Abstract Recently, attention has focused on developing methods for facilitating critical thinking in students. Scaffolding is a method that has been successfully used in many settings to support different learning goals. This study focused on the influence of scaffolding on critical thinking skills in a technology-mediated environment. The main research questions explored changes in participant use of scaffolding and influences on the evolution of critical thinking. A qualitative design guided data collection and analysis. Five graduate participants were purposefully selected from an online instructional design class and interviewed repeatedly over one semester. Major findings indicated that participant use of scaffolding moved from externally directed to internally relevant assimilation. Influences on the evolution of critical thinking included prior knowledge, reflection, feedback, project context, and perception of self as learner. Implications for research and practice are outlined.

Introduction

This paper describes a study conducted to explore the influence of scaffolding on critical thinking skills in a technology-mediated environment. With the recent increase in online education and Internet-based content, the development of critical thinking skills becomes more important, along with the development of methods for supporting critical thinking. Much attention has been focused on identifying and developing methods for supporting and facilitating learning in non-traditional environments. Scaffolding is one method that has been used in a variety of settings, ranging from one-on-one tutoring to traditional classrooms for supporting very different learning goals (Bliss, Askew, & Macrae, 1996; Graves & et al., 1996; Hogan & Pressley, 1997; Lepper, Drake, & O'Donnell-Johnson, 1997; Palincsar, 1986; Saxe, Gearhart, & Guberman, 1984; Wood, Bruner, & Ross, 1976).

Scaffolding was first defined as a process by which an expert supports a learner in the accomplishment of a task beyond the learner's individual capabilities, and then gradually fades that support as the learner becomes more competent in task accomplishment (Wood et al., 1976). Scaffolding has been used effectively in classroom environments for supporting the learning of reading (Palincsar, 1986), language (Roehler & Cantlon, 1997), mathematics (Schoenfeld, 1991), and scientific inquiry (Hogan & Pressley, 1997). In these environments, teachers interact with groups of students, providing them with appropriate support through modeling, questioning, or cued reflection and externalization of metacognition. Studies have shown that through such support and scaffolding, students gradually internalize cognitive processes and assume responsibility for and control of their own learning (Roehler & Cantlon, 1997).

Researchers have tried to broaden the availability and application of scaffolding by developing technology-mediated and technology-based scaffolding. Despite the limitations of computer-based intelligent systems in emulating the sensitivity and responsiveness of the human expert, computers were able to mediate and emulate certain facets of the scaffolding process (Chee, 1995; Guzdial, 1994; Kao & et al., 1996; Soloway et al., 1993). In most cases, these applications functioned as on-demand help systems and provided the learner with procedural and directive instructions for task completion.

Recently, a few technology-based scaffolding applications have been developed that address the internalization of cognitive strategies and higher order thinking skills. Reading Partner (Salomon, Globerson, & Guterman, 1989) focused on supporting the internalization of metacognitive strategies by providing intellectual and pedagogical scaffolding for seventh graders' reading skills. Despite the lack of fading, the continuous introduction of metacognitive questions and hints resulted in students' internalization of strategies and improvements in a near transfer task—writing.
The Web-based Inquiry Science Environment (WISE) (University of California at Berkeley, 1999), another prominent application, focused on scaffolding students' scientific inquiry and higher order thinking skills on the Internet. With the help of the software tools and scaffolding in the form of questions, students evaluated web sites and asked critical questions aimed at evaluating the utility of the site's content for a specific project. Empirical evidence indicated that scaffolding tools positively influenced students' critiques and their ability to ask critical questions (Slotta & Linn, 2000).

Research indicates that scaffolding of higher order thinking skills is best achieved through metacognitive hints and questions—directive guidance seems to engender an overt-dependence on scaffolding and reduces the capability of the learner to function independently (see for example, Kao & Lehman, 1997). Additionally, scaffolding must be overtly faded to encourage and identify the transfer of metacognitive strategies to related future tasks. Apart from techniques and implementations of scaffolding, internalization of cognitive strategies is also affected by context and task structure. Research indicates that students' ability to assimilate technology-based scaffolding is increased by providing goals and orientation (Oliver & Hannafin, 2000; Slotta & Linn, 2000).

Students' epistemological readiness and interests mediate both the use of scaffolding (Oliver & Hannafin, 2000; Sherman, 1994) and the ability to think reflectively and critically (King & Kitchener, 1994; Kuhn, 1999). For younger students, directive and instructive scaffolding may prove more effective because of students' naïve epistemologies and willingness to accept authoritative knowledge (Kuhn, 1999). For slightly older students, however, scaffolding in the form of Socratic and open-ended questions might prove more effective due to students' epistemological readiness to question and seek knowledge.

Research Questions and Design

Based on reviewed literature and studies and the purpose of the current study, three major research questions were addressed:

• How does student perception and use of scaffolding evolve?
• What processes and sources influence the development of critical thinking skills?

A qualitative research design was used to meet the purpose of the study and to address the research questions. The study was conducted in the context of a primarily online Instructional Design (ID) offered in the spring semester 2001 in a large Southeastern university. Within this online environment, scaffolding supported the performance of critical thinking tasks in ID. Data were mainly gathered by interviewing five purposefully selected graduate students within the course. Participants were selected through administration of the Cornell Critical Thinking Test (CCTT) Level Z test (Fisher & Scriven, 1997) and their willingness and ability to articulate their thinking and learning. Participant generated documents were used to cue recall during the interviews. Interview data were analyzed using the constant comparison method (Glaser & Strauss, 1967).

During the course, the students used a textbook as a primary source of content and instruction. In addition, systematic, deliberate, and static scaffolding was provided via course materials at five discrete intervals to coincide with the completion of specific class-based tasks. The scaffolding, designed collaboratively by the researcher and course instructor, was designed to facilitate deeper reflection, metacognition, and critical thinking for the execution of six class-related documents. Decisions about level and type of scaffolding were negotiated throughout the course, and scaffolding was gradually faded.

Students accessed the static scaffolding directly through the web page that described the assignment. Thus, the task was presented concurrently with the appropriate mode of scaffolding—Socratic questioning, modeling, or externalization of metacognition and reflection. The scaffolding provided for critical thinking in relation to Instructional Design was based on relevant literature in ID (Briggs, 1977; Dick & Carey, 1985; Smith & Ragan, 1993), critical thinking (Beyer, 1997; Ennis, 1987; Paul, 1990), and scaffolding (Hogan & Pressley, 1997; Rogoff & Wertsch, 1984; Vygotsky, 1978; Wertsch, 1984; Wood & Wood, 1996).

Data were gathered through two main sources: interviews and participant document artifacts, which included six assignments that were directly related to participants' individual instructional projects, and four concept maps generated at various stages by each participant. Participants were interviewed five times during the semester, at an interval of 2-3 weeks and during interviews, the concept maps and document assignments were used as visual triggers for participants to reflect on their meaning making process. Some participants also generated bi-weekly journals that detailed their thinking and experiences in ID. Also, participants posted their reflections about changes in their individual views of ID on the class bulletin board at the middle and end of the semester. Transcripts of the reflective bulletin board activities were used as additional document data, in conjunction with the reflective journals generated by some participants. The multiple sources of data also provided a source of triangulation and validity.
Major Findings
Use of Scaffolding

Initially, some participants perceived the scaffolding as directive and used the questions and examples as directions for task completion. For example, one participant said, "...it kinda coached me through the activity ... and I thought about what it was she [the instructor] really wanted you to put in there." A similar attitude was adopted by another participant who tried to "parrot the examples" in the beginning of the semester. Towards the middle of the semester, as participants became more involved in their instructional project, most began to perceive scaffolding as a guide to help them achieve their own special needs. Participants began to speak about the advantages of having a "framework ... to help you pinpoint where you need to focus on" and "prompts that [thinking] and that definitely helps." In most cases, the change in participants' perception and use of scaffolding was an acknowledgement of their individual needs and contexts. One participant admitted that she began to view the scaffolding in terms of its applicability to her project, and by extension, her life: "I'm beginning to say you know, how would this fit into my real life and what should I be concerned about getting from it and whatever."

Use and interpretation of scaffolding moved through three distinct phases—in the first, scaffolding was considered as directive instructions. In the second phase, scaffolding was used as a guide within participants' individual context. Scaffolding in the third phase was marked by interpretation and selection to suit individual needs. In the externally dictated mode, participants chose to implement the provided scaffolding literally and "answer the questions" or react in accordance to their perceptions of what the "instructor wanted." However, as participants became increasingly conscious of their individual contexts and goals, they began to perceive the scaffolding as a guide that allowed them to direct their thinking along appropriate and personally meaningful direction. Some participants used scaffolding in a customized manner from the very beginning and indicated that the customization was guided by relevance to their project goal. The other participants also indicated that they eventually changed their perception and use of scaffolding based on their individual project goals and needs. The findings of the study indicate that it is important to identify methods for alerting students to the function of scaffolding—i.e., to assist them in realizing their individual goals. In the current study, goal realization was an individual process occurring at different times. The importance of continuously defining and refining the learning goal during the scaffolding interaction is a key component of Wertsch's (1984) explication of scaffolding processes. Goal clarification has been identified as a keystone for success in the assimilation and use of scaffolding by students of different ages and in a variety of settings (see for example, Rogoff & Wertsch, 1984; Saxe et al., 1984; Slotta & Linn, 2000).

Influences on Critical Thinking

Five elements seemed to influence the evolution of critical thinking: reflection, feedback, problem context, perception of self as learner, and prior knowledge. Reflection emerged as a very important influence in the development of critical thinking. One participant often mentioned the value of reflection in changing her thinking, specifically with regard to the assignments and the necessity of looking beyond "predefined notions of how to do" things. Other participants acknowledged the novel role and the value of reflection in their activities as exemplified in the quote by this participant: "Basically I would say that reflecting is a new element that's coming into play and looking at details is not something I've had to consciously do ... and it's not something that comes naturally to me." Authors such as Kuhn (1999) emphasize that fostering metacognitive and reflective skills is of utmost importance in promoting critical thinking. Brookfield (1986) identifies reflection as one of the most "useful" tasks in helping people think critically. Consequently, those participants who engaged in reflection often and who valued reflection as a tool to promote their thinking were most likely to engage in critical thinking.

Seeking and reacting to feedback was another influence on shaping participants' critical thinking in ID. Participants often mentioned their higher regard for seeking feedback, or as one participant said: "...maybe I'm just more comfortable hearing the feedback." Feedback was rated highly by participants as a means to gather different viewpoints and as a way of becoming more "open to just different ideas or different approaches." McPeck (McPeck, 1990) cites feedback or "rational disagreement" (p. 52) as one of the primary methods for stimulating the examination of ideas. McPeck also recommends that teachers who attempt to facilitate critical thinking in their students must learn to move their teaching from more "didactic" to "discursive" modes of presentation. This approach is consistent with the findings of the study, which indicate that feedback served to refine participants' understanding.

For many participants, the exigencies of their individual project context appeared to influence the development and evolution of critical thinking. The more authentic and unstructured the problem context, the more likely that
individuals engaged in critical thinking. The two participants who addressed authentic, ill-structured problems for their instructional project acknowledged the importance of the integral nature of the project in their lives, and thereby the additional meaning and reflection gained from the experience. Research and theory offers two perspectives on these differences. King, Wood and Mines' (1990) research suggests that reflective, critical thinking is most often triggered by ill-structured problems rather than "well-structured problems" (Churchman, 1971). Two other participants who engaged in relatively well-structured projects that involved very little ambiguity indicated fewer instances of critical thinking.

Participants' perceptions of themselves as learners, as well as their perceptions of their role as learners, significantly influenced changes in their thinking. For example, one of the older participants indicated that she preferred to "mimic" the processes being presented and she consistently referred to her novice status as a hindrance for critical thinking. Another participant who characterized herself as a "creative" and "alternative" thinker, said that the analytical nature of thinking required within the course was not to her liking or style. These self-imposed conceptions of self as learner hindered critical thinking in the instance of these two participants. Brookfield (1986) suggests that adults' understanding of their learning styles, selves as learners, and patterns of learning is an important prerequisite for critical thinking. Learning styles are defined as "the characteristic and preferred way in which an adult engages in learning activities" (Knox, 1986, p. 20). Reflecting consciously on and understanding one's learning has two implications for thinking. First, an awareness of one's learning style allows an individual to select appropriate strategies for effective learning (Brookfield, 1986). In addition, such understanding can promote appropriate adaptation of learning styles to suit changed circumstances. For example, some of the other participants, while acknowledging distinct learning styles, mentioned that they tried to integrate their styles with the class requirements, and indicated higher levels of critical thinking.

The role of prior knowledge in shaping participants' critical thinking in ID was apparent in a number of instances. In the case of three participants, prior knowledge served as a basis from which to compare their current learning and experiences in the class. These three participants incorporated their prior knowledge and experiences into their understanding of ID almost from the very beginning. For one participant, prior knowledge served as a source of data for guiding and refining his thinking; for another, prior knowledge stimulated an acknowledgement of existing biases and the need to make a "conscious effort to displace yourself." In these instances, prior knowledge helped to activate a comparison of prior and current experiences and to stimulate additional thinking and reflection when an inconsistency was encountered. This finding is consistent with research on the role of prior knowledge in triggering additional reflection and the search for additional information (see for example, Baker, 1979; Pitts, 1994). In other instances, especially in the case of the youngest participant, prior knowledge conferred an authority to her thinking that impeded critical thinking and she said in explanation: "I know every aspect of it...." This attitude is consistent with research indicating that prior knowledge can give rise to counterproductive strategies such as assuming the validity of default knowledge (Phillips, 1992) or preserving information that supports one's beliefs (Klayman & Ha, 1987)

Relevance and Significance

This study has implications for different groups. First, practitioners and educators interested in developing critical thinking skills in their students might benefit from the results of this study in being able to identify how and why students choose to assimilate and use critical thinking skills when adequately supported by scaffolding. Second, using the strategies recommended in this study as a launching point, designers and developers of online or technology-mediated instruction might adapt and introduce more effective strategies for implementing scaffolding for critical thinking in such environments. Specifically, this study provides a starting point for those interested in designing and implementing scaffolding for critical thinking related to Instructional Design, and encouraging further research and design based on the results of this study.

Apart from practical implications, this study contributes some interesting theoretical perspectives on scaffolding and critical thinking. In literature on scaffolding, attention has been focused in two main areas: (1) identifying characteristics of an expert "scaffold" (see for example, Lepper et al., 1997; Saxe et al., 1984; Wood et al., 1976), and (2) identifying outcomes of the scaffolding interaction between expert and novice (see for example, Hogan & Pressley, 1997; Kao & Lehman, 1997; Salomon et al., 1989; Slotta & Linn, 2000). This study contributes to a missing perspective—the role of student characteristics in assimilating and using scaffolding. By identifying a few of the cognitive characteristics and beliefs that affect student use of scaffolding, this study offers a starting point for other researchers who are interested in further exploring the interaction of student characteristics and scaffolding.

A second area of theoretical contribution is offered in this study's description of the influences on development of critical thinking. Although students may be eminently capable of thinking critically, a variety of influences preclude the development and demonstration of critical thinking skills. The documentation and description offered in this study also offer a starting point for exploring and deriving theoretical frameworks that define the impact of student and context characteristics on the development of critical thinking.

Turning ICE into Icicle

Robert Sheehan, Department of Computer Science,
University of Auckland, New Zealand
r.sheehan@cs.auckland.ac.nz

Abstract: This work in progress, called Icicle, is a computing environment for children that is easy to learn and use. It is based on two principles: use interaction and feedback to elicit program descriptions from the users and maintain a close mapping between user actions, program commands and program representations. Children construct performers for the Icicle world and then train the performers to behave in particular ways. The training takes the form of a dialogue between the children and the system and uses direct-manipulation and programming-by-demonstration techniques to encode programs as animations.

The Icicle system came about following work on a programming-by-demonstration (Cypher 1993) turtle-graphics environment called ICE (Sheehan 1999). ICE was a successful experiment in that it was easy to produce programs within the environment that generated pictures, many of them with sophisticated effects. However children want to make games (Sheehan 2001), not just fancy pictures, and there were some things missing from ICE if it was going to be used to produce games and other forms of interactive behaviour.

Programming by Interaction

The ability to cope with interactions was missing from ICE. The only object to control was the turtle. In Icicle, interactions are at the heart of the system; this includes interactions between a child developer and the system, between different objects in an Icicle program and between a child player and an Icicle program.

The first thing children have to do when presented with a blank world in Icicle is to make a performer. Performers are the object actors in the Icicle world. They have shapes, behaviours and state information. Programs in Icicle are represented by the rules associated with performers.

When designing a performer’s appearance children can initially choose from three differently coloured simple shapes: an octagon, a square or a triangle. Rather than relying on professional clip-art, children must construct their own shapes using a simple drawing environment by modifying these initial shapes. Each performer can have as many different shapes as the children want. As Icicle programs run, performers can morph from one shape to another. This provides a remarkably flexible system for smoothly animating behaviour.

Once a performer has an appearance it can be placed in the Icicle world. A drag and drop of a shape from a performer window places a new instance of that performer in the world. The system immediately checks to see if there is a default behaviour for this new performer and if there isn’t it asks the child, “What should this performer normally do?”.

The most common behaviours for performers can be demonstrated using direct-manipulation. In particular the user can drag the performer around the screen. This results in turn and move behaviours being learnt. Similarly a different shape can be dragged onto the performer in the world – this action is interpreted as requesting a morph from the present shape to the new one. Handles on a performer can also be dragged indicating a zoom instruction.

When constructing a rule the user can undo any mistakes and demonstrate new instructions. As well as removing instructions from the rule, the undo command restores the performer to the state it was in before it was moved or morphed. When the user is satisfied with a sequence of commands he or she closes the dialog box. Turning the world on makes the performer repeatedly execute its default behaviour. If the user drags more copies of the performer on to the world they will automatically begin executing this default behaviour.

When a new interaction, such as a collision between performers occurs, and there is no existing rule corresponding to this situation the system once again asks the child to demonstrate the required behaviour. The user is asked to provide instructions for each performer involved in the interaction.

Users can be the source of interactions as well. If a key is pressed when the world is running the system checks to see if any performers have a rule corresponding to the key press. If so the appropriate instructions are executed, if not the user is asked to choose a performer and define a rule for the key press. Thus users can influence the behaviour of performers as the world runs, obviously necessary when implementing games.
Representation of the Rules

One of the problems in programming-by-demonstration systems is providing a listing of the generated program that is useful to the user (Myers & McDaniel 2001). Supplying the listing of a conventional textual program is not acceptable for novice users, in this case children. The connection between a textual program listing and the actions of objects on the screen is not clear enough. There is a gap in the novice user's understanding between the textual representation and the effect produced.

The Icicle system minimizes this gap by using animations of the action's results as the program listing. In terms of the cognitive dimensions (Green & Petre 1996) there is a true closeness of mapping between the program code and the desired behaviour - they are virtually identical. The conditions which cause the rules to activate are also animated, e.g. two performers colliding. Even for children unable to read the descriptions beneath each animation, it is clear what is being represented here.

In order to increase the perceived connection between the program code and the results of that code, changes to the code are reflected immediately in all the performers active in the world. Similarly changes to the shapes and colours of the performers in the drawing editor are shown simultaneously. The world can keep running while new performers are created and added to it or while old performers are modified. This produces a sense of liveliness that hopefully makes the performers appear more like active agents in the world (Travers 1996).

The fact that performers can only change their shapes by morphing is also an attempt to convey a sense of concreteness about each performer. A performer's shape is part of what the performer is and even though it can change shape it does it gradually in a way that preserves its continuity. When a child single steps the world forwards or backwards, it is easy to see the gradual change from one shape to another.

Parallel Processing

All performers execute their rules in parallel. When an interaction occurs the performers involved in the interaction change to run the interaction code. After the interaction is dealt with the performers return to their default behaviours. This parallel processing is not the only parallelism the system provides.

When a rule is made that comprises several instructions, such as a move, a turn and a morph, it is possible to make two or more of the instructions occur in parallel. This is useful if the user wants the performer to move along a curved path or to change shape as it moves.

Changing from sequential to parallel is simple; the user drags one instruction on top of another. The rule animations merge to show the result of the parallel instruction e.g. moving and changing shape simultaneously. Preliminary testing shows that this is easy for children to use, how much they comprehend is as yet unknown.

Similar Work

Different aspects of Icicle can be seen in a variety of children's programming environments or programming-by-demonstration systems. Klik & Play was a commercial product which turned into The Games Factory and uses interactions to ask for rules. Stagecast Creator (Smith & Cypher 1999) and Agentsheets (Repenning 1993) maintain rules which are fired when preconditions are met.

On-Line Tutorials to Move Students from PC/Windows to Unix

Mark Sherriff and Jennifer Burg
Department of Computer Science
Wake Forest University
Winston-Salem, NC 27109
burg@cs.wfu.edu

Abstract: The majority of today's college students enter their first computer science course with a working knowledge of computers, primarily PC/Windows based. Their experience with PC systems as their "native language" is then reinforced in the many universities that require laptop PCs or distribute them to incoming freshmen. Teaching students the Unix environment thus has become more difficult as students cling to the operating system that they have grown comfortable with. This paper describes a tutorial program intended to move students from PC/Windows to Unix. The self-paced tutorial lessons are written in Macromedia Director and can be accessed from the students' personal computers on the Web. The lessons begin with basic Unix commands executed through a simulated terminal window, provide remote access to an actual Unix terminal window for "real" feedback, direct students to a Unix lab at our university, proceed through more advanced Unix utilities, and offer feedback through graded quizzes.

The Problem

The growing number of laptop-equipped students in today's universities is a mixed blessing for the computer science discipline. Students entering our courses believe themselves to be quite computer-savvy, but most have been brought up on PCs/Windows and have a natural reluctance to move out of the environment that has grown so familiar to them. Their portable computers also spoil them on working in their dorms and apartments, and Unix labs that used to bustle with student activity are now mostly quiet. Most academic computer scientists, however, continue to see the value in teaching students the Unix operating system, and for many good reasons – its robustness; its groundbreaking position as a system for multitasking, networked, and heterogeneous computing environments; and the source-code transparency that lends itself to learning operating system concepts and implementation. A second problem in introducing students to the Unix environment is that user-level skills don't seem worthy of classroom time, yet we want our students to come out of our courses with a certain level of proficiency in using the operating system. We need a way to ensure minimum competency in Unix lab skills without sacrificing classroom instruction time to recite simple Unix commands that students could learn on their own. Thus, the purpose of our tutorial system is to wean PC-devoted students to the Unix environment by letting them get their first glimpse of it through their own personal computers, and to do this in a self-paced tutorial system with student accountability via quizzes and a database that records student activity.

The Tutorial

Our tutorial system is accessible from the Web at http://www.cs.wfu.edu/~burg/UnixTutorials/Tutorial.htm. We have so far implemented and tested six tutorial lessons: Lesson 1. Unix and the Unix Lab; Lesson 2. Getting Started; Lesson 3. Basic Unix Commands; Lesson 4. Creating Text Files; Lesson 5. Using Unix from Your PC; and Lesson 6. Compiling and Running C++ Programs

To clarify the difference between working directly on Unix-based computers and remotely from PCs, the first tutorial gives the students a visual tour of the Unix lab at their university. (This is the only lesson

---

specific to our university and its labs.) Students learn where the lab is located, how to get access, and how to get an account on our system. This lesson also touches on what an operating system is and how Unix relates to Windows in the computing world, along with a quick explanation of the hardware and software that we have for them to use.

**Lesson 3: Basic Unix Commands**

Command: **mv**

*Use:* Renames a file or moves it to a new location.

Try It below! Type **mv oldname newname** to rename a file. Replace oldname with the name of the file you are renaming, and replace newname with the new name.

Figure 1. Basic Unix Commands

The second and third lessons, covering basic Unix commands, are presented by means of a simulated Unix terminal window. The students are given practice with simple Unix commands in a controlled environment where errors can be checked and feedback can direct their learning. A character called "Floppy" (reminiscent of "Clippy©" from Microsoft Office) guides the students through the lessons. Lesson 4 discusses the use of text editors in a Unix terminal window. We chose to use the vi text editor. While this may not be the easiest to learn, it has the advantage of not requiring X-Windows. The students are guided step-by-step throughout the process of using the editor. In Lesson 5, we begin to wean the students from their PCs by showing them how to get remote access to an actual Unix terminal window. They are given directions on downloading and installing a remote login program, which then opens a terminal window alongside the tutorial. At the end of Lesson 5, students are given a series of exercises to try in the Unix terminal window, some of which will have them investigate new commands, command options, and error conditions more closely. For example, they are asked to remove a directory that still contains files, or they are asked to find an option for the *ls* command that lists even "hidden files." Lesson 6 introduces the use of compilers. C/C++ is chosen as their introductory language since it is the language most closely related to the Unix operating system.

**Quiz 3: Basic Unix Commands**

*Question 4*

What is the difference between *rm* and *rmdir*?

- A. one changes directories, the other deletes new ones
- B. one deletes files, the other deletes directories
- C. one lists files, the other lists directories
- D. one logs you in, the other logs you out

Current Answer:

Figure 2. Quiz 3

Each lesson ends in a 10-item quiz. At the end of the quiz, the students can, if they choose, step through the items they got wrong and see the correct answers. The quiz scores are written back to a database for the professor's reference.
Abstract: TALENT (Teaching And leading for Educational Needs with Technology) is a 2000 PT3 Implementation grant. Besides faculty and K-12 teacher training through focused workshops and weeklong institutes, TALENT has taken an innovative approach in creating 'triads' consisting of a preservice teacher, a K-12 master teacher, and a university supervisor, who function as a learning community. This learning community spans two parallel activity systems: the university and the school in which the preservice teacher is placed. The project is discussed using the framework of Activity Theory, which can clarify activities and add predictive validity to TALENT's grant efforts.

Background

TALENT (Teaching And Leading for Educational Needs with Technology) is a 2000 Preparing Tomorrow's Teachers to Use Technology (PT3) Implementation grant funded by the U.S. Department of Education. Co-directed by Bohlin, Chiero, and Harris, TALENT's purpose is to infuse instructional technology into the teacher preparation program at California State University, Fresno (CSUF). The project's overarching aim is for teacher-candidates to complete their credential programs with the knowledge and understanding to deal with the digital needs of diverse, limited English-speaking, high poverty, and rural students in the K-12 schools in which they intend to teach.

In order to empower all educators in the teacher preparation program - including university faculty both in Education and in other departments where teacher candidates take their undergraduate and subject area courses, K-12 master teachers, and university supervisors of student teachers - TALENT designed, developed, and delivered weeklong institutes and full day workshops. Topics were tailored to the participants' particular knowledge, skill, and interest level, and to their expressed needs. Typical tools taught ranged from PowerPoint, Web research, and Inspiration to digital video and virtual reality. K-12 teachers were trained along with university faculty in the institutes, and with university supervisors in the workshops. Thus, there was cross-fertilization of ideas among these three populations in the training programs (Fig. 1).

TALENT as an Activity System

In both of these sets of professional development activities, the project directors envision learning as social construction of knowledge within a community of practice. Learning is situated in authentic activities, and there is plenty of time for group
discussion and reflection to apply newly acquired knowledge and skills to both the university and the K-12 classroom. Moreover, the presenters explicitly model student-centered learning and student creation of projects.

There is a rich base of social learning theory, beginning with Vygotsky (1978) in the Soviet Union. For example, Lave (1991) envisioned knowing, learning, and cognition as social constructions, expressed in actions of people interacting within communities of practice. Kuschmann (1996) coined the term "computer-supported collaborative learning" to describe learning communities that engaged in authentic, knowledge-building tasks supported by electronic interactions. Tavalin and Gibson (Sherry, Billig, Tavalin, & Gibson, 2000a, 2000b; Sherry & Tavalin, 2000) facilitated the use of online sharing of digital art and music files within a community of experts, had students post their products to a public audience, and then had the students selectively filter the ensuing feedback for the purpose of revising and refining their work. Carroll (2001) extended this notion to the entire PT3 grant initiative, in which electronic interactions among teachers and learners help to foster online communities of learners. He considered schools – including schools of education as well as K-12 schools – as connected learning communities of teachers and students, in which some participants were expert learners and others were novice learners, sharing information, supporting one another’s learning processes, and constructing a common base of understanding and shared skills.

Engestrom (1996, 1998) pushed the limits of these viewpoints by envisioning communities of practice as Activity Systems in which individuals intentionally used tools (or technologies) to create or transform objects or concepts in order to bring about a desired outcome. In an Activity System, any given individual’s actions take place within a sociocultural framework that includes the community of which the individual is a part, together with the norms and conventions of use of those tools, and the social roles or division of labor that characterize individual actions within local collective activities. The basic difference between traditional social learning theory as characterized by Lave and Wenger (1991) and Engestrom is Activity Theory's emphasis on the transformational nature of collaborative endeavors. "Activity theory suggests that collective developments occur when, through their actions, people reinterpret their environment, rebuild their activities, and reconceive of themselves (Blackler, Crump, & McDonald, 2000, p. 296)."

It is interesting to note the striking parallel between Engestrom’s depiction of an Activity System and the process that may be occurring in the TALENT project regarding the adoption and use of instructional technologies to support teaching and learning. Moreover, the current work of Engestrom (2001) and his colleagues is now focusing on parallel Activity Systems, such as HMOs and hospitals, that share a common goal: to preserve and improve the health of individual patients. In TALENT, the university teacher preparation faculty and the teachers in the cooperating K-12 schools can be considered as a pair of parallel Activity Systems with a common goal: to foster good educational practice so that all children can learn. The learning community model links these two Activity Systems through the university supervisors and teacher candidates, (Fig. 2).

As typically takes place within an Activity System, TALENT introduces new tools to the university faculty and to the K-12 master teachers to accomplish two planned outcomes: restructured, technology-infused courses within the university, and technology-infused lessons within the K-12 schools. For the faculty member or teacher who becomes interested enough in the new tools to acquire more knowledge about their potential uses to enhance instruction, to develop a positive attitude toward incorporating them into their own practices, and to actually make the decision to implement technology in the classroom, this is only the beginning. Each trainee must go through a learning/adoption trajectory (Sherry, 1998) to gain the necessary comfort, confidence, and competence to do so. This is the purpose of the institutes and workshops and of the continuing technical and collegial support provided by the TALENT leadership, staff, and teaching community.

Besides gaining the expertise and knowledge to use new tools to enhance instruction, there is a second order effect that TALENT hopes to bring about — increased modeling of promising practices for teaching with technology, by both university faculty and K-12 master teachers, for their respective teacher candidates. For TALENT to succeed, the project directors may wish to consider fostering the coaching and modeling process among its trainees, just as student-centered learning is explicitly modeled within the institutes. However, since the master teachers are not paid for their efforts, and since the Office of Field Placement does not wish to discourage an otherwise qualified person from being a master teacher, this is a mediating factor that could serve as an inhibitor for K-12 teacher modeling. It may be fruitful to contemplate discussing this issue with master teachers because modeling could
help to empower teacher candidates. Moreover, the extent of modeling the use of technology for teacher candidates at field placement sites represents one of the research areas in the national evaluation of the PT3 grant initiative. Since these activities take place within a sociocultural context, the outcomes—technology-infused instruction—generate a "ripple effect" within each Activity System (Fig. 3 & 4).

**Figure 3. K-12 Activity System**

**Figure 4: University Activity System**

**Changing Norms**

Rules, norms, and beliefs define the culture of an Activity System. Let us focus on the cultural norms within the university and the K-12 environment. Wilson and Myers (2000) state, "Using a tool in a certain manner implies adoption of a cultural belief system about how the tool is to be used." For example, if the norm in a specific academic department at the university is to use closed-answer tests that can be scored using scantrons, and if this continues to make a professor's day to day tasks relatively easy, then new tools and assessment strategies that make his/her job harder will not be used. They have no relative advantage over the status quo. Moreover, they require extra learning and extra work that could be better devoted to teaching and research. On the other hand, if the norm within that department, say, anthropology, is to collect data from primary sources via observations and interviews, then the use of digital video could make his/her work more fruitful. Additionally, video case studies could be shared and discussed with university students, and could become part of a living archive of the community’s culture. In that case, chances are that the professor would continue to explore the use of digital video because it adds value to his/her instruction. Moreover, if other educators within the department can observe the improvement in the professor's instruction, and its effect upon the university students, then the use of digital video could very well become the norm within the department.

Besides observability, Rogers (1995) lists compatibility with potential adopters’ needs and values, relative simplicity, the ability to experiment with an innovation on a limited, risk-free basis, and relative advantage over the status quo as facilitators for innovative concepts, processes, and products. In a discussion following a training session in the January 2001 institute, three faculty members engaged in the following conversation, discussing the relative advantage of using digital photography for university students’ products:

*I'm thinking about maybe teaching some of my history students about how to make a little film.

I think that’s a good thing there. You're mentioning how you would attempt to use it. How would any of the people in the room here intend to use it, even what you have learned within the last three days here?
Well, this just adds a whole other dimension to [student projects]. There are all kinds of cultural events going on all over Fresno. Send people out with a camera and equipment, and a video camera might be a little easier. Go to the events and put together...a total essay on PowerPoint using the digital images, or a short introductory, maybe 5 to 10 minute short film on cultural events. That would be a no brainer!

The same holds true in the K-12 school situation. National surveys (CEO Forum on Education and Technology, 1999; NCES 1999a, 199b) indicate that students are more adept at using interactive technologies than their teachers. Technology is becoming the norm for school children. As the use of Internet searching and PowerPoint presentations by children increase, there is a chance that those tools will become part of "the way we do things around here" within the school setting. Technology-savvy children will tend to drive learning in their teachers as well. This is especially true if greater depth of research and more sophisticated, interactive presentations will result in greater achievement for the children. RMC Research Corporation's evaluation of several PT3 and Technology Innovation Challenge grants provides evidence from observations, interviews, and focus groups with faculty, K-12 teachers, and students, which have shown that both of these outcomes are common.

In the case of TALENT, activities are focused on changing two sets of norms. At the university, the new norm would be to focus instruction on the new California state standards for teacher credentialing, which are echoed in the ISTE/NETS standards for educators. At the K-12 schools, the new norm would be a greater focus on technology-infused, student-centered learning. However, this is moderated by the schools' focus on measuring student achievement by their performance on the Stanford 9 test - an external factor over which TALENT has no control.

Changing Roles

Its division of labor - the generally accepted roles of its members - defines the social structure of an Activity System. Generally, teachers are considered experts while students are considered learners. However, this role structure is called into question when students have greater comfort, confidence, and competence with technology than their teachers do, and are able to use tools such as word processing, concept mapping, database searching, graphing calculators, interactive mathematics applets, Web search engines, graphic art, and digital video effectively to increase their academic performance.

Consider the self-perceived role of the teacher. If that role is to transmit information, then word processing and PowerPoint will suffice, and other tools are considered unnecessary. Moreover, if a teacher is concerned about the validity of information on the Web sites that his/her students are citing in research papers, and considers that open-ended searching could jeopardize his/her role as the expert in the classroom, then there is no reason for a teacher to support such online activities. But if the role of the teacher focuses on creating a rich environment for active learning in the classroom (Grabinger, 1996), then he/she would encourage the students to use the full range of current technologies. Such activities, in turn, transform the role of the teacher to a co-learner and co-explorer. This is indeed the case in an elementary school where one of TALENT's K-12 master teachers has his second through fourth grade classes use digital video to capture learning experiences and present them to other teachers, parents, and the entire school community.

A sudden reversal of traditional roles can cause discomfort and a disturbance in an Activity System. Brown and Palincsar (1989) considered cognitive dissonance and its ensuing discomfort to be the driver of learning. If the disturbance caused by a role reversal creates learning and makes life better, then it will be sustained; else the system will reject it and return to stasis. For example, at a high school in Vermont that participated in The WEB Project, one student became the school's acknowledged expert in digital editing. His portfolio gained for him a four-year, all-expense paid, scholarship to a leading university. Subsequently, more students became interested in digital editing, and similar activities still continue at the school. As a counter-example, consider a tenured professor who considers him/herself a "stand-up lecturer", as mentioned by one of the TALENT trainees during a discussion in one of the training institutes. This individual was interested in using PowerPoint to enrich lectures with slides that illustrated historical and artistic trends. True, this is using technology, but it does not create a student-centered environment, nor will it change the role of the professor. As a result, our fear is that his/her students will leave the university teaching as they have been taught -- as transmitters of information, rather than as creators of technology-rich environments for active student learning.

In the case of TALENT, there was a wide range of potential changes in roles, with several professors writing mini-grant proposals to restructure their courses to include more university student use of technology. As a whole, the university supervisors perceived technology as useful tools for their preservice teachers more often than did the technology-savvy K-12 master teachers, who primarily saw technology as a teacher-centered tool. However, the master teachers who co-taught several of the TALENT training sessions countered this trend, often presenting and discussing products that their K-12 students had created.

The use of technology-focused learning communities would also result in some role changes. In a learning community, each of the individuals would be a co-learner and a co-contributor, constructing knowledge as a coherent team, and serving as an interface between the university and the K-12 environment. A potential outcome of the community might be a few lessons that were relevant and appropriate for the teacher candidate's classroom, together with the necessary resources and documentation.
that constitute part of a teaching unit. Another possibility would be a videotape of the teacher candidate demonstrating a promising practice for teaching with technology in the K-12 classroom. These videotapes could then be used to spark discussions within the triad. They could also be archived and used as exemplars within the teacher education program.

Changing the Community

Besides norms, rules, and roles, every Activity System has structures and boundaries that self-identify it as a system. At the university, an important structure is the criterion used for review, tenure and promotion. If a university's structure supports technology innovation with incentives like release time, extra pay, or some other form of recognition for a faculty member's effort, then the chances that more tools will be used increase.

At CSUF, there is a Center for the Enhancement of Teaching and Learning (CETL). This organization provides mini grants for faculty members who restructure curriculum in some innovative way that enhances instruction or assessment. At the end of the January 2001 TALENT institute from faculty and teachers in the social sciences, five professors wrote mini-grant proposals for restructured syllabi; all five proposals were funded. Based on this record of success, six faculty members in the June 2001 institute for faculty and teachers in the arts, music, and humanities also expressed an interest in doing likewise. Likewise, faculty members wrote two mini-grant proposals following the mathematics and science institute in July 2001.

Another distinctive feature of CSUF is its tenure and promotion process, which rewards innovative teaching practices as an element of professional scholarship. Moreover, the Provost has an annual award related to outstanding teaching with technology, which recognizes and supports the work of TALENT. If such efforts continue to be supported by the university, then the vision of the PT3 project at CSUF may well be realized.

Driving Change in Activity Systems

Two interesting research questions emerge from studying TALENT: By what process does change in an Activity System take place? And how does this differ for connected, parallel Activity Systems? Engestrom's reply would be something like this: "Disturbances within and between Activity Systems are the driving force for growth and change." When these questions were posed at the 2001 AERA conference, one of Engestrom's peers (Barab) replied, "The direction of change depends on who holds the power." Thus, further investigation into these two questions revolves around empowering the agents within each Activity System to drive change, and empowering those who reside at the intersection of two parallel Activity Systems to moderate change between the two connected systems. Shifting the balance of power created disturbances, and "As disturbances become evident within and between Activity Systems, participants may begin to address underlying issues and to create new learning." (Blackler, Crump, & McDonald, 2000, p. 281)

In conducting case studies of PT3 grantees across the U.S., we have found that there is no a priori direction for bringing about change in either a university's teacher preparation program or the field experiences of its teacher candidates at associated K-12 schools. For example, in teacher preparation programs where strong leadership resides within the school, college, or department of education (SCDE), it is the SCDE that drives change within the university and at the partner K-12 schools. In SCDEs with a Professional Development School (PDS) structure, or with schools that have some of the characteristics of a PDS, it is the K-12 teachers who often drive the change - whether inservice or preservice.

In the case of TALENT, it is the project directors, technical support people, and K-12 master teachers who drive change, while the university system is the recipient of the change, as intended by the project directors. This quotation from a veteran professor illustrates this trend:

> Quite frankly, the issue is, are we doing anything for [the students in the teacher preparation program]? I'm a traditional lecturer, and we look at what they're doing in the high school. Sometimes I have to wonder, is what I'm doing - even though I'm good at it - is it really pertinent to what they're teaching? I'm wondering what their students think, who are doing some of these really creative things such as PowerPoint...what do they think of what they learned in our classes? How useful that is? I've given them all sorts of information...maybe the younger people know how to do things that are innovative, people doing things out there in the high school...I mean, I feel like I'm in the dark ages!

However, the direction of change could easily be reversed, once the university faculty members begin teaching their restructured courses throughout the teacher preparation program, and the teacher candidates begin to carry their newfound expertise and skills into their student teaching experiences. Moreover, learning communities that link the university Activity System with the K-12 Activity System could change this whole dynamic by sharing information between the K-12 schools and the SCDE. This is a fruitful area for further investigation that could both clarify and add predictive validity to TALENT's grant efforts.
Project TALENT learning communities are currently engaged in joint activities that will be completed by the end of the current academic term. Preliminary findings will be presented at Ed-Media.

An Exploratory Study on the Effects of Learner-Controlled Sequencing and Advance Organizers in a Web-Based Environment

Vincent E. Shrader, Ph.D.
Western Governors University
United States of America
vshrader@wgu.edu

Abstract: This exploratory study investigates the effects of advance organizers and learner-controlled sequencing in a Web-based learning environment. This study used a 2 x 2 factorial, posttest only design. The two independent variables were learner-controlled sequencing and advance organizers. The two dependent variables were students' ability as measured by scores on the posttest and time spent completing (a) the instructional materials and (b) the performance test. The treatments were four Web-based tutorials designed to teach students how to produce simple Web pages using Hypertext Markup Language (HTML). The analyses showed that neither learner-controlled sequencing nor advance organizers affected student test scores. However, the results revealed an unexpected effect on the time students spent learning and applying new material. The study revealed that those who consistently took the least amount of time were students using program-controlled sequencing with advance organizers.

The Study

This study investigates the effects of advance organizers and learner-controlled sequencing in a Web-based learning environment. An advance organizer is defined by Ausubel (1963, pp. 81-82) as "appropriately relevant and inclusive materials" introduced in advance of learning which functions to provide "ideational scaffolding" for the stable incorporation and retention of the more detailed and differentiated material to be learned. For this study, the advance organizers are in the form of short paragraphs serving as metaphors that liken the components of a web page to that of a written paper or report.

This study used a 2 x 2 factorial, posttest only design. The two independent variables were learner-controlled sequencing and advance organizers. The two dependent variables were students' ability as measured by scores on the posttest and time spent completing (a) the instructional materials and (b) the performance test. The treatments were four Web-based tutorials designed to teach students how to produce simple Web pages using Hypertext Markup Language (HTML).

The topic of instruction was chosen on the basis of its unfamiliarity to the sample population. Only one out of 63 students in the same class surveyed in a previous semester had ever created a Web page. Since one of the independent variables of the study was the use of advance organizers, unfamiliarity of the material was an essential criterion. According to Ausubel (1960, p. 268), advance organizers are designed to "facilitate retention in areas of knowledge new to learners." Using an unfamiliar topic helped ensure that all students started from approximately the same baseline in learning the material.

The subjects for this study were 74 pre-service elementary and secondary teachers, 71 of whom were female between the ages of 19 and 23. All 74 students were enrolled in a technology course at a large university in the intermountain west. The study was introduced and described to students during regular classroom meeting time. Students were asked to volunteer to participate, and all those who consented were directed to go to the computer lab where they were randomly assigned to one of the four experimental groups approximately equal in size.

The posttest was a performance-based activity where the students were required to produce a Web page according to a set of criteria. A lab assistant recorded a rating for each student based on the specified criteria. This rating was used to determine student performance. In addition, each student completed a time log that indicated the time spent working on each assignment and the posttest. The time log was designed to determine if there was a significant difference in the amount of time spent between groups. Two-way ANOVAs were conducted for each dependent variable to analyze the data.
The Findings

The analyses showed that neither learner-controlled sequencing nor advance organizers affected student test scores. Whether analyzed separately or together, learner-controlled sequencing and advance organizers failed to produce significant improvements in posttest scores. Average mean scores were nearly identical for the four experimental groups. However, students who were given program-controlled sequencing took significantly less time (13 percent less) to complete the instructional materials than students who were given learner-controlled sequencing. These results suggest that program-controlled sequencing significantly reduces the time students spend learning new instructional material. In addition, students using advance organizers completed the performance test in 15 percent less time than students not using advance organizers. These results suggest that although performance scores are not affected, advance organizers have a positive effect in reducing the time students spend applying newly gained knowledge.

Conclusions

Although learner-controlled sequencing and advance organizers failed to produce more effective learning (i.e., higher test scores), these variables yielded an unexpected effect by producing more efficient learning. Program control produced more efficient learning by reducing the time students spent learning new material. Advance organizers produced more efficient learning by reducing the time students spent applying the newly learned material in a performance test. Students who consistently took the least amount of time were those using program-controlled sequencing with advance organizers. When compared to the group taking the most time, this group was 20 percent faster learning the instructional materials and 25 percent faster completing the performance test.

What are the implications of these results in educational practices? The author postulates that the combined use of program control and advance organizers can lead to significantly reduced instructional and testing time in a Web-based learning environment. The combined effect of program-controlled sequencing with advance organizers produced the same performance test results as any other combination in the 2 x 2 factorial design used in this study. The benefit is in the time it takes to obtain those results, which in this study was significantly less. When considering the proliferation of Web-based instruction and training costs increasing in the future, the implications are significant in educational and business settings or anywhere that time is a highly valued resource.

Are the Promises of Online Assessment Being Proved in Practice?
A case study into what conditions should be met in order to use online assessment successfully

Dr. E. Sjoer and Drs. S.M. Dopper
Delft University of Technology
Faculty of Technology, Policy and Management
Centre for Education and Technology, Delft, The Netherlands
E.Sjoer@tbm.tudelft.nl S.M.Dopper@tbm.tudelft.nl

Abstract: This paper describes the way teachers at Delft University of Technology make use of the new online assessment tool, called Etude. In order to judge the extent to which the benefits of online assessment will be achieved, a checklist was developed. Results show that lecturers as well as students appreciate the possibilities of online assessment, but an educational guidance program will be necessary in order to benefit optimally from the educational opportunities of online assessment.

1. Introduction
Delft University of Technology (DUT) started the development of a new online assessment system, named Etude, in 1996. The system became available to the teaching staff in September 2000. The objective for developing the Etude system was to offer teachers one system that is supported and maintained centrally. Etude is an item-banking program that provides for item entry and storage, test creation, online testing, scoring, reporting and analysis of tests. In earlier papers we described the completion and functionality of Etude (Van de Ven, et al, 1999), and reported about the use of the system in two pilot projects (Dopper and Van de Ven, 2001). At the moment of writing this paper, Etude is used at 17 different courses at DUT.

This paper offers an outline for evaluating the use of online assessment. We will identify the potential benefits of online assessment with Etude and describe the conditions for achieving these. This will result in a checklist used to determine whether teachers will realize the benefits of an online assessment system or not. We analyzed the way the present users at DUT have implemented Etude in their (online) course, based on interviews. One of these cases will be described in more detail and the results of the appreciation of students of two of the identified benefits will be presented. Finally, we will answer the research question: is the way in which Etude is used by the present users appropriate to realize the benefits of the system?

2. Potential benefits of Etude and conditions to reach them
We have divided the potential benefits in three sections, i.e. storage of items (2.1), item entry (2.2) and taking a test online (2.3). This division is based on two main functions of online assessment systems: building and maintaining an item bank, and students taking a test online.

2.1 Storage of items
An item bank is a collection of test items that may be easily accessed for use in preparing examinations. Good item bank management enables efficient and effective generation of tests and efficient re-use of items. To achieve these benefits, it is important that items are not stored in the item bank in an arbitrary order. In order to retrieve items as necessary to make revisions or to create a test, items have to be coded (Ward and Murray-Ward, 1994). In Etude the following codes can be used: key word, subject matter, difficulty level, literature, and objectives. Content codes are preferably based on objectives. Once a coding scheme is set up, there should be no modification in the coding scheme unless the entire bank is recoded (Ward and Murray-Ward 1994).

2.2 Item entry
Most of the online assessment systems on the market have a great variety of possibilities to design items, so does Etude. Five important options are described in this section.

Type of questions
The Etude system provides for four types of questions: multiple-choice questions (1 out of m and n out of m), open numerical questions with the use of variables, short answer questions and hotspot questions. Care should be taken that items stored in the bank are of high quality. An important
condition for this is that the chosen question type fits the learning objectives to be tested. For example an open numerical question is more appropriate than a multiple-choice question when students have to calculate. This implies that teachers have to rethink their old questions: Is this the best way to present the question online in order to achieve this learning objective?

**Multi-media elements**

Etude enables adding several multimedia-elements to items, such as pictures, sound, animations and video. The use of multimedia elements makes it possible to assess other learning objectives, for example asking students to identify the cavitation type by showing a video of a rotating propeller. An important condition for the use of multi-media in a test is that they are functional, i.e. that students need them to answer the question correctly.

**Feedback**

Etude offers different feedback options in order to provide students with immediate feedback. Feedback assists the learner in constructing his or her understanding. Ultimately, in the absence of feedback, learners will feel isolated, motivation to learn will drop, and ultimately learning will suffer (Rovai, 2001). It seems that students not only want to know if their answer was right or wrong, but also why it was right or wrong. So the feedback requires containing explanatory remarks. A simple "sorry, this answer is wrong, try again", is not sufficient.

**Hints**

Hints can be added to a question, with or without score discount. The difference with feedback is that a hint appears before the question has been answered and that the student can decide whether opening the hint or not. Hints have great potentials, but also high risks. Hints can help students to get on the right track, when they don't know the protocol to solve the problem. But when a student uses a hint and the hint turns out to be useless, motivation to learn will drop, especially when it means a score discount. Consequently, a hint should contain useful information for the student, for example the line of reasoning to solve the problem or a reference to resources where the answer can be found. After reading a hint students should have the feeling that it was worth using it.

**Main and sub question mechanism**

The main and sub question mechanism offers students a difficult main question, which give students the chance to earn the total score for the item. If the main-question is answered correctly, the student can go to the next main-question, if it is answered incorrectly, the student is offered a few sub-questions, which can still result in a part of the total score for the item. Main- and sub-questions can be used to distinguish between excellent students and average students. Excellent students are able to generate the protocol to solve the problem, whereas average students need help to solve the problem in little steps. A condition for a functional use of the main and sub question mechanism is that teachers know exactly what difficulties students have when solving certain problems.

