
Louisiana State University

Chadwick Higgins
Idaho State University

This study describes the research productivity of HRD faculty, their perceptions of the organizational culture in their department to support research productivity, self-assessment of their research competency and anxiety. In general, little organizational culture and support for research exists in the institutions where the HRD faculty work. A regression analysis revealed that five variables explained 56% of the variance in research productivity: teaching, research, service, and administrative allocation, and the amount of graduate assistant hours.

Keywords: Faculty Research Productivity, HRD Research Productivity, HRD Research

With the astounding growth of the HRD discipline over the past 20 years, and therefore of HRD programs throughout colleges and universities, some attention must be paid to the faculty members who are instructing those who will further develop the discipline of HRD. One such method of the development of a discipline is through the research produced by the faculty members within a discipline.

Research on research produced by HRD faculty is minimal. Williams (2000) referenced the lack of research in this area that was in accordance with findings of Podsakoff & Dalton (1987) in closely related fields. Although there is a lack of research on HRD research, individuals within the HRD discipline have recognized the importance of research within their field by both producing a handbook on research to promote the link between research and practice, and by committing to increase publication efforts.

Research within the HRD discipline is also important as a conduit of thoughts and progress toward an understanding of phenomena within the discipline. In addition, research, along with teaching and service, is a required facet of all disciplines including HRD within colleges and universities. Promotion and tenure are commonly based on the quality and amount of publications produced. In addition, program quality is commonly judged by the productivity of its faculty members (DeMeuse, 1987).

Also, in higher education, faculty with a successful publishing record and expertise in research are often admired by other faculty and students as being on the cutting edge of their field and are regarded as knowledgeable about most issues in their field. McKeachie (1994) stated that research could provide individuals with a better background to be successful teachers. It can be said that these highly productive faculty members are seen as more powerful educators and often serve as a frame of reference for junior faculty members or others who are developing their own research agenda (Levine, 1997).

Due to the value and importance of research within HRD, it is necessary to determine the factors that are associated with HRD faculty research productivity. That is, what factors are related to increased research productivity?

Theoretical/Conceptual Base

Research productivity and publications increased across academia throughout the 1990s (Sax, Astin, Korn, & Gilmartin, 1999). Specifically, within the HRD discipline, research publications have increased as evidenced by the
increased number of journals and conference proceeding dedicated to the HRD discipline as well as the increased numbers of HRD academics publishing across HRD into related disciplines. However, even with this increase in publications, the number of such on the research itself – whether methodologies utilized or quantitative vs. qualitative studies or the needs of HRD – is quite limited. Throughout an extensive literature search, no publications were located specifically identifying factors associated with increased research publications and/or productivity within the HRD discipline. Due to the significant lack of study in this area, the factors chosen within this research effort to be investigated are based on research published on faculty research productivity in closely related fields of adult education, business education, agricultural education, and industrial/organizational psychology; therefore, these factors are purely exploratory in nature.

Several variables have been reported to relate to research productivity. Key variables which occur throughout related literature include personal variables (gender, age, confidence in research ability), personal variables associated with position (time allocation, rank, years of experience, salary, size of school), involvement with graduate student research (number of doctoral committees chaired, actively seeking research opportunities), and perceived institutional support (percent of graduate students as research assistants, increased salary, decreased teaching load, mobility, recognition).

Personal variables. Research provides mixed results concerning gender and research productivity. Liddle, Westergren, and Duke (1997) found no differences between gender types for research productivity, while Osadebe (1996) and Bailey (1992) reported a higher level of research productivity by male faculty members. Kahn (1997) and Vasil (1991) reported that males have higher self-efficacy perceptions towards research, and Vasil (1991) also reported that males spend more time performing research tasks than females. Other researchers have noted that female faculty members are lagging behind experienced male faculty members in research productivity (Gmlech, Wilke, & Lovrich, 1984; Smith, Anderson, & Lovrich, 1995; Sax et al., 1999). Blackburn, Bieber, Lawrence, & Trautvetter (1991) stated that the relationship between gender and research productivity had been addressed in many studies and that little if any, and sometimes contradictory, correlations have been found.

A second variable that is often associated with conflicting results is age. Bland and Berquist (1997) observed that the average productivity of faculty seems to drop with age, however, many senior faculty members remain quite active in research activities and their products are comparable to those of younger faculty members. They also reported that there is no significant evidence that age determines a drop in productivity, but increased workloads and shifting emphasis is to blame. Gorman and Scruggs (1984) reported that age was related to research productivity. While, Greer (1997) reported that active researchers are younger. Blackburn et al. (1991) stated that the relationship between age and research productivity had been addressed in many studies and that little if any, and sometimes contradictory, correlations have been found.

Attitude towards research has been shown to relate to research productivity. Faculty members' confidence in their research abilities is related to faculty research productivity. Schaupp (1994) reported that women with higher expectations predicted higher research productivity. Bean's (1982) model of faculty research productivity included the perceived level of legitimacy in one's research as an explanatory factor. Increases in ability and self-efficacy were also related to increased research productivity in studies conducted by Vasil (1992, 1996). Jones (1993) reported that individuals who perceived their research as a value were higher producers of research.

Variables Associated with the Organization. Numerous studies have suggested that how a faculty member spends his/her time may relate to productivity (Cohen & Gutek, 1991; Gmlech, et al., 1986; Vasil, 1992). This variable was investigated by Liddle et al. (1997) showing that a correlation between time spent in research, time spent advising, and total hours worked with productivity.

Bailey (1992) found that rank is a significant predictor of research productivity. Dundar and Lewis (1998) found that departments with higher ranked faculty had higher research productivity. Vasil reported that rank is a significant predictor of research productivity (1992).

Gorman and Scruggs (1984) and Vasil (1992) found that the number of years of professional employment was related to faculty productivity. Pfeffer and Langton (1993) reported that total years in the profession had a major impact on total research, but an insignificant effect on recent research productivity. Again, Blackburn et al. (1991) stated that the relationship between educational experience and research productivity had been addressed in many studies and that little if any, and sometimes contradictory, correlations have been found.

Several studies reported the relationship between research productivity and salary (Jacobsen, 1992; Pfeffer & Langton, 1993; Rebne, 1989; Tornquist & Kallsen, 1992). Since salary often reflects research productivity levels, this was expected. Paying attractive salaries in return for performance may serve as an incentive for higher productivity from faculty members. Higher salaries may also attract productive faculty while at the same time minimizing the possibility of losing active faculty to other institutions (Pfeffer & Langton, 1993).
Another factor related to faculty research productivity is the size of the institution in which the faculty member works. Behymer (1974) studied research productivity of faculty in four-year colleges and major research universities and reported that faculty in major research institutions publish more than faculty at smaller four-year colleges. This was similar to the findings by Bailey (1992) in which found a research productivity increases from Liberal Arts II Colleges through Research I Universities. Dundar and Lewis (1998), Gorman and Scruggs (1984), and Vasil (1992) also reported that institutional size was related to research productivity. However, Blackburn Bieber, Lawrence and Trautvetter (1991) reported that the characteristics of the employing institution were not related to research productivity.

Involvement with Graduate Student Research. In the area of terminal degree training, one key variable is the involvement of faculty with graduate student research. Kahan (1997) found that individuals in doctoral programs had higher research self-efficacy and self-efficacy was related to higher research productivity. This also supported by Daly (1995) that the practice setting and doctoral education is related to higher research productivity. The research-training environment does not only benefit the students. This is supported by Dundar and Lewis (1998) when they reported that high ratios of graduate students to faculty also correlates with productivity, and the percentage of graduate students that were hired as research assistants correlated highly with research production.

More directly, Kelly and Warmbrod (1986) found that the number of doctoral committees chaired successfully resulted in higher faculty research productivity. Gorman and Scruggs (1984) also reported that participation in graduate student research was related to faculty research productivity. The participation in graduate research and attitude of graduate students when exiting a doctoral program has also been shown to relate to research productivity. Kezmaraky (1989) reported that a favorable attitude towards research upon exiting a doctoral program and not research skills is positively related to research productivity. In a more specific study of vocational education faculty, Kelly (1982) found that actively seeking research opportunities during graduate school was identified with high producers of research.

Perceived institutional support. Kelly and Warmbrod (1986) stated that "Perceived institutional and departmental support for research are seen as the most important enablers to research productivity" (p. 31). Dundar and Lewis (1998) found that the percentage of graduate students hired as research assistants correlated highly with research production. Only one study could be found (Dundar and Lewis, 1998) that addressed faculty size. They reported that programs with smaller numbers of faculty cannot compete in the area of research productivity with larger universities.

Institutional support provided in the form of extrinsic rewards (money, reduced teaching load, tenure, mobility, recognition and promotion) was investigated by Butler and Cantrell. Their study reported that depending on tenure status, various extrinsic rewards were valued higher as a motivator to increase productivity. For example, for non-tenured faculty, tenure was the most desirable reward, versus for tenured faculty, money and reduced teaching load were the most desirable rewards. This research may be indicative of variables which when present in organizations are viewed as that organization's support of increased productivity, and therefore, factors associated with productivity.