### 2.3 Taking a test online

**Just in time testing**

Students can take an online test whenever and whereever they want. Especially when the aim of the test is to practice and not to grade students, this can have great benefits. When the aim of the test is to practice, online testing can have the benefit of just in time learning. In a constructivist-learning environment students have to plan their own learning activities. A lecturer can make the test available for some weeks during the course, and students can decide themselves when the online test fits best in their learning process. This can differ from student to student. Also the place where students take the online test is flexible. They can take the test on any computer with an Internet Connection. An important condition for just in time testing is that students know the best moment for taking the test.

**Immediate feedback on scores**

When students take a test online, it is possible to give them information about their score on a question immediately after answering the question. This is a benefit of online testing compared to written tests. Moreover, after finishing the test, students immediately know their total score for the test.

**Adaptive testing**

A test is called adaptive if it is able to select an item on the basis of the student's performance on earlier items (Essenius, 1995). The advantage of adaptive testing is that students receive a set of questions appropriate to their abilities, so the test remains challenging for each individual student. Adaptive tests
can be used in training situations as well as in examinations. In a training situation the aim is to improve the performance of the students. An adaptive exam aims to assess the student's performance-level. The Etude system offers two adaptive test methods, one is adaptive for the difficulty level, the other is pre-planned by the teacher. Using the first method students get one question with a certain difficulty level, and depending on the correctness of their answer, they will get a more or less difficult question. Using the second method the test also starts with one item, and depending on the answer, the student will go into another pre-defined path of items. A necessary condition for the first method is a large item bank and calibrated items. For the second method one needs fewer items in the item bank, but the teacher has to think ahead carefully about the paths to define.

Figure 1: Checklist to determine whether the benefits of an online assessment tool will be achieved

3. How is Etude used?

We interviewed eleven of the present users of Etude at DUT. We developed an interview scheme based on the identified benefits, in order to find out what functionality they used and what reasons they had to use it or not. The results are presented in this section.

3.1 Storage of items

In order to achieve the benefit of re-using items, a coding scheme is necessary (see figure 1). However, none of the respondents use codes to classify their items. They organize their items in folders, using chapters of the book as the organizing principle. Teachers explained that the reason for not having a coding scheme is lack of time. Furthermore, they were not convinced that having a coding scheme is necessary, because of the so far relatively small number of items in the item bank (varying from 10 to 250). However, retrieving items in order to make revisions or to create a test, turned out to be harder when item banks expand. Consequently, benefits like efficient re-use of items will probably not be reached. Moreover, ordering items according to the chapters of a book has the risk that when the book is replaced, the item bank becomes useless.

3.2 Item entry

Type of questions

Teachers do not tend to rethink their old questions and think about what question type fits the learning objectives best. They start to fill the item bank with items they already have. The existing questions are mostly multiple-choice or open numerical. The interviews showed that only two respondents use hotspot questions and one respondent uses short-answer questions.

Multi-media elements

The only multi-media elements used by (half of) the present Etude users are pictures. Pictures are applied by the teachers in a functionally way. Reasons for not using sound, animations and video are "too busy with other things", "no material available", or technical reasons like "no sound card or
headphones available in the computer room" or "slow connections in student houses". None of the respondents related the use of multi-media to other learning objectives.

**Feedback**
Eight of the interviewed teachers make use of feedback. Most of the teachers use feedback for both correct and incorrect answers. Some of them also add specific feedback to different possible answers. They understand the importance of feedback, especially when the aim of the test is to practice. Those who don't use feedback yet, plan to do it in the near future. However, not all of the teachers use explanatory remarks.

**Hints**
Only three respondents add hints to their questions. This is because constructing hints is labour-intensive. Also, not all teachers recognize the added value of hints. It appears that the use of feedback is more natural than using hints.

**Main and sub question mechanism**
Only one of the interviewed teachers uses the main and sub question mechanism. It seems that the present users of Etude were not acquainted with this mechanism. Once it was explained, most of them were interested.

3.3 Taking a test online

**Just in time testing**
Nearly half of the teachers use Etude for both exams and practice tests. Two teachers use Etude just for exams and four use Etude only for practice purposes. In the case of exams, all tests are taken in a controlled assessment setting. The practice tests were available for students for some weeks, and they could decide themselves when the test fitted best in their learning process.

**Immediate feedback about scores**
Opinions differ on whether students should be shown their scores immediately. In practice test situations all teachers, except one, gave immediate feedback about the scores. They assumed that the scores could stimulate students to learn the subject matter again, or that the scores stimulated students to do the test more seriously. In case of an exam, half of the teachers offer students their scores immediately. A reason they gave for this was: "a benefit of online assessment is that students know their test result right after finishing the exam". Reasons for not showing the scores were: "fear that students would quit the exam once they know they will pass", "fear for failures in the calculating system of the scores", and "fear for a psychological effect, when students know during the test that they are doing poorly".

**Adaptive testing**
None of the present users make use of adaptive testing. They are simply not familiar with the possibility, or did not find the time yet to think about it. Half of the teachers is interested in applying adaptive testing for practice purposes in the future. Most of them consider the main and sub question mechanism to be more attainable.

4. How do students appreciate two of the promises of online assessment?

In the previous section, we predicted to what extent the teachers will reach the benefits of the online assessment tool Etude. In this section, we will address and evaluate the implications of using such a tool for a course on collaborative report writing. The course on collaborative report writing is part of the first-year module Systematic Problem Solving at the faculty of Technology, Policy and Management at DUT. Since 2000, students and tutors no longer meet face to face. Instead, all instructions, course material, exercises, etc. are provided through an electronic learning environment, called Blackboard CourseInfo (http://www.blackboard.com/). This platform has been chosen as part of a faculty wide project on ICT in education (Brakels et al. 2002). Our experience with using this platform for electronic peer review in collaborative writing has been presented in Sjoer and Brakels (2001). In 2001 the online assessment tool Etude was added to the ICT learning environment. The introduction of online assessment was meant to stimulate the students to study writing techniques.

4.1 Evaluating the use of Etude: research questions and design

The application of the online assessment tool Etude was evaluated during the autumn course of 2001. As part of the course, a three-week project has to be carried out. Part of this project consisted
of writing a report. During the three-week period, at a self-chosen moment, each student had to do an online assessment on report writing. The main goal of this assessment is that students can apply their knowledge on report writing to cases similar to those they have to write themselves. The assessment was set up in such a way that the students could do the assessment at the time when case-based exercises are useful to them. Moreover, the tutors have taken the effort to develop specific computerized feedback for every possible answer.

To evaluate the application of Etude, we formulated and investigated the following research questions.

- At what moment in the educational process do the students carry out the assessment and are they satisfied afterwards with the moment they selected?
- Did the students appreciate the immediate feedback, and did they find it useful?

To answer these questions, a questionnaire was developed. The questionnaire was split into four sections and consisted of closed questions. With respect to the research questions we asked the student the point in the writing process where they did the assessment and their appreciation of the feedback provided. 138 students performed the assessment. 84 students completed the questionnaire, which implies a response of 61%. The questionnaire was answered anonymously, directly after the course was completed.

4.2 Learning ‘Just-in-time’

In the assessment instruction, the students had been advised to take the test after they had read certain parts of the manual about report writing, but before they actually started composing, and revising texts of their own. Only 11 students followed the assessment instructions to the letter. 82% of the students indicated that they studied the course book and 54% of the students studied the course book before doing the assessment (figure 2). If we look at which moment in the educational process the student carried out the assessment, we see that more than half of them did the assessment during the writing process (as shown in figure 3). Yet, nearly a third of them would have preferred to do it earlier. Moreover, although 20% of the students indicate that they did the assessment after finishing the report, more than half of them concluded that this was a mistake i.e. they should have performed the assessment earlier on. To conclude, nearly half of the students either followed the assessment instructions (relative to writing) or indicated that they should have followed them.

![Figure 2: Moment selected for studying book](image1)

![Figure 3: Moment selected for performing test](image2)

4.3 Computerized Feedback

The students reacted positively to questions that are related to the computerized feedback. 82% of the students indicate that they appreciate getting feedback on every answer, which probably accounts for the fact that nearly 85% took the effort to read most or all of the provided feedback. The students had a higher appreciation for feedback on wrong answers than for correct answers, scoring 70% for wrong answers and 64% for correct answers on ‘useful’ or ‘very useful’. Despite the high appreciation for the feedback, 42% indicated that they had learned ‘pretty much’ from the feedback, while 36% indicated that they learned only a little. This suggests that giving feedback is very positive, but that even more effort should be spent on the content of the feedback. Especially when half of the students do not always find the feedback clear enough.
To sum up, students should be stimulated more to start the assessment before they actually start writing the report. The feedback option was appreciated greatly. It shows great promise for distance education, provided that enough effort is spent on the content and readability of the feedback.

5. Conclusions and recommendations

In this section we answer the research question: is the way Etude is used by the present users suitable to realize the benefits of the system? In general we can conclude that offering an assessment tool like Etude doesn't mean automatically that the users will achieve the potential benefits of the tool. It appears that when a new ICT tool is applied, people tend to start with the substitution of what they were used to doing. In other words, they don't adapt their method to the tool. This conclusion is supported by our interview results in several ways, as shown in the following sections.

5.1 Storage of items

Teachers use chapters of the book to organize their items, because this classification is common to them and immediately available. We recommend to support teachers to think of a coding scheme which is based on the learning objectives, because this will improve the chance that they will fully profit from the benefit of efficient re-use of items and effective generation of tests.

5.2 Item entry

Teachers start filling their item bank with existing items, instead of considering what type of question fits best to the learning objectives. This also applies the use of multi-media, especially sound, video and animations. It seems to take a lot of effort and educational insight to create items that assess the learning objectives most favorably. Part of the potential of the system is not used at all, because teachers are not familiar with it. Students as well as teachers are positive about computerized feedback. Teachers understand the added value of feedback for the learning process of the students. Students appreciate feedback on wrong answers as well as correct answers. The case on report writing shows that feedback has to be clear in order to reach the benefits. Educational assistance should focus on the quality of the feedback. Teachers don't recognize the possible benefits of hints. Consequently, they don't know how to apply a hint functionally. Educational assistance is necessary in order to make clear in what way hints can support the students' learning process. Teachers are not acquainted with the main and sub question mechanism in Etude. The same counts for the adaptive test methods. Teachers should be informed about these possibilities.

5.3 Taking a test online

Teachers should consider how to guide students in their learning process. In the case on report writing the appropriate time to take the test was included in the test instructions. This was not sufficient for all the students to take the test at the right moment. As a result of this case study an educational guidance program is being developed in order to integrate the new assessment tool successfully. It includes support on different organizational levels in order to set up well-founded code schemes, to fill item banks with high-quality items, and to implement the tool in the educational process.

Beyond Technology Training:  
PT3 Grantee Fills the Technical Support Void, Enabling Schools to  
Make the Most of Their Available Technology-related Resources,  
Helping to Bring Technology to Life in the Classroom

Susan Skuda, Project ImPACT, The University of Tennessee  
Knoxville, TN, USA sskuda@utk.edu

Abstract:  
Project ImPACT (Implementing Partnerships Across the Curriculum with Technology) is  
a first-year PT3 implementation grant awarded to the University of Tennessee in 2001. A  
primary goal of the project is to work in partnership with preservice teachers, mentoring  
teachers, local area schools and school systems to effectively infuse technology into the  
curriculum to enhance student learning. At the local school level, Project ImPACT  
provides training to mentoring teachers, interns, the university faculty supervisor, and the  
school technology coordinator on computer applications and techniques as well as  
methods of integrating technology into the curriculum. Early in the initial training phase  
of the project, local schools in one participating school district received wireless mobile  
computer labs accompanied by limited or no technical support for setup and integration.  
This paper will focus on the tremendous change that occurred in the overall dynamics of  
one specific university-school partnership as Project ImPACT stepped in to fill the  
technical support void and worked together with the participants, the school and the  
school system to bring this newly purchased technology out of the carton and into the  
classroom, and will share the tremendous explosion in technology-enhanced learning that  
ocurred as a result.

Project ImPACT (Implementing Partnerships Across the Curriculum with Technology) is a first-year PT3  
implementation grant awarded to the University of Tennessee in 2001. A primary goal of the project is to  
work in partnership with preservice teachers, mentoring teachers, local area schools and school systems to  
effectively infuse technology into the curriculum to enhance student learning. At the local school level, Project ImPACT  
provides training to mentoring teachers, preservice teachers, university faculty  
supervisors, and school technology coordinators on computer applications and techniques as well as  
methods of integrating technology into the curriculum.

Prior to the beginning of project training, teachers at one participating middle school expressed tremendous  
frustration with the very limited technological resources available to them. Most classrooms had only one  
current computer system, which primarily served as a teacher station to record grades and perform basic  
word-processing tasks. The library, which was to serve as the training center for the project, was equipped  
with several computers, but of varying ages and capabilities. As a group, teachers at this school agreed that  
there was simply no way to integrate technology into the curriculum with their limited and often unreliable  
hardware. The frustration was so great, and their outlook so grim, one group member stated that none of  
them would even be participating in the project were it not for the stipend they could look forward to  
receiving upon completion of project activities.

Before training was to begin, however, each school in this particular school district learned that they were  
to receive wireless mobile computer labs as a result of a long-term district initiative to create a world-class  
school system. After learning of the impending arrival of the new equipment, the group became somewhat  
energized, but still expressed doubt as to the practicality and logistics of using the labs in their classrooms.  
While the purchase and distribution of the computer hardware represented the achievement of an extremely  
admirable goal, the school district provided limited or no technical support for its setup and integration.
When ImPACT staff arrived to begin the training phase of the project, participating teachers expressed great frustration that this wonderful new resource remained packed in boxes and stacked in the hallway.

Immediately upon becoming aware of the situation, Project ImPACT trainers met with the administration of the school to offer their help and time to prepare the equipment for use at the school. Working together with school personnel and PTSA volunteers, Project ImPACT staff quickly set up the first of the mobile computer labs. Once operational, ImPACT trainers began to integrate the wireless lab into project training sessions.

Initial reticence soon gave way to growing enthusiasm as project participants became familiar with the new equipment and the myriad possibilities that it made available. Once the first mobile computer lab was set up and put into use, the other labs were quickly assembled as well. Project ImPACT mentoring and preservice teachers soon “adopted” the labs, taking ownership and pride in their new equipment.

Project staff and participants weathered the storm together as they worked through the initial bugs and difficulties that so often accompany the deployment of new equipment. Mentoring teachers and interns learned quickly to take things in stride when the new hardware did not always work as planned, even for instructional technology professionals. Working through the idiosyncrasies of the hardware and software together with the ImPACT staff, school personnel became far more comfortable with the equipment than they might have been if exposed in a more controlled laboratory setting.

The partnership among school personnel, volunteers, and Project Staff blossomed as the local PTSA unit hosted a reception for the superintendent of the school district, featuring a project training session using the wireless mobile computer labs so recently purchased by the district. Guests at the reception included School Board Members, the mayor of the town, members of the local Chamber of Commerce, as well as many volunteers and community activists. This presented the perfect opportunity for the project and the school to showcase their growing and mutually beneficial partnership. Delighted with the chance to see his initiative in action, the superintendent spent a great deal of time with grant participants, discussing potential use of the new equipment and the possibilities for use in the classroom. The community was once again treated to a demonstration of the newly purchased equipment as the PTSA subsequently invited Project ImPACT to participate in their annual Founder’s Day celebration by demonstrating the use of the wireless labs and explaining project training.

Stressing teamwork, partnership, and collaboration throughout the training process, Project ImPACT staff continued to work with participants as they began to plan for the integration of technology into the curriculum. Project ImPACT staff facilitated regular team meetings, at which teachers and interns began to share their technology integration plans. As one eighth grade math teacher discussed some of her ideas to incorporate technology into her classroom lessons, a seventh grade math teacher realized that she, too, was working on activities involving the very same curriculum content for her advanced class. Inspiration finally struck, and these two teachers, who had never considered working together before, began to share ideas and lesson plans. Collaboration grew from there as other teachers who were accustomed to working in the isolation of their pods and grade levels began to collaborate as well. As Project activities continued, Project ImPACT participants began to be sought out by their colleagues as a valuable resource on how to best use the new labs. Today the labs are in high demand all over the school. Technology-enhanced lessons, once thought to be impractical at best, have started to become the norm, rather than the exception.

Acting as school technology coordinator for Project ImPACT activities, the long-time school librarian recently wrote, “Thanks for all your hard work on Project Impact. It was a lot more fun than I had thought it would be and I feel like I developed some close relationships with our faculty that I hadn't had before. That's an aspect of the program I think gets overlooked—the relationship part.” What a far cry from the disgruntled comments made by a begrudging participant just a few months earlier.
Using Video-tape Language Samples and Hyper-Studio Applications to develop literacy (reading) skills in young children
Ages 4 – 8 identified as developmentally delayed in oral language and literacy skills

Denise M. Smith Ed.D., CCC-SLP
Fidel M. Salinas Ed.D.

Children who are at risk for developmental delays in the area of oral language are also at risk for developmental delays in reading. Oral language skills provide an essential foundation for the emergence of literacy competence. As school-based language intervention emerged, combined with an emphasis on a more naturalistic approach to literacy instruction, the importance of strategies such as language samples have increased in importance and utility in identifying areas of concern and devising daily lessons for improving oral language skills.

Advances in video technology have improved the accuracy of language samples. In addition, a video provides additional information such as body language and attentiveness, not available in the more traditional approach of audio-tape language samples. Technological advances in software applications such as Hyper-Studio have the capacity to utilize pictures, sound, voice, animation, and text in a combination of lessons to build oral language skills and literacy skills.

The children who participated in this study were enrolled in a cross-categorical non-graded program at a local regular education elementary school. Their age range was four to eight years. All the children were ambulatory and age appropriate in the area of self-help and gross/fine motor skills. Cognitive and language skills were at least six months to one year delayed as measured by Brigance Early Screening Inventory of Basic Skills.

University students enrolled in an upper division (junior/senior level) special education course addressing communication challenges in young children (pre-school through third grade) were the primary investigators. The course instructor and media specialist at the local elementary provided guidance in the area of analysis of language samples and development of instructional sequence of curricular lessons on Hyper-studio.

This investigation provides information in the following areas:
1) information relevant to normal and atypical development of oral language and literacy skills
2) strategies to analyze language samples
3) examples of young children’s language sample videos and Hyper-studio lessons and provide rationale for their content

1) feedback from university students regarding the relevance of the assignment and its practical application to their future employment as special education teachers.
Java WEB-based K12 Experimental Research: Formative evaluation of Research Tools

Glenn Gordon Smith
State University of New at Stony Brook
United States
Glenn.smith@sunysb.edu

Abstract: This paper discusses the formative evaluation of computer-based research tools and methodology used in a study investigating how different levels of interaction in a computer game-like situations affect the learning of spatial visualization skills. The current study, as yet not complete, uses Java Applets to implement interactive puzzles which write data back to a server.

There are three research questions in the current study: How does interaction with a computer versus observation affect: 1) mental rotation, 2) path memory and 3) mental imagery? For each research question, we constructed an online experiment.

The experiments make use of Java applets running over the internet that send data back to a server machine on the Stony Brook campus. We set up this infrastructure to achieve the goals of conducting experiments remotely with minimal loss of data and to provide a quick turn-around time for developing new experiments. All programming has been done by undergraduate computer science students for credit. In the treatments, participants were randomly assigned to either 1) an interactive or 2) an observational condition. the posttests, all participants performed the same task regardless of previous treatment condition.

Experiment 1 was designed to investigate the effect of interaction on mental rotation. The scenario experiment one is similar to the classic mental rotation experiments of Shepard & Cooper (1982). Two polygons are shown. The polygon on the right is either a rotated version of the one on the left, or it is reflected as well as rotated. The participant is asked to specify (by pressing a button) whether the polygon on the right is 1) just rotated or 2) reflected as well as rotated. The polygons are randomly generated shapes. In the treatment condition, the interactive participant is allowed to interactively rotate (with mouse) the polygons so that they are the same orientation and it is easier to verify whether the polygons are reflected. In the observational condition, the polygon on the right rotates by itself (animation) until both polygons align. In both conditions participants must specify whether the polygon on the right is a rotation only or reflected. The posttest is essentially identical to the classic mental rotations of Shepard & Cooper (1982). There is no movement or animation. The polygons are static. The participant has to perform mental rotation in his/her head and specify whether the polygons are rotated only or reflections of each other. The program automatically records elapsed time and whether they got the correct answer. For each trial, the same random polygon shape is used in both treatment and posttest. However in both treatment and posttest, it was random whether the polygon on the right was a reflected version of the polygon on the left, or just rotated. Each participant did ten trials. In both treatment and posttest, participants received feedback on their success.

Experiment 2 was designed to investigate the effect of interaction on path memory, remembering a path through a maze. The experiment had a computer game type fantasy of finding your way through a maze in the darkened interior of a pyramid. It had a treatment posttest design. In the treatment, participants are shown in top view a maze in the dark, i.e., they can see only their starting point. There were two treatment groups, an interactive group and an observational group. The interactive group used the arrow keys to maneuver a Pacman-like character through the darkened maze. When they tried to go in a wrong direction into a wall, they were alerted by a beeping noise. When they go in the correct direction, the square they move to is lit up, gradually revealing the maze. The observational group views an animation of a Pacman-like character traveling through the darkened maze, squares lit up as the character enters them. Both treatment groups received the same posttest. They are asked to remember the maze. Then they are shown a darkened square the same dimensions as the maze and asked to recall, by clicking in the squares, the path through the previous maze. They receive feedback on whether and to what degree they remember it correctly.
Experiment 3 was designed to investigate the effect of an interactively rotating a shape on a mental imagery task. During the treatment, both treatment groups (interactive and non-interactive) were asked to memorize a random polygon, with the additional hint of "What does it look like?". The interactive group were allowed to interactively rotate the shape to help them remember it. The presumption was that they would rotate it find an orientation that looked like something they recognized. The non-interactive group were shown the polygon, and asked to remember it, without being able to rotate it. The posttest mental imagery task was to specify whether a "hole in the ground", seen in profile, could accommodate the memorized polygon, either a) a rotation of the memorized polygon, b) a reflection of the memorized polygon, or c) not at all, i.e., the "hole in the ground" was the shape of a completely different polygon.

We have been conducting a series of formative evaluations of the research infrastructure with approximate 80 third through fifth graders (average age 8.5 years) from public elementary schools on Long Island, New York. The formative evaluations have taken place in computer labs of participating elementary schools on Long Island, New York, and also in computer laboratories on the Stony Brook Campus.

Younger children (such as third graders) had difficulty understanding terms like "polygons", "rotated", and "reflected". We therefore changed the terms to "shapes", "turned" and "flipped".

One of the problems we encountered early on was that it was difficult for the younger students, such as third graders, to read the instructions and understand the task. We therefore decided to add voice-over instructions. Scripts were developed for the voice-over instructions, and recorded with a non-threatening female voice to wave file formats and then incorporated into the Java applets. The voice-over instructions clearly improved participant comprehension of the tasks. Some participants had particular trouble understanding what was required for the path-memory experiment. We added a fantasy story line with voice over, "you are lost inside a dark pyramid.", and visuals of the inside of a pyramid. The fantasy story line help users understand the task and added to their engagement.

Participants expressed dissatisfaction at not knowing how or why their answers were correct or incorrect. We changed the programs to include audio, written, and animations of shapes to provide feedback as to why answers were correct or incorrect.

The largest problems so far have been with downloading and uploading data to K12 computer labs. We programmed the communication between client machines and server using Remote Method Invocation (RMI). RMI allows the Java applet operating on the client machine (the computer of the user) to invoke methods (programs) on the server machine. This implies a "higher level" more abstract level of communication than the "http" communication used by most web pages. Unfortunately, after running a number of tests at different school districts, we discovered that the "firewalls", proxy servers, and other filtering software in place in almost all K12 computer lab settings simply do not allow RMI communication between their computers and a remote server. We converted all our code over to a "http" communication, the method of communication between client machine and servers that the majority of web pages use. From the point of view of computers in K12 computer labs (and their firewalls, filtering programs and proxy servers), it appears that our programs are just calling for downloading java programs and uploading data from experiments. During a number of "dry-run" tests from K12 computer labs, data was able to get through.

Next during the first major period of experiments in school computer labs, over the course of a week, approximately 100 fifth grade students attempted the puzzles. There were major technical difficulties. With groups of 20-25 students on the running Java applets simultaneously, the download of the applets (containing a significant amount of multimedia content) was agonizingly slow.

With 20 to 25 students running the Java Applets at once, the programs froze part-way through in the vast majority of cases. We only able to run the programs with maximum of three students simultaneously. And even then, very few were able to proceed in through to the third experiment. The result was that we were able to gather a significant amount of data on the first experiment only, Mental Rotation. And that data was suspect because of the high attrition rate. One cause of the problem, we later discovered was the limited capacity of the database program, Access, we are using on our server.

We have not yet achieved our goal of setting up a web-based infrastructure for developing and conducting experiments. Various technical issues at K12 computer labs present difficulties. These include firewalls, proxy servers, filtering programs as well as the lower quality of computer hardware at schools, compared to universities. There are other problems associated with undergraduates computer science students developing the code, such as continuity between semesters and incomplete knowledge of some of the technical requirements. We have been now working on the infrastructure for a year. We project that we will be able to set up our experiment infrastructure within a few months.
Math and Distance Learning threaded discussions

Glenn Gordon Smith
Janice Grackin
David Ferguson
Risako Izubuchi
State University of New at Stony Brook
United States
Glenn.Smith@sunysb.edu

Abstract: Distance learning web-environments do not provide the most basic communication tools for discussion of math problem solving vital to math courses. A needs assessment indicates that online instructors and students need to be able to view, edit, and post diagrams and formulas directly in online postings, without going through laborious intermediary stages. MathThread, an nsf funded project, is dedicated to providing these tools to online instructors and students, supporting instructors in adapting their classes to use these tools and researching the effects of more natural math-oriented threaded discussion tools on mathematics learning. After reviewing the existing possible tools, we have formed a partnership with NetTutor who makes the Whiteboard math discussion tools. We have conducted a pilot study evaluating undergraduate students' ease of using the Whiteboard for calculus discussion. We found that most participants had little trouble understanding and using the tools.

Need

Current distance learning web-environments emphasize the written word and threaded discussions, but do not provide the most basic communication tools for discussion of math problem solving vital to math courses. In face-to-face math classes, instructors work problems, write formulas and draw diagrams on the chalkboard while students ask questions, providing a feedback communication loop. When students hand in homework, instructors and TA's can cross things out and write other formulas. This ability to demonstrate problem solving, represent problems through diagrams, and provide a communication feedback loop are fundamental to math learning, yet are awkward in web-based distance learning environments. Currently math notation, as well as diagrams, can not be directly included in online distance ed. documents. Because math notation and diagrams are NOT integral with the online distance education environments, instructors laboriously go through several steps to attach an image file with formulas and diagrams. Since students can not respond by writing math notation, this disrupts the communication loop. In a Sept. 2000 needs assessment of web-based math instructors in N.Y. State using a dominant web-based environment, instructors declared, "It has been extremely frustrating teaching math online...", and "Your project sounds very timely and useful." Instructors consistently wished they could put equations, math notation, conceptual diagrams and graphs directly into online postings (i.e., a math notation editor, a drawing tool for creating conceptual sketches, and a graphing calculator).

Literature search

Current web-based distance learning environments do not directly support formulas and diagrams, in their postings. Logically this can have at least three possible effects on math students and instructors. Firstly, it can force instructors and students to work through a number of intervening digital representations in order to communicate with formulas and diagrams. Online instructors must do this extra work if they are to deliver mathematical content. Secondly, students and instructors may avoid this extra work and force ordinary written prose to carry the extra burden of mathematical meaning, without the support of formulas and diagrams.
Thirdly, students may drop or shy away from web-based distance mathematics courses. Instructors may avoid teaching them.

It seems intuitive that these issues interfere with student mathematical learning outcomes and with mathematics instructor teaching effectiveness. Since a plethora of intuitions that turn out to be scientifically and empirically incorrect, here are some social science concepts which lend support.

The saying "a diagram is sometime worth ten thousand words" is supported by information processing theory, cognitive psychology and cognitive neuroscience. A diagram "preserves explicitly the information about the topological and geometric relations among the components of the problem" in a way that supports parallel processing by human beings. Purely verbal and symbolic descriptions force humans to sequentially parse the relationships between elements of a problem. So while verbal descriptions of math problems may be informationally equivalent to diagrams (all relations in one representation are inferable in the other and vice versa), there are many cases where diagrams are computationally more efficient than verbal descriptions (Larkin & Simon, 1995). The eye, retina, visual perceptual system and visual short term memory are object-oriented, i.e., designed to efficiently, and in parallel, process the relations between different parts of objects. At a neurological level, human visual processing has two well developed "streams" which process "what" (object discrimination) and "where" (spatial relationships between objects and features of objects) (Ungerleider & Haxby, 1998). Both streams are likely used in parsing diagrams. Similarly, while the capacity of Visual Short Term Memory (VSTM) is commonly held to be four items, if items are features of an object, instead of separate objects, capacity jumps to at least 16 (Jiang, Olson, and Chun, 2000; Olson & Gettner, 1998) i.e., if elements of a problem are presented diagrammatically as features of an object, significant learning benefits may accrue.

In current web environments, students (and instructors) may be able introduce formulas/diagrams in the the postings by going through several intermediary steps, such as using MathType within word, saving the file as a image file (GIF), and then uploading or attaching the image file to a posting. But such extra steps in the communication process cannot help but distract student's limited attentional resources away from the vital elements of new schema's they are learning and impose an extraneous "cognitive load" on the students' short-term memory (Sweller, 1994).

Previous work

There are a number of companies, consortiums and organizations working on supporting web-based math discussion. WebEQ provides an extremely well-designed interface for creating mathematical formulas that go into documents which can be posted to the web. WebEQ is an interface that has grown out of MathType, which provides an add-on to Microsoft Word, to enable the inclusion of formulas. It is notable that WebEQ is in being picked up by some distance education providers, such as Blackboard. Although WebEQ is a well designed interface, it does not provide for the inclusion of diagrams or the graphing of equations.

Another approach is the Imath Communicator (www.imath.org), a math-enabled browser, which displays, creates and edits math notation and some diagrams, by using Mathematical Markup Language (MML) an XML extension to HTML that provides for math notation. Imath has modified the open source code of Amaya (of the WorldWide Web Consortium (W3C)) to create Imath Communicator. Imath has been used somewhat successfully as a web component in distance beginning algebra courses. The advantages of Imath/Amaya approach are: 1) it is based on an extension to html, so all browsers may support this solution in the future, and 2) it is open source, allowing a diversity of programmers from around the world to potentially improve its source code. The disadvantage of the Imath approach is that it does not perform quickly with large html pages.

LiveMath (www.livemath.com), is a wonderful way to display interactive three dimensional graphs of mathematical equations over the internet. Distance educators can download and purchase the LiveMath Maker, a program that allows them to input mathematical equations and create a variety of two and three dimensional graphs of the equations. These graphs can be posted to web pages, where users can view them after downloading a free plug-in. The user can interactively rotate and view these graphs. However LiveMath does not provide a means of putting formulas, diagrams and graphs directly into online threaded discussion postings. The user must create the files with LiveMath Maker, upload the file created, and then link to the file from within a threaded discussion environment. The interface of LiveMath Maker is complicated and would likely be difficult for remotely connected undergraduates to learn. It is perhaps best used as a valuable supplementary resource.

Probably the best and most complete solution is the Whiteboard by NetTutor (www.nettutor.com). Whiteboard, designed as a chat system for math and predominantly used for round-the-clock chat-based math...
tutoring, it can also be used in asynchronous mode for math oriented threaded discussions. So far Whiteboard is the only working tool that allows users to put directly into asynchronous threaded discussions the most vital elements of math communication: formulas, graphs, and diagrams. There are no intermediary stages, just an interface that allows users to view, edit and post discussions with these elements. The NetTutor/Whiteboard could use some improvements on its interface. The company that owns it, Link Systems, is relatively small and seems amenable to making improvements. Since Whiteboard is the only reasonably complete and working product supplying the needs of math asynchronous threaded discussion, we have chosen Whiteboard as the tool we will use and they have agreed to a partnership with us.

Work is beginning and on-going

The Math Thread project has recently been funded by the National Science Foundation, through the program Course, Curriculum, and Laboratory Improvement - Adaptation and Implementation (NSF CCLI A&I). The funding starts officially January 2002 and runs for three years.

Major goals and approach

1) Provide distance ed. math instructors with basic math communication tools to fluently teach math, including direct inclusion of math notation, conceptual drawings and graphs into distance ed. postings by both instructors and students. Instructors will directly put math symbols into distance ed. documents, without converting documents into unmodifiable formats (such as image files, gif's, LaTex etc.) and adding them as attachments. Our goal is to have modifiable math notation in distance ed. documents, so instructors can easily copy, modify and annotate students' work and thereby achieve fluent of two-way math communication. Achieve by: Unite an existing distance ed. environment with a math-friendly interface, NetTutor's Whiteboard, which creates, views and edits math notation and diagrams. 2) Adapt existing web-based and face-to-face college math courses to include these basic communication tools for math. Achieve by: Through the SUNY Learning Network, a non-profit infrastructure for distance ed. at the State Universities of New York, redesign/deliver two Intro. Calculus and two Pre-Calculus courses using the math friendly communications tools. 3) Provide faculty development/support for instructors to re-design their math courses. Achieve by: During redesign of adapted courses, instructors meet with the project personnel and receive feedback on designing online math classes from other instructors at SLN, through online threaded discussion. 4) Research the impact of more natural math and diagrammatic communication on math learning. Achieve by: Once adapted courses are running in the SLN environment, research students' use of different modalities (e.g., diagrams, graphs, formulas) in their learning, for example, the correlation between diagrams use and comprehension/achievement, particularly for developmental students. 5) Facilitate the quick spread of basic math distance ed. communication tools to other math instructors a) in the Dept. of Applied Math & Statistics at STONY BROOK, b) within SLN through-out the state of New York and c) nationally. Achieve by: During redesign of adapted math courses, approach other math instructors at SLN for suggestions. Offer on-campus workshops through the Center for Excellence in Learning and Teaching (CELT) at STONY BROOK. Provide other math instructors with a simulation of a distance ed. math course using easy creation/viewing/editing of math notation, diagrams and graphs within assignments and discussions. During teaching of adapted courses, allow other math instructors to unobtrusively observe. Suggest that other math instructors use MathThread in one experimental unit. Present at the yearly SUNY Conference on Instructional Technology (CIT). Approach other distance ed. providers about using the basic math communication tools. Write papers for peer-reviewed journals and present workshops and papers at national conferences.

Validation

In a needs-assessment of 40 web-based distance education math and math-related instructors across the nation, the instructors declared, "It has been an extremely frustrating experience teaching math online...", and "This aspect of my internet course is the most discouraging. I find myself spending an exorbitant amount of time responding to students mathematically [because the infrastructure does not support it] and not enough time

1859
teaching. If this doesn't change, it will eventually be the reason why I give up teaching mathematics on the internet.”

In response to our mentioning our plans to address the problems, the following comments were made: "Your project sounds very timely and useful ", and " Yes! I am so glad that you are working on this project."

The instructors consistently asked for a common set of tools, i.e., the ability to put equations and mathematical notation directly into online postings and threaded discussions, a drawing tool for creating conceptual sketches and a graphing calculator.

Math Thread Pilot Study of NetTutor

Prior to introducing the Net Tutor software into experimental classroom settings it is important to identify human and other factors (such interface design and technical usability) that might influence how well the software would function as part of a course. Early identification of such factors provides opportunities to modify or eliminate them prior to actual implementation, or to control for the identified factors in the experimental setting and account for them in subsequent project assessment.

A series of six pilot sessions were completed. Students who had taken or were currently taking pre-calculus or calculus were recruited to participate in single sessions to evaluate the use of the Net Tutor software in a naturalistic setting. Sessions were held in a computer lab, and students received course credit for their participation.

In order to decrease any anxiety resulting from stereotype threat (Spencer, Steele, & Quinn, 1999; Steele, 1997) and/or from concerns about self-presentation or mathematical ability, students were repeatedly assured that the session goal was to evaluate the software and not their math or computer knowledge and expertise. The two-hour pilot sessions had four parts. First, participants were provided with a facilitated software tutorial, during which they could practice using the tools and ask questions. Second, participants were each assigned to a small group, provided with a set of calculus-related problems/tasks, and directed to work through the tasks using the Net Tutor tools and online threaded discussion with the other members of their assigned group. Third, participants were asked to complete a brief open-ended questionnaire regarding their experience using the software. Last, participants took part in a group interview regarding the use of the Net Tutor software and the pilot session experience.

Results of the Pilot Sessions

In general, responses to Net Tutor were relatively positive. Most, though not all, participants had little or no difficulty understanding how to use the tools (“It wasn’t hard at all.”), found most of them easy to work with, felt they had the right tools to do what they wanted to do, and felt there were enough tools provided. Several participants especially liked the graphing feature, although several would have liked a built-in graphing calculator. There also appeared to be a consensus that there was a certain awkwardness and tediousness to using Net Tutor, and participants suggested that they would feel more positive about the software if it functioned in simpler and more familiar ways (i.e., more like the MS Windows applications to which they are accustomed: “I think I would also like key commands.”). Most participants indicated that they believed they could become comfortable and proficient with the tools as part of a class in a fairly short time.

Participants’ responses to questionnaires and during interviews indicated a number of moderating factors clustered into several common themes. First, participants’ perceptions of the ease of use of Net Tutor were clearly moderated by their level of computer expertise and experience with online environments. Those who indicated a higher level of technical expertise, especially in the use of graphics software, reported less difficulty in learning to use the Net Tutor tools and in navigating the software. Also, prior experience with online threaded class discussions (e.g., Blackboard) appeared to moderate participants’ comfort and satisfaction with the group problem-solving tasks, although some dissatisfaction with the basic attributes of this function (e.g., read messages do not change color and there is not an automatic refresh) appeared to moderate even the responses of computer-savvy participants. We suspect that variability in students’ computer expertise will continue to be a major issue in computer-based classroom approaches for some time to come. Instructors implementing such approaches will need to build in adequate time for training and tutorials, especially for less technically able students.

Second, participants who perceived themselves to have less math expertise expressed some
dissatisfaction with the amount of information provided on how to use the tools. They suggested that pop-up windows that provided some definition and description of the tools and how to use them would be helpful, as well as a glossary of relevant mathematical terms.

A third group of factors clustered around personal communication preferences. There was a fair amount of variation in whether or not participants thought they would like using Net Tutor for group projects or to communicate with professors and teaching assistants. Some expressed a strong desire to ask questions face-to-face and to use pencil and paper to draw diagrams. Others felt Net Tutor would be a useful means to communicate questions to professors and teaching assistants outside of office hours. Instructors implementing Net Tutor in classes would be advised to provide adequate opportunities for face-to-face meetings with students, in order to accommodate a variety of communication preferences.

In addition, observations by the project staff suggest some concerns to be addressed in training sessions with instructors for the experimental classrooms. Despite repeated reassurances, some participants still suffered from self-presentation concerns which might be expected to negatively affect their experiences with Net Tutor and their performance. Instructors need to be aware of this and find some means of monitoring students’ participation and interactions to mediate the impact of self-presentation issues on performance. Another observation involves the recognition of a learning curve for instructors as well as students. As the skills of the pilot sessions instructor/facilitator improved, she noted that it appeared she was able to accelerate participants’ learning because her increasing knowledge meant she could more readily answer questions. Instructors should be aware of their own learning curve, and strive to be well ahead of students prior to implementing Net Tutor into classes.

Although the asynchronous component of the NetTutor Whiteboard seemed fairly usable, there were certain technical shortcomings and some features that students suggested would make the WhiteBoard more usable. In using NetTutor for an asynchronous threaded discussion, it could be more robust. It often happened that students opened up two windows with the interface, causing the browser to freeze. Additionally students called for a number of additional features, some of which are present in common distance learning environments and/or in Windows-based applications. The people at NetTutor have agreed to address these issues immediately. We feel that when these problems are fixed, NetTutor's Whiteboard will be a very serviceable tool for mathematics-oriented asynchronous threaded discussion.

These pilot sessions yielded useful information for the next phase of Math Thread, identifying and training instructors for the experimental classrooms.

Upcoming work

The next phase in our project is to train and support several online mathematics instructors to incorporate the Whiteboard tools into their existing courses. We have made a partnership with a community college in up-state New York to convert a pre-calculus and a calculus class to take full advantage of the Whiteboard tools. We will conduct seminars over the summer of 2002 to assist them with incorporating Whiteboard into the fabric of their courses. The adapted courses will be offered Fall of 2002.

Technology Innovation through Collaboration in a Teacher Education Program

Steven B. Smith, Ed.D.

Department of Teaching and Leadership
University of Kansas

ABSTRACT

Teacher preparation has emerged as a critical factor in the effective use of new technologies in education. Information technology investments may not pay off unless future teachers are given the opportunity to become technology-proficient educators. This study presents a theoretical framework for implementing technology innovation through a cohort model. Results from interviews of the first year’s participants, and the lessons learned from their efforts are reported. Findings clearly indicate that structure and ownership are essential ingredients to producing a viable and collaborative cohort model and that the power of technology integration can be realized through collaboration.

Introduction

Rapid and widespread technological growth over the past decade has had a significant effect on our society; technology is changing the way we live. Changes are most noticeable in the way we do business and the way we communicate. Many teacher education institutions are studying the way in which technological innovations can significantly influence the way we teach and learn. Today, more than at any other time in recent history, teacher preparation has emerged as a critical factor in determining the effective use of innovative technologies in education. Federal, state, and local agencies are investing billions of dollars to equip schools with current technologies and telecommunications networks. However, these information technology investments may not pay off unless future teachers are given the opportunity to become technology-proficient educators who know how to take advantage of these new learning tools to enhance and improve the education of all students.

In recognition of the urgent need for technology-proficient educators, the U.S. Department of Education, with the support of Congress, has begun a new initiative to prepare tomorrow's teachers to use technology for improved teaching and learning. In its first year, the Preparing Tomorrow’s Teachers to Use Technology (PT3) program awarded $75 million to 225 grantees in every region of the country. One of the PT3 project grantees, the Learning Generation (LearnGen) Project at the University of Kansas, focuses on the abilities of teacher education
students to assist faculty in generating technological innovations and to transfer this expertise to their teaching experiences.

The LearnGen Project has sought to accomplish this goal through the creation of Technology Innovation Cohorts (TIC). The role of each TIC is to design, implement, and assess a "technology innovation" that is intended to integrate technology into teacher education. This paper presents the theoretical framework for the project's efforts to implement a TIC model and the lessons learned from the first year's efforts.

**Literature Review**

Over the past decade, reports have indicated that the importance of technology in teacher education is not central to the teacher preparation experience in most colleges of education in the United States today (Office of Technology Assessment (OTA), 1995; American Council on Education Report, 1999). Typically, teacher educators are not prepared to model appropriate uses of information technology or to incorporate the use of technology across the curriculum. Instead, the extent of their ability to use technology centers on accessible applications (e.g., drill and practice, word processing, use of the Internet). Teacher educators tend to lack more sophisticated skills that enable them to integrate realistic problem-solving activities into teacher training programs (Abdal-Haqq, 1995; Office of Technology Assessment (OTA), 1995). If technology is to be successfully integrated across teacher education programs, preservice training that is focused on technology integration must become a priority, especially if preservice teachers are to become comfortable and competent with the use of technology in their teaching (Hasselbring, 1989; Langone, Malone, Stecker, & Greene, 1998; Office of Technology Assessment (OTA), 1995; Sheingold & Hadley, 1993; Wetzel, 1993).

When technology is introduced during the preservice years, the focus is generally on "how to" components and skill acquisition of technology rather than on effective strategies for using technology to enhance learning. Preservice teacher education students need to experience technology as modeled by their instructor(s) rather than simply being informed of its "potential benefits" (Barker, Helm, & Taylor, 1995; Bryant, Erin, Lock, Allan, & Resta, 1998; Good, 1996; National Council for Accreditation of Teacher Education (NCATE), 1997; Smith, Houston, & Robin, 1995).

There is acknowledgement among researchers that mentoring relationships are paramount to successfully assisting beginning teachers in adjusting to teaching requirements. Through supportive national, state and local efforts seeking to support mentoring relationships between experienced teachers and preservice teachers, entry-level teachers have a chance to become better prepared at facing the day-to-day challenges of the classroom. The trained mentor/observer is able to observe and analyze teaching and provide the preservice teacher with substantive and specific feedback as part of the mentoring process. The mentoring relationship is generally organized around such supportive activities as: (a) observation (visiting each other's
classroom); (b) demonstration (coaching); (c) conferencing (feedback); and, (d) joint preparation (Alderman & Milne, 1998; Gratch, 1998; Hawkley, 1998). Reports indicate that effective mentoring is based upon interpersonal communication. Through communication, mentors and mentees can develop along the three phases of the mentor/mentee relationship: (a) establishing the relationship; (b) getting to work; and (c) evaluation and follow-up (Alderman & Milne, 1998; Gratch, 1998; Hawkley, 1998; Hiemstra & Brockett, 1998).

Method
Semi-structured interviews were used to collect data about: (a) the training program, (b) the mentoring experience and (c) the technology integration efforts from TIC participants. Audio taped interviews were conducted individually for all participants and were approximately 30 minutes in duration. The twenty interview questions were broadly grouped into three categories that included: (a) TIC collaboration; (b) TIC support and interaction; and (c) attitudes, comfort, and ability to use technology. For this study, the data gathered included only the personal experiences and opinions of the TIC participants. Using the process of constant comparison, responses were coded and sorted according to themes that developed. All interviews were audio taped and transcribed for content analysis. To check the reliability of the interpretations, an independent evaluator reviewed all the recordings of interviews to confirm quotes and organization of patterns of participant responses. A second evaluator checked and coded the transcribed responses to ensure reliability. A further comparison was made of the two reviewers' codings and organizations. Member checking was also performed to ensure the credibility and trustworthiness of the data. Participants unanimously perceived the presented results as accurate reflections of the TIC experience and concerns specific to integration. The interview responses were examined and partitioned into data units by the reviewers. These data units were organized into categories established from specific themes that developed out of the interviews. These categories were grouped directly from the themes to organize the findings.

Each TIC was responsible for producing products or resources that exemplify their innovations. These might include detailed descriptions of teaching strategies, lessons, media, technology competency tutorials, or student portfolios for example. TIC developed products provided evidence of the TICs application of instructional technology. Throughout their involvement in LearnGen, progress reports were submitted by participating teacher education students. These reports reflected the progress and growth of each TIC as they developed their innovations. In addition, each TIC provided relevant information about their cohort for their cohort website as well as submitting one or more examples of their innovation(s) to be disseminated.

The LearnGen project’s purpose was to integrate instructional technology into a teacher education program through a collaborative model. Therefore, the work produced by the TICs was reviewed for evidence of the following attributes: collaboration; use of technology; the integration of instructional technology; and, emphasis on teacher education.
Discussion
Emerging from the analysis of the TIC products and interview results were several informative themes from which we were able to identify lessons to apply to future TICs. Generally, the use of technology within TICs occurred in one of two ways. The first was to use technology as a means to facilitate the work of the TIC. In this example, technology was secondary to the mission of the TIC and would be used to record or produce their final product(s). A second way in which technology was used was as a component of what the TIC was developing. In this way, technology was a primary focus of the TIC and the work of the TIC was centered around its integration into educational settings. This delineation of roles was also seen in the way in which each TIC viewed the integration of technology. Some TICs viewed technology integration as a key component to laying the foundation for further technology integration. Other TICs viewed technology integration as an opportunity to provide a direct integration of technology. These TICs approached their innovation as a way to learn new technology and integrate this technology directly into the educational setting.

Individual progress reports indicated that the TICs typically consisted of a teacher education faculty member, two teacher education students and one or more K-12 educators. Findings from the TIC final reports (reflecting their efforts and providing a description of their innovations) suggest that no two cohorts functioned in exactly the same manner. In fact, their individual accomplishments were attributable to their unique relationships brought about through collaboration. However, simply considering what the TICs “produced” or reported did not prove sufficient. Those involved and the type of interactions that occurred varied greatly from group to group.

TICs approached the integration of instructional technology in one of two ways. First, on a curricular level, several TICs explored how to integrate instructional technology into specific courses, such as what technology skills were needed by prospective teachers or what special educators expected of teachers that were to use technology to aid with adaptive instruction. Second, on a technology level, several TICs sought to develop technology-based products suitable for use in a course or a K-12 classroom, such as the legislative tracking assignment or the review and application of educational software within three professional development schools. Since the TICs work typically represented a snapshot of the K-12 or teacher education course or program, it was difficult to determine the reach or quality of the integration. With the review of the software, for example, while this was requested by the K-12 educators, there is no record if teachers in the three schools took advantage of the information.

The original expectation for TIC members was to gather and decide amongst themselves what the direction of the TIC would be and how they would accomplish it. This presented a challenge for some TICs. A teacher education faculty member observed, “I don’t think that we had enough information about the expectations of a faculty member or what a TIC should accomplish. Contrary to our original expectations, we discovered that some clear definition was essential for
the process to emerge. TICs that were formed around an idea generated by the teacher education faculty member proved more successful than those that sought to use the entire TIC to generate the idea. In addition, TICs that based their work on the initiative of the teacher education faculty member were up and running much quicker than other TICs. This is not to suggest that the other TIC members were peripheral to the process, but rather that the innovation was directed both toward the teacher education faculty member and a portion of their responsibility in the teacher education program.

Unanimously supported by TIC members interviewed was the need for an informal, yet systematic process of forming TICs. As a result, several changes were made to the cohort development process for the second round of cohorts. In order to accommodate faculty needs and offer faculty an opportunity to explore their interests, one of the co-principal investigators of LearnGen took on the role of faculty liaison. As faculty liaison, he is able to offer additional opportunities for open-ended discussions and exploration of faculty ideas, needs, and interests as they relate to technology integration. The results have been promising to date.

An intended outcome of the LearnGen project was to develop and encourage future collaborative efforts among faculty, students, and the K-12 community. The strongest evidence to support this was seen in the work and activities of the teacher education students following their involvement in the TIC. While unfortunate for the education profession, two of the TIC student members have since chosen technology-related occupations in the business world. Other students have taken on additional responsibilities related to technology either through their involvement within the school of education, or as members of technology-based projects throughout the school of education. Some students have reassessed their careers and have chosen to pursue terminal degrees. These students are considering careers in the field of higher education and technology leadership (i.e., district, administrative, or site-based technology integration specialists, technology support, and technology training).