This study uses publication in refereed research journals as a surrogate for research productivity. This approach is supported by the literature. Radhakrishna and Jackson (1993) reported that publishing in refereed journals was ranked as the most important factor when agricultural and extension education department heads were asked to rank the importance of 13 factors in the evaluation of faculty. In a related study, Radhakrishna, Yoder and Scanlon (1994) concluded "Publications (refereed articles in journals and paper presentations in conferences) are considered to be a very important component of faculty productivity" (p. 17). This finding is supported by a comment made by William J. Cooper, former Dean of the [university name] Graduate School. Dean Cooper stated that "The only magic number is zero; if you haven’t published in refereed journals, then publications in research conference proceedings, books and other publications are meaningless." (Personal Communication, August 1990). In Kelly and Warmbrod’s study (1986), most of the variance (84.1%) in their research productivity score was explained by publications in refereed journals, with the remaining variance explained by seven other variables. The decision to use refereed journal articles as a surrogate for research productivity was based on the studies cited here.

**Purpose and Objectives**

This study sought to establish the factors that explain research productivity of HRD educators who serve as the faculty in colleges and universities. In this study, publications in refereed journals were used as a surrogate for research productivity. Specifically, the objectives of this study were to:

1. Describe selected demographic characteristics of the HRD faculty in the study.
2. Describe the research productivity of HRD faculty members.
3. Describe HRD faculty members' perceptions of the organizational culture that exists in their department to support research productivity.
4. Describe HRD faculty members' self-assessment of their research confidence.
5. Describe HRD faculty members' self-assessment of their research anxiety.
6. Determine if selected variables explain a significant proportion of the variance in the research productivity of HRD faculty.

Research Methods and Procedures

The population for this study included all full-time, professorial rank faculty employed by colleges and universities in the United States that are Academy of Human Resource Development (AHRD) members. The frame for the study was from the AHRD membership list. Using Cochran's (1977) sample size formula and adjusting for a 50% return rate, a random sample of 264 faculty members was selected.

Instrumentation

The scales and items used in the instrument were selected after a review of the literature and grounded in the theoretical base of the study. The face and content validity of the instrument was evaluated by an expert panel of university faculty and doctoral level graduate students in human resource education. The instrument was pilot tested with 20 university faculty members. Changes recommended by the validation panel, when appropriate, and those identified as needed during the pilot test, were incorporated into the instrument. These changes occurred in the wording of items, the design of scales, and in the instructions for completing the instrument. Internal consistency coefficients for the scales in the instrument were calculated using Cronbach's alpha and were as follows: organizational culture/support for research scale - a = .88, faculty self-assessment of research confidence - a = .88, and faculty self-assessment of research anxiety - a = .79.

Data Collection

The responses were collected using two mailings and a systematic follow-up of a random sample of non-respondents. Each mailing consisted of a questionnaire, cover letter, and stamped addressed return envelope. A response rate of 24.2% (64 out of 264) was attained after completion of the two mailings and the telephone follow-up.

Data Analyses

The data were analyzed using descriptive statistics for objectives one through five. Backward multiple regression analysis was used for objective six. The alpha level was set a priori at .05. To determine if the sample was representative of the population and to control for non-response error, the scale means for the three primary scales and the primary variable of measure research productivity were considered to be the primary variables in the study and the scale means were compared by response mode (mail versus phone follow-up) as recommended by Borg (1987) and Miller and Smith (1983). There were no statistically significant differences between the means by response mode for the three primary scales in the instrument: Organizational Culture/Support for Research Scale - t = .54, p = .59, df = 62, Faculty Self-Assessment of Research Confidence Scale - t = .73, p = .47, df = 62, Faculty Self-Assessment of Research Anxiety - t = 1.86, p = .07, df = 62. In addition, there were no statistically significant difference between the means by response mode for the number of single (t = 1.83, p = .07, df = 62), coauthored lead (t = .18, p = .86, df = 62), and coauthored not lead (t = .73, p = .47, df = 62). It was concluded that no differences existed by response mode, and the data were representative of the population. The mail and phone follow-up responses were combined for further analysis.

Findings

The following sections review this study's findings.

Research Objective 1: Demographic Characteristics of Faculty

This research objective sought to describe selected demographic characteristics of the faculty in the study. Most of the HRD education faculty was male (35 or 54.7%). The mean age of those reporting was 51.16 years (SD = 9.37). The mean salary of those who responded to this question (t = 48), with adjusting for nine-month contract, was $59,380 (SD = $24,050), with most holding a 9-month contract (41 or 64.1%). Of those responding, 20.3% (n = 13)
were full professors, 39.1% (n=25) were associate professors, 35.9% (n=23) were assistant professors, and 3.1% (n=2) were instructors.

The participants reported their universities allocated an average of 47.9% of their time for teaching, 25.7% of their time for conducting research, 14.6% of their time for service duties, and 11.0% amount of their time for administrative duties. Many (n=47, 73.4%) had earned the doctorate. The number of doctoral students advised to completion in the past five years ranged from 0 to 50 with an average of 6.7 (SD=12.4), while the number of masters students advised to completion in the last five years ranged from 0 to 55 with an average of 7.8 (SD=13.3).

**Research Objective 2: Faculty Research Productivity**

In this study, articles published in refereed journals in the past five years were used as a surrogate for research productivity. Those surveyed reported that, in the past five years, they had published an average of 3.17 (SD=5.60) refereed journal articles for which they were the sole author, an average of 2.92 (SD=5.20) co-authored refereed journal articles for which they were the lead author, and 2.22 (SD=2.79) co-authored refereed journal articles for which they were not the lead author. The range of publication was from 0 to 33 for single authored publications, 0 to 36 in co-authored publications being the lead author, and 0 to 17 for co-authored publications not being the lead author. Of the respondents in the last five years, 32.8% (n=21) did not publish a single authored article, 29.7% (n=19) did not publish a co-authored article being lead, and 23.4% (n=15) did not publish a co-authored article not in the lead. Overall 10.9% (n=7) of the respondents did not publish in any category over the last five years.

For the purposes of this study, total research productivity was calculated as follows: the respondent was given a credit of 1.0 for each article published for which they were the sole author, a credit of .50 for each co-authored article published for which they were the lead author, and a credit of .33 for each co-authored article published for which they were not the lead author. The mean faculty research productivity score was 5.37 (SD=7.23).

**Research Objective 3: Organizational Culture**

The Organizational Culture/Support for Research (OCSR) Scale contained 20 items that assessed the faculty members' perceptions of the organizational culture and support for research that existed in their department. Responses were recorded on a five point Likert scale that ranged from 1=Strongly Disagree to 5=Strongly Agree. The scale grand mean was 2.62 (SD=.66).

**Research Objective 4: Self-Assessment of Research Confidence**

The fourth research objective sought to describe the faculty members' self-assessment of their research confidence as measured by the Faculty Self-Assessment of Research Confidence Scale that consisted of 7 items. The overall mean for the scale was 3.90 (SD=.81).

**Research Objective 5: Self-Assessment of Research Anxiety**

The fifth research objective sought to describe the faculty members' self-assessment of their research anxiety as measured by the Faculty Self-Assessment of Research Anxiety Scale that consisted of 9 items. The overall mean for the scale was 2.41 (SD=.66).

**Research Objective 6: Explanation of Variance in Research Productivity by Selected Variables**

The last research objective sought to determine if selected variables explain a significant proportion of the variance in research productivity. A backward multiple regression procedure was used to examine the amount of variance in research productivity explained by selected variables. The procedure revealed that five variables within a significant (p=.018) model to explain 56% of the variance found in research productivity (R^2=.564). These variables included teaching percentage (p=.002), research percentage (p=.002), service percentage (p=.002), administrative percentage (p=.002), and hours of graduate assistant support per week (p=.009). The variables that did not explain a significant proportion of the variance were number of masters students advised to completion, work hours, age, gender, rank, adjusted salary, organizational culture/support for research scale mean, self-assessment of research confidence scale mean, self-assessment of research anxiety scale mean, number of doctoral students advised to completion, total years in a tenure-track position, teaching at a land grant university, hours of undergraduate support per week, and research and publishing in terminal degree program.

**Conclusions**
With the majority of HRD faculty publishing articles — whether single or co-authored — over the past five years, and with only a minimal number of faculty not publishing at all, production of research is an area which HRD faculty are making a concerted effort to develop. The mean research productivity score also demonstrates the value of research production to HRD faculty. HRD faculty's perception of organizational culture/support for research is however not supportive of increased research productivity. This leads to the recommendation that some intrinsic reward system may be influencing the HRD faculty to produce research.

The HRD faculty members are somewhat confident in their ability to conduct research with the faculty being most confident in determining a research methodology. Along with confidence, HRD faculty demonstrated they are only a little anxious when producing research and have the least difficulty in reviewing articles for refereed research journals. This may further support the level of research productivity of HRD faculty demonstrated within this research effort.

In attempting to explain HRD faculty research productivity, the division of time of an HRD faculty member's duties (teaching, research, service and administrative) and the number of graduate assistant hours of support per week are driving factors for HRD research productivity within this study. Due to the lack of previous research on HRD faculty, comparisons with other studies cannot be made, and therefore, it is recommended that further research be conducted to determine the validity of these results. However, the factors presented here as the most contributory to research productivity are logical in nature, and the further investigation of these factors demonstrated that as one increases duties across each of these areas, their research productivity decreases. These factors could potentially be correlated with other factors such as total work hours or family situation to provide a clearer picture of the results.