Faculty mentoring was evident throughout the study, however, reverse mentoring was much more common. As one teacher education faculty member put it, “It was nice to be working with someone who had a technical expertise to be able to help me figure out how to take ideas that I had and...make them a reality. I think if I’d had the same level of technical expertise as them [the student], I’d question whether or not our TIC would have been as successful as it was because basically I’d talked about doing the programming and setting this thing up and I was lost.” Preservice teachers found themselves in “enviable” positions. They soon found validation among their peers and among faculty for the technical expertise they possessed. “In some way I actually became a mentor as far as instruction was concerned.” The role of the student in the TIC process was unique. This is seen as a strong indicator of the success of the TICs in general. As one student discovered, “I didn’t understand it until [faculty TIC member] led a conference in Dallas. He had mentioned while giving a presentation for the first time that I was “his” mentor.
He totally took me off guard. I hadn’t really thought about it that way. I realized that I kind of was because I was the one that was teaching technology and trying to integrate it.”

The impact of the incentives for student participation was significant. Incentives took the form of laptop computers that were assigned to each student to use as needed throughout their involvement in the project; a small hourly wage for their time commitment; and exposure to a wide variety of technologies and opportunities.

Lessons Learned

1. Faculty ownership is critical. Given the experiences of the first year, those cohorts that were formed around an idea generated by the teacher education faculty member were more successful than those that sought to use the entire cohort to generate the idea.

2. An informal, systematic process of forming and reviewing cohorts is needed. Cohorts now are required to complete a seven-stage process.

3. Mentoring plays a key role. TIC members adopted a mentoring approach to contributing to the "supportive environment" of the TIC.

4. Technology integration increased. Participants reported an enhanced understanding of instructional technology, an improved capability to integrate technology into higher education and K-12 classroom instruction, and general understanding of how to use technology as an instructional tool to meet all learners’ needs.

Conclusion
Throughout the study, participants reported an enhanced understanding of instructional technology, an improved capability to integrate technology into higher education and K-12 classroom instruction, and general understanding of how to use technology as an instructional tool to meet the needs of all learners. Clearly, this is evidence that technology integration across preservice course work is on the increase, and the potential for widespread integration is a possibility.

While the long-term success remains undetermined, those involved have come to understand that the power of technology integration is best realized through collaborative efforts. The strength of this project's efforts rests in the inclusive and collaborative nature of the TICs, the support system provided to them, the level of faculty ownership and the design, testing, and reporting of their technology innovation efforts.
"Once upon a time there was a faculty member in a school of education who wanted to involve students in activities incorporating the World Wide Web. This faculty member wandered the on-line vineyards and found K-12 vines that produced lesson plans and even content-related activities for use with elementary and high school students. The faculty member wandered for days and finally found a few vines that contained information appropriate for use in an undergraduate teacher education class and a few vines appropriate for use in graduate classes in education. Only a few of these vines were useful for what the faculty member was planning to teach. The yield from the harvest was small for the time spent in the search. The faculty member was discouraged and wondered whether the incorporation of web-based activities was such a good idea. If only the faculty member had know about MERLOT, the search would have been quicker because the types of vines are identified and would have often been reviewed by peers."

MERLOT (Multimedia Educational Resource for Learning and On-line Teaching) is a database that can assist university faculty to quickly locate sites that would contribute to the instructional process. The MERLOT database is a collection of links to web sites that present content specific information within a variety of content areas. The objective of the database is to provide a collection of materials that are peer reviewed for the educational efficacy within specific fields. In this paper, we will specifically address the Teacher Education portion of the database.

The database serves two functions. The first function is the collection of sites useful for teaching at the university level. As anyone who has searched the web for materials can attest, the time spent searching the web can be daunting. By collecting sites submitted by the developers or by professors who have used the sites with classes, the database provides a timesaver for professors engaged in instructional planning in which the incorporation of the web is desired. This is extremely important in teacher education because professors must model those behaviors and skills that teacher education students must learn and later exhibit in their classrooms. As with any group of professors, teacher education professors teach classes, attend committees, engage in service, and produce scholarly works and time is at a premium. Time spent surfing the web for appropriate sites to integrate into classes can take time away from these other activities.

The database provides not just the name and a link to the site but a brief description of the site. Sites that have a Peer Review are identified with a rating of up to five stars. A compilation of the reviews is developed and can be accessed by users to see not just specific details about how the site fared but also information about learning goals that can be addressed by the site; the intended audience and other possible audiences for the site; the prerequisite knowledge and skills needed to get the most out of the site; the type of material, and a note about special technical requirements. The inclusion of this information can help the professor quickly eliminate sites and cut down the number of sites he or she needs to directly preview for use. The database also provides the opportunity for users to make comments and to describe activities they have developed to use in conjunction with the sites.
The second function is to provide professors who have developed materials to use in their own teaching may get those materials reviewed, in a manner similar to how journal articles are reviewed.

The review process for the Teacher Education portion of the MERLOT database begins with submission. The MERLOT database is an open database in which both users and developers of sites may submit sites for inclusion. Teams of reviewers analyze the site for its quality in three areas: Quality of the Content; Ease of Use; and Effectiveness as a Teaching Tool. The quality of content includes not just accuracy but the clarity of presentation and relevance. Ease of use covers such characteristics as how easy the interface design is to negotiate for both faculty and students, how engaging the presentation is, and how interactive the site is. The last aspect that is analyzed is the effectiveness of the site for use in an instructional setting. The site is examined for the presence of objectives, potential for integration into teacher education classes, and instructional flexibility. The usefulness of the database would be limited if the organization only viewed the collected sites through “Teacher Education” without breaking the major category down into areas within the field.

The Teacher Education portion of the database is divided into subcategories that were hammered out and agreed upon by educators from around the United States and Canada. The subcategories are: Educational Foundations; Educational Psychology; Classroom Management; Diversity and Multicultural Education; Educational Research; Instructional Technology; Special Education; Student Assessment; and Teaching Methods. The database can be searched through the use of these categories or through the use of descriptors using the search function within MERLOT.

MERLOT can be a great asset to busy faculty from two standpoints. First when faculty develop web-based materials for student use, those materials can be reviewed and provide the faculty member with documentation that parallels the peer reviewed journal article. This can help faculty gain recognition for the scholarly aspects of teaching. In addition, the availability of the materials in the database can help save time in the task of incorporating web-based materials into our classes.
Using Streaming Technology to Build Video-Cases that Enhance Student Teaching on IT

Simon Wing-wah So and Sai-wing Pun
Department of Information and Applied Technology
Hong Kong Institute of Education

Hong Kong SAR, China
E-mail: {swwso | swpun}@ied.edu.hk

Abstract: This paper describes a prototype of a development project for practicum classes in the Hong Kong Institute of Education. An in-house development of a streaming video system is used for improving student teaching by building a digitized video database from a variety of sources. The main objective is to develop an interactive web-based video platform for critical analysis of significant classroom activities and events related to IT teaching skills and strategies. In designing our video system, Synchronized Multimedia Integration Language (SMIL) is used. Video clips can be synchronized and displayed in parallel with text clips showing the teaching sequences and key ideas. Viewing and critiquing the videos side by side in an on-line setting is the key learning strategy that provides opportunities to develop student teachers' reflective thinking skills and interactive reflections with their classmates through on-line forum discussions.

Introduction
In the practicum and methods classes, the student teachers usually conduct trial or experimental lessons that are prepared, taught, and then collectively critiqued. Each period can only highlight a different teaching skill and edited video tapes are sometimes used to supplement for any classroom practice. Recently, there are trends of reducing the contact hours and increasing of class size in IT practicum and methods classes. Within these classroom constraints, teaching skills taught, variety of classroom situations observed as well as number of participating student teachers are limited. The proposed interactive web-based video platform for critical analysis of significant classroom activities will provide repertoires of specific teaching skills as well as diverse classroom situations. Because of the 24-hour availability and accessibility of these videos, student teachers can achieve extensive field experiences prior to teaching practices. Researches (Risko, 1991; Stephens & Leavell, 1999) suggest that viewing video cases student...
teachers are able to examine the dynamics of school classrooms and benefit from multiple perspectives when viewing is done collectively with classmates or other colleagues in the faculty. Stephens & Leavell (1999) also reported that video minicases which are short vignettes selected as examples of teaching practice can greatly enhance student teachers' instruction ability since the vignettes are purposefully selected. Accordingly, student teachers are able to compare their interpretations with those of others when viewing the same video case or similar vignettes.

System Overviews

Traditionally, student teachers can reflect on their own teaching performance or analyse other practicing teachers' performance through videotapes with paper-based observation forms. Preset questions are usually provided for the analysis of the teaching sequences against the intended objectives, designated activities and learning outcomes. The disadvantages of this approach include the following:

1. Physical videotapes are bulky in handling and viewing;
2. It is difficult to annotate important teaching characteristics onto the videotapes;
3. Searching similar characteristics from the repository of related videotapes are not easy; and
4. Critical reflection by student teachers cannot be easily done visually and interactively;

Furthermore, video vignettes can only be produced in video segments which cannot be retrieved or managed easily. Therefore, a digital solution with online viewing, searching and critiquing is highly desirable. Figure 1 illustrates a schematic representation of our desirable system. A video case can be viewed alongside with key ideas explained. Hyperlinks for related video clips or websites to support the topics of interests are timely provided. Critical reflections related to the video segments can be collected.

Figure 1. A Schematic Representation of the Video System
In designing our video system, Synchronized Multimedia Integration Language (SMIL) is used (Alesso, 2000; Kennedy, 2002; Williamson, 2001). SMIL is ideal to our application. Video clips can be synchronized and displayed in parallel with other media information. In conjunction with a streaming server, video cases can be retrieved over the Internet. Figure 2 shows our prototype using SMIL and its related technologies. A student teacher conducts teaching in a practicum class. The four teaching sequences, namely introduction, motivation, development and consolidation, can be viewed serially or in any order by clicking the links. Key points are further explained and annotated. Also, if there are existed other video segments related to the key points, hyperlinks are provided for easy access. Figure 3 shows the related clip with the student teacher, Chan TS, after clicking on the item on Figure 2. Student teachers can also enter into the forum for critical reflection at any time as shown in Figure 4.

Consolidation

Teacher provides an introduction to the topic.

Other related clips:

Figure 3. A Sample Screen shot from Selecting "Chan TS" on Figure 2

Figure 4. A Sample Screen shot with Critical Reflection
Using streaming technology to build the video cases, the advantages of our system are the following:

1. The video cases can be viewed online;
2. We can directly and effectively index into any portion of the video clips in our repository;
3. One can easily control the timeline and important points can be re-visited at ease;
4. We do not need to split and/or merge clips into a single clip for the teaching and learning purpose; and
5. Video stream can retrieve without long delay over the Internet.

Furthermore, by responding to the on-line reflective forum, the student teachers can thoughtfully examine effective teaching principles and practices of each video case. Viewing and critiquing the videos side by side in an on-line setting is the key learning strategy that provides opportunities to develop student teachers’ reflective thinking skills and interactive reflections with their classmates. Unlike any class discussions, viewing videos in a detachment setting, student teachers can independently develop their own reflections about a specific teaching skill and then argue with their peers in the web-based discussion forum.

Conclusion and Future Work

The proposed system allows student teachers to reflect on any key events posed in the video cases as well as to link the theory into the practice more coherently. The flexibility of our system is apparent in comparison to the conventional approach of analysing videotapes for teaching practice.

Our future work on this system is to build another "meta" database which can assist us to generate the content of video cases dynamically. By using structured information of the database, we can automatically compose SMIL scripts and related files on-demand.

Abstract: This paper describes an ongoing study of the learning quality of online dialogues. It suggests the unit of a language game as suited for a learning perspective, which captures netbased collaborative learning as a process evolving in online communities of practice. The paper suggests some possible modifications to the Global Change course that will allow us to examine in a systematic way the use of an alternative analytical unit.

Introduction

Development of an instructional design that stimulates and supports collaborative dialogue on the Web may require that we start from scratch and create a design that emerges ontologically from a true integration of technology and pedagogy. Design and assessment of learning processes in such an approach should be based on the true premises of the virtual environment (Sorensen 1999). If we think beyond simply creating an online mechanism for dialog to creating a framework that will promote high-quality interaction and allow for relevant evaluation/assessment, we must search for the appropriate analytical unit. In order to do so, we need to start from a clarification of the learning perspective behind the design and construct the analytical unit from this perspective. We present a theoretically based conceptual framework based on the notion of "collaborative learning in online communities of practice" for understanding and identifying collaborative knowledge building dialogue. This includes identification of an alternative analytical and evaluative unit in distributed collaborative knowledge building on the Web, inspired by the concept of "language games". We also discuss implications of this for design learning processes that allow students to collaboratively develop "knowledge tapestries" through meta-awareness of how such language game structure is developed.

Learning Collaboratively in Online Communities of Practice

Our previous pilot study (Sorensen and Takle 2001) focused on analysis of individual comments posted by students in the Global Change course and the influence of setting requirements on higher-level thinking skills in advance of submitting the comment on the web. To examine this issue further, we posed the notion that our previous focus of analysis was misdirected and that we should focus on the thread or collections of threads rather than the individual comment as the analytical element in evaluating collaborative learning. Acknowledging this shortcoming of our previous attempts revealed that we had inadvertently suppressed the social element of dialog: our over-emphasis on contributions that can be created individually (i.e. without collaboration) was suppressing meaningful interchange among students and suppressing opportunities for true collaboration. The specific learning perspective we want to promote, "collaboration in online communities of practice", is rooted in both the principles of Computer Supported Collaborative Learning (Dillenbourg et al. 1995), and in a social theory of learning taking place in communities of practice (Wenger 1998). We base our search for an analytical unit on these theories. In Wenger's perspective, a social theory of learning must necessarily encompass the elements that denote or characterize social participation as a process of learning. Learning takes place through engagement in actions and interactions in communities of practice. Collaborative learning principles call for the perspective and functioning of group learning, while Wenger's theory points to the learning process as an aspect of the functioning of a community of practice. They both emphasize learning as an individual and a social phenomenon, and they both argue for shared, collaborative and democratic learning efforts, stimulated through participation, engagement, motivation, and ownership.
"Language Games" - An Alternative Unit?

Most attempts to analyze asynchronous electronic discourse seem to lack a theoretical base. The results of such analysis are usual pictorial maps describing the interaction over time. Some have attempted to map message-interconnection through analyzing the "threading" to make expose linkages among interactions (Levin et al. 1990; Ellis & McCreary 1985). Such studies demonstrate important aspects of the "threading facility" of most computer-mediated communication systems (CMC), but they fail to go beyond the simple characteristics of message-to-message referencing. Wittgenstein's (1974) notion of language games offer a holistic, social, and constructive view in which structural coherence forms a key point for establishing any meaningful dialogue. The theory appears suitable for capturing essentially the interactive and dynamic aspects of human communication. One of the attractive features of the language game theory is that it is very general and comprises central aspects and properties of collaborative actions in practice. In the concept of language games, an action must be interpreted in inextricable association with the activity in which it is used. We build up expectations during the course of interaction, which are based on our knowledge of various kinds of activities and their rules. Viewing the concept of games in relation to social interaction it becomes clear that a language game is realized as a sequence of actions by participants. This means that in some sense a "player" in the game knows what to do when another player has acted. Actions are subject to specific rules, and the players in the game possess knowledge of rules of the game. Knowledge of the rules is not explicit in the sense of awareness in the players. Describing a sequence of utterances in terms of games is equivalent to assigning it a structure. In particular the linguistic interaction (the dialogue) process can be understood as successive openings and closings of language games at different levels, where some games, subgames, are "embedded" in and controlled by others. Each game opened creates a set of expectations about the continuation of the game. The important role of these expectations is that each comment is interpreted according to the expectations. The framework suggested here includes the important elements of dialogue and discourse. It is in agreement with a general theory of social action and comprehension. It supports the view that human interaction can only be interpreted as part of a social context, and that "negotiation of meaning" is not a "defect" of interaction, but is rather constitutive of it, to the extent that specific interactive mechanisms exist that allow mutual understanding to emerge (Dillenbourg et al. 1995, p. 204).

Language Games: Implications for Design

Our previous attempts to establish dialog within the Global Change course created threads that had related ideas but which often lacked substantive interconnections. Students rarely joined together to mutually explore an issue in detail. In some cases there was no evidence that an initiator of a game returned to the game even though it was clearly his/her "turn". And rarely, if ever, was there any weaving of different threads to form "tapestries of dialog". Threads of dialog seem to have a natural tendency (perhaps exacerbated by our demands on dialog quantity) to diverge. We seek a solid foundation in learning theory for the development of an instructional design, since paradigms designed for face-to-face learning environments might not apply or might overlook some unique opportunities of the online virtual environment. We have suggested the concept of language games as a basis for considering the issue of closure as well as development of dialog threads. We offer some tentative suggestions that will form the basis for some of our experiments with the next offering of the Global Change course.

Abstract: This paper addresses the problems of collaboration in distributed web-based learning. It reviews, treats and discusses these problems from the learning theoretical perspective of "communities of practice" as presented by Etienne Wenger (1998), with reference to past and future web-based designs. The paper suggests the concept and design of virtual portfolio as a pedagogical tool to be implemented in the virtual environment for the enhancement of distributed collaboration in web-based learning.

Introduction

It is widely accepted that web-based learning environments, on the one hand, offer promising and qualitative potential for distributed CSCL (Computer Supported Collaborative Learning). It is, however, equally shared that they present us with complex challenges in terms of student engagement, interaction and collaboration. The problems of engagement and interaction in collaborative processes in distributed Web-based learning appear to be recurring phenomena, often stated by the literature (Kaye 1992; Mason 1993; Sorensen 1997; Dirckinck-Holmfeld 1990; Fjuk 1998). It seems to be a stubborn feature in the delivery of distributed CSCL on the web that collaborative initiatives and processes -- in their broadest sense -- have a hard time coming into existence (Sorensen 1997).

The searching for reasons to these problems and ways of solving them have produced a variety of foci and initiatives, all of which are resting on different assumptions. The role and communicative behavior of the instructor as a unit of analysis has received a considerable amount of attention, based on the assumption that the teacher's behavior in the virtual learning process to a large degree is responsible for a lacking engagement and interaction among students (Davie 1989; Feenberg 1989). Another concern has addressed the nature of the collaborative activities implemented in the learning process, based on the assumption that a main reason for lacking interaction and collaboration most likely were to be found in the way the distributed collaborative tasks and activities were designed (Collis 1996). There is no doubt that both of these research perspectives deal with very pertinent aspects of virtual learning designs and deliveries, but it is equally unlikely that they constitute the whole story, so to speak. What characterizes these perspectives, however, is that both assume the main cause of the problem concerning interaction and collaboration to be situated in the instructional and pedagogical aspects of the learning process. There are alternative studies concerned with the nature and quality of the virtual environment and its ability to support collaboration. One illustration of this is the design of the Virtual-U environment, which can be viewed as a result of design efforts especially directed towards facilitating and scaffolding collaborative interaction in web-based learning (Sorensen 1999). Other perspectives concerned with collaboration, e.g. as a broader concept than linguistic interactions, most often are to be found among software designers, developing shared tools like e.g. shared documents or shared whiteboards to facilitate "tangible" (non-verbal) collaborative (inter)actions in web-based learning.

Discussions around collaborative learning designs often mirror the latent perspective that collaborative learning is more or less synonymous to collaborative (linguistic) interactions. Only few studies seem to address, both the linguistic interaction and the non-linguistic collaboration among students as two sides of the same coin. This paper argues that linguistic interaction and the more tangible carrying-out part of the interaction cannot be separated from each other. We must build shared communities of practice, shared frameworks, and shared histories in order to support distributed CSCL.
Distributed CSCL as Virtual Communities of Practice

Collaborative learning between students is widely recognized as a fruitful way of learning. It is through collaboration that negotiation of perspectives between peers takes place, a process through which students reconsider and reflect on the perspectives of their fellow students and accommodate those to their own knowledge and beliefs (Fjuk & Dirckinck-Holmfeld 1997). Collaboration in learning creates a positive commitment that motivates participation and drives the learning process (Illeris 1981). But collaboration is not something that can easily be implemented in a learning situation. As argued by Salomon, collaborative learning demands that the whole learning environment being designed as an orchestrated whole (Salomon 1995), meaning that all the entities and processes in the learning environment (including curriculum, activities, and roles) must be taken into account. Salomon argues that the design of the technology itself is the least important factor in facilitation of collaboration in learning and that negotiation of perspectives between peers takes place, a process through which students reconsider and reflect on the perspectives of their fellow students and accommodate those to their own knowledge and beliefs (Fjuk & Dirckinck-Holmfeld 1997). Collaboration in learning creates a positive commitment that motivates participation and drives the learning process (Illeris 1981). But collaboration is not something that can easily be implemented in a learning situation. As argued by Salomon, collaborative learning demands that the whole learning environment being designed as an orchestrated whole (Salomon 1995), meaning that all the entities and processes in the learning environment (including curriculum, activities, and roles) must be taken into account. Salomon argues that the design of the technology itself is the least important factor in facilitation of collaboration in learning and that computers alone are not likely to produce a genuine interdependency that creates need for sharing, for joint endeavor and for a pooling together of minds (Salomon 1995).

In principle, we share Salomon's view. Nonetheless, one should not eliminate the role of technology, especially in the context of distributed CSCL, as there are reasons to assume that the less people meet face to face, the more dependent they become of computer tools and their quality in order to succeed in collaboration. The establishment of interdependency between peers, which (according to Salomon) is a fundament for collaboration, is also dependent on the availability of appropriate tools. Virtual collaboration gets established through technological tools allowing minds to focus on the same problem. This means that the medium, on the one hand, enables a group of people to communicate, and on the one hand, allows them to carry out non-verbal collaborative actions and produce shared reifications during their collaborative work process. These tools are important for collaboration in general, but for distributed CSCL they are essential.

The design of these tools demands an understanding of how people learn in social contexts. For that purpose we turn to Etienne Wenger and his concept of "communities of practice" in which he conceptualizes a social theory of learning (Wenger 1998). According to Wenger the core of social learning is the continuous negotiation of meaning between participants in a practice. This negotiation process is an inseparable part of practice. If there is no negotiation of meaning, there is no practice to be part of. The negotiation of meaning is an intricate process. It is not limited to linguistic behavior. It also includes our social non-verbal interactions and relations. Wenger explains the negotiation of meaning as involving two constituent processes: participation and reification. These two processes exist in duality, affecting each other and being the source of development to each other:

I will use the term participation to describe the social experience of living in the world in terms of membership in social communities and active involvement in social enterprises. Participation in this sense is both personal and social. It is a complex process that combines doing, talking, thinking, feeling, and belonging. It involves our whole person including our bodies, minds, emotions, and social relations (Wenger, 1998, p. 56).

Reification ... refers to the process of giving form to our experience by producing objects that congeal this experience into "thingness" ...Reification can refer to both to a process and its product (Wenger, 1998, p. 58).

But since production of meaning is distributed across reification and participation, a dynamic relationship between the two must be established in our design and facilitation of learning. If not, the negotiation and construction of meaning may become problematic.
If participation prevails – if most of what matters is left unreified then there may not be enough material to anchor the specificities of coordination and to uncover diverging assumptions. If reification prevails – if everything is reified, but with little opportunity for shared experience and interactive negotiation – then there may not be enough overlap in participation to recover a coordinated, relevant, or generative meaning (Wenger, 1998, p. 65).

In a community of practice the reificative and participatory aspects form what Wenger denotes as a *shared repertoire*. A shared repertoire is the fundamental resource for negotiating of meaning in a community. It is a product of a community of practice over time, including routines, words, tools, ways of doing things, stories, gestures, symbols, genres, actions or concepts that the community has produced or adopted in the course of its existence, and which have become part of its practice. Viewing CSCL as a virtual *community of practice*, a challenge for design is to apply technological tools that constitute a *shared repertoire*. The shared repertoire (the duality between participation and reification) is open and directly available for negotiation in face-to-face learning communities. But in a distributed, symbolic, asynchronous virtuality, which is fundamentally established through technology, the processes of both participation and reification must be built into the technological tools.

In our view, the lack of shared repertoire is one of the most serious shortcomings of most CSCL environments. Later in this paper we suggest the virtual portfolio as a promising concept for visualizing the shared repertoire. The virtual portfolio is interesting and valuable because it makes explicit, both the negotiation (i.e. the participatory aspects) and reification of meaning.

**Virtual portfolios – Up Until Now**

Portfolio has become a popular educational tool. It is being used in courses reaching from basic to higher education (Niguidula 1993; Leeman 1997/98), and it has been adopted as a tool for professional development and lifelong learning (Tenhula 1996). Historically, the portfolio concept has developed from artistic professions (e.g. architects, designers, models, etc.). In artistic contexts portfolios are used as collectors of the products of the artists. Likewise, a student portfolio is a purposeful collection of samples documenting the work of a student, exhibiting quality and progress.

From a pedagogical point of view there are two basic reasons for using portfolios (Arter 1995). It is a powerful tool for assessment, and it is a supporting tool for structuring and giving momentum to the learning trajectory. In any case, both of these aspects are meaningless to separate, since they appear to be two sides of the same coin. Our motivation for using virtual portfolios (VP’s) in design of distributed CSCL is their potential for structuring the learning trajectory in a way that highlights learning as a constructivist, experiential, reflective and social matter. As the concept of VP is a very open concept, many of the constructivist approaches and net-based learning environments are included. VPs provide useful frameworks for discussing and designing student centered learning environments on the net.

**Advantages of using virtual portfolios**

From the presented perspective of learning as a phenomenon, taking place socially through negotiation of meaning between participants in communities of practice, VP’s represent the following attractive potential for supporting learning:

- VP is activity oriented, as activities aiming at fulfilling learning goals may be implemented
- VP may support student-centeredness, if the VP is owned and controlled by the student
- The student may be involved in the assessment process, as the VP supports self-reflection as a learning activity. By letting students assess their own progress, students become shareholders of their own destiny, so to speak (Sorensen & Takle 1999)
- Assessment can be based on samples demonstrating authentic work focusing on the student as a problem solver
- By focusing at different entities during a time period, VP’s make it possible to observe individual student progression (Sorensen & Takle 1999)
- VP’s are artifacts especially suited for reification of meaning. They provide the learner with a "picture" of the accumulated experiences and process of development. Meaning is created, reified through visualization, and laid open for individual and collaborative reflection
- VP’s provide views and structure to the future learning process by prescribing activities ahead. It can visualize participation as history but also as future events. Structuring within course parts helps to maintain a more detailed, structured overview of course elements and supports the cognitive processes of perception,
categorization, classification, recognition, and integration of details of a theme or phenomenon into a whole (Sorensen 1996).

Nevertheless, implementing VP's do not automatically guaranty successful learning. As default, a VP provides a structure of a process over time, but the quality of the VP for supporting collaborative learning in online communities of practice is entirely dependent on the pedagogical perspective and techniques that get implemented in the VP (Sorensen & Takle 2001).

Disadvantages of using virtual portfolio
VP's also have some fundamental limitations:

- VP's are, traditionally viewed, individual tools. The focus is on the individual learner as a constructor of knowledge. One may argue that publishing a virtual portfolio on the Web will enhance collaboration, but it does not happen automatically that sharing of knowledge provides collaboration. If we want VP owners to get engaged in each other's work, we must design for that to be a VP activity.

- There is only a minor distance from supporting to controlling the learner. VP's contain the potential of being tools for control and surveillance. VP's may be used for controlling what the student should learn, and how he should learn. An instrumental pedagogical approach may be implemented in which the VP activities are shaped as tasks with predefined answers, instead of problems to be solved. Viewed from such a perspective, there is some risk that the portfolio may be a tool for reproduction of knowledge, instead of a tool for supporting democratic learning, marked by ownership, personal engagement and lack of authoritative power mechanisms.

Two Different Types of Virtual Portfolio for Collaboration

In order to illustrate the relation between participation and reification and their significance in design of a virtual community, which supports collaboration, we present two different implementations of VP's, both inspired by the portfolio idea. The first example is an implementation that strongly supports participation, but support for reification of meaning is limited by the environment. The second example is designed with reification as the primary goal. In this case, students are using portfolios for constructing their individual curriculum, but not seeking participation and knowledge construction in a social practice.

Participation but limited reification

The first example of a VP is provided by a one-year distance education course on how to employ ICT in learning, offered at Aalborg University in Denmark. The course was delivered mainly as distributed CSCL and attracted 36 participants from all over Denmark. The main part of the course was carried out over the Web, using the virtual learning environment, Virtual-U. An additional four face-to-face seminars were held during this one-year period.

Project-based group work constituted the main activity of the course. The supervision of the project work took place, both at the face-to-face seminars, but mainly asynchronously in the Virtual-U environment. In the problem-based project work, the students specialized in a particular area within the main subject. They departed from a research problem that they themselves identified and formulated, a problem that was related to their concrete daily work and work interests. The problem of their project work was elucidated through study of relevant literature and different types of data collection within the problem area.

The students were provided with a communicative forum as the collaborative space for their project work. No other structuring "environmental" facilities were offered. As argued above, a virtual environment is not necessarily a rich environment, and in order to get more overview and meaning out of their dialog the students were encouraged to create sub-conferences as their need arose (Fig. 1).

Figure 1: The VP structured by means of conferences (were used)
Although the names in figure 1 are all in Danish, it is clear that project group 2 created five sub-conferences: one for literature, one for announcements, one for project guidance, one for project steering, and one for discussing cases. Sub-conferencing may be attractive for structuring the dialog. But it is not an ideal resource for reifying a meaning, which is not obvious to everyone.

In fact, several project groups demonstrated severe difficulties in using sub-conferences for both participation and reification. E.g. the example below (Fig. 2) mirrors the collaboration of project group 1. They created several sub-conferences, but they never used them.

Many virtual learning environments reify meaning, but mainly as sequences of written text adapted to a dialogical structure. A virtual conference may mirror the negotiation process chronologically or sorted by several criteria as e.g. date, participants, thread, etc. But, as argued by Wenger (1998), although linguistic interaction is essential, it is only one of several aspects in the negotiating meaning. In principle, virtual learning environments have provided limited functionality and support for genuine group collaboration in terms of reification. In general, they provide good support for the involved participatory processes, but not necessarily for the reificative part of the learning process.

Reification but limited participation
The second example stems from a course in computer science from Ostfold University College in Norway. The subject was LAN (Local Area Network) and Intranet. It was an open and flexible course, which was attended by both local and remote students, in total 120 participants. The course was carried out without ordinary lectures, but was organized around the structure provided by the student VP. In the course the metaphor of a workbook was used (instead of the term ‘VP’), as we wanted to use the metaphor to indicate the expected work style (a book is supposed to be thoroughly prepared).

Many virtual learning environments reify meaning, but mainly as sequences of written text adapted to a dialogical structure. A virtual conference may mirror the negotiation process chronologically or sorted by several criteria as e.g. date, participants, thread, etc. But, as argued by Wenger (1998), although linguistic interaction is essential, it is only one of several aspects in the negotiating meaning. In principle, virtual learning environments have provided limited functionality and support for genuine group collaboration in terms of reification. In general, they provide good support for the involved participatory processes, but not necessarily for the reificative part of the learning process.
The workbook was divided into four chapters, one preliminary and three main chapters covering different aspects of the subject matter. In the preliminary chapter, the student was supposed to describe his/her learning goals and motives for attending this course. The three main chapters covered important aspects of the subject matter. Each of them consisted of a set of themes, which structured the work of the student. Our experience from the course was that the workbook motivated the students to work in an experiential manner (Kolb 1983). They used the workbook as an artifact where they reified their understanding. They were continuously returning to the workbook as they got more insight and elaborated on the problems, and they created workbooks based on personal experiences and interests. They also browsed each other’s workbook. They compared their own workbook with others. They borrowed ideas from each other, but they did not become engaged in each other projects. There were no real interaction or social participation. They were sharing experiences, but they were not contributing to a shared knowledge building experience. There were no common goals for sharing, no joint enterprises, no mutual engagements. In other words, there was no construction of a community of practice.

Conclusion and Future Perspectives

In this paper we have argued for the need of tools, such as VP’s, to support the processes of both reification and participation in the negotiation of meaning in distributed CSCL. This, however, appears not to be a simple task.

Although VP has been developed as an individual tool for learning, we envision that the concept can be expanded to comprise also the idea of a “shared VP” (i.e. for a group). A shared experience consists of both individual and collaborative contributions, and by collecting them and making them visible and accessible for the community of the group, a shared repertoire for collaboration may be established. The shared VP includes collaborative constructions and collaborative reflections. A shared VP should not be viewed as a substitute for the individual VP. On the contrary, a shared portfolio is dependent on the personal engagement that the individual portfolio provides. You cannot share and you cannot collaborate without having something to contribute – and without reflecting on what you contribute. And in a digital environment you are not equipped for collaboration without a set of digital resources that can present your knowledge and experience. However individual portfolios have limited value to a learning community if they are not shared and used for collective reflection and development.

Abstract: This paper describes a new methodological approach to design education on the web employed in the system called ALE. The system will be used to build a large knowledge base supporting Architecture and Civil Engineering Design Courses and to experiment a comprehensive Virtual University of Architecture and Engineering Design. The ALE system integrates the functionality of a complex e-Learning system with adaptive educational hypermedia on the Web. In this paper we outline the system architecture and focus on the design and functionality of its adaptive learning environment.

Introduction

WINDS (WINDS 2002) is an ongoing European project with the objective to implement an e-Learning environment called ALE integrating an intelligent tutoring system, a computer instruction management system and a set of cooperative tools. We have developed the current version of the system and our project partners from universities prepare more than 20 on-line courses that should be used by students from autumn 2002.

Today there are relatively many web based educational systems (e.g. Hyperwave eLearning Suite) including commercial ones available for teachers and students. On the other hand several tools for developing adaptive courseware (e.g. InterBook) exist, mainly as academic developments. But it is not easy to find a solution that would integrate the functionality of a complex e-Learning system with adaptive educational hypermedia on the Web. And this is the objective we try to address developing the ALE system.

For reaching our goals we have taken into account several of the existing standards and semi standards on learning objects, learner models and their storage and exchange (LOM 2001, AICC 2001). We build on our experience with development of adaptive hypermedia environments like ISIS-Tutor (Brusilovsky & Pesin 1994), ELM-ART (ELM-ART 1998), and ACE (Specht & Oppermann 1998).

The ALE system produces individualized courseware for students depending on their current state of knowledge, their preferences and learning styles. The author specifies the metadata according to which such adaptation methods like additional explanation, prerequisite explanation, comparative explanation, explanation variants or sorting can be implemented, taking into account the user model. In this way, the system can adapt the sequence of content blocks according to the chosen learning strategy. For instance, a concrete example can precede or complement an abstract statement if the student needs it. To reduce the cognitive overload of the learners various annotation techniques are implemented.

ALE is designed to support various learning strategies and their combinations. Paragraphs contain materials for expository (explanatory) education. Discovery learning is encouraged not only by hyperlinks but also by index terms and their interconnection with learning objects and external documents. Collaboration facilities promote constructivistic learning approaches.

This paper describes the ALE integrated environment. First we introduce the basic modules of the system. The main focus is on the adaptive learning environment, especially its domain model, user model, learning object states, annotation techniques, as well as the interconnection with the course index and external documents. Finally we summarize the paper and outline future perspectives.
ALE Modules

A user of the ALE system can have one or more of the following three roles assigned:

- Student
- Tutor
- Author
- Administrator

Each role has access to one special environment – Learning, Tutoring, Authoring and Administration. Additionally each user can access Workspace, Tools, News and Help.

The learners are not only passive receivers of knowledge but can themselves contribute to the corpus writing private or public annotations, providing feedback to the author, or discussing course related issues with colleagues and tutors in a discussion forum. In this way students can answer some questions themselves and can cultivate their ability to formulate problems and give argumentations.

The main tools provided by the system for collaboration purposes are:

- **Workspace** based on the BSCW system (Bentley et al. 1997) to store and exchange documents, support common projects and submit homework.
- **Discussion forums** created by authors for each course.
- **Annotation facilities** to add private or public notes to study materials.
- **Chat facilities** (external) for synchronous communication.

An important feature of the system is the awareness support - the user can see which other students have registered for a certain course and who is currently working in it. The underlying principle is that the system presents all collaboration tools in a thematic context of the current learning unit or index term, i.e. the students and tutors can start a discussion about a single picture or a paragraph in a course and create a cooperation folder in the shared workspace for solving a special exercise.

Students can be assessed when they solve tests and exercises. Tests are evaluated immediately and automatically. Various types of tests like single- and multiple-choice, gap fillings and matching pairs are provided and some others are planned.

More complicated exercises (e.g. design tasks or Bayesian network exercises) are carried out with special external tools, which should be installed locally on the student’s computer or downloaded as an applet. The result should be submitted as homework to the student’s folder. Additionally the system provides interface for external learning components to send messages to the learner model to synchronize external and internal learning support by a consistent learner model. These interfaces can be used to request information about a single learner and statistics about the class progress in a course and to submit information about users from peer reviewing procedures or tutor reviewing forms or automatic exercise evaluations.

The types of learning objects in ALE as well as detailed descriptions of the authoring environment can be found in (Specht 2001a, Specht 2001b). Functionality of the learning environment is described in (Specht 2002a, Specht 2002b).

Adaptive Learning Environment

The ALE learning environment (Fig. 1) is both adaptive and adaptable (Brusilovsky & Maybury 2002). It means the system can automatically adapt to the user given a user model and the user can influence the adaptation by means of the preferences. The user can always enter a configuration dialogue to specify such parameters like the preferred language, learning style (access to related questionnaires is provided), and media type. Based on this information the system selects the appropriate learning environment components and a suitable way of presentation. To support mobile users we plan to enhance the system to take into account additional parameters like computing platform, bandwidth, location, and time to specify the context of the user’s work.

Adaptation of the content presented to a particular user depends on the domain model and the user model (Kobsa 2001). Students can be clustered mainly according to their learning styles to provide certain types of learning objects with higher priority.
Architecture of COMPACT City | City as a system of places | Theory of "Places" | Meaning of space

Meaning of space

Abstract

Introduction

The second part of the lecture Areas Rapport presents two characteristics of space. Space is a very important aspect of the environment, it is not a simple or unitary concept. Space is more than three-dimensional physical space. All space is with whom designers are concerned in the design of a building. Although there is a difference between an Athenian Palace and a freeway at rush hour, we can then distinguish between designed and non-designed space. Designed space is designed meaning, oriented according to some rules, and reflecting some ideal environment. This space, actually used by social groups and reflecting their behavioral patterns, can also be called social space. While social space occurs in physical space, it is distinct from it and the congruence between the two is important.

The Meaning of Space

Fact

Figure 1: ALE displaying a learning element with highlighted index terms and the first of them explained.

The learning environment in ALE consists of the following parts (Fig. 1):

- Learning object display
- Annotated course structure
- Index terms
- External documents
- Student’s progress

Domain Model

The domain model includes the learning objects, their metadata, and relations between them. The learning objects in ALE are designed to support reusability and flexibility in production of individualized courseware. The following basic types of learning objects are provided: course units, learning units, learning elements (paragraphs, tests), and index terms.

All the learning objects can be associated with a subset of the Learning Object Metadata defined in the IEEE LOM specification (LOM 2001). The course authors can also specify basic relations between learning objects based on a subset of the Dublin core recommendations (DCMI 2001). These will include prerequisite relations, relations between course units, learning units, and learning elements. Additionally all ALE learning objects in a course unit will be linked dynamically by the underlying index defined by the course authors. Each learning element has its own didactical goal and the authors can select from a set of pre-defined templates according to the Cisco strategy for reusable learning objects (Cisco 2000).

User Model

The system records all the user’s educational events, called user episodes. These episodes include events of different types:

- Student actions
- System evaluation (tests)
• Tutor evaluation (homework)
• Student evaluation (self assessment)

Based on the episodes the user model is constructed. It includes the user preferences and the user knowledge that can be assumed (seen learning objects) and verified (by the system, tutor, or student). Concerning the verified knowledge the last record is valid, but the user (student or tutor) can specify the priorities of the resources for knowledge assessment. Additionally the user model contains also the user goals specified either as learning objects or index terms. Later on as we adjust the application for mobile users the context model will be added too.

The user model always reflects the current state of the user's progress. The information is available both for the tutor to control the student's study process and for the system to adapt the course presentation and navigation for the student. Recommendations are generated according to the user's learning style and previous behaviour of similar users but only if they were successful.

The states of the learning objects in ALE can be considered from several points of view or in several dimensions. The system distinguishes three of them that are relatively independent: user's readiness, interaction history, and tested knowledge. Additionally some other characteristics can be defined depending on the followed objectives, e.g. current task or context. Interaction history and tested knowledge can be expressed by quantitative information defining the extent of the seen learning object or the tested knowledge, user's readiness is nominal information and depends on the prerequisites specified by the author and on the interaction history of the user.

**Interaction History**

Depending on the history of the user interaction with the system a learning object can be seen, partially seen, or not seen.

A learning element is not seen if it has not been accessed yet. If the element has been accessed it is considered as seen.

A learning unit is not seen if the unit has not been accessed yet. It means none of the learning elements under this unit has been seen. A unit is seen if all the learning elements recursively contained in this unit are seen. A unit can be also partially seen, where the ratio of the seen part can be specified as SLE/LE, where SLE stands for the number of the seen learning elements and LE means the number of all the contained learning elements in the learning unit. In both cases the considered learning elements are not just directly but also recursively contained in the learning unit. The student can see both numbers to have a clue about the size and state of the learning unit.

Thus this state of a learning object can be generally characterized by quantitative information. It is the most general information about the learning object that should be always applicable.

**Tested Knowledge**

A student can check his or her knowledge by means of special learning objects called tests. Each test checks the student's knowledge that can be related to one or more learning objects specified by the author of the test (currently each test item can be associated with one or no learning object – learning element or learning unit).

Generally the student's knowledge of a learning object (learning unit, learning element – paragraph or test) can be expressed by quantitative information. This state of learning objects is applicable only if the author provides corresponding tests.

**User's Readiness**

If the author has specified the learning object prerequisites the system can distinguish the learning objects for which the student is ready from those for which the student is not ready according to the interaction history or alternatively tested knowledge.

It is nominal information that defines this state of the learning object.
Adaptive Techniques

To represent various states or dimensions of an information space various visual emphasis techniques can be used. Some studies (Bertin 1967/1999) of visual perception recommend the following visual attributes for different kind of information:

- Nominal information: texture, color (hue), position
- Quantitative information: length, position

Adaptive navigation support techniques are employed to display the annotated course structure in ALE. The different states of learning objects are represented by adaptive link annotations using icons and alternative texts. Another solution we use illustrates the level of the interaction history for a learning object by color (hue) and the tested knowledge by text size. It can be considered as adaptive text presentation based on dimming. Beside the selection of preferences of students we give the authors and the tutors of a course the possibility to adapt the applied annotation techniques depending on the target group and user features. Tutors can specify that the course annotation and navigational guidance should be more restrictive for novice users (hiding advanced materials with missing prerequisites) and less restrictive for advanced users. This is based on empirical findings and post-hoc studies preformed by (Specht & Kobsa 1999).

Course Index

With each learning object corresponding index terms are displayed. Index terms provide means to interrelate heterogeneous course contents and to find individualised paths through the learning materials. The ALE course index component maintains the index terms together with their respective descriptions, synonyms, different types of relations (e.g. is_a, part_of, related_to, is_similar_to) between terms, their occurrences in the course materials as well as in external documents. The student can access all the information about a specific term by choosing it in the Index frame.

The index component can retrieve and highlight occurrences of index terms within the course materials as well as within registered external documents. We consider it as a step towards open corpus adaptive hypermedia (Brusilovsky 2001) that is a modern trend in the field.

External Documents

External documents relevant to the course domain explain in more detail some specific issues or provide up-to-date information like specialized portals do. Such external documents serve also as resources for homework and projects. These materials can go into more details than the course or give alternative views of the domain. In the Documents frame the student can choose an external document related to the current learning object and view this document either with or without emphasized index terms.

Conclusions and Further Research

In this paper we gave an overview of the current state of the ALE system, especially its adaptive learning environment. It presents learning objects as adaptive educational hypermedia courseware. One of the primary objectives of the ALE system is to make the authoring process relatively simple and to support sharing of resources. Currently several tens of authors test the usability of the system and their comments and suggestions help us to make the system more advanced and reliable. The experience shows that creating study materials of high quality with proper metadata, relationships, index, and library is a very complex process even for teams of skilled authors.

But the potential of the system is high. The created learning objects can be delivered in a variety of ways, from classical web-based training to combinations of classroom events and online seminars, or even as personalized books. Beside the possibility for cross media publishing and the flexible combination of learning objects in individualized curricula the indexing system and the connection of the learning objects allows for personalized coaching of students.

Statewide Collaborative Web Resources for Faculty Supporting Information Literacy

Shaun Spiegel, Assistant Professor; Carol Hansen, Professor
Stewart Library, Weber State University, Ogden, UT 84108-2901
sspiegell@weber.edu; chansen@weber.edu

Abstract: Librarians and faculty working together through Utah's Academic Library Consortium (UALC) are developing a Web site to share library instruction and information literacy competency support materials statewide. These materials include handouts, guides, tutorials, interactive exercises, glossaries, lists of Web links, and assessment instruments. Through Web based sharing, each institution saves a great deal of time and effort by reducing the need for duplication of resources and increasing the quality of resources.

Background:

The Utah Academic Library Consortium was established in 1973 and has developed many cooperative programs for collection development and resource sharing. UALC includes 14 academic libraries at 11 colleges and universities; nine of these are public and two are private institutions. The mission of UALC is "to cooperate in continually improving the availability and delivery of library and information services to the higher education community and to the State of Utah." There were over 126,000 students enrolled in UALC institutions in Fall 2000. Previous UALC collaborations have involved statewide collection management for serials and online databases (Pioneer Utah's Online Library, http://pioneer.lib.ut.us/), reciprocal borrowing, and electronic article delivery services. One of the latest programs being developed is a Web site to share library instruction and information literacy competency support materials across Utah. This project grew out of the need for a statewide clearinghouse for library instruction materials and from the redesign of UALC's online information literacy course, The Internet Navigator (http://wwwnavigator.utah.edu). The Faculty Resource Web site also builds on the national instruction material clearing house model developed by LOEX (Library Orientation Exchange) in Michigan in the 1970's. As more shared databases are made available, library and Internet instruction needs are becoming more similar across institutional and geographic boundaries.

Many of the resources on the new Faculty Resource Web site were originally developed for the Internet Navigator online course. The UALC online course consists of four modules, each with its own exercises, assignments, quiz, and glossary. This course has been used successfully by thousands of distance and online learners throughout Utah and beyond since 1995. A team of librarians and faculty from throughout the state of Utah worked during Spring and Summer of 2000 to completely redesign the course in order to address the dynamic changes in library information environments and to meet the latest information needs of students. As the new content was being developed, the UALC team members realized the value of having access to much of the content in a variety of formats for multiple uses, independent of the larger course, as needed. A decision was made to develop a generic header and provide the same content in a "stand-alone" format for use in any other traditional face-to-face or online instruction sessions. This was the beginning of the Faculty Resource Web site.

UALC Faculty Resource Web Site:

The Web site idea grew from a few handouts to a more comprehensive clearinghouse of instruction materials. Although librarians and faculty have shared materials in the past, the Web site makes this much easier and more effective. A graphic designer was hired to design a generic layout for the materials. The Web site contains three main sections, plus a suggestion form. These sections are:
Instructors Pages: These pages are designed to be used by new Internet Navigator instructors. This section provides guidelines for teaching the course, including suggested grading rubrics, links to the grade database, and standardized email replies. Most of the links in this section are password-protected and accessible only to current course instructors.

Instruction Handouts: This section is a clearinghouse of instructional aids designed for librarians and faculty from all institutions. All are printer friendly, available in html and/or PDF format, and can be downloaded and customized for each institution’s needs. As this page matures, guidelines will be developed to catalog information, either by developing institution, by subject area, or a combination of the two. Handouts or Web readings with broad usage generated from the Internet Navigator course materials include: Outline of the Research Process; Using Reference Tools; Using Internet Search Engines; Using Article Databases; Using Library Catalogs; Creating Search Statements Using Keywords or Controlled Vocabulary; Introduction to HTML; Using Boolean Logic and Other Techniques to Enhance Search Statements; Publishing and Types of Publications; Critically Evaluating Information; Scholarly versus Popular Information; Note Taking Tips; Documenting Sources; Creating Annotations; and Information Ethics for Students. In addition, several interactive exercises have been developed that can be used independently of the Navigator course. Most of these are developed with Flash programming and require student interaction to complete. These include: Finding Call Numbers; Citation Builder (APA and MLA); and a Web Site Evaluator.

Instruction Web Sites: This section includes a collection of links on various instructional topics: Information Literacy Competencies; Copyright and Fair Use; Resources for Distance Learners; Teaching Tips; Instructional Technology Sites; Related Professional Associations, Guidelines & Standards; Assessment Materials & Information; Teaching & Learning Styles; Examples of Syllabi for Library Instruction; Assignment Tips & Examples; and UALC Library Instruction Pages. Current plans are to limit the number of sites listed to the best 10 to 15.

In addition to the collaboratively developed segments of the Internet Navigator course listed above, the UALC Reference and Information Literacy Committee has solicited a variety of additional materials to be included on the site from all of the UALC institutions. These include handouts, brochures, database guides, and other instructional materials. Some of these materials are institution specific, but are included as useful models. Most items, with the exception of the password protected “Instructors Pages”, are publicly accessible and may be copied, printed, downloaded and customized to meet the needs of any particular individual, class, course, or institution.

Future Plans:

This Web based collection of resources will continue to grow and expand as more quality materials are added. Future plans may include the development of more interactive tutorials using dynamic Web programming, a searchable interface, more extensive development policies and guidelines, usage statistics, publication of assessment data and other studies done on the UALC Internet Navigator course and this Web site.

Conclusion:

Information literacy instruction in Utah is becoming more similar across institutional boundaries as we continue to purchase more shared online databases and as students access other shared resources such as online article delivery and full text journals. As electronic resources and instructional pedagogies change, each institution spends much time and effort designing new learning resources and updating existing ones. Because Utah libraries share so many of these resources, there is also quite a bit of duplication. Utah is fortunate to have a history of cooperative programs linking librarians and library faculty. Sharing instruction materials statewide via the Web is a natural and cost effective outcome of UALC’s ongoing cooperative efforts. The UALC Faculty Resource Web site will serve as a central location for updated versions of electronic resource guides, offer variations in teaching and learning strategies, and serve as a center for new instructional ideas. In addition, institute-specific information may be posted as a model for others. These materials will continue to improve and expand as more inter-institutional Web based sharing occurs. This site enhances support for information literacy competency across the state and region.
Hierarchy of Navigation and its Effect on Content: A Designer's Perspective

Staples, Cary., University of Tennessee, Knoxville, TN 37996

Abstract: Over the last 3 years the author has worked with a team of Physics faculty + student designers on interdisciplinary, web development projects. Regardless of the specific visualization objectives, ease of navigation was paramount in all of the projects. This presentation will analyze projects that contain the similar attributes of: 1. large data set, and 2. varied presentation requirements, as similar design attributes were manifested in all three cases. Even though the authors were working with several different publishers and different design teams, the analysis of the information to create an intuitive navigation system yielded similar visualizations and hierarchic organizations.