Implications on HRD Research

Overall, this research study provides a basis for HRD university departments to review the perceptions of HRD faculty members concerning their organizational culture and support, and to consider the allocation of a professor's time when desiring certain research productivity levels from such individuals. This study also demonstrates the apparent dedication to the production of research with the HRD discipline that is most beneficial as the discipline continues to develop and strive to define itself more clearly. Lastly, this study strives to create a mental model of the relevance in conducting research on research in the HRD discipline to aid in the further development of the discipline.

Intrinsic and Extrinsic Work Motivators: Implications for the Incoming Air Force Officer Workforce

Stephanie K. Johnson
Jason J. Davis
Christopher Rate
United States Air Force Academy

The purpose of this study is to explore the literature relating to work motivators and to find Air Force specific data on intrinsic and extrinsic work motivators. It investigates both the occupational selection hypothesis and the occupational socialization hypothesis, and relates them to retention in the Air Force. The literature and study results note that there is more research to be done with work motivators.

Key Words: Intrinsic, Extrinsic, Work motivators

To be a cutting-edge business, employers need to be cognizant of the changing nature of the workforce. Employers, like the United States Air Force, are investing in training and recruitment while realizing that a return on that investment requires an understanding of what motivates their workforce, both intrinsically and extrinsically. A strategic source of information to both employee and employer should be the intrinsic and extrinsic motivators that are deemed important by the workforce. The purpose of this research was to explore the issues surrounding intrinsic and extrinsic work motivators. Such accurate information allows for the development of a unique operating model that mirrors the existing reality and will help to benefit both the employee and the employer.

Extrinsic motivators are rewards derived from the job but external to the work itself such as income, prestige, and security. In contrast, intrinsic motivators include rewards obtained directly from work experience such as interest, challenge, responsibility, autonomy, and other similar gratifying features.

To explore these issues four enabling research questions were developed:

1. What are the expectations of incoming Air Force officers regarding both intrinsic and extrinsic work motivators?
2. How will expectations of work motivators, or value placed on specific intrinsic and extrinsic work motivators, change as Air Force officers continue throughout their career?
3. Are gender differences significant in the value placed on various intrinsic and extrinsic work motivators?
4. What are the sociodemographic variables associated with new entrants that may account for some of the intrinsic and extrinsic workplace motivators expected by incoming officers?

It was the aim of this research to begin with a small population, incoming Air Force officers, and use their preferences to help further the knowledge of intrinsic and extrinsic work motivators. It is first meaningful to understand the characteristics of the new workforce generation as it provides a foundation from which they form these work motivators.

The Air Force Newcomers

Strauss and Howe (1997) describe the incoming workforce generation (born between 1961 and 1981) as the 13th Generation. This generation, also called "Generation X," comprises a large part of the Air Force, with approximately 70 percent of the men and women being age 34 or younger. It is assumed that strategically aligning intrinsic and extrinsic work motivators for this generation should pay dividends in the form of retention and recruitment.

Socialization influences such as parents, peers, media, education, religion, technology and culture, can guide how this generation are intrinsically and extrinsically motivated in the work environment (Burley, 1994). For example, Izzl (1998) describes fast-food dinners, over-scheduling and high-tech bedrooms as common occurrences in socializing the “13th generation.” Also, caring tasks such as childcare, elder care, lawn care, paying bills, buying groceries, washing cars, and home chores (among others) are being accomplished by hired help. In the work environment Tulgan (1995) suggests that Generation X was raised by both parents working loyally for one company, succeeding and then experiencing a downsizing, a restructuring or a buy-out. This mistrust of loyalty has brought in a generation of workers who value independence and an entrepreneurial spirit. Tulgan (1995) links their short attention spans to their environment of fast-paced technology and the information age. Specific to the Air Force, Omicinski (1999) highlights that the new generation of Air Force officers is more likely to come from fathers with no military experience to pass along to their sons or daughters.

The generation of workers preparing to enter the workforce in the next few years may have little real-world experience with work issues. Furthermore, their expectations of work motivators may be contradictory (Johnson, 2001). It is suggested that a learning model be developed that will educate and further align expectations with the reality of work issues.

Formation of Work Values

The first step in designing a learning model is to find out where new workers' values lie with regards to expectations in the workplace. As Mortimer and Lorence (1979) noted over twenty years ago: “First, people choose occupations, and thus select their work experiences, on the basis of their values. At the time of entry into the labor force, the individual attempts to select a work role that will maximize rewards deemed most important...” (p. 1364). More recently, Johnson (2001) notes “in the context of work, work values are beliefs about the desirability of various work features and are usually defined by referencing several types of rewards derived from working” (p. 317).

The research on work values reveals two competing ideas. The first is the “occupational selection hypothesis,” in which people choose their occupations based on psychological characteristics and values already in place (Mortimer & Lorence, 1979; Lindsay & Knox, 1984; Johnson, 2001). The second is based on the reinforcement hypothesis, or what Mortimer and Lorence (1979) called the “occupational socialization hypothesis” which asserts that rewards obtained on the job grow in importance over time and mold work values, whereas the absence of rewards lessens their values over time (Mortimer & Lorence, 1979; Johnson, 2001). This idea of value reinforcement through an occupation is consistent with Rokeach’s (1973) theory of values, which affirms that values will change to preserve one’s positive self-concept, and likewise valuing something that one does not have could diminish self-esteem (Rokeach, 1973).

Another issue to consider is that values formed in early adulthood are likely to change with work experience and age. Johnson (2001) argues that adolescent occupational aspirations exceed what is available in the labor market, making their work values reflect strong desires for work motivators that are unrealistic (Johnson, 2001, p. 316). Her longitudinal study found that the proportion of respondents rating each job feature as “very important” declined over the 13-14 year gap between testing phases. The question is whether or not you can accurately determine work values at the high school or college level that will be generalizable to adult worker expectations. Johnson (2001) notes that as young people gain work experience, they also gain a better understanding of the labor market and what is realistically attainable.

It is also necessary to address a possible gender difference with regard to work motivators. Studies have found that women place a greater emphasis on intrinsic, altruistic, and social rewards from work, while men place more importance on the extrinsic motivators obtained from work (Johnson, 2001; Lindsay & Knox, 1984). Johnson also found that the gender gap in extrinsic values did not lessen throughout the time between testing yet both males and females attached less importance to extrinsic values over time. As times change, this gender differentiation due to socialization is decreasing. Women are beginning to close the gap regarding the value they place on extrinsic motivators while maintaining a stronger orientation towards intrinsic, altruistic, and social rewards (Johnson, 2001). In support of the reinforcement hypothesis, as young people begin to become more realistic about what rewards are available to them in the workplace, the gender difference in work values may narrow (Johnson, 2001).

Another variable is sociological changes, particularly family roles and economic standing. Johnson (2001) describes a gender model that would predict weaker effects of work motivators for women when compared to men, with women experiencing a decrease in the importance of work motivators as they enter family roles. Additionally, family roles for males solidify their breadwinner role increasing their focus on extrinsic motivators. In general, having a family and children has been positively associated with an increase of importance placed on extrinsic motivators across both genders (Johnson, 2001). Lindsay and Knox (1984) assert that social structure variables on life changes, particularly parenthood, education, origin, race, and gender, have a big impact on the formation of work values.

Economic status also plays a significant role in facilitating the formation of work values. Mortimer and Lorence (1979) note that when an individual has inadequate economic resources, income and other extrinsic motivators assume a higher priority. Comparatively, when material needs are met the salience of extrinsic motivators lessens and the worker concentrates on more intrinsic job satisfactions (Mortimer & Lorence, 1979). Furthermore, intrinsic occupational rewards increase with occupational prestige, while extrinsic rewards are highly valued at lower occupational levels (Mortimer & Lorence, 1979).

In summary, significant trends exist in the study of work values. However, numerous studies provide support for different hypotheses, or conflicting findings with regards to gender differences, the stability of work values over time, and the impact of demographic and socioeconomic conditions on work values. This study seeks to identify
what work values officer candidates consider most important, the possible gender differences across these values, and the possible incongruity between valued motivators and current motivators that may be effecting retention rates in the United States Air Force. Most importantly, the study will seek to identify whether incoming Air Force officers will value extrinsic work motivators over intrinsic work motivators, and whether there will be any gender difference in this preference.

Method

A survey was designed to provide insight into the different values placed on both intrinsic and extrinsic work motivators. The data helped analyze how cadets from the United States Air Force Academy (USAFA) and various Reserve Officer Training Corps (ROTC) programs preparing to enter active duty perceived intrinsic and extrinsic work motivators. Comparisons were made between commissioning source and gender. Furthermore, in addition to the previously presented research questions, two hypotheses were formulated:

Hypothesis 1: There will be no difference between incoming USAFA and ROTC officers in the respect that both will value extrinsic motivators more than intrinsic motivators.

Hypothesis 2: Extrinsic motivators will be rated as more important than intrinsic motivators across genders.

Sample

The sample consisted of 343 cadets entering the active duty Air Force within the next year. Specifically, the sample contained 275 USAFA cadets and 68 ROTC cadets enrolled at universities in Colorado and Wyoming. The average age was between 21 and 22 years old. The majority of the sample had mothers with some college or trade school education that worked either full or part time while the cadet had lived at home. The majority of the fathers of the sample population had a college degree. Of the ROTC population, nine were married with the majority having a spouse that had some college or trade school education that worked full-time. Of the nine married cadets, six had children.

Instrument

An existing multipart survey, The Career Issues Survey, was directly administered for this study (Covin & Brush, 1993, 1991). The instrument language was slightly modified to fit the cadet population and context. For this study, only sections two and three of the Career Issues Survey were used (questions 57-91). These two sections contained questions related to extrinsic and intrinsic motivators. The participants completed the surveys in a classroom setting with the researcher present to answer questions.

Data Analysis

To assess for “dimensionality and commonality” (Covin & Brush, 1993, p. 36) among the 34 Likert-scaled items, a factor analysis was performed, aligning the questions into two factors – intrinsic and extrinsic motivators. The factor analysis was used to generate subscores for the two dependent variables – intrinsic and extrinsic work motivators. Next, the subscales derived by the factor analysis were utilized to compare commissioning source and gender. Once the researcher established the reliability of the factors derived by the use of a reliability analysis function, a two-way Analysis of Variance (GLM Univariate) and a Multivariate ANOVA were used to test for interactions between the two independent variables (commissioning source and gender) on both Factor One (intrinsic motivators) and Factor Two (extrinsic motivators).

Factor Analysis

The first step in the data analysis was to identify what factors would be present in the data. This was accomplished using a factor analysis. Fraenkel and Wallen (1996) describe factor analysis as “a technique that allows the researcher to determine if many variables can be described by a few factors…the technique essentially involves a search for clusters of variables, all of which are correlated with each other” (p.314). A factor analysis was performed using principal component factoring and a varimax rotation using questions 57-91 of the survey and extracting all of the questions into two factors. The questions within each factor with loadings above .5 were identified and retained (see Appendix).

To ensure that the loading in each factor was actually contributing to the factor, a reliability analysis was run. By analyzing the alpha reliability coefficient, one can determine the strength of the scale. For Factor One, alpha was .84, and for Factor Two alpha was .79. In both Factors, the alpha reliability coefficient would not have improved with a removal of any one item.
A test for correlation amongst the two factors was also accomplished. The purpose was to verify whether a relationship existed between the two factors. A Pearson product-moment coefficient ($r$) was calculated for the two factors. Correlation coefficients for Factor One and Two were .17, revealing no significant correlation between the two factors.

**Factor One.**

Factor One contained questions directed at weighing the importance of intrinsic motivators to incoming Air Force officers. After analyzing the factor loadings and the descriptors present in each question, it was decided to retain questions 72, 74, 78, 79, 81, 84, 85, 88, 89, 90, and 91. Questions 63, 86, and 87 were removed because their descriptors did not fit with the other questions.

A high score on any item in the factor would indicate that the particular intrinsic motivator is a very important aspect of the workplace to the sample. There was no significance in commissioning source, gender, or the interaction for Factor One. The data demonstrates that intrinsic motivators were rated higher than extrinsic across both commissioning sources and gender (see Tables 1 and 2). The men rated the importance of intrinsic motivators .02 higher than the women. In addition, ROTC cadets rated the importance of intrinsic motivators .01 higher than USAFA cadets. Furthermore, there was no significance in the univariate ANOVA performed on Factor One (see Table 3).

**Factor Two.**

Factor Two consisted of questions directed at weighing the importance of extrinsic motivators to incoming Air Force Officers. After analyzing the factor loadings and the descriptors present in each question in this factor, it was decided to retain questions 57, 58, 60, 64, 66, 67, 68, and 70. Questions 71, 80, and 82 were removed because their descriptors did not fit in with the other questions.

For this sample, a high score indicated that certain extrinsic motivators are important aspects of the workplace. Factor Two had a lower mean than Factor One. The female sample's mean was .34 higher than the males on this factor, which is indicated by the significance on gender in Factor Two: F (1,343)=6.74, p=.01 (see Table 4). In addition, USAFA cadets' mean was .16 higher than ROTC’s, as indicated by the significance for commissioning source: F (1,343)=6.30, p=.01. Therefore, both gender and commissioning source main effects were significant for Factor Two.

**Analysis for Research Questions and Hypotheses**

The research questions and hypotheses suggest that source of commission and gender will relate to intrinsic and extrinsic motivators. A two-way Multivariate Analysis of Variance (MANOVA) was used to test for main effects of the sample groups (USAFA cadets versus ROTC cadets, and men versus women) on the two factors. The MANOVA indicated there are significant main effects for both commissioning source (Wilks's lambda = .97, F = 4.61, df = 2/326, p = .011) and gender (Wilks's lambda = .98, F = 3.22, df = 2/326, p = .041). The MANOVA also indicated no significant interactions between commissioning source and gender (Wilks's lambda = .99, F = 2.31, df = 2/32, p = .10).

The univariate tests for the influence of commissioning source and gender were significant (p<.05) for the main effects of gender and commissioning source for Factor Two (extrinsic motivators). The interaction between gender and commissioning source was not significant in either Factor, nor was anything else significant in Factor One (intrinsic motivators).

**T-Test**

The purpose of paired-samples T-test is to compare the means of two variables for a single group. Since one of the objectives was to determine if incoming Air Force officers would value extrinsic motivators (Factor Two) more than intrinsic motivators (Factor One), a paired-samples T-test would reveal any difference. The mean for intrinsic motivators was 4.17 while the mean for extrinsic motivators was 3.69. This difference was significant on a two tailed measure, p = .000.
Another analysis component is individual question means. These means reveal on a smaller level what the extremes are for importance or what is really not important to the incoming officer within the confines of both extrinsic and intrinsic motivators. The questions rated the most important included: 1) is intellectually stimulating, 2) provides a feeling of accomplishment, and 3) medical benefits. These highest scores are inclusive of commissioning sources and genders.

Interpretation

The first research question asked what the expectations of incoming Air Force officers would be regarding both intrinsic and extrinsic work motivators. A descriptive analysis of means suggests the six extrinsic and intrinsic motivators rated the highest were: 1) Working Conditions (extrinsic), 2) Medical Benefits (extrinsic), 3) Allows adequate time for family and friends (intrinsic), 4) Provides job security (intrinsic), 5) Is intellectually stimulating (intrinsic), and 6) Provides a feeling of accomplishment (intrinsic). Conversely, the three questions rated lowest by the group, related to Factor Two, were 1) Childcare policies, 2) Maternity Leave Policies, and 3) Paternity Leave Policies (all extrinsic factors).

Since the majority of 20-21 years olds do not have immediate concerns regarding children, and USAFA cadets are prohibited from having children while they are cadets, it is not surprising that the group rated these three questions lowest. However, the more interesting finding lies in the higher rated questions. The general theme of the highly rated questions was one of internal satisfaction due to accomplishment and the work environment, rather than one based on extrinsic motivators such as money. Although this finding generally does not support our hypothesis, it speaks volumes for those entering the Air Force because it shows that they value the nature of their work, and not their pay. This is a positive consideration as most Air Force personnel have the potential to earn more income in the civilian sector. Therefore, these findings suggest that the Air Force is sufficiently tending to these needs. With regards to retention, it would be important to focus on the motivators, both extrinsic and intrinsic, and to try to maximize those in the Air Force officer work environment.

The second research question asked how expectations of work motivators, or value placed on specific intrinsic and extrinsic work motivators, would change as Air Force officers continue throughout their career. The data suggests that there is more importance placed on intrinsic motivators in the workplace rather than extrinsic motivators as can be explained by the difference in means and the paired-sample T-test. However, the first research question should be a good indication that it is a distinct possibility that the answer lies much deeper than a simple diagnosis. The answer may very well be that incoming officers value a distinct mix of intrinsic and extrinsic motivators based on individual socialization and environmental factors. In addition, without the use of a longitudinal study of incoming officers, both before entry and after a specified time in service, it is indeterminable how these values will change as their career progresses. However, the retention issues surrounding this question can be answered by the research. One of two things most likely happens. The first option is that incoming officers follow the "occupational selection hypothesis," in which people choose their occupations based on psychological characteristics and values already in place (Mortimer & Lorence, 1979; Lindsay & Knox, 1984; Johnson, 2001). Or they follow the "occupational socialization hypothesis" which asserts that rewards obtained on the job grow in importance over time and mold work values, whereas the absence of rewards lessens their values over time (Mortimer & Lorence, 1979; Johnson, 2001). The thought is that if they are following the "occupational selection hypothesis" then retention solutions are minimal because they are basing their job preference off of predetermined values. Therefore, if the Air Force occupation does not satisfy those values then the officer will most likely separate from the Air Force. However, if it is the case that they are following the "occupational socialization hypothesis," then it is important to find out what motivators are important to them as their career develops, and to positively reinforce those motivators for retention purposes.