Paper: In this case study the author will present three design projects: Biology + Genetics, Web Design and Astronomy. In all cases the intent was similar: to design an interface to facilitate the acquisition of information by beginning level college students or elementary school teachers. The interface had to accommodate text, imagery, video, animations and interactive laboratory tutorials. In short, the interface design problem was how to create navigation that left enough room for content.

Different groups of design students were included in the investigation. All three sets of students were asked to analyze the problem without the benefit of viewing the other teams work. All three teams came to similar conclusions regarding placement and organization of content, chapter, unit and site navigation, differentiation between tools and navigation, use of a site map, use of “bread-crumbling” as a navigational tool and as a design element as well as typeface use and hierarchy.

Navigation vs. Tools For the purpose of this experiment, Navigation + Tools were differentiated and defined as follows. “Navigation” refers to the resources available to the user to move through the information: either from level to level or through individual pages in a specific level. “Tools” refer to the electronic resources available to the viewer through out the experience: this includes calculators, web links, glossaries, etc.

True vs. Evaluative Audiences In all cases navigation and tools were differentiated. Navigation was considered primary, however, in all cases, every effort was made to make the navigation “intuitive”. This posed a design problem in that there was a “true” audience, the students who would need to access the information, and an “evaluative” audience, faculty and publishers who had to approve the project and who had the ability to make global changes. In several instances, the “evaluative” audience showed itself not to be as computer literate as the “true” audience. In terms of interface design, the “true” audience was much more experienced in non-linear navigation than the “evaluative” audience.

In figure 1 the template for the Genetics project is outlined. While the author does not support the notion that all sites should have the same gestalt, the author does present a template that provides a good starting point for projects with large, complex information sets.
Fig.1 | http://csep10.phys.utk.edu/klug/

Fig.2 | http://sunsite.utk.edu/verbal
Fig.3 | http://csep10.phys.utk.edu/webteacher2002/winexp/flashmenu/intro4.html

Figures 2 + 3 illustrate different uses of the same organizational principles. While text placement has moved from the right hand side to the left hand side, approximately 2/3 of the field is utilized for primary information and 1/3 is used for support information. Imagery is considered primary information in Figure 2 while text is considered primary information in Figure 3.

These three interfaces also illustrate different approaches to programming. The Genetics site was programmed in Flash, the Verbal/NonVerbal site uses Java and the WebTeacher site uses html.
Over-hyping the Web: Directories, Gateways, Resources and Higher Education Pedagogy.

Dr Stuart D Stein (Stuart.Stein@uwe.ac.uk)
Senior Lecturer in Comparative Genocide
University of the West of England

Abstract

The paper focuses on the adequacy and role of freely available Web resources in higher education courses in the social sciences. In the United Kingdom various higher education related funding bodies have been responsible for channelling resources into the provision of electronic information system resources for use by academic staff and students. Part of these has been directed at funding the development and maintenance of subject gateways. This paper explores some issues relating to the quality of the resources provided and their likely use by those that they are targeted at.

The report of the UK National Committee of Inquiry into Higher Education, the Dearing Report, 1997, noted that:

the innovative exploitation of Communications and Information Technology (C&IT) holds out much promise for improving the quality, flexibility and effectiveness of higher education. The potential benefits will extend to, and affect the practice of, learning and teaching and research. ... We believe that, for the majority of students, over the next ten years the delivery of some course materials and much of the organisation and communication of course arrangements will be conducted by computer. Just as most people will come to expect to be connected to, and to make use of, world communications networks in their daily lives, all students will expect continuous access to the network of the institution(s) at which they are studying, as a crucial link into the learning environment. § 13.1, 13.3 (available at http://www.leeds.ac.uk/educol/ncihe/, accessed 26 April 2002)

Long before this report was published, the Higher Education Councils had been investing significantly in the development of broadband-networked communications, linking universities and, subsequently, Colleges of Further Education to each other, and to Internet hubs. Universities themselves, partly through the influence of the funding councils, have sunk substantial resources into providing various electronic information system resources (EIS), and in training staff and students in their use. The European Union has also been heavily involved in providing monies for research into the uses and application of EIS in institutions of higher education, under its telematics and other programmes.

Access for UK staff and students to EIS resources is provided principally through the Joint Information Services Committee (JISC), which was established in 1992 and which has a budget of approximately £80 million per annum. Much of the online content, in the form of access to electronic publications, and electronic databases/datasets, is provided through the Distributed National Electronic Resource, DNER, which serves some 6.3 million staff and students in the UK. In the JISC five year strategy plan, 2001-05, particular emphasis is placed on the role of the Internet in enhancing learning and access to resources: “The Internet has become vital to further and higher education, not just to enhance distance and flexible learning but as a useful tool in traditional learning and teaching, administration and management and, of course, in research ... teaching staff, managers, and students are all increasingly using the Internet from home as well as at the office. Use of the Internet is nearly ubiquitous within further and higher education, as it has been for some years in the research community.” (http://www.jisc.ac.uk/pub01/strat_01_05/exec.html Accessed 11 March 2002)

Another type of resource that is made available through JISC funding, organised by the Resource Discover Network (RDN), are subject gateways, or hubs. Subject gateways are online catalogues of Internet resources. For the most part these resources are freely available to all those who access them, not only to members of the UK higher education community. These gateways provides access to a series of Internet resource catalogues that list what are considered to be high quality Internet sites and materials, selected and described by specialists from within UK academia and affiliated organisations. Five hubs are currently running, covering the Health and Life Sciences (BIOME), Engineering, Mathematics and Computing (EEVL), Humanities (Humbul), Physical Sciences (Psigate), and the Social Sciences (SOSIG).
The rationales for providing these services, leaving aside the vested interests of those funded from public sources, were stated in a paper focusing specifically on the social science gateway, SOSIG, and are twofold. First, that "the information needs of social science researchers can increasingly be met via the Internet. Electronic information resources relevant to the social sciences, including data and datasets are being made publicly available world-wide and the Internet offers the potential for researchers to access these from their desktops." Secondly, that these resources, as they can be uploaded by anyone, are of variable quality, and that staff, and particularly students, are not always in a position to evaluate their worth: "Without publishers, editors, peer-review and other 'filters', much of it may be invalid, inaccurate or irrelevant to academics." Accordingly, "the gateway provides access to Internet resources via an online catalogue where each resource has been classified and described by an information professional. The SOSIG team locate, assess and describe high quality networked resources from around the world, adding value and saving time and effort for researchers and users of their research by providing the facility to browse and search resource descriptions and connect directly to resources of interest."1

There are a number of problems with this analysis and the solution that is provided through the medium of subject gateways. First, when Internet resources are contrasted with printed materials, the underlying assumption is always that the latter are necessarily superior because of the factors mentioned above. This, of course, is far from always being the case; libraries and journals are full of materials whose worth is problematic. Second, the cataloguing is largely done by librarians, or, as they are now more commonly known, Library Information Specialists. Such specialists are unlikely to be sufficiently familiar with the detailed teaching or research requirements of academic staff in particular fields, or to possess the requisite mastery of the discipline that the resources being evaluated relate to, so as to be in a position to assess their adequacy, other than on the basis of largely superficial surface characteristics. A substantial proportion of the items catalogued by subject gateways, SOSIG and Humbul, for instance, are not likely to be of much use to either research students or academic staff. Third, it is often easier and faster to locate useful resources in a particular subject area by means of effective use and knowledge of search engines, and by links from key sites, than by way of trawls through subject directories. Fourth, the surface characteristics relied upon in the process of classification, institutional affiliation, for instance, fail to take into account that many of the resources uploaded by academic staff are of exceptionally poor quality, and should, in fact, be uploaded on Intranets, rather than the Internet. Fifth, two annual reports by the JISC Scientific Adviser indicate that neither staff nor students, in significant numbers, are using any of the EIS resources provided by the JISC, including subject gateways, despite considerable resources being expended on publicity, and the fact that most library pages of institutions of higher education in the UK reference them.2 The reason for this, although not adequately covered by the monitoring research funded by the JISC, is probably related to the fact that neither academic staff nor students have the requisite time to do so, which is reinforced by the poor quality of many resources freely available when they do. Staff and students would in all probability be better served, in both the short and longer term, by more extensive training in the effective use of search engines, and the evaluation of online resources, than by the funding of subject gateways. These, in any event, cannot conceivably keep up with the volume of resources being uploaded.

Wireless meets Wireline eLearning

Claudia Steinberger
Department of Business Informatics and Application Systems
University Klagenfurt
AUSTRIA
Email: claudia.steinberger@uni-klu.ac.at

Abstract: A lot of software products currently promise to support eLearning but only few efforts are done to detach eLearning from wireline desktop devices toward small mobile and portable ones. This paper investigates how this kind of mobility can broaden the mind of eLearning. It is pointed out that current eLearning products can be classified towards a relatively low maturity level of eLearning. Based on special constraints and additional benefits of ubiquitous learning processes are emphasized which are well suited to be supported pervasively. The Model-View-Controller (MVC) architecture is recommended as a design pattern for integrated learning solutions.

Introduction and Motivation

Economy is evolving to a knowledge based economy. The life of knowledge and human skills is shorter than ever. Well educated and skilled stuff and as a result intellectual capital is becoming the keystone for organizations to get and stay competitive in dynamic markets. For employees this fact increases the pressure to remain at the forefront of education and training throughout their whole career. Four or five year degrees are just the beginning of a life long continuing education (see also Urdan et al. 00). For organizations life long learning of their staff members is as well a competition weapon as a cost factor. Learning has to happen therefor quickly, situative and as effective as possible.

Technology has changed the way we live, think, work and learn. Technology has revolutionized business and now it must revolutionize learning. Life classroom based training is becoming too costly and cumbersome. 80 % already use computers on the job. So eLearning can be seen as a means supporting life long learning with a lot of benefits (see also Rosenberg 01, 30ff). The worldwide web, high-capacity networks and high speed computers make learning available to people 24 hours a day in their office, at home or also in hotel rooms during a business trip around the globe. ELearning enables it to access learning when it is convenient. A lot of web based eLearning solutions are available on the market jet. As we will see later on they can be assigned to different maturity levels of eLearning. But one thing they have in common: the extent of their 'anywhere and anytime' is limited mostly to resident desktop computers with very comfortable user interfaces. Through the rapid development of wireless technologies and pervasive computing (see also Burkhardt et al. 01) also the topic of 'mobile learning' (mLearning) will become more and more significant. Currently eLearning applications running on small and handsome devices supporting wireless technologies or integrating wireline and wireless eLearning approaches are almost not existent in the marketplace. This paper treats features learners will be expecting from mobile learning environments and gives so hints for the further development of appropriate applications. The following key questions are investigated:

- What are the maturity-levels of eLearning, what achieve current products and how can mobility be anchored in this context?
- What are the constraints and additional benefits for wireless learning?
- What learning processes are well suited to be supported wirelessly?
- What drives wireless eLearning and how can it be integrated best into wireline eLearning?
- How can wireless and wireline solutions be integrated best?

A conclusion summarizes the key statements and gives some future perspectives.
The Nature of eLearning

For the most people learning is symbolized through the classroom. This is the reason to see eLearning mainly as the online-version of classroom learning in the sense of eTraining. Instruction and eTraining is one perspective of eLearning, drilling knowledge in form of structured multimedia content presentations accompanied by active elements like self tests, quizzes and various communication possibilities. Constraints for successful eTraining are discussed in (Steinberger 01) and are not detailed further in this paper. Despite of its powerfulness eTraining is not always the accurate way to convey knowledge. Learning is not teaching and eLearning must not be viewed only from the point of view of eTeaching. It must be thought in terms of what the learner needs. Often there exist situations in which learning happens best and in a very efficient way through selective access to collected knowledge. Training is not necessary in this situation what makes eKnowledge an as important and successful aspect of eLearning (see also Rosenberg 01 and Maurer 00). Table 1 mentions the typical characteristics of this eLearning approaches.

<table>

</tbody>
</table>

Table 1: Characteristics of eTraining and eKnowledge

There exist a lot of eLearning products on the market supporting eTraining. Some of them also support knowledge management mechanisms but only few focus on user knowledge collection and access in particular (e.g. Future Learning Environment, Muukkonen et al.99) but mostly knowledge management systems are seen as systems separate from eLearning. Only very few prototypical eLearning products add the possibility to augment learning also to small mobile devices. But in most cases this is done only in excerpt form (e.g. downloading of the course calendar to a PDA in WebCT).

Depending on their properties eLearning products can be assigned to one of five maturity levels of eLearning. Table 2 shows some characteristics of these maturity levels (see also Lytras et al.01). The lowest level covers pure eTraining, drilling in an inflexible teacher-defined process manner locking knowledge in 'course-boxes' with no course independent random access. Level 2 enhances level 1 through eKnowledge functionality and makes knowledge available independent from its pertinence to a special course. Level 3 makes it possible for the learner to select his favorite learning process which makes the content delivery more flexible. Moreover level 4 and 5 enhance the learning possibilities through customization and integration aspects.

Table 2: Maturity Levels of eLearning

Most of today's eLearning Products are settled on maturity levels from one to two. If they support knowledge management at all it is mostly fixed to inputs from special context authors and does not provide user centered knowledge production and distribution. The user is seen almost ever as the knowledge consuming partner in a learning management environment. Learning process specification and customized learning (levels 3 and 4) are still research topics of eLearning. Anyhow some products try to integrate learning and administrative systems via a learning portal and to bridge the gap between level one/two and level five.

Borders between wireline and wireless eLearning are basically independent from the maturity level of a solution. Mobility could also be realized on level 1 and 2 but it is rarely done. Constraints for wireless eLearning and what eLearning processes are best supported in a wireless manner is discussed in the following sections.

Constraints for wireless Learning

In future we will see a tremendous increase of wireless multimedia network terminals that are similar to today's mobile phones or PDAs (handhelds). Wireless technologies like wireless LAN, Bluetooth and GPRS will multiply potential handheld applications. According to IDC in 2000 12.9 millions handhelds were sold. For 2004 they forecast 63 millions handhelds to be sold. Whereas handhelds today are primary sold to private persons IDC believes that in 2004 about 30% will be sold to organizations. About 38% will be smartphones, integrating PDA functionality with features for communication. Also the possibility to use Java (J2ME) on mobile clients will contribute to the success story of the new mobile devices also in the area of mobile wireless learning.

This mobile eLearning devices will be characterized by the following properties:

- small, portable device
- has an integrated camera
- is a full fledged PC
- 'Everynet' with high performance is always available
- has a global positioning system
- serves as electronically wallet
- has speech in- and output
- has an integrated graphic pad to enable simple notices
- serves as portable player
- can operate without socket-power for a long time

Because of the nature of their user interface these powerful mobile devices cannot compete with the user interface of standard desktop or laptop devices. The user interface is one of the key constraints for wireless augmented eLearning. This is the main reason why mobile learning must not be seen as a simple wireless prolongation of eLearning as it happens on desktop or laptop machines. Differences regarding requirements and utilization between learners using small, portable devices and learners using desktop devices have to be seen making eLearning mobile (see also table 3).

The most important criteria for the efficiency and acceptance of mobile eLearning are (see also Zobel 01,166ff):
**5 minute value:** to achieve a benefit for learners using mobile learning devices within a short time; mobile devices are mostly used in niche times to communicate or get information as quickly and simultaneously as possible (e.g. use a discussion forum). For a longer session the desktop device is mainly preferred;

**Simplicity:** to be simple and adapted to the limited display and input possibilities of the mobile device. E.g. although it is technically possible nobody would enjoy to scroll complex and multimedia content files using a PDA-like interface;

**Additional value:** to produce an additional benefit as compared with desktop solutions; one important additional benefit of mobile solutions could be the usage of context dependent information. There can be distinguished between four kinds of context in which a learner can be located (see also Zobel, 50ff):

- location context: the system knows the location the learner resides;
- behavioral context: there are some activities related with the location the learner resides;
- temporal context: there are dynamic and time dependent data related to the location the learner resides;
- interest specific context: the preferences of the learner are addressed in a specific manner;

A pure mapping of desktop eLearning functionality onto mobile devices will fail therefore. It makes more sense to support special learning processes according to the learner needs using mobile devices and boosting the strengths of the mobile approach this way. Processes that need a sophisticated user interface should rather be kept on the desktop integrating wireless activities of the learning community.

**Table 3: Differences in the way to use wireline and wireless eLearning Technology**

**What drives wireless eLearning**

The willingness of learners to use eLearning is relatively high but they will never tolerate bad solutions only because they are web based or wireless. Therefore it is necessary to support learning learner-centered with high usability fulfilling users needs. Table 4 mentions the most important learning processes that have to be supported in an eLearning environment of maturity level two from an learners point of view.

Mobile technologies could significantly augment some of these processes and support processes wireline solutions can not support. But also some processes are not well suited for mobility at all. Table 4 expresses the process capability to get wireless evaluating the 5-minutes value (A), simplicity (B) and additional value (C).

Table 4: Mobility of eLearning Processes (from ++ well suited to -- badly suited)

To summarize table 4 and the evaluation performed there it can be fixed that processes with a high mobility potential typically show some of the following typical properties:
- they focus on communication (e.g. mail or discussion forums to be supported in a SMS like manner);
- if they have to present content mobile this has to be done in a modest form (this is also valid for special knowledge retrieval) – smaller chunks of information are retrieved (with adjusted presentation templates);
- they assess eKnowledge;
- they use the mobile device as portable TVs or meapia-players to become multimedial;
- they entertain the learner in niche times ('gameboy effect')
- they are context driven

To make sure an adequate mobile process support language input and integrated graphic tablets will have to replace the desktop keyboard and mouse functionality. Appropriate bandwidth and global positioning technique are assumed.

To integrate resident and mobile process support eLearning an orientation on the MVC (Model-View-Controller) architecture seems to be adequate to realize integrated solutions (see also Burbeck 92). In the MVC paradigm the user input, the modeling of the external world, and the visual feedback to the user are explicitly separated and handled by three types of object, each specialized for its task. The view manages the graphical and textual output to the portion of the display that is allocated to its application. The
controller interprets the inputs from the user, commanding the model and/or the view to change as appropriate. Finally, the model manages the behavior and data of the application domain, responds to requests for information about its state (usually from the view), and responds to instructions to change state (usually from the controller). This design pattern makes it possible to present an eLearning model on small ubiquitous devices in a different view and with a different controller than on desktop solutions. The common model guarantees this way a global synchronized learning environment.

Conclusions

The most eLearning solutions focus desktop devices and so complex views on eLearning models. Not all eLearning processes are well suited for supporting them ubiquitous. But desktop eLearning functionality can be approved adding additional benefits for the learner through context information, ad hoc access, random access to very special information chunks, having fun and filling niche times. The best mobile process areas can be found in communication and special knowledge retrieval.

The MVC design pattern seems to be the right architecture for integrated eLearning solutions. To reach this goal mobile applications views will have to be designed in a much simpler way compared to desktop views guaranteeing a quick and simple access. In future 'Information in places' could highlight context benefits and make learning really ubiquitous. Communication tools like chats, discussion forums or instant messaging with language interfaces could be used. Global position technology could make it possible to identify persons with similar interests in the neighborhood and to start virtual initiated communication in real space at the end. ELearning systems have been seen as a 'pull-systems' until today, expecting the user to browse for information. Using mobile technology the significance of 'push-systems' will grow and proactive applications could be developed.

Open Classes in Closed Schools – Six Pedagogical Issues
In the Integration of On-Site and On-Line Learning

Ken Stevens
Centre for TeleLearning and Rural Education
Memorial University of Newfoundland
St Johns, NF, Canada, A1C 5S7
stevensk@mun.ca

Abstract: The networking of small schools between rural communities has led to the development of new electronic educational structures (school district digital intranets) and processes (virtual classes). As teachers integrate on-site with on-line instruction they are, increasingly, teaching not just in classrooms but between classrooms. New professionals are being appointed to networks of schools in Atlantic Canada: E-Teachers (electronic teachers) and M-Teachers (Mediating teachers who facilitate interaction (on-site) between on-line students and e-teachers). Six pedagogical issues have emerged in this new electronic environment in which open classes are constructed between schools that have traditionally been closed to one another.

E-Learning in rural schools in the Canadian province of Newfoundland and Labrador has moved through three phases over the last five years. The first phase began with E-learning in a single high school in which research was undertaken in science and mathematics education. In the second phase, E-learning was undertaken in a networked, on-line environment, through the creation of the Vista School District Digital Intranet (VSDDI). This provided an innovative structure in which teachers, administrators and researchers were able to collaborate in exploring issues in E-learning, E-teaching and the management of virtual educational environments. Instead of engaging in teaching and learning exclusively within a conventional school, teachers and students began to consider ways of teaching and learning between schools (Stevens, 2001). The third phase in the development of E-learning in this part of Canada began in September 2001 in a move away from research in a single school district digital intranet to a structure that spans the province. In the new E-Learning environment, ten different subjects were introduced to students across a range of grade-levels in ten school districts.

In the current school year two new teacher categories have emerged: e-teachers (electronic teachers) and m-teachers (mediating teachers who facilitate interaction, on-site, between on-line students and e-teachers). The development of E-Learning in High Schools in Newfoundland and Labrador has highlighted six pedagogical issues for teachers as they seek to integrate traditional on-site instruction with on-line learning in classrooms that have become, in effect, sites within teaching and learning networks.

Pedagogical Issue One: What is the pedagogical justification for providing instruction in virtual educational environments?

Increasing numbers of teachers in Newfoundland and Labrador High Schools now have to make professional decisions whether instruction is more appropriately provided in traditional classrooms or in virtual classes (E-learning). As many students in small schools in Newfoundland and Labrador access instruction in these dual environments, teachers have to be able to provide pedagogical justification for on-site or on-line learning.

Pedagogical Issue Two: To what extent should schools that are horizontally-integrated across dispersed sites, seek to develop vertical integration in their local communities?

Schools in Newfoundland and Labrador have, to an increasing extent, become academically and administratively integrated. Teaching and learning can, and to an increasing extent is, being provided in the emerging electronic system between classrooms across dispersed sites. This horizontal integration of schools across dispersed sites has provided new pathways for learners by extending curriculum offerings in small schools in remote locations which, until recently, was not possible because of economies of scale. At the present time schools are able to consider vertical integration within their local communities so that they can access such local resources as parents, businesses, libraries and a range...
of services. By vertically integrating to complement horizontal pathways, education can be extended to adults and "second chance" students at the community level, thereby promoting equity through the provision of opportunities to engage in a society in which learning is increasingly important. Without vertical integration, it is possible that small schools in rural communities could promote social divisions between those with access to digitized learning, and those without access.

**Pedagogical Issue Three: Should pedagogy for e-learning reflect horizontal and vertical integration?**

Schools that are horizontally integrated are able to move resources between participating sites (eg specialist teachers and curriculum materials). In this new, electronic educational environment, can collaborating schools promote knowledge-building through student collaboration? In the process of knowledge building, what is the role of peer-tutoring?

**Pedagogical Issue Four: How should e-teachers choose between synchronous and asynchronous instruction?**

The integration of on-site and on-line learning in horizontally-linked schools across dispersed sites enables teachers to choose between synchronous and asynchronous instruction. The choice of synchronous and asynchronous instruction by educational professionals, will, increasingly, have to be defended on pedagogical grounds and in terms of potential learning outcomes.

**Pedagogical Issue Five: In classrooms in which on-site and on-line instruction is available, to what extent should asymmetric knowledge advancement be encouraged?**

On site and online learning raises new possibilities of classrooms becoming places in which the development of knowledge can be both symmetric as well as asymmetric, thereby accommodating diverse approaches to learning.

**Pedagogical Issue Six: To what extent should e-learning promote the development of personal intranets?**

On-site and on-line teaching and learning is now at a stage when moves from structural intranets (eg as defined by specific schools academically and administratively interfacing in a designated region) to personal intranets can be contemplated. In a personal intranet students have the opportunity to develop understandings within customized learning environments, with access to a range of teachers. This pedagogical development has the potential to be modified to accommodate and coordinate teaching and learning styles.

**Conclusion**

Education at the high school level in rural Newfoundland and Labrador is being extended in terms of curriculum opportunities at a time when many small community schools are being closed. The integration of on-site and on-line education has promoted a situation in which there are now classes that are open to one another across dispersed sites, linking schools that otherwise remain autonomous and closed to one another. In this changing educational environment, a number of pedagogical issues have emerged. Engagement in the emerging pedagogical issues of e-learning will to a large extent define new professionals who teach between as well as in schools. As Keegan (2000) recently noted, it is time to take stock of where we are as a profession at a time of change.

TO MAKE E-LEARNING WORK, SEND CLEAR MESSAGES!

Dolf Steyn  
Senior Education Consultant  
Telematic Learning and Education Innovation  
University of Pretoria  
dolf@postino.up.ac.za

Abstract

All too often, a need is seen as e-need. Higher education and learning however calls for a human process, an interaction between facilitator and learner. A customised approach to individualised problems is more than just electronic delivery. The crucial issue is not the mode of delivery, but the skills required to facilitate learning. Unfortunately, evidence of a subtle re-definition of education and instruction seems to emerge in some quarters, a re-definition that leans toward information delivery rather than education.

Facilitators live under an impression that the necessary information is available and yet learners do not utilise opportunities to expectation. The problem can be that the message received is not an exact replica of the intended message originally sent. The 'noise' accumulated during 'transmission' obscures the true value of the 'signal'.

Fortunately an increased awareness is growing to identify best practice in terms of learning facilitation in the new technologically enriched environment. To address this issue requires more than technical competence. This paper acknowledges that a combinational approach is called for and proposes a framework within which the role of the e-options can find its rightful niche within the realities of modern educational practice once the current 'signal to noise ratio' has been modified to send clear messages.

Visual overview

1. Introduction

1.1 Background

There are no quick fixes in education. Arguments given here are not intended to be universal recipes for success. Neither are they aimed at defining simplistic solutions. This paper aims to:

✓ highlight contributing factors;
✓ identify methods by which behaviour can be understood; and
✓ elude to key concepts to be aware of when approaching technologically enhanced education.
1.2 Problem statement

The problem is discussed under the following headings:

- e Drive: technology chasing
- Miscommunication: One-way decontextualised information flow
- Lacking skills: Faculty not trained educators
- Under utilisation: Tools and opportunities available not used

2. Noise factors

2.1 'Receptivity'

Receptivity is a term used to indicate the degree to which individuals would be willing to participate out of free will. Some may see this as another opportunity for technology to provide solutions (Shih & Sorcinelli, 2000), but increased time commitment and lack of money were the top barriers to electronic delivery of education as identified by Berge & Muilenberg (2000). Simplistic solutions of throwing technology at problems do not have a realistic chance of succeeding.

To explore factors impacting on the likelihood of succeeding, one needs to first determine to what extent your audience would be susceptible to change interventions.

2.2 Factors influencing receptivity

The first dimension to receptivity is the locus of apparent need. Should change agents offer interventions on issues that perceived as valuable in order to address an immediate need, individuals would be more likely to participate. Another factor impacting on the receptivity deals with the effect of change on individuals and their ability to deal with change in a manner that is constructive. Brock & Salerno's 1993 change cycle is valuable reading in this regard.

People who should find themselves in the early stages of the change cycle, experience feelings that will prohibit them from utilising the opportunities to work through those changes. The feelings of people who are experiencing the first three stages of change namely loss, doubt or discomfort, are not the type of feelings that foster thoughts conducive to the types of actions that will bring people to volunteer for developmental activities.

Receptive attitudes are fertile ground and add value to co-operative learning environments. This correlates with the high value rating respondents gave to networks and peer support.

Change per se can therefore not be identified as the sole determinant of whether people will utilise the opportunities for development or not. The key factor is the reaction to the change and the resulting attitudinal position within the change cycle.

Unless learners are made aware of this impact of change on their attitudes, their natural reactions to change therefore would indicate an inverse proportionality between the likelihood of volunteering participation and their exposure to change.
Lucidity

2.4.1: Availability

Some pieces of information are just not available. Non-existence is one form of not being available, but there is a magnitude of information that is available in the sense of existence, but possibly not available for lack of access. Factors like fire walls, privacy and language come to mind together with instances where information was not properly recorded in the first place like the techniques used to create many of the Seven Wonders of the World. Breivik moves beyond the issue of media as prime determinant of access. "...But where most politicians see the problem as one of access to computers and the Internet, a growing number of leaders in higher education see it more as an issue of literacy — information literacy (Breivik, 2000)."

For the purpose of this paper, availability is representative of the combination of three interdependent elements of availability namely:

✓ Ability of the individual to utilise opportunities;
✓ Practical accessibility of the information; and
✓ Existence of applicable information.

2.4.2: Clarity

Unless instructions and or guidelines are understood properly, their impact would be limited proportionally to the lack of clarity.

The problem of clarity is not limited to everyday language issues. Subject specific terms and layout can also reduce clarity. See http://lme.mankato.msus.edu/class/629/dhmo.html for an example. The fact that information is available does not guarantee that the true meaning will be clear to all.

2.4.3: Context

The University of Pretoria currently has a (recently improved) maximum Internet bandwidth of 5Mbps. Compare this to the 155Mbps that Dutch institutions have for international Internet access and the staggering 622Mbps link available between some universities! (Steyn, 2001).

While the merits of global competition are not the issue here, the need for adoption of theorems for local conditions and context becomes apparent.

2.5. Dependency

Professor Robert Kraut from Carnegie Melon University caused a stir some three years ago when he reported his findings. His studies revealed that the social networks of heavy Internet users declined and that they reported feeling of loneliness (Kraut, 1999). Now he seems to have results from a follow up study that contradict his earlier findings (Guernsey, 2001).

When it comes to group dependence and the adoption or rejection of technological options individual characteristics like learning style preferences will come into play.

2.5.1: Learning style preference

All individuals do not work in groups as a result of choice. Social learning style preferences differ. Kneak (2001) distinguishes between individual & group learners The intention is not to say that individual learners cannot function well in a group, but their natural choice would not be to be dependant on others.
2.5.2: Dependency impact

The preference of the target audience for either individually or group centred approaches are not crucial to the success of technology as a factor in facilitating learning. This is because there are various technical options available that can accommodate either preference. What is important though is that facilitators take note of these factors, provide alternatives and accommodate the individual differences.

Dependency is not sufficiently crucial to singularly determine success. Important though, to keep its implications in mind. A metaphorical way of thinking about dependence could be to compare it to a flat surface. Nowhere higher or ‘better’ than anywhere else, yet representative of a whole open area of positions and possibilities.

3. Filtration

In order to create a visual model and enhance understanding, the quality of communication can be improved or 'filtered' by interrelating these issues.

3.1 Receptivity and Lucidity

Plotting these two factors against each other creates four quadrants.

Receptivity Low        Lucidity High
                      2
                      3
                      4
Lucidity Low

This first quadrant is the one where barriers need to be broken. To only make information available would not be likely to add major value, as individuals low on receptivity, would not be likely to conscientiously take on-line courses or participate in discussion groups.

The barrier of low receptivity can be broken by first moving to quadrant # 2. In this instance the information is still readily available, but this time the receptivity of the audience stems from their perception of need.

Where quadrant 2 conditions apply, people may be receptive enough to browse through web page content, since they could get access to information in their own time and according to own priority. Clearly a position of choice.

The final quadrant where there is a common receptivity, but lacking lucidity. The reason for the lacking clarity needs to be explored in order to address the problem. If the problem resides in lacking skills to access the relevant information, interventions to provide the necessary skills may be received positively.

A different approach would be apparent when the information is not available or consensus not reached. Where competence and access allows for electronic discussion, there are various virtual communities that will be able to assist in identifying solutions or options.

3.2: Receptivity and dependency

Plotting these two factors against each other again creates four quadrants.
Quadrant A is where learners typically are not receptive, but highly dependent. These people like to work in groups, prefer synchronous communication and contact.

Technological options are not likely to prove the ideal tool for the situation.

Quadrant B holds the double high. The high receptivity provides the opportunity for peer interaction and reflection activities. While this traditionally is the domain of physical contact, some technological innovations like chat rooms or video conferencing could also play a part.

Individual learners with low receptivity typify quadrant C people. Again something needs to be done to break the non-receptivity. Mettal recorded such a case.

"... ignored our services. Word soon came around that he was horrible ..., but he still avoided us. One of his friends ... suggested that he talk to me about it. ... He came over and we talked for several hours. I gave him "new perspectives" on what was happening between him and [his peers] ..., etc. (Basically, I talked to him about to be a nice person.) The next semester went much better. I was shocked that such a short intervention helped, but he has thanked me several times since (Indiana, 2001)"

The last quadrant (D) in this interrelation deals with highly receptive individuals. Technology has much to offer these people. The search capabilities of computers make information available to work with at leisure. Some individual interventions may be necessary in order to equip the individual with the skills to utilise the technological options.

"A colleague that would not touch the computer for his life now uses computers in his instruction (Louisiana, 2001)."

3.3: Receptivity, Lucidity and dependency

All three these factors can be combined in one three dimensional interrelation with x, y and z axis.

The front octants containing the low dependency quadrants and the back octants containing the High dependency quadrants. This relation may assist facilitators to sufficiently analyse each particular situation in order to class it accordingly.

Attempting to assign particular technological solutions to specific combinations would limit the use of the classification to the items specifically measured and mentioned. A more inclusive and flexible understanding comes from evaluating the factors in terms of their impact on technology use.

The impact of the dependency dimension is not as important to determine whether technological solutions could be applied, but rather to inform on different options which need to be considered.

4. Conclusion:

Facilitators need to adjust to the new environment. Strategies should allow for differences in personality types and their reactions to change. The variety of new possibilities and technological options requires more than technical competence. This paper acknowledges that instructional design should be a combinational approach and calls for and proposes a framework within which the role of receptivity, lucidity and dependency could be interrelated to inform on issues that will impact on acceptance of new strategies. Technological options will find its rightful niche within the realities of modern educational practice once the current 'signal to noise ratio' has been addressed to send clear messages.

A Case for Multimedia: Designing a Problem-Based Interactive Learning Environment

Anne Strehler
Department of Telematic Learning and Education Innovation
University of Pretoria, South Africa
astrehler@postino.up.ac.za

Carina A Eksteen
Department of Physiotherapy
University of Pretoria, South Africa
ceksteen@medic.up.ac.za

Abstract: This paper discusses the development of a multimedia case study which will provide the opportunity to develop the cognitive and communicative skills in the management of the neurological patient. The authors argue that the substantive structure of the discipline is constructed when the methodology (syntactical structure) of the discipline is implemented. The paper considers elements of an authentic learning environment and discusses the challenges for the instructional designer when designing for authentic learning environments. The paper furthermore provides a brief description of the program and documents the findings of the first formative user evaluation.

Introduction

The implementation of a problem-based curriculum and problem-based learning in the Department of Physiotherapy in the Faculty of Health Sciences at the University of Pretoria has resulted in the development of new learning environments which move away from traditional approaches to physical therapy (physiotherapy) education.

The focus of problem-based learning (PBL) is the integration of facts, concepts, principles, skills and techniques directed at solving a unique clinical problem and the mastery of cognitive, psychomotor and communicative skills inherent to the subject being studied. Problem-based learning aims to reduce the shortcomings of the more traditional approaches to physical therapy education, in which learners focus on the memorisation of facts, concepts, skills and techniques which are then applied to clinical practice.

Eksteen and Slabbert (2001) distinguish between the substantive and syntactical structure of physical therapy as a discipline. The substantive structure refers to the conceptual structure of the body of knowledge of a discipline. The syntactical structure refers to the way in which a body of knowledge about a discipline comes into being or the process implemented to gain new knowledge in a discipline.

Implementation of problem-based curricula and the concomitant adoption of problem-based learning (PBL) approaches to physical therapy education do not implicitly guarantee the successful mastery of the relevant skills. The implementation of problem based learning in the Department of Physiotherapy, University of Pretoria, has been problematic due to factors such as a lack of basic knowledge about the problem-based learning approach and the fact that it is very time consuming to implement this approach. Another concern is that even though the learner collects, analyses, organises and critically evaluates content or knowledge with the primary purpose to use this knowledge in practice, assessment practices focus heavily on the content base of the curriculum. (Eksteen & Slabbert, 2001).

Physical therapy practice always constitutes a problem to be solved as a point of departure, therefore, despite these shortcomings and the concern that problem-based learning as it is currently being implemented is not based on the substantive and syntactical structure of the discipline, physical therapy education should continue to have
as its focal point the construction of new meaning through solving relevant problems. Construction of meaning and preparation for the demands of practice can best be achieved within the context of problem solving because problem-based learning is an apprenticeship for real-life problem solving.

**Foundations of problem-based learning**

Problem-based learning (PBL) has many applications. It can briefly be described as a learning experience during which the learners use an iterative process of assessing prior learning, identifying what they further need to master, gathering information; and collaborating on the evaluation of hypotheses in light of the data collected, in order to solve the problem (Stepien & Gallagher, 1993).

In the process of problem-based learning, learners crisscross a variety of disciplines. They build substantial knowledge bases through increasingly self-directed study. Through collaboration with their peers they refine and extend their skills and knowledge base, within a conceptual framework (of the discipline), in such a way that will promote transfer of knowledge and skills to solve new problems. The learner is continually constructing meaning. The role of the teacher/educator also changes in the problem-based learning approach. Teachers take on new roles in problem-based learning, acting as facilitators, coaches and tutors, probing findings, hypotheses and conclusions, sharing their thinking when students need a model, and encouraging the development of metacognitive skills.

There are three factors which facilitate learning within a problem-based approach:

- prior knowledge is activated;
- the greater the similarity between the formulated ‘problem’ and reality, the better the learner’s success in acquiring the relevant skills;
- new knowledge is better understood, processed and recalled if the learners have the opportunity to elaborate on the knowledge they have mastered within the conceptual framework of the discipline (Schmidt, 1983).

A study which investigated the processes used by students in developing conceptual knowledge in physical therapy found that the students in the study used an active, experiential approach to learning that included a reliance on the senses during the learning process. The study concluded that the type of learning processes used by students may be enhanced by educational methods such as collaboration and group learning, situated cognition and use of authentic contexts, cognitive apprenticeship and whole-part-whole learning (Graham, 1996).

**Instructional design for an authentic learning environment: a case for interactive multimedia**

The need for authentic contexts within which to design learning environments and experiences in a physical therapy program has many challenges for the educator. While there may be differences in the exact implementation, all physical therapy education programs have both an academic and clinical component. Learners are required to complete a certain number of hours in the clinical setting. The amount of time spent in the clinical setting does not guarantee that the learners will be exposed to the entire range of problems – both in quantity and complexity – within a specific specialty. There are also many ethical issues which arise when designing learning environments in the clinical setting, which require learners to have mastered the relevant cognitive, psychomotor and communicative skills before entering their clinical blocks.

These constraints could prompt the physical therapy educator to look at alternative methods for providing problem-based learning experiences. Alternatives include practice in a simulated setting in a laboratory and, more recently, the use of technologies such as the world wide web and interactive multimedia. The principal theorists of situated learning have rejected the idea that the computer could provide an authentic learning context, arguing that the courseware becomes the learning environment and not the authentic situation. However, researchers and teachers have continued to explore the model of situated learning using the computer and there is increasing agreement that such technology can be used effectively without sacrificing the authentic context of the learning experience (Herrington & Oliver, 2000).
It was within this context that the Department of Physiotherapy at the University of Pretoria requested funding for the development of a series of interactive multimedia programs, based on the problem-based learning approach, which would engage the learner in an authentic learning environment. The author of this paper is responsible for the instructional design of the program.

**Instructional design challenges**

Instructional design of interactive multimedia learning environments grounded in a problem-based learning approach needs to consider both the requirements for authentic, problem-based learning and instructional design theory. Development of educational multimedia programs has in recent years largely been driven by constructivist learning theory and traditional instructional systems design.

The task of the designer is to incorporate contextual factors appropriately into the design of interactive multimedia learning environments (Boyle, 2001). The central challenge for educational multimedia designers is to create contexts that promote effective learning. As designers, we need to engage learners in interactive scenarios. We impact on the learner through our skill in creating these contexts. The skilled designer who can design / create the context and interaction in such a way that the actual courseware becomes seamless will have made progress in overcoming the criticism of the situated learning theorists, namely that technology becomes the focus for learning instead of the authentic context.

**Description of the program**

The content specialist had been afforded the opportunity to capture on video the complete evaluation of patients with selected neurological deficits. The range of problems these patients presented was both unique and complex. Learners in the clinical setting will seldom have the opportunity to perform such comprehensive evaluations. The instructional designer was requested to use all the video footage and the information provided by the content specialist to create an interactive multimedia learning environment with a case study approach as the methodology of choice. The specific module (theme) in the first series of case studies is the management of the patient with an upper motor neuron neurological diagnosis. The content specialist also intends that the program enable the learner to acquire the way in which new knowledge is generated in the discipline - the methodology of the discipline.

The management of the patient is divided into several phases:
- The comprehensive evaluation of the patient – subjective, objective and biomechanical evaluation;
- Identification of the specific problems the patient has (problem formulation);
- Formulating the goals for the management of the patient (goal formulation); and
- Planning the treatment.

Each section has several questions which guide (facilitate) deep learning (construction of meaning). The learner must, in most cases, study the video clip available at that point in the program and then attempt to answer the question. Answers are entered electronically and saved for later retrieval. Once the learner has attempted the answer he/she may view the expert answer. There are a total of 22 questions in the program.

Exercises which require the learners to reflect on their success in terms of their competence in the completion of the tasks / questions are included at strategic points in the case study. The aim with the reflection exercise is to facilitate the construction of the conceptual framework (body of knowledge) of physical therapy as learners work through the case study. The expert answers play a key role in the self evaluation and reflection of learners on their process of acquiring the relevant competencies required from them in the clinical field. The process, as well as the competencies learners have to implement while working through the case studies, simulate the syntactical structure of physical therapy as a discipline. The instructional designer designed an interactive approach - the use of game techniques, question and answers and multiple choice questions - to facilitate learner interaction with the content.
The techniques, tools and strategies used by the designer, together with this valuable material, greatly facilitated the creation of a unique learning environment which could be extended far beyond the clinical sessions which a learner could, at most, hope to experience. The latter together with the reflection exercises facilitate self evaluation, the development of metacognitive skills and independent, self-directed learning. The option to revisit such an authentic context, using the electronic medium, also transcends the many ethical problems which arise when working with patients in the clinical environment. Table 1 summarises the design elements which contribute to the problem-based learning approach and the creation of an authentic learning environment.

Table 1: Operationalisation of design elements to meet criteria for problem-based and authentic learning

**Evaluation of the program**

Due to the fact that the design and use of multimedia for problem-based learning is a new experience for the instructional designer, content specialist and learners it was decided to commence with formative evaluation very early in the development cycle. Development commenced in March 2001 and the first evaluation was conducted...
in September 2001. Thirty seven final year students, who were due to write their final examination in October 2002, participated in the evaluation. Both the instructional designer and the content specialist designed questionnaires for the learners to complete at the end of the evaluation session. The instructional designer also observed the learners using the program. The content specialist focused on the learner’s perceptions of the contribution of the program to the learning process. The instructional designer looked at elements of the instructional design which could both positively and negatively affect their learning. Particular attention was paid to navigation issues.

At the time of evaluation some of the expert answers had not yet been finalised, the knowledge base was only available in a dull, non interactive text-based format and no help screens had been designed. The learner also had limited control over certain features of the program. This included control over the video clips and the ability to navigate backwards and forwards in the program. It had been decided that the learners had to work through the questions in the exact order determined by the content specialist. Learners could only return to previous screens by following a linear path through the program. The programming required when using the multimedia in a computer laboratory rather than a stand alone PC was also not complete. The first evaluation session aimed to investigate some of the functionality of this programming. The instructional designer anticipated that there might be some problems with the manner in which learner input was stored and displayed. These potential problems were communicated to the students at the beginning of the evaluation session.

**Evaluation of the instructional design and learning environment**

The open-ended questions in the questionnaire generated a host of responses. The responses were categorized and the number of responses in each category quantified. Tab.2 summarises the design elements which the learners liked and which contribute to an effective learning environment. Tab 3 summarise the design elements which the learners disliked and which could negatively influence effective learning.

to be more concise and to the point, presented as a bulleted list
Lack of information about how to use the program.
Program was very long and time consuming
Parts were very monotonous
Content screens contained a lot of information

Table 3: Design elements which the learners disliked and which could negatively influence effective learning

Some of the problems experienced during the evaluation related to the incompleteness of the program and the fact that some of the programming appeared to be incorrect. A few students commented on the inappropriateness of the content of the expert answer to the question.

Future direction for the development

Despite the problems and many suggestions for improvement, the overall impression was that learners perceived the program as a useful tool which is both comprehensive and thorough. During the evaluation learners were requested to provide suggestions for improving the program. The most frequent request was for better control over the video clips and navigation in the program. Some of the comments seemed to indicate that the interface design and navigation were not yet seamless. Learners should not have to waste time struggling to use the technology, but should rather be able to interact effectively with the learning environment.

Further development will focus on implementing the suggestions and improving and refining the design. The content specialist will also be looking at the formulation and layout of some of the expert answers as well as limiting the questions to those which facilitate learning most effectively - avoiding questions which make the duration of the programme too long.

Conclusion

The development of a multimedia program using a case study approach to problem solving is in itself an authentic learning experience, especially when the case study is based on a real patient. The challenge for the instructional designer is to consciously design the learning elements in such a way that the nine criteria for an authentic learning environment are operationalised and that the focus remains on the learning environment and not the technology.

Abstract: This paper offers a new perspective in teachers’ education regarding the effective technology integration. The core theoretical background is Case based Reasoning. We develop a knowledge repository filled by indexed stories collected directly from teachers who use technology in their classrooms. The index is developed and under continuous revision according to the experience we gather through the interviews. The stories are collected and the system developed by a consortium of eight universities. The stories can be retrieved in a Web-based interface, that is powered by a custom made engine, that uses a near-neighbor algorithm. Future research will be around the use of this system by teachers and teacher educators.

Rationale

A 1998 National Center for Education Statistics (NCES) study, Teacher Quality: A Report on the Preparation and Qualifications of Public School Teachers, that although many educators consider technology as a vehicle for transforming education, only 20% feel well prepared to integrate technology into the classroom. To improve the level of technology integration, a 1999 study entitled Will New Teachers be Prepared to Teach in a Digital Age? recommended that researchers, professional societies, and education agencies should identify, study, and disseminate examples of effective technology integration on an ongoing basis.

Mission

In order to meet these challenges to educate tomorrow’s teachers to effectively integrate technology in their classroom instruction, we at the University of Missouri have begun the Knowledge Development for the Technology Integration Community Project. This project is a Catalyst grant from the U.S. Office of education that involves a consortium of eight partners institutions collaborating to address issues in creating and diffusing technology integration knowledge.

The project's mission is to build a K-16 community of practice through a case library of teacher stories about technology integration. In order to fulfill this primary goal, we have designed a case library for teachers and teacher educators and are currently collecting and indexing cases to be added to our case library. Once completed, teachers and teachers’ educators will be able to access successful and unsuccessful attempts to integrate technology from the case library. The case library is being built according to principles of case-based reasoning.

Theoretical Background – Case based Reasoning (CBR)

In order to educate teachers and teacher educators to effectively integrate technology into instruction, we should expose them to stories generated by other teachers. One way to do this is by exposing them to narratives or stories or cases that have been compiled into a case library (database of stories made available to learners as a form of instructional support). Why should we do this?
Supporting learning with stories can help new teachers and teacher educators to vicariously gain experience. Some researchers believe that hearing stories is tantamount to experiencing the phenomenon oneself (Ferguson, Bareiss, Birnbaum, & Osgood, 1991). This kind of reasoning (reasoning from stories or cases) provides support for “inferences necessary for addressing the kinds of ill-defined or complex problems that come our way in the workplace, at school, and at home” (Kolodner, 1997, p. 58). The process of understanding and solving new problems using case libraries has three parts: recalling old experiences, interpreting the new situation in terms of the old experience based on the lessons that we learned from the old experience, or adapting the old solution to meet the needs of the new situation (Kolodner, 1993).

This whole process is described by Aamodt and Plaza (1996) as the CBR cycle. An encountered problem (the new case) prompts the reasoner to retrieve cases from memory, to reuse the old case (i.e. interpret the new in terms of the old), which suggests a solution. If the suggested solution will not work, then the old and or new cases are revised. When the effectiveness is confirmed, then the learned case is retained for later use. The main process in developing a Case Based Reasoning tool for problem solving is as presented by Jonassen et al (1999).

Collecting and Indexing Stories

Currently, we are collecting stories to be included in our case libraries. The story collection process is being carried out by Knowledge Scouts at eight different institutions. These scouts are making appointments with teachers in schools and interviewing them. We applied elements of the critical incident method into our interview strategies. The interviewers then transcribe the interviews, and the team at Missouri will index the interview and build narrative sequences out of the interview.

Building the Retrieval Engine

For the retrieval, we use a near-neighbor algorithm to match a query-case (given by any user at our web-based interface) with existing cases. For this purpose the query case will be converted into a feature vector, and therefore can be used in the knowledge repository. The user-friendly interface is a web-based, dynamically created out of our Oracle database and allows the user to search and browse.

Future research

When we have added and indexed a sufficient number of cases into the library, we plan to begin studying how teachers and teacher educators will use the case library. We hope to be able to present research findings on these questions at the next conference.

References

Arguably the biggest ‘buzz word’ of the current year has been ‘learning or knowledge object’. To understand the learning object and why it should be such a highly desirable commodity, we need to unpack not only this concept but more importantly revisit some contributing concepts and constructs (more buzz words) that support the building of truly pedagogically informed reusable objects (Boyle & Cook 2001). The words and relationships explored in this paper are:

- **Learning or knowledge objects** - the desirable construct in today’s E-learning environment.
- **Ontologies and ways of expressing them through topic maps** as they allow us to define and describe the components of an entity
- **Metadata and XML** used to create categorise, label and communicate the value of these objects
- **Hermeneutics and phenomenology** as they refer to the interpretation of experience and events and evaluation of learning events

**Learning or knowledge objects**

Learning objects (also known as knowledge or instructional objects) are digital learning events that are discrete, reusable, able to be aggregated and are tagged with defining Metadata. The impetus for the development of learning objects comes as much from not wanting to reinvent the wheel as wanting to find
ways to adequately define and categorise online instructional events. The form, size and shape of these
learning objects can be as varied as the respective face-to-face events from lecture, course or discussion to
simulation and role-play.