The third research question sought to identify gender value differences on various intrinsic and extrinsic work motivators. The data does not support gender differences related to intrinsic motivators; the gender main effect was significant for extrinsic motivators (Factor Two). One might argue that the differences in values placed on the extrinsic motivator questions are most likely due to different gender roles and the different value systems across genders. This finding warrants further research. As of now, data suggest no significant motivators that will drastically impact retention for one gender that would not also have a positive impact on the other. The fact that male rated extrinsic motivators as slightly higher than females is in accordance with past research (Mortimer & Lorence, 1979; Lindsay & Knox, 1984; Johnson, 2001).

The fourth research question asked if there were any sociodemographic variables associated with new entrants that may account for some of the intrinsic and extrinsic workplace motivators expected to be delivered by their employer. It can be assumed from the data that cadets planning to enter the workforce are expecting some type of
assistance from their employer with issues related to work and family. An interesting demographic finding was that the majority of mothers of the cadets had worked either full or part-time while the cadet had lived at home. Additionally, all of the spouses of the ROTC cadets had jobs. This is an indicator that issues of work-family balance had been present during their formative years in which both of their parents worked.

In summary, although the study answered the research questions quite well, it rejected both of the hypotheses. Intrinsic motivators were in fact rated higher than extrinsic motivators, which is the exact opposite of the prediction. The first hypothesis predicted that there would be no difference between USAFA and ROTC incoming officers in the respect that both will value extrinsic motivators more than intrinsic motivators. Although there was no significant difference between USAFA and ROTC on their ratings of intrinsic motivators (Factor One), commissioning source was significant for extrinsic motivators (Factor Two). In addition, both groups rated intrinsic motivators higher than extrinsic motivators. The second hypothesis stated that extrinsic motivators would be rated as more important than intrinsic motivators across both genders. Again, since intrinsic motivators were rated as more important across both commissioning source and gender, this hypothesis is also rejected.

A major objective of this research has been to ascertain work motivators of incoming officers into the active Air Force. The efforts have resulted in data that can help assist with recruiting, retention and education. Additionally, the data begins to lay the foundations for future development in the area of intrinsic and extrinsic workforce desires. Toward this goal the research yielded results which indicate that incoming Air Force officers can differ in their work values. Further studies of work motivators, especially specific to Air Force officers are needed. A longitudinal study would reveal the changing nature of work motivators that would immensely help form a better learning model for the United States Air Force and other employers. Ultimately, this could increase retention and make for a more reliable and efficient workforce.

References

Appendix

Factor One (intrinsic motivators) includes questions:

72. Requires originality and creativity
74. Encourages continued development of knowledge and skills
78. Gives you the responsibilities for taking risks
79. Requires working on problems of central importance to the organization
81. Provides change and variety in duties and activities
84. Permits advancement to higher levels of responsibility
85. Permits working independently
86. Is intellectually stimulating
88. Permits you to work for superiors you admire and respect
90. Permits you to develop your own methods of doing the work
91. Provides a feeling of accomplishment

Factor Two (extrinsic motivators) includes questions:

57. Level of Pay
58. Child Care Policies
60. Vacation policies
64. Working hours
66. Medical benefits
67. Maternity leave policies
68. Yearly pay increases
70. Paternity leave policies
71. Allows adequate time for family/friends
80. Provides ample leisure time off the job
81. Provides comfortable working conditions

MBTI: A Tool to Enhance Team Learning

Brenda S. Gardner
Sharon J. Korth
Xavier University

Using teams of employees to get work done in organizations is becoming increasingly more common across the world. This article focuses on an approach to training HRD professionals to learn and model effective team behavior. It describes how the MBTI is used as a tool to enhance team learning in a graduate level HRD program. Conclusions and recommendations for HRD academic and training programs are explored.

Keywords: Teams, Learning Styles, Academic Programs

Across the world, organizations utilize teams in the workplace. From the United Kingdom, Australia, Ireland, Malaysia, and the United States, descriptions of workplace teams abound (Wellins, Byham & Dixon, 1994). While some of these teams are domestic, with all of the members from the same country, the increasingly global workplace has led to the creation of many transnational teams as well. The number of teams used in the United States has increased since the 1980s when total quality and other similar management philosophies pointed to team-based work environments as the success formula of the future (Dobyns & Crawford-Mason, 1991). When faced with the challenges of a changing workforce, global competition, technological innovations, decreases in productivity, and shifting work values, many U.S. organizations used teams as part of their newly designed work structure.

Problem Statement

HRD professionals are often responsible for the training of teams in the workplace and must understand the elements of team learning and effective team behavior. The best learning comes from personal experience, so the challenge is to provide HRD professionals with team learning experiences that they can transfer to the workplace.

Theoretical Framework

The Myers-Briggs Type Indicator has been used extensively in organizations and educational institutions and is based on the work of the Swiss psychotherapist Carl Jung (Myers, 1993; Provost & Anchors, 1987). The MBTI reflects individual preferences for energy (Extraversion and Introversion), information gathering (Sensing and Intuition), decision making (Thinking and Feeling), and lifestyle (Judging and Perceiving). Each of these four dimensions is measured on a scale; sixteen unique personality types result from the combination of the four MBTI preference scales.

One common use of the MBTI is with learning style research. For example, extraversion has been found to be associated with preferences for working in a group, whereas introversion is related to working individually. Sensing is associated with practical interests, while intuition is related to tasks that call for imagination. Research has shown that students high in the thinking dimension prefer objective material to study, while those high in the feeling dimension learn through personal relationships. Finally, the judging component relates to formalized instruction, whereas the perceiving component corresponds to informal problem solving (Lawrence, 1984).

Lynch & Sellers (1996) developed descriptions of four college/learning environments based on a quadrant combination of MBTI attitude and perception preferences which were most applicable to learning (1996) (See Figure 1). Lawrence (1994), and Lynch and Sellers use combinations of the first two dimensions of the MBTI to describe different types of classrooms.

The MBTI has also been used extensively to enhance teamwork. According to Hirsh, the MBTI specifically aids team members by:

- reducing unproductive work
- identifying areas of strength and possible area of weakness for the team
- clarifying team behavior
- helping to match specific task assignments with team members according to their MBTI preferences
- supplying a framework in which team members can understand and better handle conflict
- helping individuals understand how different perspectives and methods can lead to effective problem solving
- maximizing a team's diversity in order to reach more useful and insightful conclusions. (Hirsh, 1992, p. 7).

Premise and Research Question

This research is based upon the premise that (a) teams are common in today's workplace; (b) HRD professionals must learn and model effective team behavior; and (c) academic and training programs must be developed that teach and model team behavior. The cycle of learning and performance starts with academic/training programs teaching team-related skills to HRD professionals, continues as HRD professionals utilize these skills on their jobs as they train others, and leads to improved team skills for employees.

The following research question served as a guide for this study: How can the MBTI be used as a tool to enhance team learning in academic settings?

Methodology

In this study, quantitative and qualitative data were collected in a course on organization behavior, offered during the first
semester of graduate study at a private US university, as part of an academic program in HRD. To determine personality
and learning type preferences of HRD professionals, data were collected from a total of 241 HRD graduate students over a
six-year period enrolled in this course, and were analyzed using Statistical Package for Social Sciences (SPSS) for

The students were all working adults, ranging in age from 21 to 56, with a mean age of 37, standard deviation of 7.98.
Seventy-six percent of the group was female, and years of full-time work experience ranged from 0 to 37, with a mean of
13.2 and a standard deviation of 8.02. During the second meeting of the organization behavior class, the Myers-Briggs
Type Indicator-Form G (MBTI), developed by Katharine Cook Briggs and Isabel Briggs Myers, was administered to the
students by the researchers who were also the professors of the course.

In addition, qualitative data were collected through participant-observation and document review. Documents
included course materials, assignments, as well as student learning journals and reflective papers. Data were analyzed by
constant comparative method (Lincoln & Guba, 1985), reflecting on the meaning of what was heard and seen, and using
existing literature when useful.

Results and Findings

**MBTI Personality Preferences**

This study found that in this HRD graduate student/practitioner group, the majority of students were Extravert,
Intuitive, Feeling and Judging. This contrasts with the national US adult norms of majority preferences in Introvert,
Sensing, and Thinking (Hammer & Mitchell, 1996). Preferences of other related fields are also included in Table 1, and
indicate similarities with the HRD group in the judging preference (Myers & McCaulley, 1985).

**Use of MBTI to Design Team Training**

Gathering data about personality and learning style preferences in relation to energy, information gathering, decision
making, and lifestyle provided researchers with a layer of analysis useful in the design and implementation of team
training in the classroom, as well as a tool that these students could use in their own teams in the classroom and back on-
Researchers worked with students to help them understand how preferences could aid in improving their classroom groups, as well as the teams they were implementing and leading in the workplace. After reviewing and processing Jung's personality type theory and its relationship to the students' MBTI results, researchers organized students into small groups of 6-7 for group projects lasting over two semesters. Teams were organized, however, not by any grouping of specific MBTI types, but toward a mixture of gender, race, and levels and type of work experience.

Activities designed to help the students increase their self-awareness using MBTI personality preferences included, of course, the administration of the MBTI and thorough processing of its results. Researchers posed questions of the students such as: How do I prefer to gather information and make decisions? What leadership qualities do I value? How do I prefer to learn? What irritates me about my teammates? How can I contribute to the team? How do I react to conflict? How well do I listen? How do I give and receive feedback? What role do I play in a group setting? How well do I lead or follow? For example, students with Introversion-Sensing-Thinking-Judging (ISTJ) profiles are likely to be thorough, systematic, hard-working, and careful with detail. With this heightened self-knowledge, these students may better understand why they value traditional, hierarchical approaches to leadership and why they get irritated at those who do not follow through with commitments. Two project assignments specifically helped students increase their self-awareness: entries in a learning journal kept over two semesters, and a comprehensive analysis of the student's learning as a culminating project for the year.

To assist students in applying personality type theory to groups and teamwork, researchers organized experiential activities for the teams which were processed using MBTI results. For example, problem-solving activities and outdoor leadership activities all provided data that could be analyzed by the students using personality type theory. Group projects culminating in a presentation, report and group analysis were natural areas in which group process questions were asked of the students: How do we manage our meetings? How do we make decisions or solve problems? How do we manage our projects? How do we develop shared goals and create/maintain commitment to those goals? How do we create a climate that fosters trust and openness? How do we balance utilizing the strengths of our members while fostering individual personal development? For example, "time" can become an issue with teams and their management of meetings. Team members with the Thinking preference may prefer to be brief, concise and task-oriented, while those with the Feeling preference may take the time needed to build and maintain interpersonal relationships. Once team members understand that these differences exist and recognize the value of both perspectives, they can leverage them to enhance the effectiveness of their team meetings. Again, the experiences and analysis using personality type theory aided in the students' understanding and improving their classroom group, as well as how to better lead and implement teams back in their workplaces.

Course feedback from the students has been generally very positive. Informal comments, information provided on the written individual and group analysis papers, and formal end-of-class evaluation results indicate that the students find the MBTI a useful tool in increasing their self-awareness and enhancing their classroom and workplace group functioning. One student, in her individual analysis, explained that knowing about the different MBTI preferences helped her realize that she may have been misjudging the quiet members of her group as lacking commitment. As a result, she was able to appreciate their differences in style and help find ways to utilize their strengths. Another student reported about how he successfully used one of the experiential class activities with a group he was facilitating in the workplace.

MBTI Learning Styles Consideration for Training

The MBTI can also provide insight into learning style preferences of class participants. Because there will be a mix of styles in any group, it is important to create training that includes learning activities appealing to all preference types. Knowing the learning style preferences of the participants in a given group as well as the types of corresponding activities allows the flexibility to adapt the training to meet the specific needs of the group.

Applying these ideas to team building training implies that there will be a variety of individual and group activities, and that some portions of the training will be practical, hands-on, and structured while other portions will allow for personal exploration. The intent is to utilize an assortment of methods so as to tap into current learning strengths as well as to stretch and increase the participants' learning abilities in other dimensions. Researchers utilized discussions, psychomotor activities (including outdoor experiential exercises, if possible) and group work to appeal to the extraversion
dimension. Conversely, reading, individual work, and time for internal processing were also included to support the learning strengths of those with introversion preferences. Some parts of the instruction, for example, on project management, progressed in a step-by-step manner (extravert-sensing), while other parts involved having students find their own way in the material (introvert-intuition), such as in conducting research and writing papers. Finally, the course involved a mix of prescribed tasks, such as the development of an annotated bibliography on an HRD related topic (introvert-sensing), and discovery tasks, such as finding creative ways to solve hypothetical problems in a group (extravert-intuitive).

Conclusions and Recommendations

First, academics who design classroom training for HRD students may wish to use a tool such as the MBTI as a "lens" in which to review their instructional methods to determine balance and appropriateness for their group. The HRD graduate student sample reported in this article indicated that the least favored learning environment was Introvert-Intuitive, which was also reported in Lynch and Sellers' 1996 study. In a number of studies, however, Introvert-Intuitive is a very common personality style and learning preference for college professors (Lynch & Sellers; Murphy, 1987; Myers & McCaulley, 1985). (See Table 1). If professors "teach to type" (create a learning environment consistent with their own learning style preferences), a mismatch may occur between learners' preferences and professors' activities. Awareness of the implications that may develop in the classroom as a result of this type of situation can be a first step for reviewing the curriculum design for a course.

In contrast, the most favored learning style preference was Extravert-Intuitive for HRD graduate students. HRD professionals who are designing classroom training in the workplace for other occupations such as engineers, health care professionals, computer analysts, etc., would also do well to determine if their own preferences for learning activities might be overshadowing the learning needs of their students.

Finally, much more work must be done to study the role of the HRD professional in team learning and team/organizational effectiveness. This paper described how knowledge of the MBTI personality and learning styles can be used to design training for team members in the classroom. More research is needed to establish measures of team learning and transfer of skills back on the job.

Clearly, the study described in this paper is just a beginning. Further research is needed in each phase of the team learning/performance cycle (academic programs, team development in the workplace, team and organizational effectiveness) and to determine the connections between the phases (See Figure 2).

Figure 2. Team Learning/Performance Cycle

This paper showed how the MBTI can be used to enhance the team learning of HRD professionals in an academic program. In the workplace, HRD professionals have the primary responsibility for developing and implementing team-
related training so that employees can develop the necessary competence. Further, they have an obligation to model effective team behaviors themselves. How do HRD professionals learn these important team skills? The team learning/performance cycle starts with academic programs increasing their HRD students' self-awareness and learning about groups and organizations. HRD professionals must take an active role in learning how to model and teach effective team behaviors so that teams are trained for success, the learning/performance cycle continues, and organizations maximize their capabilities to transform in order to meet strategic goals.

Using Technology to Help Foster Critical Thinking and Reflection in Distance and Classroom Instruction: A Poster Presentation of the “R9” Process

David Ripley
The University of Canterbury

This poster presentation describes the development and application of the "R9" process, an original pedagogical strategy designed to increase critical thinking and reflection in domain knowledge-based courses, in both distance education and face-to-face classroom settings. Individual steps of the process are described and examples of its application are provided.

Key Words: Critical Thinking, Reflection, Pedagogy

The importance of critical thinking and reflection in education has been stressed repeatedly over the past several years, in national and international journal issues, numerous books and articles, and workshops held by various education authorities (Baron & Sternberg, 1987). Since this poster presentation is primarily about the R9 process and its use, there is no intent to provide a comprehensive review of the very broad range of critical thinking literature. However, critical thinking and reflection are discussed to the degree necessary to position the R9 process for the reader within that body of thought. It is important to note that the R9 process evolved from a desire to develop a pedagogical approach that would allow one to make critical thinking and reflection a part of the normal conduct of a domain knowledge-based course, rather than conferences, entire a desire to provide a course on critical thinking, such as that described by Mingers (2000).

Theoretical Framework

The literature on critical thinking and reflection covers a broad spectrum. Critical thinking, in particular, can be viewed from various perspectives.

1. One can take the limited perspective of a highly focused problem-solving approach of a typical total quality management (TQM) manual.
2. One can move to a broader -- but still skill-based -- approach that is more about the how and what of critical thinking. This would be more in keeping with the informal logic movement (Ennis, 1987; Kiersky & Caste, 1995; Quellmalz, 1987; McPeck, 1990).
3. Beyond this can be found what one might term a more socially conscious perspective. To use Alvesson's and Willmott's (1992) term, a "softer" approach (p. 432) that shows some concern for higher-order human needs.
4. One can also move toward positions that indicate the goal of critical thinking should be social emancipation. This latter position is more in keeping with the ideas of critical pedagogy and critical practice (Mezirow, 1990; Freire, 1970), and moves toward critical theory (Habermas, 1994; Foucault, 1994) and critical social science (Fay, 1987).

On such a spectrum, the position of the R9 process is relatively modest. I wanted to provide something more than the basic problem solving of a TQM manual but something less than a call for emancipation or a study of critical social science. The process is closer to the informal logic movement than to the socially conscious perspective. I would like my position to be congruent with Said's (1983) comment that "It is not practising criticism either to validate the status quo or to join up with a priestly caste of acolytes and dogmatic metaphysicians" (p. 5). I am taking Said somewhat out of context -- he was referring to literary criticism -- but the thought warrants reflection in this context. In the context of the domain knowledge-based course, I want to concentrate on fundamental questions such as those raised by Hughes (1996). Are the arguments and propositions sound in a logical sense? Do the conclusions follow from the premises? Are the premises justifiable? What are the underlying assumptions? A good working definition for critical thinking for my purpose is that of Brookfield (in Mezirow, 1987), which states, "Being a critical thinker involves more than cognitive activities such as logical reasoning or scrutinizing arguments for assertions unsupported by empirical evidence. Thinking critically involves our recognizing the assumptions underlying our beliefs and behaviours. It means we can give justifications for our ideas and actions. Most important, perhaps, it means we try to judge the rationality of these justifications" (p. xviii). In using Brookfield's definition, I use the phrase "recognizing the assumptions underlying our beliefs and behaviours" in a very applied way.
sense rather than, for example, referring to the assumptions that might underlie one's whole structure of personal values.