Downes (2001) succinctly describes the programming roots of learning objects. To delve more deeply into
the construction and organization of learning objects, it is necessary to introduce another concept from
computer programming, object-oriented design (e.g., Montlick, 1999). The idea behind object-oriented
design is that prototypical entities, once defined, are then cloned and used by a piece of software as
needed. (Downes 2001 pp 7)

Speaking from an educational perspective, Reigleuth and Nelson (1997) propose that the breaking down
into instructional components (learning objects) is akin to the typical practice of instructors when they
develop a course or learning sequence. The content and relationships are broken down and the learning
strategy and evaluation is then selected for each component. However it is the technological not the
educational agenda that dominated the earliest discussions of development, categorisation and location of
learning objects. We cannot deny the importance of this aspect, for reusable objects would not find users
if the content and form were not able to be effectively defined, described and delivered. More recently
and very importantly there has been a cry for pedagogical aspects of learning objects to drive the process
of development and definition. (Boyle & Cook 2001, Ip & Morrison 2001) Indeed Ip & Morrison would
draw us back to the programming roots of the term learning objects and propose that until the contextual
rendering of these objects occurs they are not learning objects at all but digital resources.

The issues that surround the value of the seemingly simple concept of learning objects appear manifold
and go directly to the heart of the nature of instruction. The actual objects, their granularity,
interoperability and reusability and how the learning event/s or exchanges they involve can be fully
described, identified and evaluated are topics for hot debate. How small do components need to become
to be discrete and reusable? What exactly does it mean for a learning object to be reusable? For whom is
it reusable and can it be rendered for all learning contexts and paradigms? How will instructors be able to
identify and select the appropriate learning objects for their instructional context?
Can these learning objects be seen as dynamic and iterative in an evaluation cycle involving their users?
We hope to touch on some of these issues and highlight some of the key researchers working through
these issues.

Epistemological Ontologies

Traditionally ontology dealt with the area of metaphysics, which defined the fundamental distinct entities
to which existence could be ascribed. Within a particular area of interest, such as that of Teaching and
Learning Systems, we need to qualify this to allow a plurality of ontologies of which a specific one
constitutes a valid domain in its own right. Smith (Smith, 1998) thus distinguishes R-ontology (reality-
based ontology) and B ontology (epistemological ontology). While the first deals in the general meaning
of ‘being’, the second provides the basis of a conceptualisation of a particular domain.

Ontology construction of this kind is now an accepted tool in a number of disciplines. In the field of
Geographic Information Systems, for instance, Fonseca and Egenhofer describe one such system thus.
Ontology plays a central role in the definition of all aspects and components of an information system in
the so-called ontology-driven information systems. The system presented here uses a container of
interoperable geographic objects ... This approach provides a great level of interoperability and allows
partial integration of information when completeness is impossible (Fonseca & Egenhofer, 1999 pp.14).
Researchers have described the value of this process, even at an intermediate or tentative stage. Gaede
and Stoyan state, Supposing that universally valid terminology is neither near nor realistic, partial
domain as well as pedagogical ontologies ... have already proven fruitful. (Gaede, & Stoyan, 2001 pp.
535).

Epistemological ontologies form a suitable area for the use of these methodologies. Of particular
relevance to learning systems, constructivism offers one such radical approach, which has been
characterised as an epistemology of learning rather than a framework of teaching (Nunes, McPherson,
Rico, 2001). Thus it has been argued that A constructivist epistemology views knowledge as a construct of
individual’s understanding. When individuals come together, such as in a learning environment, their
construction undergoes continuous revision due to cognitive conflict which occurs as a result of different
Nevertheless, even this social constructivist viewpoint still poses the question of how methodologically a constructivist epistemology can be incorporated in an objective model of learning. One approach to this we could postulate would be to attempt to derive a constructivist epistemological ontology. This would allow the interfacing and inter-relating of different constructivist models into a single coherent working framework. Would this aim violate the underlying principles of constructivism? This need not be the case as the process of ontology derivation itself, as dynamic and subject to progressive development, could be considered within the constructivist framework, as an activity at a metalevel, carried out by constructivist educational practitioners rather than the learners themselves.

Ontology construction can also employ techniques, such as conceptual graphs and topic maps. Furthermore, development environments exist that will allow these in turn to be mapped to HTML/XML representations. For instance, the collaborative environment, Veda (Prata, Paraguacu & Reis, 2001 pp.1512), is described in the following manner. The conceptual graphs ... provide a form to represent knowledge through the ontology (application domain) and logic (logical first-class). Following its formalism, we can represent graphical form in linear form and create a computational model. This computational model together with the features of hypertext, allows indexing the knowledge in HTML format. In addition to the techniques discussed earlier for ontology development generally, the process of constructivist ontology construction can draw on a variety of other techniques from various fields. Stutt, for instance, suggests the use of “ontological and other (problem solving) categories from knowledge engineering, a basically constructivist rather than mirroring approach to knowledge and, finally, computational models of and computer support for argumentational structures” (Stutt, 1997). It is an approach similar in principle to this, which could utilise topic map representations to derive learning objects implemented in XML, that we intend to investigate further.

Conceptual Graphs and Topic Maps

The technology of topic maps is nothing but formalising relationships of concepts using topics, associations and occurrences, in a machine-readable and platform independent format. The connection to the real world and its learning material is maintained by links called “occurrences”, which allow for linking out of the abstract topic cloud to files, URLs, or learning objects in a learning environment.

From a technical standpoint, topic maps can be represented using valid XML documents with basically three different sorts of elements: topics, associations and occurrences. A topic is anything the designer of the map wants it to be, mostly the abstract representation of a “thing” or a concept, which is connected to other things via associations. These associations are themselves topics, and an association has roles for the two topics it connects, defining the role each connected topic is playing in the association. With this set of elements it is possible to structure and represent an ontology in an abstract and technologically independent manner. The topic map itself is created while parsing (“reading”) the topic map exchange document and building the n-dimensional mesh of topics and associations in the memory of the computer.

When two topics are merged, the result is a single topic whose characteristics are the union of the characteristics of the original topics, with duplicates removed. It is an approach similar in principle to this, which could utilise topic map representations to derive learning objects implemented in XML that system designers need to investigate further. Consider if we chose a given a domain, for instance civil engineering, where it is rather easy to divide the domain into basic concepts (such a concept would be “Newton” – apple falling from tree...). Then it should be possible to create a topic map made out of these concepts and linking associations, thus covering the domain knowledge on an abstract level. The next step is to mediate these concepts through learning objects such as course material or resources (text, animation, movie and audio) which itself is built so that it is basically context-free, modular, reusable in different places. Given those two conditions a learner might ‘walk’ his/her way not only through predefined paths (defined by teacher for a certain course or lesson), but also leave the path and look via the topic map to adjacent topics, and from there to other learning objects.

XML and Metadata Standards
XML, Extensible Markup Language is a W3C recommendation (not yet a standard), derived from SGML (ISO standard), somewhat similar to HTML, as it is markup, but with freely definable tags.
Metadata is commonly described as being "Data about data", which provides a means by which the multimedia's semantics can be described in a structured fashion for use by various applications. More technically Metadata is standardized information to describe digital information resources (Dourer, 2000 pp. 74). Metadata can be seen as sets of rules and meaning/usage of tags lead to the following specifications: IMS, Dublin Core, LOM, SCORM, and EML. On a higher level Metadata can be viewed as technical/administrative Metadata vs. didactical Metadata (http://eml.ou.nl/forum/fag/index.htm#A10).

It is possible to define one’s own tags, which allow a parser to know what text between tags (element) is. This gives not only the freedom to separate the content from the formatting (big advantage, as we can now reformat according to the meaning or being of an element), but also the freedom to define things according to our needs. This includes the possibility to set up rules allowing or forbidding the existence of an element at a certain position (e.g. within other elements) using DTDs or schemata a parser can determine the validity of a given XML document against a given set of rules. With this, we have a first step towards the computational model mentioned; machine readable content with mark-up allowing for meta-information and meaning.

Holzinger et al (2001), Kassanke et al (2001) and Bick et al (2001) very ably unpack the development and need for educational Metadata and the instructional uses of XML. Current approaches more or less focus on the representation and structuring of learning contents, e.g. the Learning Material Markup Language (LMML) (Suess, 00). Another good example for the increased significance of XML in CAL is the XML binding for the Instructional Management Systems Project (IMS) Learning Resource Meta-data Information Model, which is based on the IEEE Learning Technology Standards Committee (LTSC) Learning Object Metadata (LOM) base document (Anderson, Wason, 00). (Bick et al 2001 pp. 145)

The indexing could occur in a broader Metadata framework using such emerging tools as the Open Archives Metadata Harvesting Protocol, an important new infrastructure component for supporting distributed networked resources. The Protocol is a mechanism that enables data providers to reveal their chosen Metadata, whether it be XML or some other. This approach brings ontological construction into a more comprehensive systems and services architecture (Lynch, August 2001).

What kinds of issues need to be considered pedagogically? The current IMS specifications contain implicit pedagogical models. The absence of a generalized representation of pedagogical models has the potential to lock out other models, and indeed ones that have yet to be developed. This could lead to all kinds of practical problems, especially in terms of interoperability. The EML philosophy is that EML should be capable of a complete description of a course, including the content, the work processes between the actors (learners and staff), and that this description should be independent of the LMS (learning management system) in order to ensure long-term interoperability, sustainability and opportunities for re-use.

Herme neutic Analysis

Hermeneutics and phenomenology are closely linked and although they share common concerns, they offer different perspectives. Phenomenologists focus on the lived experience of people, and seek out the commonalities and shared meanings, whilst hermeneutics refers to an interpretation of language. Hermeneutics derives from the Greek noun 'hermeneia' which translates as 'interpretation'. Hermeneutics has a dual value in helping educators to understand how learners experience both conceptual change and how they use the new learning environments, and hence it has insights to offer in terms of usability testing and evaluation. In this sense hermeneutics can offer a model for pedagogy, to promote active learning, whilst at the same time acting as a research tool for exploring the individual and collaborative learning experience (Rogoff, 1990).

As a research methodology, hermeneutics assumes that meaning making is embedded in the process of dialogue between interpreter and narrator. The hermeneutic circle is a way of articulating and interpreting discourse. Hermeneutic phenomenology is based on the philosophy of Heidegger and Gadamer (van Manen, 1990) Hermeneutic phenomenology is both descriptive and interpretative. It is an attempt to do the impossible, to construct a full interpretation of some aspect of the life-world, and yet to remain aware that life is always more complex than any explication of meaning can reveal. (van Manen, 1990 pp.18)

A conception always has two dimensions, one focusing on what people experience, i.e. the content or the referential aspect, and the other focusing on how someone thinks about the specific phenomenon, i.e. the
According to phenomenography, knowledge is always linked to specific content and can only be described as knowledge about something. This means that knowledge is always provisional and qualitative. To become more knowledgeable in a subject implies a qualitative change to a deeper and more complex understanding of a phenomenon. Marton's work is a key influence in establishing a phenomenographic approach to researching learning and teaching. Knowledge objects can be designed to engage students in deep learning, which promotes real understanding. By students engaging in critiques of existing theories and ideas new knowledge and understandings can arise. (Marton & Booth, 1997)

Phenomenography offers a unique approach to understanding student experiences. The process can uncover the essence of a phenomenon by gathering stories from students engaged with learning objects in an e-learning environment, interpreting those stories and offering implications for practice. It is akin to action research in that the students are not simply subjects of the study, but active participants. The research process creates opportunities for reciprocal learning, metacognitive learning for the student and an awareness of how the e-learning environment is experienced by the researcher.

Hermeneutic analysis can show the development of varying perspectives from which individual learners understand a task. It can also track the development of a joint approach to a collaborative task and can illuminate the process of learning. A fine-grained hermeneutic analysis can provide a framework for 'listening to' what learners can tell us about the appearance of the shared space to individual contributors. It can tell us how individual perspectives are different from one another, and from our own as researchers or as instructional designers. This insight will prove to be vital when evaluating the effectiveness of electronic learning materials designed to foster a social construction of knowledge.

Conclusion

Can hermeneutic analysis be used to evaluate pedagogically based learning objects designed from constructivist epistemological ontologies defined in XML Metadata? It really isn't just a string of highfalutin buzzwords but a question to stimulate thinking about the full cycle of development of learning objects. This paper set out to explore is the nexus of conceptual and theoretical foundations, systems design and current pedagogical frameworks found to be relevant on the road to developing true learning objects. If we can begin by investing the time to construct thick epistemological ontologies and make explicit ontology/ies through representational tools like topic maps, we can begin to answer the detractors who see learning object development agenda as being stolen by programming considerations. These topic maps in turn can be translated into the rich data carriers and renderings possible with XML and Metadata. The representation of the domain in related and merged topic maps has the potential to allow learners to articulate, direct, share, relate and critique the learning experience from their personal perspective. The hermeneutic analysis discussed here gives designers and instructors the opportunity to do that listening to learners. In terms of usability testing this approach offers insights into how learning is experienced, not simply how the instructional designer conceptualises it. The learning process is not separate from specific learning content and context. The learning experience is a composite of the learner, the domain and the e-learning environment.

Introducing a “Means-End” Approach to Human-Computer Interaction: Why Users Choose Particular Web Sites Over Others

Deepak Prem Subramony
Department of Instructional Systems Technology
Indiana University-Bloomington
United States
dsubramo@indiana.edu

Abstract: Gutman's means-end theory, widely used in market research, identifies three levels of abstraction - attributes, consequences, and values - associated with the use of products, representing the process by which physical attributes of products gain personal meaning for users. The primary methodological manifestation of means-end theory is the laddering interview, which is claimed to generate better insights than other qualitative/quantitative methods. This study asked: Can means-end theory, and its concomitant laddering methodology, be successfully applied in the context of human-computer interaction research, specifically to help understand the relationships between Web sites and their users? The study employed laddering interviews to elicit data concerning Web site attributes, their consequences, and user end-values. This data was duly processed and the results were subsequently appraised. Examination determined that means-end chains indeed characterize the process by which physical attributes of Web sites gain personal meaning for their users, thus proving the theory's applicability.

Introduction

Gutman's means-end theory (see Gutman 1982), which discusses the core underlying values that motivate consumers' purchase decisions, is immensely popular in the marketing research community (Peter & Olson 1994), and enjoys an impressive track record in the commercial sector where it is often used to generate message strategy themes for promotional campaigns (Gengler et al. 1999). The most common methodological manifestation of means-end theory in the field of marketing research is laddering, a method by which the core attributes and values that motivate product users are identified through a special form of in-depth, one-on-one interviews that force the respondent up a ladder of abstraction, thereby bridging relatively concrete product meanings at the product attribute level with more abstract meanings at the consequence and personal value levels (Gengler et al. 1999).

In support of laddering, Fortini-Campbell (1990) claims that other quantitative/qualitative social scientific research methods - such as focus groups, surveys, and demographic information - often fall short of generating key insights about a product and of identifying a target audience in concise and well-defined terms, since common responses to the question of why a person chooses a particular product do not even begin to describe the deep underlying psychological and emotional reasons that influence people's choices.

Meanwhile, the celebrated consumer psychologist and University of Minnesota Professor Emeritus Dr. William D. Wells suggested to this researcher that means-end theory could very well prove to be an excellent point of reference for unearthing the underlying core values that motivate Web site users as well, and that he did not know of any prior studies that have used this theory in the substantive context of Web usage, or anywhere else within the broader field of human-computer interaction or HCI (W. D. Wells, personal communication, July 2000).

This study could therefore be a potentially valuable introduction of this new theoretical and methodological framework to the field of Web usage research in particular, and HCI in general. It is hoped that the insights uncovered by this study - along with those generated by subsequent studies of a similar nature - could be subsequently drawn upon to describe and delineate the characteristics of distinct Web user segments, through the use of techniques such as consumer prototyping, at an appropriate future occasion. Information of this nature would be of great potential significance to academic researchers, as well as to professionals in the Web industry.
Research Question

This research study essentially poses the question: Can means-end theory, and its concomitant laddering methodology, be successfully applied in the context of human-computer interaction research, specifically to help understand the relationship between Web sites and their users? The study attempts to explore this question by employing a laddering methodology with the aim of eliciting data concerning the site-attributes, consequences, and end-values that motivate Web users to choose particular Web sites over others. With the resultant data at hand, detailed analysis can be done to conclude if means-end theory is indeed useful in the context of Web usage in particular, and HCI in general.

Review of Literature

Means-End Theory

Means-end theory examines the important meanings that users associate with the products they choose and consume, by distinguishing three levels of abstraction associated with the use of a product (Olson & Reynolds 1983): product attributes; consequences of product consumption; and personal values of the user. Product attributes are concrete meanings that represent the physical or observable characteristics of a product. Consequences of consumption are more abstract meanings that reflect the perceived benefits/costs associated with specific product attributes. Finally, personal values are highly abstract meanings that refer to centrally held, enduring beliefs, or end states of existence, that people seek to fulfill through their choice and consumption behavior (Rokeach 1973). Taken together, this pattern of associations from attributes to consequences and from consequences to personal values represents a special type of knowledge structure called a means-end chain (Gutman 1982, Howard 1977, Olson et al. 1983). The means-end chain model provides a simple way of characterizing the basic pattern of relationships by which the physical features or attributes of products gain personal relevance or meaning for users (Gengler et al. 1999).

Laddering

Laddering is the principal methodological manifestation of means-end theory. It is a technique by which the core attributes and values that drive product users are identified through a special form of in-depth, one-on-one interviews (Wansink 2000). This procedure is called laddering because it forces the respondent up a ladder of abstraction, and thus bridges relatively concrete product meanings at the attribute level with more abstract meanings at the consequence and personal value levels (Gengler et al. 1999). This is done by repeatedly asking “Why is that important to you?” questions. Data gathered by laddering interviews is analyzed to produce an accurate depiction of the concepts germane to the decision and the relationships between associated concepts, facilitating inferences and enabling the researcher to identify patterns that might not be evident in the raw data (Gengler et al. 1995, 1999).

Reynolds & Gutman, in their seminal (1988) article, describe the processing of laddering data as follows: The initial task of the data processing is to content-analyze all of the elements from the ladders, recording the entire set of ladders across respondents on a separate coding form, and developing a set of summary codes that reflect everything that was mentioned. Once the summary codes are finalized, numbers are assigned to each. These numbers are then used to score each element in each individual respondent's ladder. The next step involves the construction of an implication matrix, which displays the number of times each element leads to each other element. Once the implication matrix has been prepared, a hierarchical value map (HVM ) can be constructed, which graphically represents all the respondents' ladders in the aggregate. Once a HVM is constructed, one typically considers any pathway from bottom to top as a potential chain representing a perceptual orientation that warrants consideration.

Reynolds & Gutman (1988) claim that that such quantitative processing of qualitative interview data is one of the unique aspects of laddering. They cite several particularly valuable types of information afforded by HVMs obtained through laddering procedures, which can serve as a basis for segmenting users with respect to their value orientations for a product class or brand; assessing brands or products in a fashion similar to the use of more traditional ratings; evaluating competitive advertising; and developing advertising strategies.
Method

Interviewing

As part of the study, 50 in-depth laddering interviews were conducted. Through these interviews, an attempt was made to examine two different kinds of Web site use by respondents: use for primarily entertainment purposes; and use for primarily information gathering purposes. These distinctions were made on the basis of several preliminary interviews with random Web users, which suggested that they generally browsed the Web either to gather information relevant to their professional lives, or to access content that contributed to their personal lives by entertaining them. To operationalize the distinctions for the purpose of this study, a particular Web site was deemed an “entertainment” site if the respondent described his/her use of the site as primarily entertainment-oriented; and was deemed an “information” site, if the respondent described his/her use of the site as for primarily information gathering purposes. Of the 50 laddering interviews, 25 concentrated on entertainment Web sites and the other 25 on information Web sites.

The laddering interviews were conducted over the first four months of 2001. Respondents for the interviews were of diverse ages and ethnicities, came from varied walks of life, and were distributed across three U.S. states—Minnesota, Illinois and Connecticut. In each interview, the respondent was first asked to name his/her most favorite Web site, and to subsequently define whether s/he considered it to be an entertainment Web site or an information site. Once the particular genre of the Web site (within the broader entertainment/information category) was established (e.g. News, Astrology, Sport, Cooking, Music, Motorcycles, Chat, Search Engine, etc.), Reynolds & Gutman’s (1988) “preference-consumption difference” technique was used to elicit attribute distinctions. The respondent was asked to name two other competing Web sites of the same genre as his/her favorite site, and was then asked why s/he favored this particular site over the other two. In the interests of consistency, only the highest-rated attribute was used as the basis for building an attribute-consequence-value ladder during the remaining part of the interview.

Data Processing

Strictly following the pioneering methodological procedure established by Reynolds & Gutman (1988), once all 50 laddering interviews were concluded, the first step in analyzing the data gathered using the interviews was to develop a set of summary codes that reflected every attribute/consequence/value mentioned by the respondents. Then followed the assignment of numbers to each code. Once the codes were established and numbered, their numbers were then used to score each element in each ladder producing a “raw” matrix (not shown here) with rows representing an individual respondent’s ladder and columns corresponding to the sequential elements within the ladder. The number of columns corresponded to the number of elements in the longest ladder. With these coded raw matrices compiled, the final set of matrices, i.e. the implication matrices, were constructed in order to display the number of times each element leads to each other element, both directly and indirectly. In these matrices, the numbers are expressed in fractional form, with direct relations to the left of the decimal point and indirect relations to the right. Once the implication matrices were prepared, work started on the construction of the respective hierarchical value maps or HVMs. The HVMs were gradually built up by connecting all the chains formed by considering the linkages in the implication matrices, with a cut-off level of two direct relations established for the purpose of plotting the HVMs (Fig. 1-2). In these HVMs, any pathway from bottom to top can be considered as a chain representing a significant perceptual orientation.

Findings

Both sets of interviews raised six attribute codes each. It is noteworthy that 10 out of 12 attribute codes (barring “Better Site Design” and “Familiarity of Site”) deal with content issues. From this data, it appears that content has been a very important factor in the choice of Web sites for the respondents in this study. Meanwhile, it is also interesting to note that both sets of ladders elicited exactly the same value codes—Satisfaction, Relaxation, Happiness, and Emotional Security. This indicates that both sets of respondents were essentially motivated by the same set of values in their choice of Web sites, whether for entertainment or for information.
Furthermore, among the consequence codes, some are reasonably similar to each other (e.g. Save Time/Energy, Find/Interact with Other People, More Time for Other Activities, Success), while others are unique to entertainment Web Sites or to information Web sites. There could possibly be some valuable aspects of Web site usage indicated by the above differences also.

Meanwhile, looking at the HVMs can reveal certain interesting segmentations in the manner by which attributes are linked to particular consequences and values. For instance, in Fig. 2, a clear division can be made down the center of the map, between the linkages leading to Positive States of Being and on to Satisfaction/Emotional Security on the one hand, and the linkages leading to Get Information Quickly/Save Time and on to Relaxation/Happiness on the other. Similarly, in Fig. 1, the path leading from Location/Community-Specific Content to Emotional Security/Happiness is fundamentally different from that leading from, say, Larger Quantity of Content to Satisfaction/Relaxation.

Figure 1: Hierarchical Value Map for Entertainment Web Sites

Furthermore, among the consequence codes, some are reasonably similar to each other (e.g. Save Time/Energy, Find/Interact with Other People, More Time for Other Activities, Success), while others are unique to entertainment Web Sites or to information Web sites. There could possibly be some valuable aspects of Web site usage indicated by the above differences also.

Meanwhile, looking at the HVMs can reveal certain interesting segmentations in the manner by which attributes are linked to particular consequences and values. For instance, in Fig. 2, a clear division can be made down the center of the map, between the linkages leading to Positive States of Being and on to Satisfaction/Emotional Security on the one hand, and the linkages leading to Get Information Quickly/Save Time and on to Relaxation/Happiness on the other. Similarly, in Fig. 1, the path leading from Location/Community-Specific Content to Emotional Security/Happiness is fundamentally different from that leading from, say, Larger Quantity of Content to Satisfaction/Relaxation.
Figure 2: Hierarchical Value Map for Information Web Sites

Thus, a marketer attempting to segment users of his/her information Web site could reason thus: “There are basically two types of users of such sites. There are those that visit these sites in order to achieve certain positive states of being, which leads to improved performance/ recognition, which in turn helps them to succeed and to avoid negative states. This helps them contribute to other people’s lives, thus achieving emotional security and satisfaction. These users seem to be attracted to location and subject-specific content. Meanwhile, there are those busy people that visit solely to get information quickly, which helps them save their precious time. This gives them more time to devote to other people/activities, which brings them relaxation and happiness. Such users look for site attributes such as familiarity, high-quality content, and good design.”

Similarly, the marketer for an entertainment Web site could reason thus: “There are two types of users for sites like mine. There are those that use the sites to interface/network with other users, relate, build relationships, foster community ties, and thus achieve emotional security, happiness, and avoid unwanted mental states. These “people-minded” users are attracted primarily to location-specific content. Meanwhile, there are those who basically use these sites as a means of avoiding unnecessary efforts. With the time they save, they perform activities that helps them achieve positive goals. This helps them to relax, and to succeed, which in turn brings them satisfaction. It looks like these “success-minded” users desire access to a large, varied quantum of content through the site.”

Implications

Therefore, can means-end theory, and its concomitant laddering methodology, be successfully applied in the context of HCI research, specifically to help understand the relationship between Web sites and their users? To begin with, the very fact that all of the 50 respondents who participated in the laddering interviews were able to name distinct site-attributes, articulate the consequences of these attributes, and identify the end-values served by these consequences, suggests that means-end chains do undeniably characterize the basic pattern of relationships by which the physical attributes of Web sites gain personal relevance or meaning for
their users. It can thus be proposed that means-end theory can indeed be applied in the context of new media research, to help understand the relationships between Web sites and their users.

Meanwhile, it was also possible to successfully perform all the analysis techniques detailed by Reynolds & Gutman (1988) on the data gathered by the laddering interviews conducted as part of this study. This included formulation of meaningful content codes, compiling the raw matrices with coded rows representing individual respondents' ladders, preparing the implication matrices from the above coded data, and finally plotting the hierarchical value maps. If means-end chains could not be used to describe the relationships between Web sites and their users, it can be argued that it might not have been possible to perform all of the above operations and obtain consistently meaningful results. For instance, the fact that all 30 potential perceptual orientation chains in the HVM for entertainment Web sites (Fig. 1) and all 31 chains in the HVM for information Web sites (Fig. 2) make logical sense is an example of the results' meaningfulness.

Besides, the fact that a majority of the respondents named content-related site-attributes as most relevant to them is in congruence with the opinion of many leading webmasters that good content is what motivates users to visit a Web site more than any other site attribute. To quote Silverio (1995 section 4 para. 2), "You can make your pages look absolutely fabulous but if they don't say anything, nobody's going to care." Meanwhile, according to Nelson (2000 para. 7), "Content is everything," and encourages repeat visits by users.

Final Remarks

The most important contribution of this study, in the researcher's opinion, is its successful demonstration of the applicability of Gutman's means-end theory — an important part of marketing research literature — in the context of human-computer interaction research (or more specifically, Web usage research). By describing the relationships of 50 Web users with their favorite Web sites in terms of attribute-consequence-value linkages, the study indicates that means-end chains definitely characterize the basic pattern of relationships by which the physical attributes of Web sites gain personal relevance or meaning for their users. The chief limitation of this study is that the current findings may not be generalizable to the whole universe of Web users, since the study only involves 50 respondents selected on a non-random basis. But then, the object of this study was simply to be an introductory demonstration of the use of a new theoretical and methodological framework within the substantive context of Web usage research, and not the formulation of meaningful hypotheses about the characteristics of Web users. The latter could be the goal of a future study, or meta-analysis, that enjoys access to a much more extensive set of interview data. This might actually permit the drawing of generalizable inferences, which would be of great significance to academic researchers of HCI as well as to professionals in the Web industry.

Automatic Camera Control System for a Distant Lecture with Videoing a Normal Classroom

Akira Suganuma Shuichiro Nishigori*

Department of Intelligent Systems, Kyushu University, Kasuga, 816–8580, Japan
E-mail: suga@limu.is.kyushu-u.ac.jp

Abstract: The growth of a communication network technology enables us to take part in a distant lecture. Although many lectures are held by using Web contents in universities, normal lectures using a blackboard are still held. The later style lecture is good for teacher’s dynamic explanation. All the way to modify it for a distant lecture is to capture by a video camera. When we video lecture scenes for the distant lecture, a camera-person usually controls a camera to take suitable shots; alternatively, the camera is static and captures the same location all the time. Both of them, however, have some defects. It is necessary to control a camera automatically. We are developing ACE (Automatic Camera control system for Education) with computer vision techniques. This paper describes our system, our camera control strategy and an experiment of applying it to a real lecture.

1 Introduction

The growth of a communication network technology enables people to take part in distant lectures. There are various methods to held such a lecture. For example, it could be held by an web page-based method and a method of sending visual and audio of lecture scenes. One of the authors have been studying some supporting systems for a distant lecture. In the recent years, Suganuma et al. [Mine 2000, Suganuma 2000] have been developing a Computer Aided Cooperative Classroom Environment (CACE) and an Automatic Exercise Generator based on the Intelligence of Students (AEGIS) for the web page-based lecture.

Indeed some lectures, for example the information technology or the programming, are frequently held by using visual facilities or computers in many universities but many lectures are held by the traditional style. It seems that such lectures will not disappear in the future although they will hold by combining the blackboard and a visual facility such as an OHP or Power Point software. We are, consequently, also developing another supporting system for the distant lecture with videoing the traditional lecture. This paper describes an Automatic Camera control system for Education (ACE).

We envisage that scenes of a lecture held in a normal classroom are recorded by a video camera and students in remote classroom take part in the lecture by watching the scenes projected on a screen. Figure 1 illustrates a form of the distant lecture by videoing the traditional classroom. A teacher teaches his students in an ordinary classroom. There is a blackboard in the room. He writes and explains something on it. Watching it and listening to his talk, students in the room take part in the lecture. Some cameras are setting in the room and take a lecture scene in order that the captured scene is sent to distant classrooms. On the other hand, students in the distant rooms take part in the lecture by watching a scene reflected on a screen.

When we video lecture scenes for the distant lecture, a camera-person usually controls a camera to take suitable shots; alternatively, the camera is static and captures the same location all the time. It is not easy, however, to employ a camera-person for every occasion, and the scenes captured by a steady camera hardly give us a feeling of the live lecture. It is necessary to control a camera automatically. ACE enables people to do it for taking suitable shots for a distant lecture. Receiving a scene from a camera, ACE analyses it and recognizes the complexion on the lecture. ACE judges what is important in the scene and controls the camera to focus on it. If the sent scenes are most suitable and effective, the educational effect on the students in the distant rooms is as good as that of the students in the room.

*Currently, Sony Corporation, Japan
In this paper, section 2 presents design of ACE and our strategy of camera control. Section 3 describes the algorithm to extract the latest object written by a teacher on a blackboard, and section 4 describes an experiment to apply ACE to a real lecture. Finally, concluding remarks are given in section 5.

2 Overview of ACE

2.1 Design

We have designed and implemented ACE, which is an application based on Computer Vision Technique. When we designed it, we assumed the following:

- A teacher teaches his students by using only a blackboard.
- Students aren’t reflected in the scenes captured by the camera.
- A teacher isn’t required to give the system a special cue.

The first assumption means that the lecture captured by ACE is a traditional one. The teacher writes something on the blackboard, and explains them. Indeed he teaches his students using OHP and/or other visual facilities in the resent years, but many traditional ones are held in many schools.

The second assumption is made to decrease processing costs. If students are reflected in the scenes, ACE always has to distinguish a teacher and them. This processing is complex and take much time. It is easy to satisfy this assumption if we take a scene from the ceiling.

Finally, the third assumption is very important for a teacher. If a teacher gives ACE his special cue such as to press a button of a remote controller, ACE may control a camera more easily. ACE has only to keep waiting his cue in that situation. If the teacher, furthermore, put on a special cloth, on which some color markers are attached, it is easier to detect his position and/or action. The special cue and the special cloth, however, increase the load on the teacher. He may omit to give ACE his cue. He ought to concentrate his attention on his explaining. We decided, consequently, we didn’t require him to give ACE his cue.

The overview of ACE is shown in Figure 2. ACE requires two cameras. One is a steady camera and the other is a active one. The steady camera captures a whole blackboard at a constant angle for image processing. The captured image is sent to ACE system running on a PC over an IEEE-1394 protocol. ACE analyzes the image and decide how to control the active camera according to a camera control strategy shown in section 2.2. The control signals are sent to the active camera over an RS-232C. The active camera, hereby, takes suitable shots. The visual and the audio are sent to the distant room. Students in the room watch and listen to them, and take part in the lecture. In our study, we are interested in how to video the lecture held in normal classroom. We are using a known method or product as a way sending the video via the network.
2.2 Camera control strategy

What does ACE capture? It is a very important thing for the system such as ACE. One solution is to take the scenes that students want to watch, but in this case many scenes are probably requested by many students at the same time. Although this solution needs the consensus of all students, it is very difficult to make it. We decide, therefore, that ACE captures the most important things from a point of view of a teacher. The most important thing from teacher's point of view is also difficult. We guessed the objects that teacher was explaining were the most important things for all students. When he explains something, he probably wants his students to watch it. He frequently explains the latest object that he have written on the blackboard. We decided consequently that ACE captured the latest object written on the blackboard.

When the lecturing scenes are videoed, both constantly changing shots and over-rendering shots are not suitable. A changeless shots are, if anything, more appropriate than those shots. It is important that students can easily read contents on the blackboard. The shots captured by ACE is shown in Figure 3. ACE usually takes a shot containing the latest object and a region near it in a discernible size. The blackboard often consist of four or six small boards like a picture in Figure 4. A teacher frequently writes relational objects within one board in this case. Now, ACE takes a shot by the small board such as figure 4-(a). On the other hand, ACE takes a shot zoomed in on the latest object after the teacher has written it on the blackboard such as figure 4-(b). After a-few-second zooming, ACE takes an ordinary shot again.

If we take the scene by a steady camera, the shot may be like a shot in Figure 4. In this case the camera must capture the whole blackboard, because the teacher writes something anywhere. The characters in this shot are too small for students to read. The shot of ACE is superior to that of the steady camera.

3 Extracting the latest object

3.1 Background subtraction

We use a background subtraction technique to detect objects on the blackboard. The background subtraction technique is a method to detach the foreground image from the background image. In the method, the background image is captured before opening the lecture. The image contains only the blackboard on which written no object.
We cannot contain a teacher. We can get some objects on the blackboard and in front of blackboard when we subtract the background from the image captured by the same camera during the lecture.

We adopted a background model [Haritaoglu 1998] in our system. This model is robust against a noise such as a flickered noise and so on. The platform is lightened by fluorescent lamps in a normal classroom. There are usually many noises such as flickered ones in a shot when a video camera captures objects lightened by them. ACE needs a robust method against noises for this reason.

In the original background model, the background image is modeled by representing each pixel by the following values; its maximum \( \text{Max}(p) \) and minimum \( \text{Min}(p) \) intensity values and the maximum intensity \( D(p) \) difference between two pieces of successive frames observed during capturing the background image. Pixel \( p \) is a background pixel if the intensity of pixel \( p \) satisfies the following: \( \text{Min}(p) \leq D(p) \) or \( \text{Max}(p) \geq D(p) \). The first inequality represents the lower-bound in order that the pixel belongs to the background, the other represents the upper-bound.

We specialized the method for the lecturing scene. The foreground objects segmented by the technique are something to write on the blackboard, something to erase on it, the teacher and so on. We need only the written object. Their pixels appear only above the upper-bound because the object written on the blackboard is brighter than the blackboard. Our method takes, therefore, no longer the pixel whose brightness is less than the lower-bound. ACE segments the object by using only the above second inequality.

The foreground objects are extracted by thresholding and noise clearing. The objects represent highlighted pixels in the background subtraction image.

### 3.2 Separating an object from the foreground image

The foreground image almost always includes a teacher. We would like to detect only the written object. If we mask teacher’s region, we can get the region correctly. We have to detect, therefore, teacher’s region. We assumed that all the moving object is a teacher. A method using a subtraction between a frame and a frame that captured after a short interval is usually used when we want to detect a moving object. ACE calculates the subtraction image and makes moving objects highlight. ACE makes a rectangle circumscribed highlight pixels the temporal teacher’s region. After all pixels in teacher’s rectangle in the foreground image are changed to dark ones, the remnant highlight pixels are the written objects if teacher’s region is segmented correctly enough. ACE makes a rectangle circumscribed the highlight pixels, and deals with it after this processing.

### 3.3 Remake the background model

We have to distinguish the latest object and others. ACE keeps tracing the latest object written by a teacher from our camera control strategy described by section 2.2. Once the object has been detected as the written object, it doesn’t need to be detected more than twice. After detecting the latest object, ACE re-calculates the values of the background model for each pixel in the region of the object. ACE always detects, therefore, only the latest one.

### 3.4 Timing of zooming in

We cannot control a camera even if we get the region of the latest object. We have to find the timing of zooming in. If ACE zooms in on the written object before a teacher has written, ACE must take a scene occluding the object behind the teacher body. After guessing whether the teacher finished writing, consequently, ACE zooms in on the object written by him at that moment.

The rectangle circumscribed the latest object usually change frame by frame. This main reason is the following:

- The rectangle increases or decreases because the teacher wrote something new or erased something.
- The masked region changes because the teacher moved to write something new. Then the rectangle increases or decreases.

Shortly, the rectangle changes when the teacher is writing something. On the other hand, he usually clears the object to make his students watch it after he has written. ACE take advantage of this feature to guess whether he finished. The rectangle does not change when he cleared the object. ACE counts the number of frames in which the rectangle does not change. If the number is over a threshold, then ACE judges the teacher finished writing, and control a camera to zoom in on the written object.
4 Applying ACE to a real lecture

4.1 Condition
We have developed ACE and done an experiment of applying it to a real lecture. We held two 25-minutes lectures on Mathematics for 85 undergraduates. A teacher taught them by only using a blackboard. One of the authors played the role of the teacher. Although he knows the detecting algorithm of ACE, he taught by usual style. Sort of thing, he behaved as disadvantage for ACE. We videoed the lecture scene by ACE and by a steady camera in order to compare their shots. These shots were recorded on video cassettes and played them in classrooms. We divided 85 students into two groups, each group discretely watched the video lectures projected on a screen. We evaluated ACE in terms of the following:

1. How correctly did the student copy contents from the screen to his note?
2. How good were the shots of ACE by comparison with that of the steady camera?

4.2 How correctly did the student copy contents?
We designed ACE to capture the latest object because a teacher often explains it. Is this strategy adequate enough to video a lecture scene? We evaluated the videoing strategy of ACE from a point of view that students could make a note. We made the students make a note for this evaluation. We told the students before the lecture that we would collect their notes after the video lecture and check that they were made properly. We precomposed a master note and wrote the all contents of it on the blackboard all through the lecture.

After the lecture we collected their notes and compared them with the master note. We counted their missing in each note. The result is shown in Figure 5. 36% of all the students can perfectly copy the contents from the shots captured by ACE. 45% of the students make only one mistake. There are some small characters such as the index of a formula in this lecture scene. Many mistakes are caused by them. Almost all students make not more than three mistakes. Although there was a few students that hardly copied the contents from the screen to their note, this reason was that they sat down far from the screen when he took part in the video lecture. As the results of this estimation, almost all students can make a note correctly enough to learn it. The shots seem good enough.

4.3 How good were the shots of ACE?
We asked five questions to the students after each video lecture. They scored each scene captured by ACE and the steady camera, from 1 to 5. The average scores of each question are shown in Table 1. We omitted the third question for the scene captured by the steady camera because it always contains all objects on the blackboard. We used the t-test to compare these scores. Our null hypothesis is "The scene captured by ACE is as good as the scene captured by the steady camera."

The score of the scene captured by ACE is better than that of the scene by the steady camera, except the first question. Since ACE focus on the latest object, the scene does not always contain a teacher. Then the first evaluation of ACE is lower than that of the steady camera. On the other hand, a teacher is relatively small because the scene captured by the steady camera contains the whole blackboard. Teacher's action is hard to interpret in the scene. This is why the score of the steady camera is also low. Our null hypothesis, therefore, is not rejected with both 1% and 5% level of significance in this question. The point of the third question is, furthermore, what we abandoned at design of ACE. We were afraid that many students could not watch something to want because ACE zoomed in on the latest object. When they copy the contents, they often miss watching what and when they need, if timings of their watching do not synchronize with that of ACE's zooming in. Sure enough, the score is lowest of all scores of ACE.
Table 1: Questionnaire

<table>
<thead>
<tr>
<th>Questions</th>
<th>Steady</th>
<th>ACE</th>
<th>Null hypothesis</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Could you watch the teacher's action well?</td>
<td>3.27</td>
<td>3.19</td>
<td>Accept</td>
</tr>
<tr>
<td>2. Could you watch the objects on the blackboard well?</td>
<td>1.58</td>
<td>2.75</td>
<td>Reject</td>
</tr>
<tr>
<td>3. Could you watch the object you wanted?</td>
<td></td>
<td>2.49</td>
<td></td>
</tr>
<tr>
<td>4. Were you given a feeling of the live lecture?</td>
<td>2.71</td>
<td>2.86</td>
<td>Accept</td>
</tr>
<tr>
<td>5. Could you give the scene an overall score as a lecture one?</td>
<td>2.12</td>
<td>2.49</td>
<td>Reject</td>
</tr>
</tbody>
</table>

(1% level of significance)

Our null hypothesis is rejected with 1% level of significance in the second question and the fifth question. In both of them the scores of ACE are better than that of the steady camera. The evaluation of ACE is, therefore, superior to that of the steady camera. Neither of the scores, however, is high. In this experiment, the quality of the audio of our videos was not so good. Teacher's voice was, especially, hard to hear because we recorded it not by a wireless microphone at his breast but by a standard one on a desk. This is why the magnitudes of the evaluations are not large. If the quality had been better, they would have been larger. Because there were many feedbacks that described the low-quality audio. The shots captured by ACE is, consequently, good enough to video a lecture.

5 Conclusion

We have designed a camera control strategy for videoing a lecture and developed a prototype of ACE. We evaluated, moreover, it with applying it to a real lecture. As a consequence, we make sure that ACE is a useful tool for videoing a traditional lecture.

ACE takes a suitable shot if the teacher explains the object as soon as he writes on the board. It cannot take, however, a suitable shot when he explains something written in past. He usually teaches his students pointing the objects which he wants them to look at. Interpreting teacher's action and/or posture, ACE could capture more suitable scene. We will make ACE interpret it. We assume that a teacher teaches his students with a blackboard. But he sometimes also uses with an OHP. We will also make ACE be applied to such a situation.

Automatic Generating Appropriate Exercises Based on Dynamic Evaluating both Students’ and Questions’ Levels

Akira Suganuma Tsunenori Mine Takayoshi Shoudai

Graduate School of Information Science and Electrical Engineering, Kyushu University, Kasuga 816-8580, Japan
e-mail: {suga@is, mine@is, shoudai@i}.kyushu-u.ac.jp

Abstract: Popularization of computers and the Internet enable people to hold lectures using Web contents as a teaching material. Although teachers have prepared a lot of Web contents, most of them are used so as only to be browsed by students. If we arrange some exercises according to lecture notes and prepare an answering mechanism for the exercises via the Internet, students can attempt the exercises any time. This paper proposes AEGIS (Automatic Exercise Generator based on the Intelligence of Students) that generates exercises of various difficulty levels according to each student’s achievement level, marks his/her answers and returns them to him/her. It is necessary for AEGIS to evaluate dynamically both the levels in order that it selects a suitable question for each student. This paper also declares the validity of the method with a simulator.

1 Introduction

As the Internet has come into wide use, WWW environments provide lots of opportunities to various fields. In the educational domain, many Internet technologies enable people to hold lectures using Web contents as a teaching material and even develop new lecture methods using the technologies. Web data are, therefore, being expanded rapidly as useful materials.

We have devoted ourself to develop a Web-based self-teaching system and to build the tools for helping students understand their subjects [Sato 1997, Mine 1998, Fujimoto 1999, Suganuma 2000]. Through our experiences teaching in classes and developing such systems, we recognize the necessity of both a method evaluating students’ achievement levels and generating exercises suitable for the students automatically.

For example, in trying to make some exercises for the students in a class, we have to take at least their achievement level into considerations. The well-considered exercises are useful not only to measure the achievement level of the students, but also to improve their performance. Unfortunately, it is not an easy task for any teacher to make exercises with the difficulties suited to their achievement levels. Besides, it is very important to mark their answers to the exercises and return the marked results to them for keeping their learning enthusiasm. These tasks become harder in proportion to the number of the students in a class[Hirokawa 1996].

In this paper, we present the automatic student’s achievement level evaluator that generates exercises from tagged documents, presents them to students and marks their answers automatically. We call the system AEGIS (Automatic Exercise Generator based on the Intelligence of Students)[Shoudai 2000, Mine 2000]. AEGIS generates the three question-types from the same tagged data. Guessing the achievement level of each student from his/her trial history, AEGIS selects the most suitable question-type and exercise for him/her according to not only his/her achievement level but also the difficulty level of the exercises. It is necessary for AEGIS to evaluate dynamically both the levels in order that it gives each student a suitable question. Although many CAI systems have been proposed, our system is different from them in the points of re-usability of pre-existing electronic materials and re-estimation of both the levels. We have already proposed the method to re-estimate them[Mine 2000] but have not yet validated it competently. This paper declares the validity with a simulator.

In what follows below, the remainder of this section discusses related works. Section 2 describes the exercise generating process by AEGIS and the specification of the tags designed to generate an exercise. Section 3 describes the algorithm to re-estimate the achievement level of a student and the difficulty level of a question. Section 4 discusses experiments and their results to show the validity of the algorithm described in Section 3, and Section 5 shows the overview of AEGIS. Finally, concluding remarks are given in section 6.
Related Works  A lot of automatic quiz generators have been proposed. Browning et al. proposed Tutorial Mark-up Language (TML for short) to generate questions automatically [Browning 1997, Browning 1998]. TML has a couple of tags to specify a question, a multiple-choice and a message. It requires a correct answer in a multiple-choice tag to mark a student’s answer to the question. Carbone et al. proposed CADAL Quiz [Carbone 1997], which generates a multiple-choice quiz from a question database. After marking a student’s answer, CADAL Quiz returns the result to him/her and to tutors. Both of them restrict the question type only to a multiple-choice quiz. On the other hand, ClassBuilder [ClassBuilder] generates many kinds of quizzes and grades a student’s answer. However, all of them do not mention any effect of making the difficulty level of question-type change according to the students’ achievement level. In order to improve their performance and keep their enthusiasm to attempt the quiz for a long time, it is indispensable to consider their performance level for generating their exercise. This point is the difference from other systems. AEGIS makes use of pre-existing electronic documents so as to embed tags in them, generates exercises automatically with tagged documents according to students’ achievement levels, and re-estimates both their levels and the difficulty level of the generated question through marking their answers.

2 Automatic Exercise Generating

There can be several types of a question in every subject. Since our aim is to make a computer generate an exercise and mark a student’s answer to it, we thus restrict the question-types to the following three: multiple-choice question, fill-the-gap question, and error-correcting question. Figure 1 shows examples of these question-types. All of these question-types can be constructed from a sentence by replacing one or more consecutive words with a blank or a wrong expression. We call the region to be replaced, hidden region. We note that these three question-types have different difficulties even though they are constructed from the same hidden region.

The exercise generating process from teaching documents is summarized as follows: (1) Setting a hidden region, (2) Selecting a paragraph or sentence(s) from teaching documents, and (3) Constructing a candidate list. These three steps are deeply related to the teachers’ intentions. It is not easy to extract such intentions automatically from the teaching documents. AEGIS system thus deals with tagged documents including the information such as hidden regions and candidate lists.

In order to embed the above three kinds of information in teaching documents, we define the following three tags: QUESTION tag that surrounds a question region, DEL tag that indicates a hidden region, and LABEL tag that surrounds the relevant sentence/s to the DEL tag. Figure 2 shows the tagged data to be used for generating the examples in Fig. 1. Replacing the word “in” which is located between DEL tags with a blank generates the example of the fill-the-gap question. In addition, the value of CAND “an, on, at, by” constructs the candidate list of the multiple-choice question. On the other hand, replacing the hidden region with an element in the value of the CAND generates the error-correcting question. Thus we can generate three question-types from only one question region where the above tags are embedded. The additional three attributes of DEL, which contain the information of the difficulty to solve an exercise, are LEVEL, GROUP, and REF. They specify the difficulty of each hidden region.
Figure 3: Definition of tags for exercise generation

region, and the connections to other hidden region.

Figure 3 shows the definition of the tags described above in BNF. The LEVEL attribute must be provided because AEGIS initializes the difficulty level of the hidden region with its value. On the other hand, the others are not essential attributes. When a value of CAND attribute is utilized as a distractor, AEGIS generates only a fill-the-gap question.

3 Re-estimation of Achievement Level and Difficulty Level

It is very important for AEGIS to estimate an achievement level of a student because it generates exercises according to the level. Such a student level fluctuates constantly because AEGIS measures it whenever the student answers a question. The achievement level of student $i$ at time $t$ is calculated with the following formula:

$$ s_{i,t} = \begin{cases} 
  s_{i,t-1} + \frac{\sum_{j \in Q} (q_{j,t} - s_{i,t-1}) \delta_{i,j}}{\sum_{j \in Q} \delta_{i,j}} & \text{if } \sum_{j \in Q} \delta_{i,j} \neq 0 \\
  s_{i,t-1} & \text{otherwise}
\end{cases} $$

where $Q$ is a set of questions that he/she answered in the recent 30 trials and $q_{j,t}$ stands for the difficulty level of question $j$ at the time when the achievement level $s_{i,t}$ is calculated. The weight value, $\delta_{i,j}$, is 1 if student $i$ correctly answered question $j$ whose difficulty level is more than his/her achievement level $s_{i,t-1}$ or he/she incorrectly answered question $j$ whose level is less than $s_{i,t-1}$, or 0 otherwise. The achievement level of student $i$ is initialized to 1 when he/she tries a question at first time. The student who has continuously answered a lot of questions correctly, obtains a higher achievement level, and can attempt more difficult one. He/she can try more difficult ones if he/she answers them correctly again. On the other hand, the achievement level of the student who answered most of the questions wrongly, becomes lower, he/she comes to attempt easier ones. Continuously answering them correctly, he/she can gradually attempt more difficult questions.