Moving from critical thinking to reflection, we return to Mezirow, who tells us that the three functions of reflection are to guide action, to give coherence to the unfamiliar, and to reassess the justification for what is already known. In the R9 context, the latter function is stressed. In relation to reflection, Schon (1987) quotes Alfred Kyle, a Dean of Engineering, as saying, "We know how to teach people to build ships but not how to figure out what ships to build" (p. 11). In part, my goal is that, as students learn how to build Dean Kyle's ships, they also learn (and practice) a bit about how to figure out which ships to build. I want to see students progressing toward becoming the reflective practitioners envisioned by Schon, who think and rethink some of their positions and assumptions, and practice what Schon (1983) called "reflection-in-action" (p. 50).

The second positioning issue relates to whether or not critical thinking can (or should) be taught separately, as a general skill applicable across domains of knowledge as advocated by the informal logic movement (ILM) (Ennis, 1987; Paul, 1990; Siegel, 1990). McPeck (1990), contrary to the ILM, insists critical thinking can only be taught in the context of a domain of knowledge. One cannot just think, but has to be thinking about something; and if that something were a domain one knows nothing about, critical thinking would be highly unlikely, if not impossible. My position here was to take somewhat from both schools of thought although, per McPeck, we are dealing with a specific domain of knowledge. I conceptualised three components of critical thinking (as it relates to the R9 process) as shown below and in poster 1.

Figure 1. Conceptualised Components of Critical Thinking and the R9 Process

<td>B. Learned Critical Thinking and Reflection Skills</td>
<td></td>
</tr>
<tr>
<td>Capability</td>
<td>A. Basic Reasoning Capability</td>
<td></td>
</tr>
</tbody>
</table>

Component A, basic reasoning capability, we seem to be born with. It equates very highly with IQ (McPeck, 1990), as well as what Cattell referred to as the we might find in a 12 or 13-year old adolescent (Merriam & Caffarella, 1991). Component B, learned critical thinking skills, we are taught -- for example in critical thinking courses in university. One can find various lists of just what these skills are, and as McPeck noted, the skills may vary depending on whether the aim is to win the argument or to seek knowledge and truth. For our purposes, I am talking about such skills as Kiersky and Caste (1995) listed: identifying, analysing, and evaluating arguments; identifying fallacies; understanding inductive and deductive reasoning; and spotting implications and assumptions. For component C, crystallised knowledge, I borrowed the term crystallised from Cattell, since I suggest it equates to what Cattell called crystallised intelligence. Roughly, this is intelligence that is grounded in life experience -- including acquired problem-solving skills and what some might call wisdom. As noted by Cross (in Merriam & Caffarella, 1991), education and experience heavily influence crystallised intelligence. Finally, component D, domain knowledge, represents the course content area. For example, if the course is human resource development, we are talking about knowledge in that domain. In terms of figure 1 components, my graduate students typically have good reasoning capability (component A) and some crystallised knowledge (component C) including some degree of critical thinking ability learned through experience. They may have some knowledge of the domain (component D), but few if any have normally had critical thinking courses, per se (component B). The domain knowledge component (component D) is our primary course content. The challenge was to include a critical
thinking and reflection component, but as part of the process of teaching the domain knowledge content. My response was the R9 process.

**Contribution to HRD Knowledge**

The major contribution of the R9 process is to provide a method to deal with two significant issues for both distance and classroom instruction. The first is week-to-week involvement and participation. How can one get everyone effectively involved in the class and interacting with the other students? The second issue is matching the structure and routine of courses to student needs and expectations, while maintaining a degree of rigor appropriate for graduate courses. R9 requires participation and involvement with others. As one of my MBA students put it, “There’s no place to hide”. The critical thinking and reflection components require considered, rather than spontaneous positions. Simply put, the R9 process involves a sequence of 3 cycles of reading, reflecting, and responding related to the material within each teaching/learning segment. The sequence and content of the steps is further described in table 1 and poster 2.

**Developing the Process**

My journey to the R9 Process spanned six courses and about five years. Five of the courses were totally asynchronous on-line courses that were part of a distance master’s degree program in instructional and performance technology, and one was an MBA course in human resource management that met once a week for two hours. Asynchronous courses provide for the exchange of views through a bulletin board-type posting process, but do not provide for live, real-time conversation, such as one would have in a chat room or with one of the instant messenger services, such as AOL and Microsoft provide. In the MBA course, we had that opportunity for face-to-face interaction. The journey was not all about methodology, but was also about my own learning how to be effective in a distance environment.

**Courses One and Two.** Courses one and two were conducted on a DOS-based program called First Reader – very basic by today’s standards, but adequate for our purposes. As noted, the students, mostly adults working full time, were participating in a distance master’s degree program. I tried to approach the class with adult learning principles in mind. This included such things as validation of the participants’ past experiences, recognition that they were self-directed learners, involvement in establishing learning objectives, and finalising course design. In addition, I tried to get students to share in class governance. Evaluations indicated frustration with what students perceived to be a lack of clarity as to what was required of them. In course two, I tightened things up by laying out the objectives in advance and taking care of major structure items, but I still tried to provide a lot of room, and let discussions go where they would. Since we were more focused, the results were somewhat better, but participation and interaction was still not at the level I believed we needed and student evaluations still indicated a desire for more structure and clarity.

**Course Three.** As a result of my course two experience, I made a major shift with course three by going to a high degree of structure. The class was relatively small. I came up with two major discussion questions each week and half the class were required to respond to each question. In addition, students were assigned to provide feedback to three people who had the other question. I rotated this so that over the semester, everyone provided feedback to everyone else more than once. The feedback would then sometimes lead to further discussion but from an assessment standpoint, their requirement was one response and three feedback assignments weekly. I did learn that I had to be careful with my comments. If I made a comment on a response, for example, that comment would become the school solution and influence the people providing feedback – in effect cutting off their critical thinking process. The quality of work was good and student evaluations indicated they really liked knowing exactly what was required of them.

**Course Four.** In course four we moved to Lotus Learning Space, which provided more technical options, including web access, and more functions within the course. I stayed with the approach of assigning questions and specific feedback responsibilities. This was a larger class, so I increased the number of discussion questions. In addition to responding to an assigned question, each student gave feedback to people who had responded to different questions. The only downside here was that the assignment scheduling began to get a bit complex. The scheduling becomes a little difficult when one must (1) ensure students aren’t providing feedback to people who had the same question and (2) ensure that feedback assignments rotate to different people throughout the semester. I adopted a
minimalist style, with a focus on ensuring that students were going down the right path, rather than trying to dazzle them with brilliant comments. I provided individual feedback messages commenting on responses and feedback quality, feedback on their individual assignments, and would of course respond to a problem, but not in the depth some others did. I would more likely point students to where they could find an answer for themselves. Again, I was pleased with the work of the students and students' evaluations of the course were very good.

Course Five. In course five we moved from Lotus Learning Space to a customised version of Lotus Notes. This was a most interesting class. One of the things that had concerned me was that while I was getting everyone involved and working with everyone else, I wasn’t getting the degree of reflection that I felt we ought to have in a graduate course. Since we didn’t have the option of the small graduate seminar, I decided to add a requirement to the responses and feedback that was called the definitive response. After receiving feedback, the students who had a particular question (in this course there were six weekly questions, each assigned to three students) had to develop and post a final answer. Since this is a heavy workload -- three tasks within a week -- I varied the format somewhat during the semester, and breaks in the routine proved welcome. Since I wanted the definitive responses to evidence some reflection and perhaps reconsideration, I tried to introduce the idea of critically appreciative feedback that would help those who had answered the questions expand their thinking. We were getting some good critical thinking in the responses, but not in the feedback. The feedback tended to be rather vanilla -- “I particularly liked this and that, nice job overall, keep up the good work”. One of the most interesting things to come out of this course was the reaction to trying to get students to be critical in their feedback. The term feedback seemed to represent a very value laden concept for some students and most of this group resisted doing anything that was not seen as positive and reinforcing. Again, I was pleased with the work and 90% of the evaluations were quite high.

Course Six. Following course five, I gave more thought to the critical thinking-reflection issue and came up with the R9 process which involves three cycles of reading, reflecting, and responding (see table 1.). A major take-away from course five was the use of the term feedback. I dropped it and instead now use the term critique. I stress that the students' task, more than anything else, is to help expand the thinking of the person who prepared the response, and they can't do this by saying "good job, keep it up". Rather, they must point out what they see as flaws, point out other perspectives, and suggest alternative ideas. The process as described was used successfully in my next distance course and in course six.

Course six presented a difference challenge in three ways. First, in adapting a process developed for on-line courses to an MBA course that meets once a week for two hours. Second, in adapting to a new platform, WebCT. Finally, the class had 37 people with 10 basically permanent groups that stay together through the programme. The groups varied in size from 3 to 5, which further complicated scheduling. I dealt with this by assigning questions by groups, but still with individual initial responses. Critique responsibilities were also assigned by groups, but were still individual work. I rotated the groups for whom one’s own group provided critiques. Rather than posting the definitive responses, each group provided a short presentation at the weekly class meeting. They had to point out their initial positions, what they learned from critiques, and what their final position was. They also had to mention the best critique they received. This was followed by a few minutes for questions and discussion. This was the first use of WebCT in our MBA programme. Within a few weeks I began to get student comments (both in person and via WebCT) that this was a good way of learning. Calling the task following initial responses a critique rather than feedback seemed to have the desired effect. While I occasionally had to nudge students about various aspects of their critiques, there was no resistance to the concept of critically reviewing responses. The class reacted favourably to the use of this process, and I perceived that considerably more real discourse and thinking was going on than in the lecture-based courses I had taught previously in the programme. A major difference was in seeing students offer considered positions, taken after they had done some thinking and after exposure to other perspectives, rather than just spontaneous positions taken and offered in the immediacy of the classroom meeting. Student ratings of the course were up from the preceding two years, which had followed a more traditional lecture and discussion format. (Note: Since course six, I have used R9 in two other face-to-face courses with excellent results -- both in terms of student ratings and my perceptions of the thinking and learning that was occurring.)

The R9 Process

The basic R9 process activities are shown in table 1 and in poster 2. The intent of the process is to provide a structure that takes students beyond just reading for retention and recall. It encourages them to think about the assignment contents (through question design), to think about and respond to others' comments, and then, in the
light of critiques and other responses, to reflect upon, rethink, and perhaps revise their response to the original issue raised by their question.

<td>Revise the response, in collaboration with others who had the question, determine the definitive response to the question, and post that response (or present, in a face-to-face class).</td>
</tr>
</tbody>
</table>

Using R9 in Distance Education Courses or On-Campus

It is important to explain the process clearly at the beginning, so that requirements and expectations are clear. Many students will not have used such a process before, and in particular, the idea of providing critiques to each other needs explanation. There is an advantage for the on-campus course here, since the course can be taken into the computer lab during the first meeting to practice the response and critique process with some very simple questions. It may take a few weeks for a distance education class to shake down. On the other hand, all but new distance education students will be used to similar software, and it is primarily the three read, reflect, respond cycles that need to be explained. Examples of how both a typical distance education week and how a typical on-campus course might be structured and scheduled are shown in poster 2.

Application Issues

The Use of Technology. Technology that effectively handles asynchronous communication in a bulletin board-type format is essential for the process, but this does not have to be particularly sophisticated. R9 has been used successfully with a graduate-level distance education course using a version of Lotus Notes software and in an on-campus situation with three different levels of courses using WebCT software.

Flexibility. There is more opportunity for flexibility in the process than one might expect. For example, by opening the weekly assignment sheets early, say the preceding Friday, those who want to do most of their work on the weekend can contribute to the definitive response from the current week and develop their initial response for the next week.

Scheduling. If the process is structured so that during the semester, (a) students will receive critiques from everyone in the class, (b) students will work with everyone else in the class in developing definitive responses, and (c) all students will have had responsibility for coordinating collaboration on the definitive responses, then scheduling is critical.

Questions. The questions are very important in order to promote critical thinking. They should require the student to think and perhaps question what the reading has to say, do some analysis, take a position, and support it. Most students handle the initial response issues fairly well.

Critiques. Critiques tend to be another matter. It may take a few weeks to get students into the flow of critically appreciative critiques — trying to help other students expand their thinking and perhaps see other perspectives. The on-campus instructor has an advantage here, with the opportunity for weekly face-to-face reinforcement of the type critiques that are needed. Grading. It is important that a significant part of the course grade be a function of successful participation in the R9 process. Participation in the process needs to be important enough that students know they cannot ignore it. Whether critical thinking and reflection is occurring is at least as important, if not more important, than the specific ideas developed. Grading should not inhibit expression in the process.

Role of the Instructor. Front-end work by the instructor is of course important in all courses, but perhaps even more important when using R9. Considerable preparation of the resources that will be needed in the software platform being used is required. Once class begins, one must be constantly monitoring responses and critiques, and
it is very important to say enough that students know the instructor is there. If, for example, marks are going to be
lost due to a superficial response or critique, the student should be told immediately via private message. The
primary public place for the instructor to offer comments and critique is in connection with definitive responses,
whether posted or presented in class. At that time, one can ensure key learning points are covered.

Strengths and Limitations of the Process

The R9 process is offered as one answer of how to increase critical thinking and reflection in teaching domain
knowledge-based courses. It can be a useful tool for increasing critical thinking and reflection, and improving the
quality of dialogue in both distance and face-to-face courses at the graduate level. It is to some degree a leveler in
that it minimises the ability of particular students to dominate or others to not participate. This has been useful when
integrating groups of students whose prior education has been in systems where the approach was focussed on
content recall with other groups of students who have had more exposure to a more critical, questioning approach.
While some students feel the workload is heavy, most seem to appreciate the course being clearly laid out and
knowing exactly what they have to do. This seems to be very important to degree-seeking adults who are working
time and may have families, and whose time for study is limited.

On the other hand, there are undoubtedly subject matter areas, as well as levels of students (for example, some
undergraduate levels) where this approach might not be appropriate. In addition, there will be students who want a
more free wheeling approach with less structure and who may become frustrated. Also, it is somewhat time-
intensive for the instructor, particularly as class size increases, and I have not yet discovered a way to adapt it for
really large classes.

Using Technology to Help Foster Critical Thinking and Reflection in Distance and Classroom Instruction: A Poster Presentation of the “R9” Process – Poster One Miniature

**Critical Thinking Defined**

"Being a critical thinker involves more than cognitive activities such as logical reasoning or scrutinizing arguments for assertions unsupported by empirical evidence. Thinking critically involves our recognizing the assumptions underlying our beliefs and behaviours. It means we can give justifications for our ideas and actions. Most important, perhaps, it means we try to judge the rationality of these justifications.” (Brookfield, in Mezirow [1987], p. xviii).

**Reflection**

Mezirow (1987) tells us that the three functions of reflection are to guide action, to give coherence to the unfamiliar, and to reassess the justification for what is already known. Schon (1987) stresses reflective practice. I want to see students progressing toward becoming the reflective practitioners envisioned by Schon, who think and rethink some of their positions and assumptions, and practice what Schon (1983) called "reflection-in-action" (p. 50).

**Perspectives on Critical Thinking**

1. The limited perspective of a highly focused problem-solving approach (i.e. a TQM manual).
2. The broader -- but still skill-based -- approach that is more about the "how and what" of critical thinking. This is more in keeping with the informal logic movement (Ennis, 1987; Kiersky & Caste, 1995; Quellmalz, 1987; McPeck, 1990).
3. A more “socially conscious” perspective. To use Alvesson’s and Willmott’s (1992) term, a "softer" approach (p. 432) that shows some concern for higher-order human needs.
4. Those perspectives that suggest the goal of critical thinking should be social emancipation. This latter position is more in keeping with the ideas of critical pedagogy and critical practice (Mezirow, 1990; Freire, 1970), and moves toward critical theory (Habermas, 1994; Foucault, 1994) and critical social science (Fay, 1987).

Publication Date: February 2002

II. REPRODUCTION RELEASE:

In order to disseminate as widely as possible timely and significant materials of interest to the educational community, documents announced in the monthly abstract journal of the ERIC system, Resources in Education (RIE), are usually made available to users in microfiche, reproduced paper copy, and electronic media, and sold through the ERIC Document Reproduction Service (EDRS). Credit is given to the source of each document, and, if reproduction release is granted, one of the following notices is affixed to the document.

If permission is granted to reproduce and disseminate the identified document, please CHECK ONE of the following three options and sign at the bottom of the page.

The sample sticker shown below will be affixed to all Level 1 documents:

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL HAS BEEN GRANTED BY

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)

Level 1

Check here for Level 1 release, permitting reproduction and dissemination to microfiche or other ERIC archives media (e.g., electronic) and paper copy.

The sample sticker shown below will be affixed to all Level 2A documents:

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN MICROFICHE, AND IN ELECTRONIC MEDIA FOR ERIC COLLECTION SUBSCRIBERS ONLY, HAS BEEN GRANTED BY

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)

Level 2A

Check here for Level 2A release, permitting reproduction and dissemination in microfiche and in electronic media for ERIC collection subscribers only.

The sample sticker shown below will be affixed to all Level 2B documents:

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN MICROFICHE ONLY HAS BEEN GRANTED BY

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)

Level 2B

Check here for Level 2B release, permitting reproduction and dissemination in microfiche only.

Documents will be processed as indicated provided reproduction quality permits. If permission to reproduce is granted, but no box is checked, documents will be processed at Level 1.

I hereby grant to the Educational Resources Information Center (ERIC) nonexclusive permission to reproduce and disseminate this document as indicated above. Reproduction from the ERIC microfiche or electronic media by persons other than ERIC employees and its system contractors requires permission from the copyright holder. Exception is made for non-profit reproduction by libraries and other service agencies to satisfy information needs of educators in response to discrete inquiries.

III. DOCUMENT AVAILABILITY INFORMATION (FROM NON-ERIC SOURCE):

If permission to reproduce is not granted to ERIC, or, if you wish ERIC to cite the availability of the document from another source, please provide the following information regarding the availability of the document. (ERIC will not announce a document unless it is publicly available, and a dependable source can be specified. Contributors should also be aware that ERIC selection criteria are significantly more stringent for documents that cannot be made available through EDRS.)