The difficulty level of a question is carefully configured, because AEGIS uses it to calculate the students' achievement level and refers it to generate a suitable question for a student. Since the teachers set it up with the attribute LEVEL of DEL tag, they can assign the upper and lower limits of the difficulty level of a hidden region. However, there may be a gap between the difficulty level evaluated by the teachers and that found by the students. A question evaluated by the teachers as an easy one, may not always be answered correctly by lots of students, and vice versa. AEGIS, therefore, utilizes the value of the attribute LEVEL as an initial value of the difficulty level of
the hidden region, and calculates the level dynamically at regular intervals with the following formula:

\[
q_{j,t} = \begin{cases} 
q_{j,t-1} + \frac{\sum_{i \in S} (s_{i,T} - q_{j,t-1})\xi_{i,j}}{\sum_{i \in S} \xi_{i,j}} & \text{if } \sum_{i \in S} \xi_{i,j} \neq 0 \\
q_{j,t-1} & \text{otherwise}
\end{cases}
\]

where \( S \) is a set of students who answered the question \( j \) between time \((t-1)\) and \( t \), \( s_{i,T} \) is a student's achievement level at time \( T \) \((t-1) < T < t\). The weight value, \( \xi_{i,j} \), stands for 1 if students whose achievement level is more than the difficulty level \( q_{j,t-1} \) of question \( j \) answered it wrongly or students whose level is less than \( q_{j,t-1} \) answered it correctly, or 0 otherwise. This equation is a recurrence formula, and \( q_{j,0} \), which is the initial difficulty level of question \( j \), is given with the attribute LEVEL of DEL tag by teachers.

The above formula calculates a new difficulty level of the question for each question-type. Since the teachers assign the upper and lower limits of the difficulty level of a hidden region with the attribute LEVEL of DEL tag, AEGIS sets the upper (lower) limit as the initial difficulty level of the question to be generated in the error-correcting question (multiple-choice question). That of the fill-the-gap question is assigned the mean of the upper and lower limits. After calculating the new difficulty levels, AEGIS sets the maximum (minimum) value among the three-question types as the upper (lower) limit of the difficulty level of the hidden region.

4 Evaluation with Simulator

AEGIS estimates dynamically both the achievement level of each student and the difficulty level of each question with the equations defined in Section 3. In order to examine their validity, we investigated the following three things: 1. How does AEGIS estimate the inherent achievement level of a student? 2. How does AEGIS estimate the inherent difficulty level of a question? 3. Can AEGIS provide only questions suitable for a student?

We assumed that the probability that a student answers a question follows the function of both the inherent difficulty level of the question \( q^{(\text{TRUE})} \) and his/her inherent achievement level \( s^{(\text{TRUE})} \), and that he/she can correctly answer the question with 50% probability if \( q^{(\text{TRUE})} \) is equal to \( s^{(\text{TRUE})} \).

1. Re-estimation of the achievement level of a student

Based on the student's achievement level calculating formula defined in Section 3, we made AEGIS calculate the achievement level \( s^{(\text{AEGIS})} \) of three students whose inherent achievement levels are high (\( s^{(\text{TRUE})} = 8 \)), middle (\( s^{(\text{TRUE})} = 5 \)) and low (\( s^{(\text{TRUE})} = 2 \)). We used 100 questions whose difficulty levels are distributed at the equal interval from 0 to 10.

Figure 4 shows the variance of \( s^{(\text{AEGIS})} \). Since all of their levels, \( s^{(\text{AEGIS})} \), are set to 1 at first, the three curves in the graph start from 1. They were gradually separated each other because they answered questions...
correctly or incorrectly based on their inherent achievement level. Each curve of \( s^{(AEGIS)} \) in our simulation approximates closely the value of \( s^{(TRUE)} \) that we presupposed. AEGIS can consequently distinguish between them.

2. Re-estimation of the difficulty level of a question

Based on the question's difficulty level calculating formula defined in Section 3, we made AEGIS calculate the difficulty level \( q^{(AEGIS)} \) of three questions whose inherent difficulty levels are high \( q^{(TRUE)} = 8 \), middle \( q^{(TRUE)} = 5 \) and low \( q^{(TRUE)} = 2 \). We at first set \( q^{(AEGIS)} \) to a different value far from \( q^{(TRUE)} \), that is, \( q^{(AEGIS)} \) of the questions whose inherent levels were 5 or 8 was set to 1, and that of question whose inherent level was 2, was set to 8.

In order to estimate the movement of the difficulty level of these questions, we used the two real distributions, called Class A and Class B, of achievement level of students who were given a lecture by one of the authors. Class A is superior to Class B. We assumed that the distributions did not change during our experiment.

The curve of \( q^{(AEGIS)} \) is shown in Fig. 5 for the data of Class A. Each curve of \( q^{(AEGIS)} \) approximately converges to its inherent difficulty level \( q^{(TRUE)} \). The students in Class A tried to solve a lot of questions of higher difficulty level. Although we would have expected that the current difficulty level of a question tried by many students would influence the change of the new difficulty level of a question, the result of our experiment on Class B becomes similar to the curve in Fig. 5. We can conclude that our method can well estimate the difficulty level of each question.

3. The difficulty level of questions generated by AEGIS

We prepared three trial histories each of which belonged to high, middle, and low achievement level students. We applied 1,000 questions of various difficulty levels to these students so as to confirm that AEGIS generates good questions suitable for the students' achievement level. We assume that each 100 questions are uniformly distributed between difficulty levels 0 and 10.

Figure 6 shows the distributions of the difficulty levels of questions which each student tried to solve. A student of high (resp. middle, low) achievement level tried a lot of questions of high (resp. middle, low) difficulty level. Let \((x, y)\) be a pair of the mean value \(x\) and the standard deviation \(y\) of each distribution of the curve in Figure 6. \((x, y)\) of each curve is \((1.6, 0.78)\), \((4.6, 0.87)\) and \((7.6, 0.96)\), respectively. The result shows that AEGIS generates questions suitable for the students' achievement level.

5 Overview of AEGIS

The AEGIS system consists of three databases: Exercise DB (EDB for short), User Profile DB (UPDB for short) and Level Management DB (LMDB for short), and three main database managers: Exercise Generator, Answer Evaluator and Level Manager[Mine 2000]. The overview of AEGIS is shown in Fig. 7.
Teaching documents with the tags are compiled into the EDB and LMDB. All of the question regions are indexed sequentially and each hidden region is labeled with its own subindex of the index of each question region. The level of a hidden region, which is deeply related to the level of the question to be generated from the hidden region, is stored in the LMDB together with the index of the hidden region. The level of each hidden region in LMDB is reexamined regularly. UPDB keeps students’ trial histories with their current achievement levels.

6 Conclusion and Future Work

We discussed our new Web-aided system AEGIS. The system is currently implemented in Perl scripts, PostgreSQL and CGI. AEGIS measures the student’s achievement level every time he/she answers a question, and regularly re-estimates the difficulty level of questions in order to generate suitable exercises according to his/her achievement level. AEGIS is consequently utilized as not only a system generating exercises but also a tool classifying questions because the re-estimated level keeps close to their real difficulty level.

Experimental results with the simulator showed the effectiveness of the algorithm estimating both the achievement level of a student and the difficulty level of a question as were expected. We have a plan to evaluate this system by applying it to the real courses of Computer Literacy, which are taken by more than 2300 students at Kyushu University. We hope it will work fine as an educational tool for every student and help him/her to understand his/her subjects. Also, we will implement a tagging tool and an algorithm to generate another kind of exercise that allows more than one correct answers.

Instructional Design of Scientific Simulations and Modeling Software to Support Student Construction of Perceptual to Conceptual Bridges

Jerry P. Suits, Department of Chemistry, McNeese State University, Lake Charles, LA 70609-0455 USA
suits@mail.mcneese.edu

Moustapha Diack, Science/Math Education Department, Southern University, Baton Rouge, LA 70813-9614 USA
MDiack@aol.com

Abstract: This paper describes the theoretical basis for a constructivist design which can help students develop a set of mental models that increasingly correspond to scientific models that explain or predict scientific phenomena. These student-constructed models can be linked to form perceptual-to-conceptual bridges via two complementary instructional pathways: (1) interactive multimedia simulations can enhance the student decision-making process in a learning environment by providing guidance through trial-and-error experiences that culminate in productive experimental outcomes; and (2) student-generated modeling software can allow visualization of a simple mechanism, which is shown as perceptual icons which can be combined in a meaningful manner that shows conceptual entities and their interactions. The design of both types of software can support scaffolded student understanding of the connection between a scientific phenomenon (studied in the laboratory) and its underlying scientific principle (studied in lecture).

Introduction

With the help of scaffolded support provided by instructional design, students can begin to generate mental models based upon their interactive experiences with simulated phenomena that allow them to visualize scientific principles. Furthermore, modeling software can be designed to help them construct their own scientific models which are composed of simpler models that provide a concrete mechanism for them to build more complex models (White 1993, Frederiksen et al. 1999). In other words, simulations and modeling software can serve complementary functions when the former provides a decision-making task that allows student prediction of a phenomenon (i.e., the simulation outcome), while the latter provides an explanation of a phenomenon in terms of its underlying model that drives the simulation.

In the domain of chemistry, several researchers have found that student understanding of chemical principles and phenomena are linked to their ability to visualize the particulate level of matter (Gabel 1993) and then to use this level to connect the more abstract principles to the more concrete phenomena. Thus, it follows that if students use the particulate level to construct their own mental model, then they could use that model to predict the outcome of a simulated phenomenon. This paper features the pedagogic content knowledge needed to begin instructional design for these two forms of learning technology, i.e., simulations and modeling software, that serve complementary functions.

Traditional instruction usually does nothing to help students (Kim et al. 2000) because phenomena and principles are studied in different places (laboratory vs. lecture room) and usually at different times during the semester. Also, it focuses on a passive, information-communicating method of instruction. Conversely, this paper emphasizes the use of technology to provide an active, constructivist approach that is designed to engage students in authentic experiences in scientific thinking and activity (White 1993).
Goal

The major goal of this paper is to describe how two related types of software can be designed to complement each other: (1) interactive multimedia simulations (IMS) can provide opportunities for student decision-making regarding the experimental conditions (parameters) and observation of the consequences of these decisions when their simulation is run; and (2) student-generated modeling software (SGM) can allow student construction of their own model within the constraints set by the appropriate scientific models. Thus, the students are generating their own model, which can serve to describe a simple mechanism that explains the underlying abstract features of a scientific phenomenon.

Concrete Level Versus Abstract Level

The abstract level of a scientific principle represents the apex of a hierarchical pyramid that is based on a foundation of concrete-level phenomena. Experts can use these abstractions to explain a wide range of phenomena and to apply them appropriately when solving complex problems. Also, they can use these abstractions to organize information into larger chunks of information, which can reduce the load on working memory. In sharp contrast, novices tend to view these abstractions as information to be memorized or as algorithms to be applied to problems in a very inflexible manner. Thus, they can only engage in constraint-based reasoning that uses abstract principles (e.g. $P \cdot V = n \cdot R \cdot T$) as variables in an equation which they manipulate to find a quantitative answer (Frederiksen et al. 1999). On the other hand, when novices use SGM software they can benefit from a causal-based reasoning strategy that they have learned through their own construction of scientific models. A laboratory setting can give students “hands on” experience with a domain-specific phenomenon; however, they may be so busy manipulating the apparatus that they fail to observe the phenomenon as it occurs in real time. Conversely, an IMS of the same phenomenon replaces the physical manipulation of experimental apparatus with the mental manipulation of the experimental parameters that determine the experimental outcome. Thus students participate in experimental design rather than mimicking a pre-determined procedure that may have little meaning to them.

Intermediate Level of Abstraction

Both IMS and SGM software emphasize an intermediate level of abstraction that connects and gives meaning to concrete-level phenomena and abstract-level symbolic notation systems (mathematical equations or verbal generalizations). This intermediate level usually displays icons (dots for molecules or arrows for vectors) that help students visualize abstract objects (atoms, electrical charges, or biomolecules) and/or processes (chemical reactions, flow through electrical circuits, or cellular metabolism). The icons serve as cybernetic manipulatives (Kaput 1995) that are similar to physical manipulatives (molecular model kits, or wooden counting blocks).

Interactive Multimedia Simulations

An IMS can fully engage the decision-making processes of students while extending the range of phenomena that can be explored. IMS’s use models of scientific phenomena and data from real experiments to allow students to determine the experimental parameters and hence to design experiments. Upon running the experiment, they receive feedback about the experimental outcome. If the outcome does not meet their expectations, they can change the experimental conditions (parameter(s) or their values) and rerun the experiment. In addition, an IMS enables the student to create idealized simplifications for scientific systems and to transform abstractions into concrete manipulative representations (White 1993). This transformation allows them to see dynamic representations of phenomena that are connected to more abstract representations. Thus, they can relate and apply their formal knowledge to their everyday situations (White 1993). This “intuitive knowledge” is a flexible and generative type of knowledge (diSessa 2000) that can be used as the building blocks to construct conceptual knowledge.
We plan to illustrate the effectiveness of an IMS with an example that can be found at www.riverdeep.net under the “High School Science Gateways” section and the “Understanding Chemical Equilibrium” subsection. Specifically, an acid/base titration allows the student to explore an animated sequence that shows how acids and bases react during the titration process. The Logal Express simulation engine used in this IMS was selected for the following reasons: (1) it is interactive and it provides students with a microscopic visualization of chemical concepts and related graphic representations; (2) it provides a comprehensive content-rich chemistry curriculum, correlated to National Standards; and (3) it features a user-friendly interface, a scripting language, and a simulation engine that allows the authors (and their graduate students) the opportunities to customize and modify existing simulation activities to suit our specific curricular and instructional needs.

Abstract

Figure 1: Student interactions with models, simulations, and phenomena (Diack & Suits 2001, Suits & Hypolite 2002; Originally adapted from Raghavan & Glaser 1995).
Student-Generated Modeling Software

Properly designed SGM software allows student construction of the underlying scientific model that drives the IMS explorations described above. For example, in an SGM-based titration, icons can represent the active part (H+) of an acid molecule (HA, A is a negative ion) and the active part of a base (OH-) from an ionic compound (MOH). The student can select the amount of acid and base to represent four reaction conditions (Frames): (1) the starting condition in which only acid are present in the receiving flask, (2) the "buffered" condition in which H+ predominates over OH-, (3) the equivalence point at which the amount (moles) of H+ is equal to OH-, and (4) the final condition in which OH- predominates over H+. If a molecular model kit is used, then the student must disassemble each condition (Frames 1 to 4) before reassembling the next condition. Thus, it is difficult for novices to understand the causal relationships between the conditions because working memory is limited (Sweller et al. 1998). Conversely, a computer can "run" each condition in the proper order (Frames 1 to 4) to show the progression of interactions among chemical species (H+, OH-, and the product H2O). Thus, the student has created a situation model that serves as an "external memory aid" (Newton 1996) for each condition (1 to 4). In addition, the computer can present an "animated filmstrip" (Williamson & Abraham 1995) which can serve as a sequence of discrete causal events that follow a simple mechanism (White 1993).

Figure 2: Student construction of four situational models (frames) and their links in an animated sequence.

In our initial trial with this SGM example, we audio-taped a student as he built the four reaction conditions (Frames 1 to 4) described above. The student had just finished his second semester of college general chemistry lecture and a 2-credit hour laboratory techniques course. Prior to his modeling experience, he had done countless calculations involving titration data for his lecture courses, plus physical manipulation of the titration glassware during an acid-base titration experiment in the laboratory. However, it was only during the building of these models (Frames 1 to 4) that he "suddenly realized" that mixing acid (H+) and base (OH-) "just made water." In other words, he was able to visualize the essence of an acid-base chemical reaction for the first time despite his more concrete experiences with acids and bases in the laboratory and his more abstract/mathematical calculations performed during his lecture courses. He recommended that this "model building" exercise be used as a pre-laboratory activity for students so that they could understand the titration process before they actually performed the experiment. Currently, we are working to carry out this student's recommendation by designing an appropriate SGM software program on this chemistry topic.

This causal model enables students to envision causal mechanisms that are implicit in an abstraction (e.g., calculations used to solve titration problems). The abstraction, in turn, allows the student to predict and explain a wide range of domain phenomena (White 1993). For example, the students could use the same iconic manipulatives to represent the process of precipitation of a solid when to aqueous solutions of ions are mixed together. Also, this visualization process helps students encode a complex set of information as a simpler knowledge structure (situation model) that can be stored and recalled as needed. They can literally "see" linkages between a set of these structures (Frederiksen et al. 1999) because the "emergent properties" of the lower level model (e.g., each individual condition, 1 to 4) become the primitive elements of the more abstract, derived model (e.g., the sequence of conditions). Overall, two distinctive but complementary mental pathways...
can provide an intermediate level of abstraction: (a) intuitive knowledge developed from experiences (diSessa 2000), and (b) causal reasoning models (White 1993).

**Implications for Instructional Design**

The design of IMS and SGM technologies should be most effective when three levels of design are used to make instructional decisions (Lavoie 1995, Suits & Courville 1999, Suits & Lagowski 1981). Briefly, the goal for the primary level of design is to help students solve a scientific problem. Thus, instructional features must be constrained by the structure of the scientific discipline (Suits & Courville 1999). In other words, the nature of the learner’s interaction with the simulated phenomena must be authentic with respect to scientific principles. On the secondary level, the goal should be to use instructional design principles as external constraints designed to keep learners “on task” such that the level of task demands roughly matches the student’s level of knowledge and skills (Suits & Courville 1999). Finally, on the tertiary design level, the student should be challenged to solve a complex scientific problem (primary level) while being provided with just enough guidance to sustain their progress in solving the problem (secondary level). Guided inquiry (Suits & Lagowski 1981, Zuckerman et al 1998) allows the integration of multiple sources of information without overwhelming the learner’s cognitive load capacities (Sweller et al. 1998). This form of instruction is consistent with the constructivist view (Collins 1996) in which students can invent and adapt cultural tools for thinking about scientific ideas (Zuckerman et al 1998). The instructional design of IMS and SGM technologies should help students use sketches and mental pictures (icons) as visual representations (Kozma et al 2000) to build a bridge between the perceptions of the simulated phenomenon (Kleinman et al 1987) and their conceptions of abstract scientific principles (Connell 1998). Thus the purpose of this paper is to illustrate how technologies can scaffold higher-order learning tasks that allow student freedom to explore a phenomenon while constraining student expression towards correct scientific representations.

IMS and SGM technologies can provide the scaffolded support that students need to connect their perceptions of phenomena to the conceptions of abstract scientific principles. Technology, based upon good tutoring practices, should be designed (Roehler & Cantlon 1997) to: (1) offer explanations, (2) elicit active student participation, (3) verify and clarify student understandings, (4) model objects and actions to make thinking visible (Linn 1995), and (5) encourage students to be autonomous learners (Linn 1995) who are responsible for their own learning. Furthermore, scaffolded guidance should be faded as the learner gains the ability to construct and integrate knowledge within a scientific domain. This paper describes the basis for some of the instructional design questions that should be addressed when IMS and SGM are used to provide perceptual-to-conceptual bridges to help students connect phenomena to scientific principles. Instructional design can produce software that initially models a domain at a low level of complexity and employs causal reasoning, which exhibits a simple mechanism at an intermediate level of abstraction (White 1993). This process should supply scaffolded guidance (Roehler & Cantlon 1997) that is faded as the student gains domain-specific competence and confidence in his/her performance. This guidance can help make “thinking visible” when students are aware of their selection and use of problem-solving strategies (Linn 1995).

LEARNING THROUGH ONLINE DISCUSSION: WHERE'S THE BEEF?

MODERATOR: Karen Swan, University at Albany

Asynchronous online discussion, while significantly different from face-to-face communication, seems a significant factor in the success of online courses. In online discussion, all students have a voice and no students can dominate the conversation. Accordingly, many researchers note that students perceive online discussion as more equitable and more democratic than traditional classroom discussions (Harasim, 1990; Levin, Kim & Riel, 1990). Ruberg, Moore and Taylor (1996), for example, found that computer-mediated communication encouraged experimentation, sharing of ideas, and increased and more distributed participation.

Because it is asynchronous, online discussion also affords participants the opportunity to reflect on their classmates' contributions while creating their own, and to reflect on their own writing before posting it. Researchers argue that this creates a certain mindfulness among students and a culture of reflection in an online course (Hiltz, 1994; Poole, 2000). In addition, many researchers familiar with computer-mediated communication have noted what Walther (1994) refers to as the "hyperpersonalness" of the medium. Participants in online discussion seem to project their personalities into it, creating feelings of "immediacy" that build online discourse communities (Gunawardena & Zittle, 1997; Poole, 2000; Rourke, Anderson, Garrison & Archer, 2001).

The question remains, however, as to whether students actually learn anything in online discussion. Hewitt, for example, provides evidence that most threaded online discussions are overwhelmingly divergent and argues that convergence is an important part of knowledge building. Likewise, McLoughlin and Luca (1999) distinguish between knowledge construction and knowledge reproduction, and suggest that we need to develop frameworks for analyzing the negotiation and revision of knowledge.

This panel will explore issues of learning through online discussion. It will ask the questions "Can students learn from online discussions, and if so under what conditions?" and "What might count as evidence of learning through online discussion?" Specific topics to be covered are:

Perceived Learning and Social Presence in Asynchronous Online Courses, Jennifer Richardson, Purdue University.

Research has demonstrated that social presence affects student outcomes as well as student, and possibly instructor, satisfaction with a course (Moore, Masterson, Christophel, and Shea, 1996). Teacher immediacy behaviors and the presence of others are especially important issues for those involved in delivering online education. This presentation will report on a study which used survey data to explore the
relationship between students’ perceptions of social presence and their perceived learning in online course environments. Implications of the study effect the design and instruction of online courses in terms of students’ perceived learning and satisfaction with the instructor. Instructors need to be aware of the impact that their immediacy behaviors and social presence or lack thereof may have on their students’ satisfaction, motivation, and learning.

Using the Discussion Board as a Learning Tool: Facilitating Multiple Perspectives. Linda Polhemus, University at Albany

Students learn from online discussions that promote the integration of multiple perspectives. Online learning communities are created when discussion threads are generated. Discussion threads are generated when values and experiences are integrated into messages that promote alternative perspectives. Students from SUNY Learning Network (SLN) participated in interviews, observations and responded to a questionnaire related to knowledge building communities in online learning. Interviews addressed issues of navigation, expectations and beliefs about online learning. Selected students were also video taped when participating in the online discussion using a picture-in-picture device to capture student reactions when ‘thinking aloud.’ In addition, questionnaires were distributed to students enrolled in graduate level courses and discussion threads were analyzed. Results revealed that when students read and respond in the online discussion, their exposure to multiple perspectives enhanced their perception of knowledge building. Evidence of learning through the online discussion is apparent in the observations where students summarize the messages of others, build upon their ideas and make connections to their own personal experiences. The ability for students to reflect upon the messages of others, navigate the discussion board’s interface at a high level, and read and compose messages which are of high quality result in learning engagement at the critical or literate level.

Embedded Formative Evaluation of Student Learning. Michael Danchak, RPI

Current web toolkits such as WebCT and BlackBoard provide tools for quizzing and discussion. However, in order to use these tools one must leave the content. Quizzing and surveys really do not address recitation well. In addition, the bulletin board does not “force” a contribution before the students can see all the postings. I will describe a Java applet based tool we built that allows the instructor to ask either multiple choice or discussion questions. Once answered, the student sees the instructor’s answer and may see other students’ responses, at the instructor’s discretion. The applet can be embedded directly in any html content page and can be used for either synchronous or asynchronous feedback to the student.

Higher-Order Learning Through Computer Conferencing. Liam Rourke, University of Alberta

The educational claims made for computer mediated discussion are largely cognitive in nature—discussion promotes critical thinking, self-reflective thought, higher-order learning—the list is impressive. Yet, researchers in this domain have rarely used techniques developed specifically to investigate cognitive processes. Thus, many of the claims remain speculative, anecdotal, or hyperbolic. Protocol analysis is one
technique that has proven to be useful for revealing the mental processes of subjects engaged in a wide variety of tasks. An analysis of students' concurrent verbalizations as they read and respond to messages in a computer conference provides direct evidence of the mental processes in which they are engaged. This presentation summarizes the provisional results of a protocol analysis study involving upper-level, undergraduate humanities students engaged in a computer conference. Eight students were recorded individually as they read and responded to messages that appeared in the computer conference supplement to their face-to-face course. Two distinct sets of cognitive processes appeared to be occurring among the participants—sociocognitive conflict (Doise & Mugny, 1985) and narrative cognition (Bruner, 1990). In the former case, students composed coherent and rhetorical interpretations of course readings, received critical feedback from others, and re-evaluated their original interpretations. In the latter, students embedded their interpretations of course material in autobiographical narratives, and immersed themselves empathetically in the narratives of others. Within these two sets of cognitive processes, there was evidence of many potentially valuable sub-processes including metacognition, internalization of the discourse process, cognitive flexibility, and naturalistic generalization.

Can We Assess the Quality of Learning in Online Conferences? Catherine McLoughlin. Australian Catholic University

While computer-based tools to support asynchronous dialogue and discussion are now part of many on-line units of study, there is a lack of research on how to assess the quality of such interactions, and in particular, how they support learning. Mason (1991: 161) posed the question: 'Are conference interchanges more than merely the outpourings of lonely or loquacious students?' Since then several theorists have provided interaction analysis/content analysis techniques to examine the construction of knowledge in computer conferencing. These are reviewed in the light of constructivist theories of knowledge and the adoption of a socio-cultural model of learning, emphasizing social interaction and dialogue as central to learning. If knowledge construction is to be evaluated rather than knowledge reproduction, we need to assess the processes that support such construction, and consider negotiation and revision of knowledge. For tertiary students, working with others in teams, evaluating others' perspectives and the ability to communicate abstract ideas are recognized and valued educational outcomes. A valid framework for analysis would therefore require a focus on process variables, such as how learners negotiate and interact, and product variables, such as the content and outcomes of learner interactions. Educators need practical assessment tools to evaluate on-line discussion and show the potential of on-line forums to support collaborative learning and construction of knowledge.

PARTICIPANTS

Michael Danchak is Professor of Computer Science at Rensselaer Polytechnic Institute in Troy, NY. He has been teaching at a distance for more than 10 years and is currently researching tools and techniques for making online courses more interactive.
Jennifer Richardson is an Assistant Professor of Educational Technology at Purdue University. Jennifer has extensive experience both doing research in the schools in terms of technology as well as conducting evaluations of educational technology programs and products. Her interests include educational technology professional development, social aspects of web-based learning, and integration of technology into educational environments.

Linda Polhemus is currently a doctoral student enrolled in the University at Albany’s Educational Theory and Practice program and director of Rensselaer Polytechnic Institute’s Online Learning Forum. The Online Learning Forum is a professional development program addressing the needs of K12 teachers. Linda’s research interests focus on the integration of instructional technology and distance education.

Liam Rourke is a Ph.D. student in Department of Educational Psychology at the University of Alberta. He has published several papers on the topic of computer conferencing in higher education (www.ualberta.ca/~lrourke/liam.html) and is currently investigating how and what students learn through discussion.

Catherine McLoughlin is an Associate Professor and Head of the School of Education at the Australian Catholic University in Canberra, Australia. She is National President of the Open and Distance Learning Association of Australia. Catherine has researched and published in the area of online teaching and learning, and designed a range of learning resources for distance learners. Her main research interests are development of innovative assessment practices online, and the evaluation of learning.

Karen Swan is an Associate Professor of Instructional Technology in the School of Education at the University at Albany. She has been teaching online courses for five years and has presented and published on issues of interactivity and social presence in online courses.

Situated Professional Development: The CATIE Model
Karen Swan, University at Albany
Sybillyn Jennings, The Sage Colleges
Lester Rubenfeld; Center for Initiatives in Pre-College Education

Abstract
This presentation will describe a qualitative study investigating the Capital Area Technology and Inquiry in Education (CATIE) model of situated professional development for technology integration in schools and classrooms. We call the CATIE model "situated" because it places educational technology experts in schools on an ongoing basis where they collaborate directly with teachers to develop and deliver technology enhanced lessons. Teacher learning about technology integration is thus situated in authentic technology integration activities. What we think is unique about the CATIE model is that mentors work with schools and teachers on a long term, daily basis, that they work to incorporate technology use into existing curricula, and that they work in real classrooms directly with teachers and students. The CATIE program thus tends to reach most of the teachers and administrators in a school, and we can see the results in terms of student learning, technology integration, and changes in school cultures. Findings from data collected to date, including monthly mentor reports, interviews with mentors, teachers, and school administrators, classroom observations, and student artifacts, will be used to support discussion of the model.

Background
Recent large scale studies of computer usage in schools (Panel on Educational Technology, 1997; Educational Testing Service, 1998; Becker, Ravitz & Wong, 1999) have precipitated public debate concerning the efficacy of using computers to support instruction, and have highlighted the need for professional development in this area. While emphasizing the need for professional development and pointing to the relationship between it and more sophisticated uses of technology in schools, these and other studies suggest that our understanding of what sorts of professional development programs impact technology integration at school and classroom levels needs to be improved. What we do know is that the teacher training, "expert model" of professional development (Sparks, 1994) does not work, especially when it comes to learning about educational technologies and their integration across the curriculum. Indeed, teacher lore suggests that traditional inservice teacher education has little impact on teaching practices in general. Smylie (1989), for example, found that teachers ranked inservice training last out of fourteen possible opportunities for learning. What teachers ranked as most important was direct classroom experience. Even exemplary professional development programs find it difficult to maintain support for teachers (Carey & Frechtling, 1997), to encourage sustained discourse among participating teachers (Schlager & Schank, 1997), to "scale up" (Corcoran, 1995) through the inclusions of all teachers, and to develop, test, and disseminate new teaching and learning ideas. Researchers agree that new models of professional development are needed, and that such models must include a focus on the development of local cultures of interest if they are to be sustainable.

Situated Professional Development
Putnam and Borko (2000) relate recent trends in research on professional development to new understandings of the nature of learning and knowing that collectively have been labeled "situvative"
(Greeno, 1997). They identify three conceptual themes central to situative perspectives – that cognition is situated in particular physical and social contexts, that it is social in nature, and that knowing is distributed across the individual, others, and tools (p. 4) – which they believe have important implications for professional development. Putnam and Borko argue that how teachers learn new methods of teaching is no different from any learning. If knowledge and learning are indeed situative, then the most effective inservice education will be situated in authentic classroom practice.

To our knowledge, such perspective has not been used to frame either the development of, or research on, professional development programs aimed at technology integration, although a situative perspective is widespread in the research and development of technology-based educational programs. It only makes sense, and yet most professional development programs aimed at technology integration are instructionist, application-driven workshops or summer “institutes” well removed from classroom practice. Some have argued that while not optimal, such approaches are often the only practical solutions to meeting large-scale professional development needs with limited resources (Wilson & Berne, 1999). What little research there is suggests such activities have little impact on the day-to-day integration of computing technologies into classroom teaching and learning (Panel on Educational Technology, 1997; Educational Testing Service, 1998).

The CATIE Program

It is hard to see how approaches that consistently have had little or no effect on classroom-based technology integration can be deemed “practical,” thus we decided to try an “impractical” approach. The Capital Area Technology and Inquiry in Education (CATIE) program was established through the Center for Initiatives in Pre-College Education (CIPCE) at Rensselaer Polytechnic Institute as an innovative means for addressing technology-based, constructivist-oriented staff development in elementary schools in the greater Troy (NY) region. This unique program places technology experts in elementary school buildings where they serve as mentors to teachers interested in integrating the use of technology into their day-to-day classroom activities. The school-based mentors provide training to teachers on technology utilization, but, more importantly, the mentors work with teachers to jointly design computer-supported lessons that incorporate technology into existing classroom curricula. Teacher learning about technology integration is thus situated in authentic technology integration activities.

Typically, the mentors first meet with teachers, both individually and in groups, to discuss how technology might be used to enhance learning in planned units on particular topics. Mentors try to avoid planning that is either artificial or focused on specific software applications. They then work with teachers to design computer-supported lessons that are integral parts of larger, classroom-based learning units. They encourage inquiry-based, student-centered, constructivist uses of computing technologies, but they do not insist on them. Often, mentors model best practices in computer-based teaching and learning by taking the
lead in implementing jointly created lessons. They then guide teachers in designing and implementing their own computer-based lessons, gradually fading their support as teachers become more confident in the use of electronic technologies.

Mentor support, however, does not just disappear. Each mentor structures his or her schedule according to their school and participating teachers' individual needs. Generally, the mentor is available two or three days each week for a period of two years or more to work with teachers and students on a continuing, as needed basis. Many teachers, having mastered a particular technology tool, return to their mentor for help in utilizing other applications in their teaching. Some teachers just come to share with their mentors the ways in which they are using technology on their own, and some mentors meet regularly with groups of teachers to discuss technology integration. As mentors become a part of the culture of the school, formal and informal conversations of this sort become more common and ongoing, and a discourse community grows up around technology integration.

**Methodology**

The research design was qualitative. Questions addressed included the impact of the CATIE program on teachers' integration of technology into regular classroom teaching and learning, CATIE's impact on the culture of technology integration in individual schools, and the affordances and constraints on that process across schools. We were also interested in how CATIE mentors viewed their work. Because the nature of technology integration clearly seems to be situated in individual schools (Swan, Jennings & Meier, 2001), we looked at each of the schools in which CATIE mentors worked as a single case within the larger investigation of the CATIE program.

In the 2000/2001 school year, there were ten CATIE mentors working in 14 elementary schools in four school districts in the greater Troy, NY area. The schools in which mentors were placed were all urban, but ranged in size from quite small (12 teachers) to quite large (101 teachers) and varied in ethnic and SES characteristics by neighborhoods. In 2000/2001, CATIE mentors worked with 188 teachers and over 4,000 students. They turned in monthly reports detailing the teachers and students they worked with, lessons jointly developed, and any outstanding successes or problems they encountered. Mentors also met biweekly with the researchers to discuss the same. The researchers visited all schools at least twice, where they observed mentors work with teachers and students and took field notes. They also conducted onsite interviews with mentors, school administrators, and teachers with whom the mentors were working, and collected samples of student work.

Data sources thus included the monthly mentor reports, notes from mentor meetings, transcripts of interviews with mentors, teachers, and school administrators, field notes, and student artifacts. Data analyses consisted of the constant comparison method to look for emergent themes.
Preliminary Findings

Clearly, the CATIE program exhibits the features Putnam and Borko (1997) identify as essential to effective teacher education:

- Teachers involved in the CATIE program are treated as active learners who construct their own learning to meet their own specific professional needs. CATIE mentors serve as facilitators for that learning but follow and respect the directions it takes.
- Thus, teachers in the CATIE program are empowered to use technology in their teaching (through the on-site support of the mentors) and treated as the professionals they are.
- In the CATIE program, teacher learning about technology integration is situated in classroom practice.
- CATIE mentors model constructivist, student-centered teaching with technology in their work with both students and teachers. Mentors thus treat teachers the way they would have them treat students.

Mentors spend the majority of their time working with teachers and students in the computer labs of their participating schools, although they also assisted some classes within their own classrooms. The latter is the goal of the program and is increasing but we are still not satisfied with the lack of classroom usage. This seems to have to do with the availability and quality of equipment in schools and classrooms, but the relationship is complex and interesting. In some cases, for example, classroom usage is hampered by the lack of computers with Internet access in classrooms. However, in several schools CATIE is involved with, there are multiple computers with Internet connections in classrooms that are not well utilized. In these schools, there is also a high quality computer room. In these schools, teachers seem more comfortable with the computer room because it affords each student a computer and so allows teachers to work in more traditional modes. Indeed, the one school in which more use is made of classroom computers the computer room computers are older and incapable of running more complex programs such as Hyperstudio.

A related goal in CATIE is to encourage teachers to look beyond their current uses of technology. This seems to be happening with the more technology-experienced participating teachers, and with teachers involved in their second or third years with the program. The CATIE program has also made significant gains in helping teachers less familiar with educational technology become comfortable in its use. An interesting finding involves what we are calling the “learning by lurking” phenomenon—teachers who have been only peripherally involved in CATIE become involved after the program has been in their school for several years. To date, CATIE mentors have assisted approximately 350 teachers in fourteen schools in four school districts to create and implement lessons that integrate the use of technology into regular classroom activities.

Flexibility and adaptability were found to be central to best practices in mentoring. Mentors' ability to work with variations in teacher learning styles, pedagogical approaches, and prior experiences, as well as with
existing school technology resources were found to significantly influence technology integration in schools and classrooms. An unexpected finding regarding mentors was their programmatic focus. The CATIE program’s mission is focused on teachers. In interviewing mentors, however, we found that many mentors were at least as concerned with student learning as with teacher learning. The effect of such focus is being investigated.

Teacher perceptions of the CATIE program were overwhelmingly positive. Teachers uniformly reported increased knowledge of computing technologies, greater confidence in using them, and more creative teaching with computers. Positive outcomes for students, including greater independence, heightened self-efficacy, and increased motivation, were also noted by participating teachers. In most of the schools we visited, the CATIE program was seen as a valued part of the school culture, and many teachers noted changes in technology integration school-wide as a result.

Educational Significance
The CATIE program seems to be positively affecting technology integration in the schools in which it is operating. In this its fourth year of operation, its effects are becoming clearer. Most important of these, is the saturation of technology integration into the schools in which CATIE mentors are working. After several years of being present in schools, the CATIE program is reaching most of the teachers in those schools, which in turn seems to be changing their culture to include technology integration. Perhaps the best measure of its success is that one of the CATIE districts is adopting mentoring as the preferred means of technology training. Common sense indicates that the CATIE program is successful because it is reaching out to teachers in the physical and social context of their practice, because it provides ongoing, long-term support for technology integration, and because of the personal relationships mentors are forging with participating teachers within the culture of the schools in which they work. Its success thus supports a situative perspective on teacher learning, especially teacher learning about technology and technology integration.

TECHNOLOGY & LITERACY LEARNING: A NATIONAL SURVEY OF CLASSROOM USE
Karen Swan, Robert Bangert-Drowns, Joseph Baltrus, Annie Moore-Cox, and Ron Dugan;
Technology Integration Project
National Research Center on English Learning and Achievement; University at Albany

objectives/purposes

This presentation will report on the Technology Integration Project's work to date documenting the use of technology in middle school English language arts classrooms. The purpose of this ongoing national study is to explore the ways in which middle school English language arts teachers are using electronic technologies to enhance literacy learning in their classrooms. In particular, we are interested in teachers' conceptions of "technology integration," how they frame their uses of technology within a larger curriculum, and how technologies can support teaching strategies that have been shown to enhance learning in the English language arts.

theoretical frameworks/perspectives

This study builds on the work of Henry J. Becker and others at the Center for Research on Information Technology and Organizations (CRITO) that documents teachers' uses of computers (Becker, Ravitz & Wong, 1999), and on the work of researchers at the National Research Center on English Learning and Achievement (CELA) that identifies effective strategies in English language arts teaching and learning (Center on English Learning and Achievement, 2000).

Becker and the CRITO researchers have found that, although it is still true that a majority of teachers use computers very little and that the majority of intensive experiences students have with computers are outside the academic disciplines, a growing number of subject matter teachers do have their students use computers frequently and do so with a new focus on accessing information and improving their writing and general communication skills. First, among these are English language arts teachers. Indeed, at the middle school level, 30% of students' experience using computers takes place in English classes. 75% of the secondary English language arts teachers surveyed used computers at least occasionally in their classes, and 24% used them twenty or more times a year. (Becker, Ravitz & Wong, 1999) The CRITO report gives some insight into what kinds of computer applications English teachers are using and what learning objectives they are focusing their technology use on. It was not intended to tell us, however, how technologies are being used to support literacy learning.

CELA researchers have identified six approaches to English language arts teaching that have been shown to enhance literacy learning across many CELA research investigations. These are:

- using diversity to enhance learning
- increasing the cohesiveness of curriculum and instruction
- raising the level of student engagement in higher order talk and writing
- aligning curriculum with assessment
- scaffolding student performance of new and difficult tasks
- helping struggling readers (Center on English Learning and Achievement, 2000).

What CELA reports to date cannot tell us is how electronic technologies can and are being used to support such approaches.

methodology

To investigate the ways in which English language arts teachers are using technology to support literacy learning, the authors of this paper instituted a national nomination process. English language arts, library, and/or technology coordinators from all states and regional NCTE (National Council of Teachers of English) and RTEC (Regional Technology in Education Consortia) directors were contacted and asked to nominate middle school English language arts teachers who were making extensive and/or interesting use of computers in their classroom teaching. Technology using teachers were also recruited through the
Nominated teachers were asked to respond to an online survey which requests that they describe two lessons they use that incorporate technology, as well as asking for certain demographic and technology usage information. The survey thus focuses on specific classroom uses of electronic technologies. Survey results are being analyzed not only for technologies and applications used, but for how teachers frame technology-supported lessons and how they support literacy learning. Selected teachers will also be interviewed by phone to further explore these issues.

**Data Sources**

The data sources for the study are technology using middle school English language arts teachers. Teachers participating in the study, thus, do not represent average English language arts teachers. Rather they were chosen to provide a sample of what is being done by exceptional technology using teachers in the middle school English language arts areas. The study is national in scope for breadth and to take into account possible regional variations in usage. The middle school domain was chosen not only because it matches the focus of larger CELA projects (Center on English Learning and Achievement, 2000), but because it has been shown to be where technology is most used in English language arts teaching and learning (Becker, Ravitz & Wong, 1999).

**Results/Conclusions**

To date, nominations have been solicited, nominated teachers contacted, and 72 online surveys from teachers in 30 states collected. This data is being analyzed in terms of teachers’ conceptions of technology use, in terms of how they integrate technology into existing curricula, and in terms of how technology is being used to support the six approaches to English language arts teaching that have been shown to enhance literacy learning (Center on English Learning and Achievement, 2000). We are currently conducting phone interviews with these teachers that additionally probe the above issues as well as issues of assessment and English language arts standards. By the time of the annual meeting, we anticipate having collected and analyzed all the data, including teacher interviews, on which we will report.

Preliminary findings suggest that electronic technologies are indeed being used to support the six approaches identified by CELA as enhancing literacy learning, most particularly using diversity to enhance learning, raising the level of student engagement in higher order talk and writing, and scaffolding student performance of new and difficult tasks. In addition, participating teachers frequently mentioned computer support for what might be termed the development of learning communities. They frequently spoke of more active and authentic learning, motivation, and the use of extended and collaborative projects. Almost all of them stated that students worked better together on computers, and that all students were included in the class work. Teachers also spoke of their role as changing from lecturer to facilitator.

Participating teachers generally used computers at least 30% of the time in their classes, although some used them a good deal more. As the CRITO researchers found, teachers with greater access to computers used them more often. For example, one teacher who had laptops for every student used them 70% of the time. Our survey also confirms the baseline of use that CRITO reports — word processing and information access using CD ROMs and the Internet. Teachers in this survey, however, went way beyond these uses. They used concept mapping software such as Inspiration to explore their own and others ideas. They used email to communicate with peers and experts around the world. They used multimedia and presentation software, such as PowerPoint and HyperStudio to publish and present their work, and digital cameras, scanners, and graphics packages to illustrate it. Many made and edited digital movies. Some used simulations available on the World Wide Web, such as the virtual tour of Ann Frank’s house; others made use of online drill and practice exercises in grammar and comprehension. Interestingly, many used spreadsheets and databases to organize information and create knowledge.
educational significance

Across the nation, schools and school districts are investing heavily in computer hardware and software, often using state and federal grant monies as well as local tax and bond revenues. Yet little or no information is available about the most effective ways to leverage that investment into higher literacy achievement for students. This study is designed to identify the variety of ways middle school English language arts teachers across the country are using electronic technologies to support literacy learning. What we are finding is that computer using English language arts teachers are using a wide variety of software a good deal of the time to support approaches known to enhance literacy learning as they develop learning communities in their classrooms. Their pioneering work can serve as models for school and teachers who would like to integrate technology into English language arts teaching and learning.

University of Alberta, Canada
mail@real-lifecomedia.ca

Abstract: Adapting narrative principles from traditional media lets course developers and writers draw from a rich aural and visual tradition to craft a new language for on-line learning. This paper highlights techniques that may be adapted from traditional media to inform the creation of content, task and navigation for interactive educational media.

In a world of increasing speed, complexity and competition, we must engage learners through meaning that resonates with their sensibilities and experience. The rich, interactive learning environment enabled by computer technology challenges us to engage people in creating their own meaning as a foundation for further learning. Taking up the suggestion by Plowman (1994) to borrow well-known narrative conventions from film to design both structure and interface, this paper highlights narrative strategies from traditional media that are adaptable to developing content for interactive educational media.

Narrative strategies from traditional media

That the structure of all narratives, at least in Western society, is the same has created a very stable framework for audiences (Lacey, 2000). The three-act structure, well-defined as early as Aristotelian times and formalized in the Hollywood film, is aptly explained by Hunter (1994) as an introduction (set-up), in which we place our heroes up a tree; a complication (conflict), in which we throw rocks at them; and a resolution (climax) in which we get them back down. Within this framework, many techniques have emerged to engage audiences through traditional media such as theatre, the novel, film, radio and television that are adaptable to educational interactive media.

In considering narrative techniques developed in traditional media, we should consider Lacey’s advice that “Narrative does not deal with reality at all[,] but strives to create an illusion of reality by referring to other sign systems” (p. 77). Devices like book covers, film posters, radio theme music, title sequences in film, and, for our purposes, CD-ROM jewel cases and on-line course home pages, give learners cues to the genre, metaphor or interface of the lesson as well as its content.

From dramatic writing comes the need for a premise (Egri, 1960) progressing to a climax, “the pinnacle of concentration of all meaning and emotion... the decisive centre of audience satisfaction” (McKee, 1997, p. 108). Novels immerse us inside characters in a different environment to let us better understand ourselves and our purpose (Wilson, 1990), and furnish narrative genres such as the picaresque, the epistolary and the serial (Hawthorn, 1997), which, like the cues noted above, create shortcuts by drawing on knowledge external to the actual content. Film gives us time-manipulation devices like cutting between scenes and dissolves to flashbacks (Mast, 1976)—although these were criticized by early purists as drawing undue attention to the medium (Salt, 1983)—and the distinction between what we perceive through the characters (diegetic) and beyond their perception (non-diegetic) by way of superimposed music, images or voices (Lacey). Radio reminds us of the power of oral narratives to immerse listeners (Tolan, 2001), and, with television, echoes serial literature in its episodic approach and in offering narrative “arcs” spread over a season (and analogously, over a course). The need to engage audiences through an opening “teaser” and to build to a high point just before cutting away, although motivated by commercial breaks (Miller, 1980), may be applied to modularized interactive media lessons. In fact, writers can draw on tactics from new media itself to hold learners’ attention by, for example, leading them through a suspenseful (but lesson-laden) labyrinth known to harbour hidden obstacles or lurking adversaries. This is what Murray would call “achieving coherent dramatic form by shaping our terror into a pattern of exploration and discovery” (p. 137).
Guidelines

Experiences with narrative in traditional media provide a wealth of lessons for writers seeking to engage learners in constructing their own meaning through interactive educational media. A review of the literature on traditional narrative tools suggests the following guidelines for developing content for interactive educational media:

1. A premise or theme of a lesson, expressed in terms of human behaviour and carried through to a logical conclusion, can create deeper meaning for learners.
2. The three-act structure of introduction, complication and resolution, so well-engrained in Western thought, provides a solid frame for building a lesson.
3. We can engage on-line learners more deeply by casting them in "immersive" roles and allowing them to chart their direction through the narrative.
4. Immersing learners inside other characters, in a different environment, can help them to better understand themselves and their purpose.
5. Using the first person can provide access to a character's innermost thoughts, and multiple points of view. Unreliable narrators can add to the critical skills demanded of the learner.
6. Lessons can be structured along narrative forms well-established by novels and filmic genres, which enrich the lesson and save time by incorporating learners' prior, external knowledge.
7. Further layers of meaning are available through non-diegetic devices such as background music, superimposed images or voice-overs.
8. Time, space and perspective can be illustrated by employing classical filmic techniques such as double exposure, different types of shots and dissolves.
9. Different stories can be linked through a common motif; differences can be lessons, too.
10. Sound, used alone, offers great power to co-opt the audience's imagination. Key points may be delivered, along with other means, by voice-over while freezing or thickening the screen.
11. An episodic approach, with a fixed cast of characters can provide continuity to a series of teaching modules by building on preceding lessons, and referencing prior foundations as refreshers or as needed to understand ensuing points.
12. We can capture learners' interest with a tantalizing opening sequence and hold it through tests or other breaks by building the lesson to a narrative high point just before they occur.

The familiarity and interactivity of narrative structures make them ideally suited to on-line learning. The nascence of interactive media and its educational applications present a tremendous creative challenge for course developers and writers. Adapting, and perhaps even improving on, narrative principles from traditional media allows us to draw from a rich aural and visual tradition, and to help craft a new language for on-line learners who seek to rise to Murray's call to turn their terror into discovery.

Could oral communication be successfully taught entirely online?

Sherry Tanian, Edith Cowan University, s.tanian@ecu.edu.au

Kandy James, Edith Cowan University, k.james@ecu.edu.au

Abstract: This paper discusses the formative stages of an ongoing study to develop a course in oral communication that can be taught entirely online using chat rooms, bulletin boards and synchronous videoconferencing. It addresses the reasons for the development of the on-campus oral communication course, its structure, pedagogical foundations and its evolution from the face-to-face and distance print-based delivery modes to be taught entirely online. Due to current technical limitations a simulated online course will be developed and conducted under experimental conditions using a Local Area Network. This study will not only assist oral communication instructors, but also instructors developing a wide range of courses for online delivery.

Background to the Study

The need for improved oral communication skills has been expressed by employers, academics and students (Merrier & Dirks, 1997). Oral communication is the top skill sought by employers, however, this skill is lacking in most business graduates. A compulsory 15-hour oral communications course to improve students' oral skills was introduced in 1999 for all business students studying on-campus at a Western Australian university. The course was initially designed for the internal students. It was later developed to include distance students using print-based materials. The challenge now is to develop it for online delivery.

The pedagogical basis for the original course was founded on constructivist principles, collaborative online learning, adult learning and the situated learning model. Particular attention was given to the elements of authentic learning model outlined by Herrington (1997) that is, authentic content and activities, modelling of process by experts, multiple roles and perspectives, collaborative construction of knowledge, reflection and articulation, coaching and scaffolding, and authentic assessment. The course provided opportunities for students to learn and practise communication skills applicable to the business world.

The face-to-face course was structured as a two-hour seminar and a one-hour tutorial repeated five times. A typical seminar, with approximately 50 students, provided the background information for the module through student discussions, activities, question and answer sessions and demonstrations of presentation exercises. Each tutorial, with groups of 10-12 students, was further subdivided into teams of 3 or 4. This structure provided support, a nurturing environment, and time for students to practise and develop the required communication skills. The aim is to replicate as many of the essential ingredients as practicable via online delivery.

Feedback about the face-to-face course was positive and class members noted their peers' development. Students appeared more confident, readily participated in class discussions, attended regularly, gave positive, objective and encouraging feedback, and provided professional presentations. They considered the skills transferable to other units and general life. The test will be whether these positive evaluations persist when the face-to-face element of the course is removed.

There has been a push from students, governments, tertiary institutions and the workplace for the development of flexible delivery modes. Online learning has quickly become a pervasive study option, offering "anytime-anyplace, one-to-one or one-to-many communication venues. Online learning is a particularly attractive option for meeting the diverse needs of adult learners (Vician & Brown, 2001). Much of the research into online teaching and learning, however, has concentrated on the use of interactive multimedia by an individual, and communications with other students and the lecturer via chat rooms or bulletin boards. Less research has been published on synchronous videoconferencing as a means of communicating with other students and lecturers through computer cameras. Mason (1991) suggested this method offered 4 advantages: It is more motivating for learners by focusing group energy, it helps develop a sense of social presence and group cohesion, provides
quick feedback that supports decision making, and provides structure and discipline to encourage students to keep up-to-date. A recent US study (Clark & Jones, 2001) used the Internet to teach oral communication, however, students were required to attend class for the practical component; their actual presentations. While this method may be suited to those students who prefer a different delivery mode, it is not suitable for students (particularly those living in remote locations) who want to complete the entire course off-campus.

**Online Oral Communication Experimental Study**

A combination of delivery systems will be used in this experimental online study not only to provide a better learning environment (Berge, 2000), but also to replicate the successful face-to-face course. Students will progress through each module by accessing information either online using the software package “Blackboard” or via a CD-Rom. The CD-Rom will contain video clips of examples, demonstrated techniques, past student presentations and key hints from the lecturer. Students will complete “class” activities either individually or with other students via chat rooms and bulletin boards to enhance their learning.

The main oral presentation exercise for each module will be completed via synchronous videoconferencing. This will allow for peer coaching immediately following presentations, a component of the internal course considered essential. Until more advanced technology becomes available there could be problems with voice synchronisation, time delays and computer breakdowns, so the student presentation experience will be simulated using Intranet. Five linked computers, with cameras attached will be set up in separate rooms. For each simulated session the first student will give their individual presentation via the camera, the second student in the team will facilitate the self- and peer-evaluation, and the third student will evaluate. Student roles will be rotated until all students present, provide feedback and facilitate. For the purpose of this study a video camera in the room will record student actions, visible signs of apprehension, and their handling of the program.

Before being given access to the course itself, students will receive individual personal training in using “Blackboard” and be asked to complete a pre-test questionnaire online. This questionnaire will measure levels of communication apprehension (CA), willingness to communicate (WTC), shyness and self-perceived communication competence (SSPC). After the course students will do a post-test to determine any changes. Student satisfaction will be measured by questionnaires, focus groups and interviews.

**Summary**

This paper has outlined the developmental stage of a work in progress aimed to deliver an oral communication course entirely online. It has highlighted the critical success factors of the existing face-to-face course that would have to be replicated to ensure positive learning outcomes in the proposed online course. Although the new course will be trialed in a simulated experimental setting, it should provide a good indication of the potential for success for such a course when the technology becomes sophisticated enough for complete online delivery. The insights gained from this experiment will be of use to educators involved in development of other online courses, especially those where synchronous feedback would be an asset.

Skills Needed for Managing Multimedia Development – Invisible or Visible?

Pina Tarricone
Edith Cowan University, Centre for Schooling and Learning Technologies, Australia
g.tarricone@ecu.edu.au

Joe Luca
Edith Cowan University, School of Communications & Multimedia, Australia
j.luca@cowan.edu.au

Abstract: All multimedia project managers strive to have projects delivered on time, on budget and to the required quality. In the quest to achieve this success, much research has been performed and literature written about project management techniques to enhance this process. Increasingly however, it is being recognised by both employers and researchers that project managers not only need administrative and management skills, but also other skills, which are related to their management style and emotional intelligence. This paper investigates the range of skills needed by a project manager immersed in a multimedia development environment, and are classified in a continuum from “visible” to “invisible”. These are compared and contrasted to consider the impact of emotional intelligence on the overall project success, including the team synergy.

Introduction

Collaborative teamwork focused on project work is becoming an increasingly popular process by which companies seek to increase efficiency and effectiveness to increase their profits (Thomas & Pinto, 1999). This is placing pressure on a greater number of “modern day project managers” to act as visionaries, technical experts, negotiators, sales people and so forth. These individuals are required to master the various, sometimes-competing demands of their jobs by striking an effective balance between the roles they undertake. Current research is advocating that successful completion of projects requires project managers and team members to have effective generic skills (Bennett, Dunne, & Carre, 1999; National Board of Employment Education and Training, 1996). This concept is gaining huge support from industry as well as higher education funding authorities, and many reports from around the world are advocating that vocational and higher education institutions need to focus more on improving students generic skills rather than just providing content knowledge (Australian National Training Authority, 1998; Candy, Crebert, & O’Leary, 1994; Dearing, 1997).

According to Wysocki (1995, p.14), project managers need skills in three broad areas: managing/administering, applying technical skills and using generic skills. The management/administrative and technical skills or “visible skills” such as scheduling, planning, legal issues and costing are well documented and supported by a myriad of training courses. However “Invisible skills” needed by project managers have only just recently been recognised as being important by both academics and industry employers. These are represented in Figure 1 as a continuum, in which technical and management skills such as computer programming, design or authoring skills are easily proven or observable. But hidden or “invisible” skills are not always easy to demonstrate i.e. how can you predict if a candidate has good conflict resolution skills or collaboration skills?

This type of classification is also supported by Belassi & Oya (1996) who developed a framework, based on a wide literature review, for predicting project success factors. In their classification, they also recognise the importance of project manager and team member attributes as critical success/failure factors for project development. They grouped four factors that can potentially affect the success of a project:

- Project manager and team member factors - such as ability to delegate authority, ability to coordinate, perception of role and responsibilities, communication skills, technical background and commitment;
- Overall project factors - such as size and value, uniqueness of the project activities, urgency, density of project and life cycle;
- Organization factors - such as support from management and project organisational structure; and
- Environment factors - such as politics, economics, technology, client issues, competition and sub-contractors.

Figure 1 illustrates these broad skill sets as a continuum, showing technical and administration skills on the “visible” side of the scale and generic skills and emotional intelligence on the “invisible” side. This paper contends that each of these four broad skills are needed for successful project management. However, the main
focus of this paper will be on emotional intelligence and its relationship and impact on successful project management.

**Figure 1: A spectrum of project management skills**

**Skills Needed for Multimedia Project Management**

In the field of multimedia development, project managers must "juggle" a range of team, business, administrative and production aspects, as shown in Figure 2. These aspects have a direct effect on profit, delivery time and final product quality (Department of Industry Science and Technology, 1995). Clearly, project managers must have skills and experience in these areas to help create successful products, which are a mixture of administrative, management and technical understanding of the media.

Increasingly however, it is being recognised that the "visible" skill set shown in Figure 2 is not enough for success. Generic skills and the individual's management style are increasingly being promoted as being a critical component in having successful outcomes. Employers now actively seek employees with problem solving, collaboration and communication skills. These skills are considered important for both project managers as well as all other team members to help promote the development of successful projects.

**What is emotional intelligence?**

The concept of emotional intelligence and its impact on project management, team management and overall project success, especially in multimedia design and development is relatively new. Salovey and Mayer (1990) initially conceived the concept and coined the term Emotional Intelligence. This concept was derived from Gardner’s (1983) theory of multiple intelligences. The notion that there is not one intelligence, but several intelligences, forms the basis of multiple intelligence theory. Gardner (1983) identified seven intelligences -
musical intelligence, bodily-kinesthetic intelligence, logical-mathematical intelligence, linguistic intelligence, spatial intelligence, interpersonal intelligence and intrapersonal intelligence.

Intrapersonal and interpersonal intelligences were used by Salovey (1990) to form the basis of the initial comprehensive theory of emotional intelligence (Goleman, 1995; Yost & Tucker, 2000). Personal intelligences or the initial idea of emotional intelligence, though essentially derived from Gardner’s multiple intelligences, does not explore feelings but focuses primarily on the cognitive aspects of feeling (Goleman, 1995). Salovey and Mayer (1990) used this as a basis for their definition of emotional intelligence, which they define as the “ability to monitor and regulate one’s own and other’s feelings, and to use feelings to guide one’s thinking and action” (p.189). This definition identified five main domains: knowing one’s emotions, managing emotions, motivating oneself, recognising emotions in others and handling relationships.

Goleman (1998b) adapted Salovey and Mayer’s model as a basis for his discussion of the theory of emotional intelligence and its implications for everyday life including the world of work. The model includes five emotional and social competencies: self-awareness, self-regulation, motivation, empathy and social skills. These are each discussed below.

**Self-Awareness**

Self-awareness is the ability to understand and interpret one’s own feelings through internal reflection. The ability to be critical about thoughts and make changes to behaviour can lead to an in-depth understanding about one’s self, which leads to a better understanding of others. Lanser (2000) places a strong emphasise on the importance of self-awareness in guiding and perfecting job performance, including interactions with colleagues and in the establishment of positive and productive leadership and teamwork skills. Leaders and managers need to be especially aware of their feelings as they may allow uncontrolled emotions to impact on the dynamics and culture of the workplace or team. Overt expressions of negative emotions rather than controlled self-awareness of one’s own emotions can lead to conflict and can create an unpleasant working environment. Cherniss (1998) emphasises that effective leaders are self-confident, which is reflective of their own emotional self-awareness, and ability to control their emotions.

**Self-Regulation**

Self-awareness of emotions enables managers to then practice self-regulation, which is the ability to use emotions to facilitate the progress of the task or the project (Goleman, 1998b; Lanser, 2000). Being able to regulate emotions especially during conflict, pressure, stress and deadlines facilitates the smooth progress of the project and promotes positive, effective working relationships with team members and clients. Goleman (1998b) explains that handling emotions and putting the task first rather than emotions aids in the attainment of the required goal. Through self-awareness, project managers need to be able to self-regulate their emotions, and then facilitate the attainment of the project goals through positive, productive relationships with colleagues in a team environment.

**Motivation**

Being able to motivate team members into contributing their best is very powerful. Workers are discretionary in their application to a project – they will only give if they feel they are being supported, nurtured and inspired. Managers need to create an environment that stimulates, enhances and empowers team members to become motivated and apply themselves fully to the project (Grossman, 2000). Successful leadership requires intrinsic motivation, persistence and vision (Cherniss, 1998). Project managers are not only responsible for their own motivation but are also play a key role in motivating the team and colleagues. Goleman (1998b) and Lanser (2000) propose that motivation is an essential element of emotional intelligence that pushes us forward through the positive and negative aspects of working life by showing initiative, perseverance and dedication, as well as being goal orientated, focussed and proactive. Grossman (2000, p. 19) explains that the managers and leaders with high emotional intelligence “can motivate members of an organization to work more effectively and efficiently – in short, produce a better product” (p. 19).

**Empathy**

Goleman (1998b) contends that empathy is understanding and interpreting colleagues’ feelings and being able to identify with their feelings on issues through understanding their perspective and cultivating rapport with people from different ‘walks of life’. Empathic project managers have an awareness of the diversity of personalities and are accepting of the diversity of people and the impact culture can have on interactions within a team environment (Book, 2000), defines empathy as the “capacity to see the world from another person’s perspective” (p. 43). This skill allows project managers to understand other peoples’ behaviour without
commenting its appropriateness or inappropriateness, which has the potential to turn adversarial relationships into collaborative alliances.

**Social Skills**

Social skills are essential for the development of positive, effective relationships with colleagues and the ability to interact with team members to deter conflict, be aware of, ease and dissipate underlying tensions that can accumulate and have a negative impact on working relationships and project success. Project managers need to be able to stimulate cooperation, collaboration and teamwork through well-developed social skills (Goleman, 1998b).

It’s not hard to think of examples of managers or team members that don’t have these skills. Often, these people are referred to as “abrasive”, “cold”, “unfeeling”, “self-centred”, “inflexible” or “boring” and are usually hard to work with. The following section describes how emotional intelligence plays an important role in project management.

**Emotional Intelligence and Project Management**

Grossman (2000) believes that there is “more to management than a keen intellect and grasp of technical knowledge. The difference between success and mediocrity most often can be attributed to a leader’s mastery of softer skills—abilities and approaches grounded in emotional intelligence” (p.18). This is also supported by Tucker (2000), who contends that successful project management requires strong technical and theoretical knowledge as well as emotional intelligence. Project failure generally does not occur because of lack of technical knowledge, but more often because the project manager has a deficit of emotional intelligence, which is essential for project success and team cohesiveness and effectiveness.

Book (2000) explains that emotional intelligence is more important than theoretical and technical skills. He considers self-awareness, self-regard, self-actualisation, flexibility, social skills and open communication as essential attributes for successful project management. Project managers should “feel comfortable with themselves to acknowledge their mistakes and flaws...and have the capacity to tolerate not knowing all the answers” (p. 45).

Emotional intelligence is also reflected in management styles. Carlos & Taborda (2000) promote that new management styles are needed in the industry, which focus on team orientation strategies and empowerment, rather than the traditional command and control paradigm. This type of management style places an emphasis on organic commitment and involves everybody in decision making with participative approaches to problem solving. They contend that this management style encourages employee initiative and an atmosphere of “high-expectations, appreciation, and excitement” (p. 42).

The value of empowering team members, and providing a supportive project environment (rather than goal-directed) is supported through a study performed by Tampoe & Thurloway (1993). From the responses of a range of knowledge workers in different organisations, they determined that many of the respondents’ drives to succeed were adversely affected by approaches that focus on deliverables rather than the empowerment of teams. They concluded that the trend towards flattening hierarchies, multi-skilling and teamworking result in increased effectiveness as well as motivation.

The review of the literature promotes that project managers must create an environment that fosters emotional intelligence and encourages team members to contribute. Some organizations are not flexible enough and don’t allow or recognise the potential for team members to contribute beyond the expectations of the job. However, by leading through example, fostering creativity and imaginative thinking and allowing others to provide an input into the development of the project can promote greater project and team success. In order to promote positive, progressive, effective working environments, project managers need to have a combination of technical knowledge and well-developed emotional intelligence including self-awareness, empathy, social awareness and be highly motivated and be able to inspire and motivate team members.

Based on Goleman’s (1998a) work, Table 1 has been developed which identifies attributes of each emotional intelligence competency. Through the literature we have identified representative examples of each competency that relate to project management.

We have shown that management and technical competencies need to be complemented with behavioural or affective competencies in order to promote the development of successful projects. In summary, Martin (1993), through a synthesis of literature, reinforces the legitimacy and wisdom of recognising an affective dimension in decision-making. The dimension reflects sensitivity to feelings, emotions and the plight of employees, customers and others by listening to the “voices of the heart”. He suggests that managers should avoid making decisions, which are based solely on the cognitive domain, that are based solely on rational and analytical reasoning, and proposes that quality business decisions are based on both cognitive and affective understanding (Figure 3).
1. Definition

<table>

Table 1: Emotional Intelligence & PM Competencies (modified from Goleman, 1998a)

Likewise, Goleman (1998a) contends that emotional intelligence is twice as important for leaders than technical skills and intellect. Excellence in performance relies on emotional intelligence as a major ingredient for success. As managers "move up the ladder", higher levels of emotional intelligence are needed than at levels where technical skills are essential. In recruiting project managers, employers should be aware of emotional intelligence requirements, as outlined in Table 1. Martin’s decision making dimensions of affective understanding and cognitive understanding have been adapted, as illustrated in Figure 4, to reflect our belief,

**Figure 3: Dual dimensions of decision making (Martin, 1993)**

**Figure 4: Skills Needed for Effective Project Management**
based on the literature, that the combination of “invisible” and “visible” skills affect decision making quality and have a direct impact on effective project management and project success.

Conclusion

Project managers need to consider not just technical and management skills for successful project management, but also generic skills and emotional intelligence at the “invisible” end of the scale. As illustrated in this paper, emotional intelligence is clearly an important skill for successful project management, team management and helps promote project success and quality decision making. Project management courses should therefore focus not only on the “visible” skills but also on “invisible” skills. Project managers would gain immensely from courses that provide them with an understanding of the impact of generic skills and emotional intelligence on overall project success and team synergy. We suggest that developing these “invisible” skills should be part of any project management course.

Construction of Web-based Japanese Listening Program and the results of its Preliminary Experimental Results

Yaeko Nakanishi, Lumi Tatsuta Dokkyo University (Japan)
1-1 Gakuen-cho Soka, Saitama Japan 340-0042, tatsuta@dokkyo.ac.jp

Abstract
In this paper we present the overall framework and the content of a web-based Japanese listening program and its preliminary experimental results. The program is basically designed not only to help learners of basic level Japanese to develop their perceptional skills of Japanese sounds but also to be used as a remedial course for higher levels of students who still have problems of discerning segments of Japanese sounds and syllables. We believe that the listening for perception is an area which can fully take advantage of multimedia as it enables us to make interactive and interesting exercises and serves learners with a dynamic learning environment where they can learn at their own pace, irrespective of their abilities or learning preferences. The rate of achievements and participation of each student are automatically recorded and the students can see their own process of progress in both histogram and numerical charts. The evaluation of the program was performed by means of a questionnaire and comparing the results of pre- and post treatment tests. In the preliminary experiment we could observe a positive response towards the program.

Keywords: Japanese Education, Listening for Perception, Sound Segments, Syllables, Accent Patterns, Management System

1. Introduction
Since 1999, the Language and Culture Department at Dokkyo University has started to admit foreign students without any previous knowledge of Japanese. In order to let them acquire enough knowledge and skills in Japanese in two years and educate them to be ready for studying specialized subjects in Japanese, we have organized four levels of Japanese courses which amount to approximately 1,100 hours of study in total. The schedule and the contents are very tight and demanding. Under these circumstances, it is necessary for us to prepare as much efficient and interesting teaching materials as possible. Generally, studies for developing sound recognition skills are time consuming and tedious, and the students tend to lose interests and do not pay enough attention to the listening for perception. One way to solve this problem and to use time more efficiently is to construct a CALL listening program which provides students with interactive and interesting exercises, namely, a dynamic learning environment where they can learn at their own pace, irrespective of their abilities or learning.

2. Content of Listening and the Purposes
The content of listening can be divided into “listening for perception” and “listening for comprehension.” The studies on comprehension process have demonstrated various aspects of listening activities, not to mention the roles of supra-segmental characteristics of the input, those of background knowledge and context have been duly emphasized. While listening, students are encouraged to use their background knowledge and the contextual information so that they can predict and understand the forthcoming information. They are instructed to listen for purpose and the meaning, but not to pay too much attention to an individual sound. While the latter type of listening has been emphasized, the former type, namely, “listening for perception” seems to be less emphasized in the recent classroom activities. Considering that students should practice both types of listening exercises from the beginning, we have decided to construct the program consisting of two types of listening with equal emphasis, and will investigate the relationship between these. Few of the Japanese listening programs demonstrate data on its implementation as a part of classroom activities. Here we also present a preliminary evaluation of the program after having used it for forty days on the basic level of students at Dokkyo University.

3. Framework of the Listening Program
A number of interesting pronunciation and listening exercise texts have been developed (1). Most of them, however, are not internet-based (2). What is new about our program is that it is internet-based and thus can provide a dynamic learning environment where any learners who are interested in developing their listening skills can learn at their own pace, abilities and preferences. Unlike traditional listening materials introduced above and disobased training, this interactive program on the web ensures learners a control of the learning process, which is expected to help students maintain their motivation for learning.

The program consists of two parts: Part One centers around various sound recognition exercises and Part Two with different types of listening comprehension exercises. Part One is further arranged to cover three main areas: 1) "recognition of individual sounds," 2) "discerning syllabic structures" and 3) "recognition of accent patterns." Since the difficulties in learning Japanese sound system lie not only in distinguishing individual sounds, but also in recognizing a syllabic structure of words and accent patterns, we have decided to choose these topics as the first step to develop Japanese listening CALL materials on the web. The top page of the program (Fig.1) functions as an index page, from which students can jump to any one of these exercises by clicking the exercise number.

4. Part I – Sound recognition exercises

Sound recognition exercises consist of five stages: 1) recognition of one syllable, 2) recognition of words, 3) discrimination of two similar words, 4) discrimination of two similar short sentences and 5) extracting the words in long sentences. Students can jump from one exercise to the other if they want to, but in the classroom situation, the instructor encouraged them to go through from stage 1) to stage 5). Figure 2. shows an example of a sound recognition exercise in which students click the corresponding "hiragana" (a Japanese alphabet) on the screen upon having heard the "alphabet." Since Japanese is a syllabic language, the number of syllables is limited. Thus it is possible to let the learners discern each syllabic sound as a basic part of listening exercises by means of minimal pair. The order of the recorded "hiragana," as in an Exercise 1), "recognition of one syllable," is constructed to alter automatically whenever they start working on the exercises from the beginning. This device has been arranged so that the students will not find the task boring and ineffective. Neither can they rely on the route memorization of the order of the sounds. However, in case learners want to do other exercises, they can jump back to the index page and choose any exercises they prefer to do.

Figure 3 presents another type of sound recognition exercise. In this exercises students listen to the word and write the word by dragging down the appropriate "kana" syllable out of the chart on the screen. When the answer is correct, the "OK" mark and the illustration, which depicts the meaning of the word, appear on the screen and confirm that the answer is correct. This kind of visual information can not only help them understand the meaning of the word but also serves them to enjoy the program. In order to make these exercises more interesting, the illustrations are sometimes constructed to move.
4-1. Exercises on syllabic structure

In addition to the exercises introduced above, where the students should recognize segmental sounds, we have exercises designed to let learners pay attention to the number of syllables and syllabic structure. Even though Japanese is frequently cited as an example of a language with relatively simple syllabic structure, it is not easy for non-Japanese students to recognize the syllabic structure and count the number of syllables in any given word. The Japanese syllable is defined fundamentally in terms of the number of syllables in the word and each syllable holds isochronous duration. What is particularly difficult is to recognize consonant clusters such as /tt, kk, ss/ and a syllabic nasal /N/ as one syllable, especially so to the learners whose languages do not admit such consonant clusters and a nasal segment as one syllable. There is one more problem we have to deal with; that is the treatment of long vowels, namely /aa, ii, ee, uu, oo/'. These long vowels should be basically pronounced with the length of two isochronous durations, while short vowels with one. For example, the [ba] of the word "obasan" [obasaN] is a short vowel and the [baa] of the word [obaasaN] is a long vowel. The first one has four durations and means "aunt", and the second one has five durations and means "grandmother." Since there are basically no striking quality differences between long and short vowels in Japanese, it is very difficult for learners of Japanese to discern them. These do not only impose problems in listening but also in writing and in speaking. Considering that errors in these area are carried forward even after many years of study, exercises in three areas are extensively presented in the program (Fig. 4).

5. Exercises on accent patterns

In addition to those mentioned above, we have prepared the exercises in which learners are trained to recognize word accent patterns. In English, for example, accented syllables are pronounced louder, longer and more clearly than unaccented syllables. In Japanese, accent has nothing to do with them, but it rather involves changes in voice pitch. The words with the same phonetic segments but with different location of accented syllable often signify totally different referents in Japanese. For example, the words "Ame" with the first syllable accented, and "aME" with the second syllable accented mean "rain" and "a candy" respectively. Accordingly, to be able to discern the accent pattern is also another important task for the learners of Japanese. In this area, we also provide various types of exercises with different ways of carrying out the tasks such as "to click the correct answer out of multiple choices," "to answer whether the accent patterns of the two words they hear are the same or not," and "to make up accent patterns on their own" by clicking the circles as shown in Figure 5.

6. Listening Comprehension Exercises
Part Two consists of various listening comprehension exercises whose contents are closely related to certain topics, situations, grammar points and communicative functions. In preparation for these exercises, we have tried to incorporate the aspect of interactions between the learners and the program. Our intention is supposed to some extent be reflected in the various manners of answering the questions and doing the exercises. In this program other than multiple types of exercises, we have designed exercises in which the system lets learners draw pictures by cutting and pasting the items given on the screen and make up answers on their own. Figure 6 is an example where this "cut-drag-paste" manipulation is used. The task is to put the clothes, bags, shoes, and ribbons on the bear while listening to the story. Upon completing the task, they click the answer bottom, and the picture of the bear appears next to the one made up by the student. Fig.7 is another type of manipulation adopted in Part Two. The task is to indicate the way to arrive at the destination. While listening to the directions, such as, “Go straight and turn right at the corner of a flower shop...” students have to click a number of squares which consist of roads. The color of these squares changes when they click them like a red carpet is gradually spread. When students click the answer key, the black ball starts roll down the road which leads to the correct destination.

7. Management System

All of these exercises are equipped with a Managing System which is constructed by using Perl. As shown in Fig.8, the teacher who takes a role of administrator registers students in the Server. At the moment, only the students who give their registered ID and password can gain access to the program. Upon completing each exercise, a percentage of correct answers is automatically calculated and presented on the screen (Fig.9).

Even though in the preliminary experiment, we used the program in the classroom situation, our objective is to let the students use this computer assisted listening program as a part of homework or as an extra training on individual basis. Accordingly, dates and degree of participation are recorded and sent to the instructor's homepage linked to this program. From administrative point of view, as its being an internet based system, this program can provide efficient time-saving method of keeping track of each learner's progress and can also record each learner with the items of tests' scores as shown in Figure 10. Not only the instructor can look into the development of studies achieved by each one of the learners but also the learners themselves are able to get into their own page and look into the process of their own achievement.

Other than these automatic feedback, students can receive messages from the instructor. Naturally, whenever they have
any problems, they can ask for a help by e-mail.

8. Preliminary Experiments
8-1 Results of Questionnaire on the program

One of the main purposes of this preliminary experiment was to find out how they would react to the computer-assisted listening learning and to see what should be done to make the program easy to handle for them. In order to confirm their reactions, we carried out a questionnaire after a 40 days period of session consisting of three hours of classroom activities and individual studies in their free time. Objectively speaking, the part of the sound recognition exercises, even though we have designed it to be interesting and varied, is rather monotonous. Thanks to the advantages of computer's being multi as well as student-centered media, however, the students did not get bored but became very much involved in the activities and expressed their wish to participate in this listening program. Table 1 shows the results of the evaluation given by the students. The scale of evaluation was from number 5 to 0 and the number 5 stands for the highest score.

Table 1 Results of Questionnaire – Evaluation of the Program by the Students

As seen in the table, their overall reactions towards the CALL learning were very positive. Many of them expressed their wish to continue this type of studies.

8-2 Quantitative evaluation of the program

During the experimental period, regular class activities were conducted as normal to cover the course syllabus. The students were recommended to access the materials until they would complete all the exercises with final score of 90 points or better. How long and how much they would study was up to them. With the help of the Management System we could monitor their learning progress and confirm that all of the students had fulfilled the task. At the end of the designated period of time, we conducted a listening test for perception. The quantitative evaluation of the program was performed by comparing the results of pre- and post treatment tests. The mean score of the test before the implementation was 82.3, and the score after the implementation was 85.4, and the overall rate of progress was 18.6%. Taking into consideration that the regular class activities were conducted during the period and the rate of the improvement was rather slight, it might be difficult to claim that the improvement in their listening skills was achieved solely by the program. Also there are still many issues to be considered to obtain reliable data to judge the efficiency of the program including the number of the participants and the content of the test.
Even though a concrete analysis of the results is to be performed in due course, we can say that the results of the tests indicate that the program could help them improve their listening skills to some extent.

9. Conclusion and Future Plan

As for the content of the listening program, there are two important tasks that remain to be fulfilled. One is to prepare exercises to instruct super-segmental aspects of the Japanese sound system: rhythm, prominence and intonation and the other is to complete Part Two - Listening for Comprehension. Another task is to carry out an extensive experiment to evaluate the effectiveness of this listening program. The content of the test should be examined and a large number of subjects should be involved to get a reliable data. The method of experiment should be also reconsidered. For example, we will divide students into two groups. The first group studies Japanese sounds using this program, and the other group studies the exactly same contents using a conventional means of study: namely, a paper and tape recorder. If the group of students who use the computer make more progress than those who use a conventional method of learning; namely, a tape recorder, we will be able to ascertain effectiveness of the CALL materials. However, this kind of experiments is not easy to carry out without collaboration from other universities or institutes. Speaking of quantitative measurements in general, we also have to keep in mind that there are many variables to be considered, such as students' motivation, aptitude, and affective conditions. Accordingly, the results may not be straightforward and distinctive in quantitative terms (3). We believe that to figure out how these variables affect the learning process on Web is also an important area to be studied in the future.

Finally, we would like to confirm that the preliminary study of our CALL program has proved its usefulness to improve students' listening skill. More significantly, it had indicated that the program could provide a learning environment where the students were able to actively engage in the learning of Japanese sounds and to maintain their motivations.

Note:
(2) “Nala-u (Nihongo Accent Learning Aid – Universal)” by Yukihiro Nishinuma. This is one of a very few multimedia programs on speech sound education in Japanese.
(3) There have been a few research on developing a CALL listening program, but few of them have systematically covered the various aspects of the listening activities and have been actually used as a part of classroom activities and proved its efficiency (Mizumachi et al, 2001)

Abstract: This brief paper describes the implementation of one tool for modeling of workflows of authoring courses through of one graphic editor based on SVG technology.

Introduction

Workflow modeling techniques can express in the form of a graphic, a flow of activities as the collaborative authoring of courses through WWW, even so, the implementation of these models is one of the main difficulties found in the use of workflow technologies. Seeking to facilitate this implementation the project "Conception of Cooperative Environment for Editing Multimedia Documents with Workflow Technology" (CEMT) proposed the creation of a graphic workflow editor with base in the software Amaya (Vatton, 2001), the Amaya Workflow (AW). The objective of AW is to facilitate the determination and implementation of workflows for courses, for that it generates through a graphic interface based on standard SVG (SVG, 2001) an XML file with the instructions of a workflow that specifies the authoring or execution of a course. After the files have been generated they can be sent for a workflow machine that will interpret and execute the projected workflow.

The environment

The software Amaya is the official Browser/Editor of W3C, now is being developed in INRIA, this software have among other resources a support for technologies XML and SVG. SVG is a pattern of graphs representation official's of the W3C, Amaya hold an editor of graphs that follows this pattern and have as base this editor the project CEMT made the implementation of AW, that is an editor graph of the technique of workflow modeling "Workflow Process Model " developed by Casati/Ceri (WIDE, 1997).

With this editor a user can define a workflow graphically conform the model of Casati/Ceri. Paralleling with the generation of graphic SVG the AW generates a file XML that contains all data about the workflow that is being modeled, for this, the project CEMT needed to define a DTD of Workflow, the files XML that follow this DTD are capable to store information that can recompose the flow of the model and the necessary information for its execution.

The objective of AW is to facilitate the determination and implementation of workflows for courses in the WEB, for that it generates through a graphic interface a file XML with the instructions of a workflow that specifies the authoring or execution of a course. The files are generated so that after they are interpreted and executed by a workflow machine.

Implementation

The AW (Amaya Workflow) is a workflow editor/browser with any features that facilitates the graphic edition of documents that express a workflow in accord with the symbols and semantics of the modeling technique Workflow Process Model.

The user can edit the document using a graphic tool added to the software Amaya, this graphic tool consists of a palette with symbols of the modeling technique Workflow Process Model.

With a palette of symbols the user add workflow elements (that visually are geometric graphics) in the document, conform the symbols are added, the workflow is structured with its tasks, super tasks, forks, joins and
connections, generating in this way the files that describe graphically the logical flow of the activities and in the format XML the logical structure of the workflow.

Each element have a list of attributes where information about the workflow that is being modeled are stored. Many attributes are automatically set for the system conform is made the graphic distribution of the elements. Other attributes should be set for the users, to fill and to edit these attributes the user needs to select the element in that want to add attributes and soon after to fill or to alter a form where the referring data should be inserted.

For each document edited in AW two types of files are generated:

- A file that follows the standard SVG that can show the graphic drawing of the workflow in any application that interprets standard SVG.
- A XML file that follows the DTD of Workflow, this file will have only information related with the Workflow, no graphic information will be contained in him although these information be extracted of the graphic distribution of the elements and of its attributes. As this file have all the information of a workflow, a workflow machine can read, to interpret and to set up this workflow.

Future works

The AW is just a part of the project CEMT, and its use, evaluation and adaptation to the remaining of the project are some of the future important works related to this editor. Concisely the project CEMT tell that: A specialist in workflow should project in AW a workflow for the authoring of a course, the files XML generated by editor AW about this project will be sent to a workflow machine that will interpret the files and with base in this files will build, will execute and will coordinate a cooperative environment for the authoring of a course in the Web, and the content of this course can be multimedia, hypermedia resources like SMIL. In this context the AW would serve as a tool that would generate a file XML with instructions for a workflow machine in an agile way, for this the AW still needs to be correctly adapted to the CEMT project.

Conclusions

The editor can be considered with a resource that can help in the interaction Human-machine because (1) of an agile and efficient way, it help in the construction and visualization of workflows, facilitating the interaction and human interpretation of the models and (2) it generates automatically SVG files with the data graphs of the workflow and XML files with information about the logic of the workflow facilitating the interpretation and the processing of these models for computer systems as Workflow Machines.

References

Abstract: This paper reports on the development of a peer-to-peer based tool to share and reuse learning objects, by making it easy to publish and search over their metadata [5]. The goal of this work is to leverage the popularity of file sharing applications such as gnutella [3] and napster [4] in the context of learning content.

1. Introduction
The evolution in peer-to-peer (P2P) networking [9], inspired us to examine the possibilities of P2P in the scope of share and reuse of learning objects. We report on the first outcomes of this work here. There are many infrastructures that rely on LOM, most notably ARiADNE [6,8].

2. Peer-to-peer
Peer-to-peer networks are networks in which every computer performs the same task. This approach can be contrasted with a client/server based architecture, where the server provides dedicated services and clients access the services offered by the server to implement a meaningful interaction with the end user. In a peer-to-peer environment, every peer publishes its own information. When a peer goes offline, only the information stored in that peer becomes unavailable. When performing a query, a peer queries its own information and sends the query to other peers, which perform the same task. The partial results from the different peers are merged and the result of the query is returned to the sender. In a peer-to-peer network, all hosts interact as equals. There is no need for a central server which needs a lot of maintenance costs. As a consequence, a great advantage of a P2P approach is that the system becomes much more robust. When a peer gets disconnected from the network, only the information it manages itself becomes unavailable.

3. LOMster
LOMster is a project that addresses sharing of learning objects on a P2P base with the following functionalities.

Publishing
1. First of all, a user can select the learning objects he wants to share with other users, by dragging and dropping. The idea is that users may find this a more natural way to make their material available for share and reuse than uploading it to a central server.
2. When the user adds a file to the system, the tool should generate as much metadata as possible [10]. In our current prototype, only file size and file name are taken into account. The user can add additional metadata manually.

Searching
1. A user can formulate boolean combinations of search criteria over LOM fields. LOMster sends its query to all other known peers. Replies from peers include the full LOM description of the results. Relevant learning objects can then be downloaded in the next phase.
2. Finally, a user can inspect the state of the current downloads and uploads.

To store the metadata on a peer, we could not use an RDBMS as that would impose too heavy a load on the typically rather simple user stations that LOMster is intended to run on. Rather we store all metadata in an XML file. To implement LOMster, we relied on the JXTA [2] P2P Framework. LOMster search-messages in JXTA have 3 fields (fig. 1):
1. In the peer-id-field a search-message indicates to which peer the answer needs to be sent.
2. The query identifier distinguishes different queries from the same peer.
3. Finally, the query-field contains the search criteria.

<search>
<peerid>peer-id</peerid>
<qid>query-id</qid>
<query>query</query>
</search>

Figure 1: structure of search-message
conditions expressed in XSLT. When another LOMster peer receives the search message, it processes the query. For each relevant learning object, it generates an answer-message structured as in fig. 2.

1. The first field contains the peer-identifier of the peer that generated the answer.
2. The qid-field defines the query being answered.
3. The last field contains the metadata of the relevant learning objects.

4. Related Work
The Edutella project also addresses the share and reuse of learning objects. This open source project also uses the JXTA framework. Instead of an XML binding, Edutella relies on an RDF binding of LOM. This project seems to have a slightly more mature status than LOMster, as more extensive field trials are already well developed.

5. Future Work
As we mentioned above, users often find it cumbersome to insert new material in a client-server based repository. We are exploring whether LOMster-like approach may help in overcoming this problem: contributing new material now simply entails dropping the relevant files in the shared directory. Although this approach may lower the effort for making new material available, it also results in rather poor and limited metadata, unless the user still spends considerable effort on the detailed description of the learning objects involved. One way to tackle this problem is the (semi-)automatic generation of learning object metadata. We are currently investigating how such techniques can be integrated in LOMster, as well as in our more conventional client server based metadata environment [10].

Mental Models: Do they exist, how are they taught, can they be measured? Preliminary research findings using computer based systems.

Martin Tessmer
Research Professor of Instructional Technology
Associate Director, e-Learning Center
University of Colorado at Denver

This paper will be a synthesis of the author's research into methods for teaching and measuring mental models. The presentation will be organized as answers to the three most pressing questions about mental models.

Do mental models exist? Possibly.

Although the "mental models" learning objective have been widely discussed in design literature, there have been no construct validation studies to establish it as a distinct learning outcome. Sheehan and Tessmer (2000) conducted a construct validity study of the mental models construct to determine if it was distinct from related learning outcomes of concepts and problem solving. To conduct the study, 112 US Navy engineering students were given five types of computer-based tests following a minicourse on electrical circuits: memory of definitions (to test for verbal information learning), circuit identification (concept learning), calculation (rule learning) troubleshooting (mental models and problem solving), and inference (mental models). A factor analysis of test results indicated that mental models measures indicated there might be a construct that is distinct from verbal information and has concept learning as one of its subcomponents. However, inference test results did not indicate that the construct is different from its component outcome, problem solving. Further validation studies are needed to indicate that mental models are in fact different from problem solving.

How do you teach mental models? Answer 1: have students build an expert system using a computer based authoring system.

Students acquire a mental model when they learn the proper place and relationship of its component parts. Consequent with constructionist and constructivist learning theories, students may best acquire a model by building the model itself. This building can be accomplished through two concurrent student learning activities:

1) Arranging the system components into their proper spatial or conceptual space within the model. This is the mental map of the system. For example, learning a mental model of a house by knowing the arrangement of the roof, roof trusses, walls, subfloor, etc.

2) Indicating the relationship between the model components. Knowing how one component interacts with other components is what distinguishes mental model learning from mental map learning. For example, knowing that the roof trusses support the roof.

One way to enable these two learning activities is to have students construct an expert system of the system to be learned, to have them program the components and relations while building an expert system advisor. A recent study by Mason and Tessmer (2000) indicated that this mental models strategy might be both effective and engaging.

Study Description. In an experiment conducted by Mason and Tessmer (2000) students used an online expert system to develop an expert system advisor on a brake system. Students had to input the relations between brake system components and their relationship to system malfunctions. The learning assumption behind this experiment was that students might construct an effective mental model of a system if they have to build the system itself. This model building not only requires that they put the system components in their proper relationship to one another (a necessary but not sufficient condition for learning a mental model) but that they also describe the functional relationship between the components: how they affect one another (another necessary condition).

Method. 28 adults were recruited to learn about automobile brake systems. Students' pretests indicated little or no brake system knowledge. Students had their brake system knowledge tested before they read a two-page text about the brake system, adapted from the World Book Encyclopedia. They were tested immediately afterward, using troubleshooting and inference questions as measures of mental models learning. Following the test students had to build an expert
system of the brake system, one that would advise users on brake system problems. Students were tested again after the expert system task, using more troubleshooting and inference measures. Students also answered an email questionnaire about their learning experience.

Results. Students exhibited no significant mental models learning gains after they read the brake system text but indicated significant and substantial learning gains after they completed the expert system task. Moreover, students indicated that the expert system task was engaging and enjoyable, even though they had never constructed an expert system. The results indicate that expert systems are worth consideration as mental models learning strategy for adult learners.

How do you teach mental models? Answer 2: have students build an expert system by assembling a graphic representation of one using a CBT system.

Expert systems have students learn a model by helping system users troubleshoot the problems the system may have. As such the model activity focuses upon learning the rules for system component interactions. Another strategy is to have students build a complete visual model of the system, arranging model components and their functional relations into a "big picture" model of the system as a whole. Such graphic representations can be done for abstract systems (e.g., the stock market, how a bill becomes a law) as well as concrete ones (brake systems, houses).

Method. In this study a CBT construction activity was developed using Macromedia's Authorware multimedia authoring system. Using such a CBT system enables a learner to pull model components and relations into place and to receive contextual feedback when they are put into the correct and incorrect locations. The model constructed was about the internet; how messages are received and transmitted. Students pulled internet components into their locations on the screen (router, server, home computer) and pulled over functional statements about the relations between the components (e.g., "directs message to the proper server"). Pulling the wrong component into place resulted in feedback cues ("no, this is where messages are sorted"). Students were then tested on internet system troubleshooting.

Results. At present only pilot test groups of 12 or less have been used to test the system, so there are no statistically significant results to speak of. However, preliminary test results (Bland and Tessmer, 1999) have indicated that students find the system building activity engaging and profitable. In this presentation the Authorware model-building learning activity will be demonstrated.

How to you measure mental models learning? Multiple measures are advisable.

As a relatively new and unproven construct (Sheehan and Tessmer, 2000), there is still some debate about the proper ways to assess it. One of the more popular methods has been through the use of modeling software, specifically PCKnot and KnotMac (Schvaneveldt, et al, 1993). This software builds a model of a student's conceptual map and compares it to the conceptual map of one or more experts, providing a numerical measure of the strength of correlation. Tessmer and Perrin (1998) tested the reliability of this measure and found it to be questionable, while other popular measures (troubleshooting, inference) remain unexamined. The current prescription is to use multiple mental models measures at the same time, not only to achieve a more accurate measure of mental model learning but also to assess the soundness of the measures themselves.

In this presentation a five-page minipaper will be distributed, complete with research results and references. Each type of computer-based strategy and measure (the expert system, the Authorware system, the online concept-mapping test) will be demonstrated.
Teachers, Identity, Psychological Capital and Electronically Mediated Representations of Cultural Consciousness

Sharon Tettegah
Department of Curriculum and Instruction
University of Illinois, Urbana-Champaign
United States
stettega@uiuc.edu

Abstract: This paper documents key issues in electronic mediated visual representations of social identity, based on the teacher’s psychological capital in computer mediated communication (CMC). Psychological capital is beliefs, perceptions, attitudes and thoughts. The origin of psychological capital is related to cultural consciousness. Cultural consciousness is defined as the part of an individual, which is derived from the amount of transmitted cultural mores, values, ethics, worldviews and ways of being that is expressed in the behaviors of everyday practices. In short psychological capital and cultural consciousness is how teachers talk about classroom teaching and learning in CMC. This paper further sought to capture ways which teachers talked about their communities of practice in their classroom environments.

Introduction

What is identity? What does it mean to document key issues in electronic mediated visual representations of social identity? This paper will define visual representations, psychological capital and cultural consciousness. This paper introduces a new model for analyzing teachers’ conversations in computer mediated communication (CMC) environments. This conceptual paradigm seeks to capture ways in which teachers talk about their communities of practice in their intercultural and cross-cultural classroom environments by looking through the lenses of social identity. Social identity is "a combination of those social categories which defined his or her place in society and which had been internalized to define the self, together with their value and emotional significance attached to that membership" (Tajfel, 1982, p.255). Specifically, my goal is not to capture the actual events of teacher behaviors in a teacher’s classroom, but to capture ways in which the teachers talk about their identities (this includes behaviors, as well as other aspects of identity), and how their identities can emerge from the actual talk that occur in CMC. By using CMC, the goal is to unmask psychological capital to arrive at a better understanding of cultural consciousness that is embedded in social identity. While considering prior research, this model seeks to engage educators in dialogue that can allow them to capture and construct textual images of their psychological capital through (CMC) so that we may better understand cultural consciousness as it relates to teaching and learning in intercultural, multicultural and cross cultural classrooms.

Psychological capital and cultural consciousness is different from Bourdieu's definition of social and cultural capital (1977; 1986). In short, Bourdieu's approach focused on the distributions of power in relationships within group memberships and social networks; However, this conceptual paradigm focuses on collective utterances from individuals (teachers) that are grounded in social historical meaning (Bahktin, 1981; 1986).

My goal is to create the constructs, psychological capital and cultural consciousness. I sought to develop new conceptual tools that could better define teacher’s thoughts, perceptions, beliefs and attitudes that are situated in their social identities. I use the construct psychological capital to refer to the collective of the later. Cultural consciousness defined, is the part of an individual, which is derived from the amount of transmitted cultural mores, values, ethics, worldviews and ways of being that are expressed in the behaviors of everyday practices based on social identity. The construct psychological capital is related to cultural consciousness. Psychological capital is how teachers think, believe, act, know, and cultural consciousness is what teachers do when they interact with themselves and others socially.

Social science is influenced by society’s values and ideologies, by the social and cultural background of its practitioners (Turner, 1996). The practitioners, in this case, are teachers and other educators. Some important questions that arise are: What do teachers think when interacting with students from different groups? How do they feel when they experience intercultural, cross cultural and multicultural classrooms? What do teachers experience when they enter the door of a classroom of 30 students from Hispanic cultures? A teacher’s psychological capital may be limited for Hispanic groups. If their psychological capital is limited, then what happens within their cultural consciousness as they approach the students?
Conclusions

In conclusion, the constructs of psychological capital, social identity and cultural consciousness embedded in electronic visual representations of voice are new and recent phenomena (Kress, 1998). Visual representations are very important for teachers because the visual/textual representations represent voice of voices that are associated with experiences, memories, attitudes, beliefs and practices in an Internet/WWW environment. This conceptual paradigm seeks to further to capture ways in which teachers talk about their communities of practice in their multicultural, intercultural and cross-cultural classroom environments. The constructs of psychological capital, dialogue, speech genres and social identity embedded in an online or web based environment through CMC can result in what we refer to as electronically mediated cultural consciousness. If the visual text as a mode of representation is systemic, rule governed, as well as simultaneously an effect of the values of the culture and social identity in which it is used, then it may be possible for teachers and other educators to know and make meaning of their own and other’s social identity by visual representations (text) to construct images of their multiple voices in electronically online mediated environments (Kress, 1998).

This conceptual paradigm seeks to provide a means for teachers from diverse backgrounds, where they can engage in communities of dialogue, using CMC, regarding their social identity and about their experiences teaching in a cross-cultural or multicultural classroom. By examining social identity and intergroup dialogue of teachers, I hope to add to the current research a better understanding of teachers’ social identity, psychological capital and cultural consciousness towards intergroup relations. CMC structured forums will allow teachers to structure their inquiries where they may feel comfortable. It will enable them to dialogue in inter-cultural virtual communities so that they can engage in discussions that may assist with modifying their psychological capital. Through their own unmasking of their identities and psychological development they could be better prepared to teach children from diverse backgrounds and interact with families from diverse backgrounds.

Computer mediated communication (CMC) empowers teachers to engage in conversations about their teaching philosophies and practice. It allows educators to better understand how talk, based on psychological capital, is culturally embedded. It also allows freedom of voice using textual representations, to facilitate volatile issues teachers face in intercultural, cross cultural classroom environments and multicultural environments. CMC provides a means to express multiple voices and notions of self. Many times when we experience courses and others in formal academic environments our multiple voices and identities are suppressed. This can be self-imposed or directly imposed by others. Our psychological capital and cultural consciousness are freed through binary systems of matter (wires, numbers, etc.). In many cases we have to step outside the community to view the other self.

A Brief Overview of An Instructor Facilitated Instructional Chat System (IFICS)

M.O. Thirunarayanan
Florida International University
United States
thiru@fiu.edu

Aixa Perez-Prado
Florida International University
United States
pereza@fiu.edu

Abstract: The authors have designed and developed a theory-based chat system. The text-based chat system is designed to reduce the cognitive load experienced by students in text-based chat rooms that are used for instructional purposes. This brief paper describes the major features of the chat system.

Purpose of the Paper

The confusion and overlapping conversations that occur in text-based chat rooms (Thirunarayanan, 2000; and Thirunarayanan and Perez-Prado, 2001) are two of several factors that contribute to students’ “cognitive load” in chat rooms. The purpose of this paper is to provide an overview of a chat system that is designed to reduce the cognitive load that students experience in text-based chat rooms.

A Brief Definition of Cognitive Load

According to Cooper (1998), “Cognitive load refers to the total amount of mental activity imposed on working memory at an instance in time.” He (Cooper, 1998) goes on to state “The major factor that contributes to cognitive load is the number of elements that need to be attended to.” In text-based chat rooms, there are many things that compete for students’ attention. Messages from different sources, the quantity of textual information appearing and scrolling off the chat window, and the mental energy expended in composing their own messages, are some of the many factors that increase the cognitive load experienced by students.

Major Features of the Instructor Facilitated Instructional Chat System (IFICS)

A theory-based chat system named “Instructor Facilitated Instructional Chat System” (IFICS) has been developed to reduce students’ cognitive load. By enabling the instructor to act as a facilitator, the chat system reduces the confusion and overlap that students experience in many real-time text-based chat systems. Instructors who log into the chat system see two windows on their monitor, unlike students who are presented with only one window. When students type and submit their comments, their comments first appear on a part of one of the instructor’s windows and also in a part of the window that is visible only to the student who typed the comment. The instructor can read all the comments typed and submitted by the students, and can select and send appropriate comments that then appear in a part of the window that is visible to all students. The instructor can facilitate discussions by first reading, selecting and then sending appropriate comments that are submitted by students, to the chat area that is visible to all students. The instructor can also send comments to all students and these appear in a separate part of the window that is visible to all students.
The instructor has the following four choices when it comes to dealing with the comments submitted by students as they discuss course content with each other:

1. Approve the comments made by one or more students after selecting them.
2. Disapprove a student’s comment after selecting the same.
3. Disapprove a selected comment and also provide a reason to the student for not selecting the comment.
4. Ignore the comment for the time being and send it to the end of the list of comments that have been submitted by students. Such comments can be considered again at a later time.

Another major feature is one that gives instructors the opportunity to type and save up to four comments before a chat session begins. For example, one of these comments could be “Consider the topic under discussion from another point of view” or “What are some other perspectives that can shed light on the topic being discussed?”. When the situation warrants, the instructor can, at the click of the mouse, select and send one of these four pre-saved comments to a part of the window that is visible to all students. This is another way that the IFICS enables instructors to facilitate discussions in text-based chat rooms.

Conclusions

Separating the window that is visible to all students into four parts enables students to focus on the content without having to try to mentally separate the content from the instructions and other messages that are extraneous to the content being discussed. The initial development of IFICS is complete and the system is currently being field-tested. Research will soon begin to determine if the system indeed accomplishes the purpose it was designed for, namely reducing students’ cognitive load in text-based chat rooms.

On the Effectiveness of a Programming Coach in a Distance Learning Environment

Pete Thomas
Department of Computing
The Open University
Milton Keynes
UK
MK7 6AA
p.g.thomas@open.ac.uk

Abstract

Previous research into the behaviour of students while learning to program by automatically recording their actions has revealed that such recordings contain a wealth of information that can be collected together into a diagnostic tool that can support students' learning. The first step has been to construct the Coach, a software component that can be invoked on demand to provide a variety of support based on students' previous experiences. The Coach has undergone an initial stage of usability and usefulness testing to determine its effectiveness in practice. This paper describes the design of the Coach and reports on a small-scale experiment to assess its effectiveness with two groups of students. It was found that students did indeed turn to the Coach for help and that the control group also searched for help, but had to get it elsewhere. The paper also reports on other differences in behaviour between the two groups.

Introduction

Students on the Open University introductory course in computing M206, Computing: An Object Oriented Approach (M206 2000), are taught the OO paradigm using Smalltalk. The students, of which there are approximately 5000 per presentation, are taught at a distance. The teaching is supported by a series of practical activities performed with the LearningWorks system (Goldberg, Abell et al. 1997). The LearningWorks environment consists of over 30 LearningBooks, each one of which contains a set of practical activities. The structure of a LearningBook is based on the paradigm of a book in that the student can read through some pages of material that describe practical activities which have to be carried out in other pages of the book (Woodman, Griffiths et al. 1999). The early programming exercises ask students to interact with a series of micro-worlds in which they observe the effects of small portions of Smalltalk code; later exercises ask the students to construct their own code.

The left-hand side of Figure 1 shows the contents list of LearningBook 06, LB-06. All LearningBooks are divided into a sequence of sessions. A session is designed to be studied in one continuous interaction with the computer. Each session comprises a sequence of practicals, and each practical has an associated discussion page. Thus, students are encouraged to attempt a practical and then examine the discussion where the outcomes of the practical are examined.

Figure 1 The interface of a typical LearningBook

On the right-hand side of Figure 1 is a page from LB-06 shown detached from the LearningBook containing the Amphibians micro-world. This micro-world is intended to support the learning of message sending. The Amphibians page also contains an evaluation text area in which students can enter small sections of Smalltalk code for the system to
evaluate. In later LearningBooks, the idea of a workspace is introduced where students can enter significantly larger pieces of code and investigate their execution (see Figure 2).

Given this novel approach to the teaching of programming, we were interested to know how effective it would be. Therefore, we set up a significant research project (Thomas, Macgregor et al. 1998) to investigate how students learn to program in this environment. Our first step was to develop a student Observatory - an electronic system for recording the actions that students take when interacting with LearningBooks (AESOP 2001). An analysis of the recordings (Thomas and Paine 2000) showed a variety of student behaviours, particularly when dealing with errors (Logan and Thomas 2001). Therefore, we set about adapting the observatory software to provide additional support for error message comprehension and error correction - the Coach (Paine 2001). This approach opens up the question of how effective the Coach would be. There are two aspects to this question. First, how easy would students find the system to use and second, how useful would students find the system? The effectiveness of the Coach would be ascertained by examining the extent to which students used it to solve problems. In this paper we shall discuss the effectiveness of the Coach; the usability issues are discussed in (Thomas, Paine et al. 2000).

The Coach

Whenever the LearningWorks system detects an error in an item of Smalltalk code, it issues an error report. Figures 2 and 3 show two kinds of report. In Figure 2, the error report is shown highlighted. To obtain help with this error the student can invoke the Coach by clicking on the appropriate button. In Figure 3, the report appears in a modal dialog box that would normally be cleared by clicking on the OK button. However, in the modified system, the student has the option of invoking the Coach. The result of clicking on the Coach button is a new window similar to the one shown in Figure 4.

The prototype Coach window has two main areas. At the top of the window is a tabbed area labelled ‘Actions’ which enables the student to scroll through a history of their actions. This uses the Observatory’s recording of the student’s actions throughout the LearningBook. The error report is shown highlighted and, in Figure 4, is a textual representation of the contents of a dialog box similar to the one shown in Figure 3 (the DIALOG is the error report and the CHOICES are the buttons that appear in the box). The second tabbed area that occupies most of the window shows a series of hints, the first of which is headed MEANING and contains an expanded explanation of the error that has been detected. The remaining items on the Hints page are possible reasons, given contextually, for the occurrence of the error. The hints contain hyperlinks to the Glossary containing definitions of the terms used in the descriptions. The remaining tabs give access to possibly useful materials such as the main teaching texts (Chapters), links to related web sites (Links) and a graphical Smalltalk syntax analyser (Precedence).
Effectiveness experiment

In a small experiment designed primarily to investigate usability issues, we took the opportunity to study the effectiveness of the Coach. 14 student volunteers were provided with two additional LearningBooks, each containing a small number of practical exercises related to the work of LearningBooks 09 and 10. The practicals asked the student to evaluate a number of simple expressions, each of which resulted in an error, and to attempt to rectify the errors. Those with the Coach were told of its purpose, but were not required to use it to solve the problems.

The experiment used an independent samples design to compare the actions of students who used the Coach with those who did not (Siemer and Angelides 1998; Budgen and Pothong 1999). Students were divided into two groups, providing us with 2 conditions. In condition 1, students were provided with the additional LearningBooks, the AESOP Recorder and Coach software. In condition 2, students were given the additional LearningBooks and the AESOP Recorder software (i.e., they did not receive the Coach software). Students were assigned to a condition on the basis of a pre-experiment questionnaire aimed at controlling variables related to gender and age. This resulted in 8 students being assigned to condition 1 group and 6 to condition 2 group. Having completed the test exercises, the students e-mailed their recording to us for analysis.

Post-Questionnaire

Once they had finished the tests, all students were asked to complete a questionnaire designed to assess usability and usefulness issues. When asked to rate the ease of completing the tests on a scale of 1 (difficult) to 5 (easy), on average students without the Coach rated the practicals as easier (4.4) than students with the Coach (3.75). Generally, students who used the Coach found the amount of information on its interface slightly distracting. When asked about the likelihood of using the Coach in other LearningBooks on a scale of 1 (unlikely) to 5 (likely), on average they said 3.25.

The following comment from one student summarises experiences with the Coach: “The information in the Coach was useful, although it was a little difficult to home in on the appropriate comments for the problems I had. When I went back to using LearningWorks I found myself looking for it in my next LB and on a couple of occasions wishing it was there. Sometimes the Smalltalk error messages are difficult to interpret and I think the Coach would help.”

Analyses of LB Test-09 Coach Recordings

Of the 8 students with the Coach, 7 used it ‘for real’. One student did not open the Coach at any point during either test LearningBook. All 8 students attempted all of the practicals. Figure 5 shows the percentage of students who used the Coach on each practical activity: it only includes those students who used the Coach to help them attempt to solve the practical i.e. not those who simply opened the Coach to look at it. It shows that, for each practical, some students felt the need to use the Coach.
With the exception of 1 student in one practical, all students with the Coach who solved the problem in a practical did so without looking at the discussion pages. However those students without the Coach who solved a practical sometimes looked at the discussion page before the solving the problem, as shown in Table 1. A few students without the Coach software also looked at the discussion page but did not solve the practical. We concluded that some students in each group needed additional support to solve the problems.

Table 1: Students without the Coach who looked at the discussion before solving each practical

Figure 6 shows the percentage of students who correctly solved the problems that had a single specific solution. There were students in each group who failed to solve some problems. In three out of these four cases, more students without the Coach succeeded in solving the problems. Nevertheless, in practicals 1, 8 and 11, some students without the Coach tried the practicals only after having read the discussion, so one might conjecture that not all students in this group would have successfully completed these exercises. However, the results of the post-questionnaire indicates that the group with the Coach were weaker. This is confirmed by the number of student errors (other than those mandated by the practical activities) in which those without the Coach made on average 18.83 errors each, whereas those with the Coach made 23 errors each on average.
A summary of the data extracted from the recordings for LB Test-09 from students with and without the Coach software is shown in Table 2.

Table 2 A summary of LB Test-09 recordings.

From Table 2 it can be seen that students with the Coach spent, on average, over twice as long in LearningBook Test-09 than students without the Coach.

Students with the Coach appear to do LB Test-09 in more sittings that student without the Coach (shown by the higher number of ‘Open’ events). Students with the Coach also on average accessed more hyperlinks than students without the Coach. This is to be expected as students with the Coach have access to the Coach Links, Chapters and Glossary pages which all contain a number of hyperlinks.

We analysed the results of the second test (LB Test-10) in a similar way. The difference between the two groups of students was less marked particularly in the amount of time spent solving the problems. This is to be expected as students get used to using the Coach software. This gives us confidence that using the Coach need not be a significant overhead, especially when it is clear that some students look for additional support to solve some problems.

**Future work**

We have implemented a revised Coach interface and slightly amended the two test LearningBooks so that we can repeat this experiment during the 2002 presentation of the course but with a much larger sample of students.

The next major step in the development process is to utilize the data contained in the student recordings to improve the feedback given by the Coach based on actual student experiences. Figure 7 shows the architecture of the system as envisaged. The basic idea is that the Coach obtains its data from a database on a student's machine (downloaded with the Coach). The local database is augmented with additional data based on the student's interactions with the LearningBooks (using the Events Analyser component). The recordings are sent to a central recordings database as with the present system. The recordings will contain all the events that occurred in each LearningBook, including those related to the use of the Coach since it is a LearningBook, too. The complete set of all students' recordings are analysed to update a central database of Coach data. Students will be able to update their local database with revised Coach data as and when they wish. In this way we hope to be able to adapt the Coach in the light of all students' experiences.

![Diagram](image)

Figure 7 The Coach System

A third avenue for exploration is to follow up on a discussion of models of intelligent tutoring in (Gertner, A. & VanLehn, K (2000)) by using the Coach to provide a model of how a given problem should be solved. This will be
based on work in another area [Thomas, 2001] for which we are developing mechanisms for specifying tasks and identifying attempts at solving them. We want to see how these mechanisms might be used to create a model of how a problem is to be solved and to detect student attempts at the solution. As the student tries to solve the problem, his/her actions are compared to those that the model would make. If the student’s actions diverge sufficiently from the model, the Coach would offer the student some advice or feedback.

Conclusions

Overall, the majority of students who used the Coach found it useful. However, the prototype interface was found to be distracting and students found it difficult to home in on the appropriate hint. We obtained useful feedback on the interface and have simplified it. On balance, the Coach seems to offer a beneficial tool that some students found attractive.

We believe that the Coach is effective and that it is worth investing further effort to improve it. In particular, we can see ways of adapting the Coach to individual student needs. We also believe that it will be possible to provide further help through the idea of a model solution and comparing it with student attempts at solving programming problems.

The Computer, The Discipline and the Classroom: Two Perspectives

Bart Thurber
Professor of English
University of San Diego, United States
email: thurber@sandiego.edu

Jack Pope
Director of Academic Computing
University of San Diego, United States
Email: pope@sandiego.edu

Abstract: The authors present two case studies in the use of computers in the classroom, one involving an introductory computer science class, the other an upper division literature class. After describing each case, the differences are discussed, showing that pedagogical models developed for one discipline may not transfer to another, and that the discipline itself, beyond instructor's preferences or institutional policies, may determine what works and what doesn't.

Introduction

Our goal in this paper is twofold. First, we'll indicate that the successful use of information technology in the classroom depends more on the synergy between teacher, student and the learning context than on the technology itself. The use of technology -- as the primary vehicle for teaching (distance learning) or as an adjunct to the more traditional classroom -- is effective only insofar as it addresses this synergy. Second, we will maintain that one under-recognized factor influencing teachers, students and learning contexts is the discipline itself, in a way that goes beyond simply paying appropriate attention to learning (or teaching) styles. We offer two case studies, one drawn from an introductory computer science course, the other from an upper division literature course, in support of these claims.

Enthusiasm for online learning is of course high for students who live in areas not easily served by the traditional classroom, and courses accessible anytime and anywhere can provide valuable learning experiences for mature students who work full time and take courses when schedules permit. But the use of online learning tools within traditional campus-based course delivery structures has become popular as well [1]. James Duderstadt, President Emeritus and Professor of Science and Engineering at the University of Michigan, suggests that universities must themselves take a leadership role in remodeling the universities of the 21st century, and that new information and communication technology tools will play a key role in that mission, suggesting that universities will continue to have a physical existence, whatever their virtual roles may become[2]. This is not a completely uncontroversial claim; in a New York Times article, John Chambers, then Chief Executive Officer for Cisco Systems, asserts that "the next big killer application for the Internet is going to be education. Education over the Internet is going to be so big it is going to make e-mail usage look like a rounding error." [3].

As the situation has developed, however, and as other researchers have begun to look at what now seem to be inflated claims, online education has emerged as one aspect of a larger picture. Prosser and Trigwell [4] argue that both teachers and students benefit from an increased awareness of their own personal experiences, approaches and perceptions of the learning process and that this awareness facilitates positive learning outcomes. In particular, they emphasize that "good teaching involves an awareness of students' perceptions of teaching technologies (including information technology) used in teaching" and that these perceptions can significantly impact the learning experience either positively or negatively. Given their results, the successful use of information technology in the classroom is clearly more dependent
on interactions between teachers, students and learning contexts than on the technology; it may even indicate that there are some things technology cannot appropriately do, a point to which we shall return.

On the other hand, learning opportunities newly available through the use of technology can support desired learning outcomes—provided (our second claim) those outcomes, as defined not simply by the instructor or the institution but by the discipline itself, are congruent with what the technology can provide.

Astin's comprehensive study of student development characteristics in various higher institutional settings [5] points out that active engagement of students in interdisciplinary courses, course with discussions, debates, and class presentations strongly correlates with critical thinking skills. To the extent that technology can facilitate (or at least create the opportunity to provide) such active learning strategies, the effort will not only increase student involvement in the course, but also increase understanding of course concepts by relating them to independent inquiry and debate.

The question is whether available technology can actually do that.

Case Studies and Examples

Our first case study involves an introductory computer science class. Pope's goal in implementing web-based tools the course was to increase opportunities for communication and participation. The class was small (approximately 25), but there was a considerable amount of material to cover and the topics that dominate the headlines—Microsoft Antitrust litigation, Privacy in Cyberspace—provide fertile ground for discussion. He began using WebCT as a tool both for distributing informational materials and for on-line testing. In doing this, he relied on the students to read on their own time; his discussion/lecture now addresses related but different concepts in supplementing the text. Making the quizzes available online provided more opportunity for group and class discussion.

Students were positive; they could find their grades, course syllabus, assignments and topic notes in one central location.

In designing this kind of structure Pope was of course not alone. The University of Central Florida, for example, adopted a similar approach to improve its course in American National Government. There, the goals of the restructuring were practical as well as mission-oriented. The course enrolled over 2000 students in sections of 80-100 students. Classroom space was in critical short supply; increasing the number of sections was not a viable option. But the course also had a retention problem and surveys indicated that partially web-based sections had somewhat higher retention rates. Building on this, the department designed a web-based asynchronous learning environment based on web-based modules to encourage student participation. Class meeting time was reduced by two thirds. Bruce Wilson reports “students are, by necessity, more actively involved in the learning process. And instructional technology can also enhance students' critical thinking skills. ... The use of the Internet in teaching Political Science gives instructors more opportunities to design activities that involve students' direct participation and to follow clearly set instructional goals.” [6]

Herman D. Lujan [7] alludes to the tendency of many faculty to “narrowly define 'good' teaching and learning as something that occurs in a time-bound, synchronous classroom setting.” Pope believes that students in his computer science course benefit not only from in-class—'synchronous’—discussions and demonstrations but also from the ability afforded by new online tools to communicate and learn using the tools that promote asynchronous learning opportunities.

Unlike Lujan, however, Pope is not convinced online learning fits in every teaching and learning context. It fits in this course because much of the material and the broad topics under review can be organized in a modular fashion and students can easily take part in discussions outside of the class context using WebCT. Fine for an introductory class, not so fine for an upper division, seminar-style class in advanced topics in mathematics.

This class meets twice a week—once in a regular classroom and once in a hands-on computer lab. But based on his experience Pope has come to believe that hands-on access is a more critical component of the instructional paradigm than the web-based asynchronous tools. This is a rather tame observation in 2002—the case for instructional computing labs in science and computing education was made by the mid 1980s; nevertheless, the classroom context heavily influences teaching methodology. Without the lab, there'd hardly be time, and fewer topics, for discussion! The point is that successful teaching requires the clear evaluation of the goals of the course [derived from the discipline], the context in which the teaching and learning takes place [the classroom itself], and finally the learning strategies that best fit both.
Finally, Pope also viewed the electronic interface as an opportunity to evaluate his own teaching. In any implementation of electronic technology in the classroom, a major evaluation of course objectives and teaching strategy is required, and he found this to be a welcome necessity. Drawbacks were a lengthy development and the availability of trained support staff.

Thurber, teaching an upper division class in English literature, had a different experience. It was not obvious to him that the standard distributed education model was appropriate, given both the mission of the university and his actual task, which was to investigate, in this case, the work of the English poet William Blake. He does not give quizzes as such, although short exercises related to that moment's discussion do take place; there is no “lecture” and therefore no lecture notes. The course itself, in addition, was already as “interactive” as he (and his 24 students) could stand. Instead, the goal was to use the Web to investigate the nature of hypermedia, particularly as the poet in question, Blake, had done an 18th century version of the same thing. His goals, therefore, were far more specific to the actual material—more contingent, more dependent on the actual poetry than on any idea about how to teach poetry.

He created, therefore, a course website (www.sandiego.edu/~thurber/CyberBlake) and asked the students to create their own hypermedia websites in lieu of the traditional paper—the rationale being, once again, not simply that hypermedia may be worth investigating on its own, which it may be, but that, given this poet’s practice, hypermedia are an appropriate, perhaps the most appropriate, response. The student’s response was positive, in each case suggesting that the course be given again. Typical remarks included “It’s about time English Departments did this,” “an English course that is actually practical,” and “I feel like I’m a writer too, doing something a little bit like Blake.”

The course model that evolved, however, has almost nothing in common with Pope’s. There was a course discussion board; very few students used it, feeling that opportunities for interaction were already sufficient; a few found it intimidating, while others viewed it as just another course assignment. (Participation in the discussion board was optional. Thurber wanted to see what would happen if it was not required.) There were electronic office hours; no one ever showed up, as students uniformly felt either that they already had sufficient access to the instructor, or that personal interaction was preferable. The emphasis was on the student’s ownership and exploration of an electronic medium, the Web, rather than on using the Web to enhance communication or provide additional course materials.

**Observations and Conclusions**

It is about the differences between these two course structures that we would like now to reflect. Crucial to Pope’s model was the use of the Web in the transferal of information from the instructor to the student. Indeed, he viewed, as is common, class sessions as adjuncts or supplements to information provided online.

But this is already not a model that transfers readily to an upper division literature class. Advocates of distributed learning have traditionally emphasized that the use of electronic communications present opportunities for teacher-student interaction that effectively shift the educational focus from “teacher-centered” to “student-centered,” away from the traditional lecture format and towards distributed learning. But is the “transmission” of information, by itself, what college courses are for? If so, never mind the traditional lecture; colleges have been masquerading as libraries or, now that the technology is available, web sites. As far as the humanities are concerned the “transmission” of information is only one function college courses serve, and in some respects the least important.

While we acknowledge that modern educational philosophy mandates the critical importance of engaging the student in interactions that will impact his or her mastery of the subject matter, it does not then follow that the hallmark of student-centered learning is the use of computers in the classroom. Particularly if, as at our university, classes are small and instructors, on the whole, couldn’t lecture if they wanted to. Is the give and take in small, discussion-centered, quasi-seminar situations comparable to what we can do in online discussion groups, even with real-time audio and video? If it isn’t, what are the differences, and what is the educational impact of those differences? In the absence of hard answers to those questions, we wonder what’s really at stake. What is being transmitted, pre-eminently in literature classes but in the humanities generally, is not the “information” we possess about, for example, Shakespeare, which is trivial, but the nature and kind of conversations we have and have had about his work. Knowledge in the humanities is both a process (not a result) and always contingent, socially constructed and crucially dependent on the context in which it is acquired. (The French Revolution in the eyes of post-1848 Europe was one thing; to Woodrow Wilson it was another; to ourselves it is yet
something different.) From this perspective the transmission of information via the web is a non-sequitur. It isn't the Web that's the problem; it's the word “transmission.”

Using computers according to the first model, therefore, at least interferes with and may even negate the goals and methods of the humanities—not because humanities instructors are Luddites (some are), but because the pedagogical model such approaches embody originated in one discipline, or set of disciplines, and don’t readily transfer to another. Using computers according to Pope’s model would deny Thurber and his students the chance to do what they want to do, which is both to learn what a writer actually did and to forge a response, together, to what she actually did. Here is where the under-appreciated difference between disciplines—world views, at some point—comes into play. There is no, and there had better not be, any such thing as socially constructed knowledge in the sciences. (Actually this is a matter of current debate. What physicists thought about the significance of Maxwell’s equations in 1890 was a different than what Einstein thought fifteen years later.) In the humanities, on the other hand, and particularly in literature, there is no knowledge except what has been socially constructed—beginning with the fact that literature is made of language, the most social of all constructions, and including the fact that no writer, no matter how august, is a writer unless someone, somewhere, chooses to read her. The artist has an intent, to be sure, but that intent is only one of many variables connected to our mutual investigation of what a work actually is. Reader-response theory, as a matter of fact, would have us believe, in general, that readers are actually as responsible for what a work does as the author is—maybe more so, in some constructions. Whether that is true or not, none of us reads or could read Shakespeare as Shakespeare did; but we still read Shakespeare! What’s that, then? Shakespeare is Shakespeare but he’s also us reading Shakespeare, in ways that he could not have foreseen but which are, still, what Shakespeare “is.” For now. Meanings change; there are no “laws” in the sense that there are for the hard sciences.

Thus when Pope says, for example, that it’s a good thing that online discussions can happen any time, that it frees people from the constraints of time and space so that they can say anything from anywhere, Thurber’s response is—why is that good? It would depend on the crucial insight that online discussion is the same as or better than the kinds of discussions his students and he have in real time, with their real bodies and their real minds in a real place, zoned into a writer they want to try to understand. Is virtual discussion discussion? (We know, for example, that people write and talk differently, and that they behave differently on- or off-camera. What are the differences, are they significant, and are virtual discussions better than, the same as, or worse than virtual discussions? And for what ends? There has been surprisingly little research in these areas, particularly as different disciplines are involved.)

Even, Thurber notices, Britain’s Open University, one of the oldest and most successful implementations of computer-based instruction (http://www.open.ac.uk), supplements online material with local study centers (and tutors) at learning centers around the world. On this model, the discussion, always specific, always local, and always the joint product of the persons present on that occasion, is preserved, together with ancillary electronic material and the opportunity, which he welcomes for his classes, for students to write back at the sea of electronic media they are surrounded by, owning the web by helping, in a small way, to create it.

Thurber makes one further point, however. Crucial to his thinking about the use of computers in the classroom is what he has taken to be the centrality of hypertext (and hypermedia) in the classroom. As things have developed, however, he is beginning to wonder whether hypertext—at least as it was once envisaged—has failed. If it has, the use of computers—any computers at all—in his classroom becomes problematic.

In one sense, of course, it is absurd to say that hypertext has failed—the Web itself is evidence that it has not—not to mention media-rich computer programs, whether or not they live on the web. Hypertext, and more generally hypermedia, are the cornerstone upon which contemporary electronic communications stand, the cornerstone as well of the new IT economy, with its multiple and still evolving political, social, and psychological impacts. Hypermedia used creatively, moreover, as a medium of expression with its own aesthetics, continues to be produced, if in small quantities. It was this last area—the possibility that interactive technologies could be the means by which student author-readers could create new kinds of texts—that most interested and excited Thurber.

But in this context the early promise of hypermedia has not been realized. We do not go to see interactive movies, though attempts have been made, nor, on any meaningful scale, do we find ourselves reading interactive novels. Hypermedia on the web and elsewhere have developed as economic, more than literary or artistic, engines. Interactive games are arguably interactive fiction—but games more than fiction, image more than text; but text—language—is at the heart of Thurber’s commitment to his own discipline.
It is true that interactive textuality continues to be investigated in the academy—notably at Brown University, MIT, the University of Texas at Austin—but these attempts too have failed to generate impact beyond those who are already persuaded. Hypertext has not swept away text; hypertext fictions bear approximately the same relationship to fiction that performance art bears to drama—marginal, contingent, rather that the revolution many of us thought was coming.

But whether or not this is true, our conclusion is that each of us is still en route to a full understanding of the implications of electronic technologies for higher education. We would emphasize, however, that our different disciplines seem to require different choices, different ways of using those technologies or reasons for not using them. One size does not fit all!

Students' Epistemological Beliefs and the Learning of Introductory Computing Concepts

Denise Tolhurst
School of Information Systems, Technology and Management
University of New South Wales
Australia
d.tolhurst@unsw.edu.au

Abstract: Epistemological beliefs have been shown to influence cognition and learning, motivation, persistence in problem solving and navigational strategies in software use. Brownlee, Purdie and Boulton-Lewis (2001) have also been shown that learning environments can influence students' epistemological beliefs. Observations of students in a first year undergraduate introductory Information Systems course at the University of New South Wales, Australia revealed learning approaches and behaviours that suggest simple epistemological beliefs. Results of a survey of students' epistemological beliefs support these observations, leading to a reconsideration of pedagogical approaches adopted in teaching the course that might lead to the development of more complex epistemological beliefs. The motivations for the redesign of the core information systems course and the resulting restructure to include web-supported independent activities and lecturer facilitated workshops are described in this paper. Results from the first implementation of the course revision in early 2002 will be presented to Ed-Media 2002 conference delegates.

Epistemological beliefs are those concerning the nature of knowledge and learning: beliefs about how individuals come to know, how knowledge is constructed and how knowledge is evaluated.

'Epistemological beliefs' is an area that is increasingly seen as influencing learning and cognition, and an area of investigation afforded greater attention by the research community in recent times. Beliefs about knowledge have been shown to influence factors such as student's motivation, persistence or problem solving approach (Kardash and Scholes, 1996; Schommer, 1994b; Jacobson and Spiro, 1995). Kardashian and Scholes (1996) draw attention to 'A growing body of evidence (that) suggests individuals' epistemological beliefs play a critical role in strategic learning in general and higher-order thinking and problem solving in particular' (p261). Schommer (1994b) suggests that '... epistemological beliefs affect the degree to which individuals (a) actively engage in learning, (b) persist in difficult tasks, (c) comprehend written material, and (d) cope with ill-structured domains. In each of these areas, the evidence suggests that epistemological beliefs may either help or hinder learning' (p302). In a summing up the same article Schommer concludes that '... there is enough evidence to suggest epistemological beliefs are critical to the learning process' (p315).

Jacobson and Spiro (1995) identify '...epistemic cognition as a relatively recent area of cognitive enquiry of potential relevance to hypertext investigators' (p305). They identify students epistemic beliefs as being associated with '... such learning problems as the failure to integrate new knowledge with prior knowledge, use of rigid criteria for monitoring reading comprehension, and poor performance on comprehension measures' (p306). Based on the work of Spiro, Coulson, Feltovich and Coulson (1988) they also suggest that '... over simplification of complex and ill-structured knowledge contribute to the formation of conceptual misunderstandings at postintroductory stages of learning' (p306). As a result of their 1995 study Jacobson and Spiro describe preliminary evidence which suggests that students holding a simple set of epistemic beliefs were less able to learn and apply their knowledge after using a hypertext system than students who possessed a more complex set of epistemic beliefs. It is apparent that epistemological beliefs are not only important to learning generally, but also to learning with computer-based materials.
Epistemology is an area with its roots in philosophy that is generating increasing interest (Belenky, Clinchy, Goldberger & Tarule, 1997; Brownlee, Purdie and Boulton-Lewis, 2001; Hofer, 2000; Hofer & Pintrich, 1997; Jacobson, Maouri, Mishra & Kolar, 1996; Schommer, 1990; Schommer, 1994a; Schommer & Walker, 1997; Spiro et al., 1988). Initial work in the area in the form of a number of longitudinal studies involving mostly young American men at college was undertaken by Perry (1970) who suggested a model based on nine developmental stages in intellectual and ethical development as the results of. Perry’s work came under attack in the late 1970s due to its focus on an ‘elite male sample’, with Belenky, Clinchy, Goldberger and Tarule responding with a study focusing on American female subjects from academic institutions and from human services agencies (1986). Belenky et.al. proposed a model based on ‘... a set of epistemological perspectives from which women know and view the world’ (p15). Kuhn (1991), Baxter Magolda (1992), and King and Kitchener (1994) have also suggested alternative developmental models, Kuhn with levels of ‘argumentative reasoning’, Baxter Magolda with four different ‘ways of knowing’ and King and Kitchener with three ‘reflective judgement’ stages.

A recent prolific researcher in the area of epistemological beliefs, Marlene Schommer, suggests that epistemological beliefs are far to complex to be captured in one dimension of developmental stages and has proposed instead of a set of five independent epistemological dimensions, each having a range of possible values. These dimensions include certainty of knowledge (absolute to tentative), structure of knowledge (simple to complex), source of knowledge (handed down by authority to derived through reason), control of knowledge acquisition (ability to learn is fixed at birth to ability to learn can be changed), and speed of knowledge acquisition (knowledge is acquired quickly or not-at-all to knowledge is acquired gradually). Schommer (1994a) proposes these dimensions as a starting point to the line of investigation of dimensions of epistemic beliefs, as she suggests that the five dimensions are unlikely to encompass all possible aspects of epistemological beliefs. Hofer’s (2000) investigations in the area of personal epistemology have shown that epistemological beliefs are not unrelated to the discipline of study being undertaken, and are not ‘domain general’ as suggested by Schommer.

Consistent with the work of Jacobson and Spiro (1995), Tolhurst and Debus (2000, and 2002 in press) found that the navigational strategies and learning approaches adopted by students’ using complex software may be influenced by their epistemological beliefs. Dimensions of Schommer’s epistemological beliefs were found to be relevant to this study were those of certainty of knowledge, structure of knowledge, source of knowledge and speed of knowledge acquisition. It was found that if students possess naive beliefs of knowledge, such as belief that knowledge is absolute, is simple, is handed down by authority and is acquired quickly or not-at-all, then this is likely to affect the way that they use software to seek information. With less sophisticated beliefs students were likely to believe that there is one answer to be found, and it will be found quickly if the software is authoritative or it will not be found at all. With such beliefs, students were not likely to persist in information seeking beyond the situation in which they locate any information they believe satisfactorily answers a question, on in the event that they do not find an answer relatively quickly. Conversely, with more sophisticated beliefs students, were more likely to seek additional information to that first identified and persist in the event of being unsuccessful at first.

Of particular significance to the work discussed in this paper is the research by Brownlee, Purdie and Boulton-Lewis (2001). Brownlee et.al conducted a study with Australian tertiary students at the University of Queensland that show it is possible to significantly influence students' epistemological beliefs and produce positive learning outcomes. Brownlee et.al. measured students beliefs before and after a course of study in which two groups of students experienced a year-long of study in which one group was required to reflect on their epistemological beliefs using personal diaries. They found that the group involved in reflective practice experienced a statistically significant shift to more complex epistemological beliefs that those students who did not. They conclude that student epistemological beliefs are able to be influenced, and that this has implications for how educators develop learning environments.

Based on the work of Brownlee et. al. that epistemological beliefs can be influenced, a study in-progress is discussed in this paper which seeks to determine whether changing established learning
environments might encourage in students more complex epistemological beliefs, and hence encourage more appropriate study approaches in tertiary students.

Research Study In-progress
Background

After evaluating course outcomes, staff teaching first-year undergraduate students introductory courses in the School of Information Systems, Technology and Management (SISTM) at the University of New South Wales (UNSW) have begun questioning the pedagogical approaches practiced in teaching. Observations of student behaviour have identified attitudes and practices that are of concern to staff, in that many students: rely strongly on teaching staff to provide content and guidance on assignments; rely on a single source of information (often the internet) rather than consulting a range of sources; tend to quote large sections of text from sources with little attempt to 'paraphrase' material or integrate ideas from different sources. The results of an epistemological beliefs questionnaire provide support for the impressions that staff hold, indicating that in the main students possess naive epistemological beliefs.

Epistemological Beliefs of Current Student Group

In first session of 2001 the Epistemological Beliefs Questionnaire (Schommer, 1998) was completed by 201 students studying the first undergraduate Information Systems course. Table 1 shows the results of that survey.

From the data presented in Table 1 it is apparent that the epistemological beliefs of the majority of our students are consistent with the study practices observed by staff. The subscales (range of 1 to 5, 5 represents strong agreement) with the highest mean values small standard deviations suggest that students in the main: seek single answers (mean=3.17, sd=.35), depend on authority (mean=3.21, sd=.58), and avoid ambiguity (mean=3.17, sd=.55). Other values also support evidence of simple epistemological beliefs in the majority of the students, in particular: concentrated effort is a waste of time (mean=2.70, sd=.70), knowledge is certain (mean=2.76, sd=.49) avoid integration (mean=2.70, sd=.41), and ability to learn is innate (mean=2.71, sd=.7). It would seem that the current course structure (2x1-hour lecture and one hour tutorial/laboratory per week) does not support more complex epistemological beliefs in students that are associated with more desirable learning approaches and outcomes.

</thead>
<tbody>
<tr>
<td>In an attempt to address the problems identified, the first year core undergraduate course in Information Systems is being restructured in a way that minimises formal lectures where content is provided by an 'authority'. In place of the formal lectures students will spend half of their structured course work undertaking web-supported independent work in preparation for workshop sessions in which experienced staff facilitate learning activities. The workshops will be classes of no more than 30, in place of participation in lectures of up to 250 students. Rather than be passive learners in lectures, students will be required to be actively involved in their own learning in both the independent web-supported activities and workshops. They will be required to undertake guided and independent research from multiple sources (on-line, computer-based and non-computer based), involve themselves in group discussions, case studies, project work, debates, design activities, software activities, role plays and peer evaluations. It is expected that the work that they undertake will challenge any tendency to settle for 'simple', quick or 'first' answers, single sources, and the seeking of information from the lecturer as an 'authority'.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Anticipated Outcomes</th>
</tr>
</thead>
<tbody>
<tr>
<td>It is expected that the changes to the course structure to be implemented for the first time in 2002 will foster a more desirable 'academic' approach to learning in our students, encouraging greater student independence and supporting more sophisticated epistemological beliefs. By developing more complex epistemological beliefs it is anticipated that students will be more likely to appreciate the complexity of knowledge, seek information from multiple sources and integrate the ideas they find from these sources and rely less on the 'authority' of the lecturer. It is anticipated that in their computer-based research work that students will be willing to persist in information seeking beyond the situation in which they first locate any information they believe satisfactorily answers a question, on in the event that they do not find an answer relatively quickly.</td>
</tr>
</tbody>
</table>

By June 2002, the date of the ED-Media conference, quantitative results from Schommer's Epistemological Beliefs Questionnaire (1998) and qualitative results from student interviews...
following the first teaching of the newly structured course will be available for presentation to
delegates.

International Education Online: Project THRO

Howard Tolley, Jr.
Department of Political Science
University of Cincinnati
United States
Howard.Tolley@uc.edu

Abstract: Active learning, case based teaching, and simulations have become increasingly popular tools for international education. In order to realize the full potential of Internet2, Teaching Human Rights Online at http://oz.uc.edu/thro provides: 1) interactive cases that give students immediate feedback at any hour they answer questions online; 2) collaborative problem solving exercises for multi-national teams; 3) structured formats for real world cases and hypothetical scenarios to focus on critical international issues; and 4) internet videoconferencing for students around the world to confront their differences. TV news broadcasts routinely feature a split screen conversation between international reporters in different countries. As internet connections improve, students from different countries will have similar opportunities to meet face to face online. Rather than dehumanize learning, new technology should mediate direct communication between diverse groups whose members may never travel abroad to meet in person.

Introduction

New technology creates extraordinary opportunities for global learning communities but also threatens to dehumanize higher education. Teaching Human Rights Online (THRO) is an interdisciplinary, multi-campus project begun in 1997 that employs interactive cases and internet conferencing to foster critical thinking and normative reasoning through collaborative interaction. Six THRO exercises apply information age technology to the type of problem based instruction found in the classical works of Sophocles and Thucydides. Antigone encourages students to decide whether an individual may invoke natural law to defy a ruler who demands obedience in order to avert anarchy. (Cranston, 1983) The Melian Dialogue confronts students with enduring questions of power politics and universal justice. How can technology improve on the personal interplay of student and teacher realized in classic drama, historic debate, and Socratic dialogue? In its first four years, Project THRO published six contemporary teaching cases as issues of an electronic journal that will continue to solicit and disseminate interactive exercises for internet conferences.

Project Partners

Political Science professor Howard Tolley initiated THRO in association with the University of Cincinnati Law School's Morgan Institute of Human Rights and with College of Education professor Dan Wheeler. THRO faculty associates in the U.C. Colleges of Education, Arts and Sciences, Law, Business, and University College collaborated in preparing interactive problems online as a supplement to traditional assigned readings, class lectures, and discussion. External grants from the U.S. Institute of Peace and the Ohio Learning Network supported instructional technology professional development workshops in September 1999 and March 2001 as well as follow-up distance education courses at the graduate and undergraduate level. The two faculty development workshops brought 100 faculty from eight countries and ten states to the U.C. campus for sessions on asynchronous and synchronous internet conferencing with text, audio, and video (with Polycom ViaVideo). The training identified the best applications for low bandwidth connections as well as for Internet2 high speed access.

As a result of the workshops, THRO-Net now lists eighty-five associates including faculty in Australia, Bulgaria, India, South Africa, and Turkey. Email discussion groups with minimal technical requirements enable THRO to reach the widest audience for text chat interactions. U.C. makes the case materials available online at no cost to individuals as well as to instructors who use the problems either as a course assignment or for structured exchange with classes at other institutions. English speaking teachers and students anywhere in cyberspace may use the exercises both as individuals and in organized interaction between classes at different campuses. Each THRO case has a teaching note for course instructors.

THRO promotes three distinct cross-disciplinary collaborative relationships:
Case-writing Associates led by Political Scientist Howard Tolley develop teaching problems. During academic year 2002-03 a political scientist on sabbatical from Earlham College will work on a THRO case as a scholar in residence at the Morgan Institute.

Project Associates led by Education Professor Dan Wheeler adapt, evaluate, and train others to use instructional technology. In support of its major information technology initiative, U.C. was a founding member of the Internet2 consortium, received a $328,000 NSF grant to support connections to the Next Generation Internet, and belongs to the ITEC-Ohio consortium with eight university and two corporate partners. Wide bandwidth connections now provide acceptable quality audio and video streaming between U.C. and other Internet2 institutions.

Teaching Associates registered on THRO-Net assign the cases to students and may arrange online text or videoconferences with others in the network.

Goals and Methods

THRO envisions a third dimension of “IT” beyond “information” and “instructional” technology to accomplish an “interpersonal” objective. Online simulations with classes in different countries can provide to more students at less cost Model U.N. type learning opportunities enriched by multinational participation. Traditionally each school participating in a simulation represents a different state’s delegation. With the latest technology, students from a U.S. class might join different multi-national work groups online, collaborating electronically with students of other countries to prepare for a videoconference simulation or seminar. Students in multiple locations working together on international human rights cases realize several important advantages:

- Increasing the diversity of the participants. Students in a single classroom are often quite homogenous and tend to assume that their own notion of rights is universal. Interaction with students from other countries develops a better understanding of cultural relativism.
- Increasing the realism of simulation. When one of the educational goals is to teach students to work with people from other countries, having participants who are actually from different countries adds greatly to the value of the role-playing exercises.
- Providing an independent audience. Students are motivated to take their work more seriously when there is an audience beyond their own classroom.
- Promoting collaborative learning. When classes work together via telecommunications, they must collaborate to make the exercise work. This is in addition to the collaboration that is directly involved in the case-based exercise.

For over fifty years proponents of the Universal Declaration of Human Rights have challenged advocates of cultural relativism in philosophy, history, law, international relations, and education. (Renteln, 1990. Gewirth, 1982) The United Nations proclaimed 1995-2004 as a Decade for Human Rights Education. Students in law, business, or the social sciences begin a THRO case with individual activity by using a personal computer to access materials needed to answer online questions about a human rights dilemma. At any hour students can answer multiple choice and short essay questions online and receive immediate feedback identifying errors and offering model answers. (Haladyna, 1997, Wiggins, 1998.) Analysis of student responses enables case authors to design improved items that measure and promote higher order thinking—analysis, application, problem solving, and evaluation. The student writes short advocacy arguments in support of rival claimants before reaching a balanced judgment in a concluding synthesis. THRO cases involve actual rather than hypothetical situations. Case updates keep online material current with active links to relevant web sites. The multidisciplinary human rights cases not only require critical thinking about political and legal decisions but also pose moral dilemmas that demand ethical reasoning.

Prior Work

Active learning, case based teaching, and simulations online have become increasingly popular tools for international education. First generation education initiatives on the internet have not realized the full potential for personal interaction online. Some hardcopy cases on international issues published by Harvard, Georgetown, and the University of Washington’s Electronic Hallway (www.hallway.org) can now be downloaded off the web. Case instructors exchange email and post messages to share teaching ideas, but students derive little added value for costly instructional technology. Business cases at www.i-Case.com add audio and video streaming to standard text without engaging students in active problem solving or collaborative learning.

Several efforts to arrange multi-campus simulated Model U.N. activities online have been short lived. The costs of televideo ISDN or satellite transmissions have been prohibitive. International text conferences on the
internet have provided a low tech alternative. Business faculty in Association Global View (www.globalview.org) create hypothetical scenarios for student management teams in different countries to negotiate contracts and trade agreements. Since the 1970s Project ICONS of the University of Maryland (Starkey, 1996; www.icons.umd.edu) has sponsored online negotiation simulations employing text exchange rather than videoconference technology. THRO seeks to have greater impact by bringing together students from different cultures in structured videoconferences that examine their distinct approaches to ethical reasoning.

A Unique Approach

THRO is unique in adding interactive self-assessment online, using actual situations, and providing a videoconference option made possible by Internet2. THRO currently provides eight active learning course modules that employ technology to improve not only critical thinking about human rights but also to facilitate student interaction with classmates, their instructors, and fellow learners in other countries. (See http://oz.uc.edu/thro.)

- Rape and Genocide in Rwanda: The ICTR's Akayesu Verdict
- Slavery in Burma? Doe v Unocal.
- Sanctions or Engagement: SLORC and Myanmar
- Business Ethics and SLORC: Unocal and the Yadana Gas Pipeline

Those cases have been successfully used for both video and text conferences connecting students from Cincinnati with classes in North Dakota and Ankara, Turkey. Specifically THRO targets undergraduate and graduate/professional courses in the social sciences, history, jurisprudence, philosophy, comparative religion, ethics, international studies and education. At a large university where commuter students rarely collaborate on educational projects outside of class, asynchronous communication in cyberspace can increase interaction with peers and faculty. (Bloom, 1956; Dewey, 1933; Gamson and Chickering, 1987; Perry, 1970; Romm and Mahler, 1986)

THRO capitalizes on the latest instructional technology to employ a unique combination of learning strategies—active, authentic, collaborative learning with educative assessment and cross-cultural exchange. Email exchange and electronic bulletin boards facilitate advance collaboration by students preparing as co-counsel for in-class role-playing. Videoconference simulation or online discussion with students from other institutions and countries also requires advance posting of advocacy papers in electronic text. THRO cases encourage students to become independent, learning from each other without relying exclusively on teaching professionals. The instructor's role shifts from a "sage on the stage" to a "guide on the side." Direct exchange with peers abroad stimulates more thorough preparation and a deeper understanding of the difficult quest for universal human rights norms. Engaging individuals from another culture encourages students to work through their own beliefs and assists them in understanding why others may see the world differently. Cross cultural dialogue based on THRO exercises could bridge the digital divide to include students at historically African-American institutions and also facilitate improved cross cultural interaction at universities with significant minority and international student enrollments.

Guided by a course instructor, students communicate with classmates by using an electronic bulletin board and exchanging email. At a large university where commuter students rarely collaborate on educational projects outside of class, asynchronous communication in cyberspace can increase interaction with peers and faculty. Teaching Notes for each THRO problem describe in-class role playing exercises that require advance collaboration online by student work groups. Properly used by a skilled professional, technology should enhance student preparation for in-class simulation and facilitate cooperative problem solving. The resulting classroom exchange should be more, not less personal.

New videoconferencing technology such as Polycom ViaVideo should provide considerably more valuable learning opportunities. Instructors can engage their classes in simulations and seminar discussions with students of different cultures. After examining a case problem from their American perspective, students can learn directly and personally how individuals of another faith or country assess the same situation. Synchronous text chat room interaction has become a common and all too often aimless exchange. Live video and audio transmission on the internet overcomes the anonymity and impersonal quality of text chat. THRO problems establish a structure for instructors to maximize the educational value of a live videoconference. Rather than dehumanize learning, video communication hardware should mediate face to face conversation between diverse groups whose members may
never travel abroad to meet in person. With desktop videoconferencing equipment an instructor can arrange personal interviews with academic experts and non-governmental human rights activists working on the issue.

Evaluation

During case development, THRO obtains formative assessment by peer review and pilot testing before a final version of each interactive exercise and teaching note become available online. Each THRO case was subject to peer review at one or more professional meetings that included the North American Case Research Association, 1997, 1999, and 2001; World Affairs Case Research Association 1998; International Studies Association, 1997 and 1998; International Political Science Association, 2000.

For overall project evaluation or summative assessment, an advanced doctoral candidate in education has used the Flashlight Student Inventory developed by AAHE to assess collaborative learning and changes in study methods by students completing the exercises in professor Tolley’s class. Statistical analysis of student responses to multiple choice self-assessment items identifies items by level of difficulty and ability to discriminate. Professor Wheeler has also completed preliminary research comparing students taught online and offline. Course instructors provide feedback after using THRO cases, and the project director monitors global use with software that tracks hits to each page in the web site.

Peer reviewed articles and book chapters about THRO (Tolley, 1998, 1999, 2000), conference presentations, [1] course adoptions beyond U.C., and grants from the U.S. Institute of Peace and Ohio Learning Network demonstrate growing acceptance and impact in several disciplines. THRO enables instructors to use classical forms of active learning--the case method, simulation, and Socratic dialogue—not only in the classroom but also in cyberspace communication between students of different cultures. Project THRO was recognized by the American Political Science Association as the best political science website for 2001.

Future

In 2002, the project will complete three cases under development providing distinct perspectives on the Unocal Corporation’s Yadana pipeline project in Burma/Myanmar—business ethics, claims of forced labor in U.S. courts, and U.S. sanctions policy. New cases are planned on the International Criminal Court and the death penalty.

The University of Cincinnati THRO project directors are committed to developing global distance education partnerships employing the most advanced instructional technology. The project will seek grant support to provide overseas partners with videoconferencing equipment. With external funding, one THRO exercise has been translated into Spanish and disseminated with the English versions both online and with an interactive CD-ROM. Future transnational conferences should enable multilingual students to debate issues raised in THRO exercises with peers in Spanish and French speaking countries. It might also be possible to obtain simultaneous translation during online conferences using foreign language majors or international students.

Ethnic hostilities, famines, arbitrary detention, torture, and killing of political dissidents and their families threaten both individual liberty and global security. Human rights education for the next generation of lawyers, teachers, politicians, journalists, and businessmen deserves high priority. Project THRO can pioneer a unique method of transnational education that moves beyond the Jessup international law moot court and undergraduate Model U.N. programs. Future transnational videoconferences will build key constituencies for a global civil society—advocates trained to bring human rights claims before national and international tribunals, leaders of nongovernmental organizations, teachers and professors, government officials and community activists.

Task-Generator: A Portable System for Generating Learning Tasks for Intelligent Language Tutoring Systems

Janine Toole, Trude Heift
Department of Linguistics
Simon Fraser University
Canada
{toole, heift}@sfu.ca

Abstract: This paper describes the Task Generator, a component of an authoring tool for an intelligent language tutoring system. The Task Generator automatically creates learning material from authentic texts. The architecture is designed so that it can be readily ported to create learning material for other languages, with minimal resource requirements. This paper reports on a recent study which evaluates the accuracy of the system.

Introduction

The goal of authoring tools for Intelligent Tutoring Systems (ITSs) is to reduce the cost in time and expertise that is required to produce a usable intelligent learning environment. This paper describes the Task Generator, a component of an authoring tool for an Intelligent Language Tutoring System (ILTS). The Task Generator allows teachers to automatically create learning material by merely specifying the learning objective and providing samples of text which are likely to contain examples of the learning objective. The primary advantage of the Task Generator is that the authoring tool is more usable since the tasks and expertise required of the user are reduced.

Since we have developed intelligent tutors for a variety of languages (English, German, Greek), the architecture of the Task-Generator is designed so that the system can be readily ported to create learning material for a variety of languages, requiring only those linguistic resources that can be expected to be widely available. The Task Generator is currently implemented for English.

This paper is organized as follows. Section 2 introduces the basic functions of the ILTS for which we created the authoring environment, and introduces the authoring environment itself. Section 3 describes the architecture of the Task Generator and its implementation for English. Section 4 reports on the findings of a study to evaluate the accuracy of the tool. Concluding comments can be found in Section 5.

Intelligent Language Tutoring Systems & Authoring Tools

The goal of the ILTSs that we have developed is to provide meaningful and interactive vocabulary and grammar practice for second language learners, as illustrated in Figure 1. Each system analyzes sentences from the student and detects grammatical and other errors (see Schneider & McCoy 1998). The feedback modules of the system correlate the detailed output of the linguistic analysis with an error-specific feedback message. Unlike other ILTSs (Gerbault 1999, Yang & Akahori 1997, 1999), in our system feedback is individualized through an adaptive Student Model, which monitors a user's performance over time across different grammatical constructs.

In order to make intelligent tutoring systems useful to a wide audience, it is necessary to have authoring tools which allow the tutor to be modified. Ideally the authoring tools can be used by the instructors themselves. However, as Murray (1999) points out, when developing authoring tools for ITSs there is a tradeoff between usability and flexibility.

We have argued elsewhere that in the language learning domain usability can be maintained without significant loss of flexibility. This paper describes additional means by which the usability of ILTS authoring tools can be increased. As a first step, the basic functions of the authoring tool we have developed are described. Following this, we introduce the issues which the Task Generator addresses.
The authoring tool, the Tutor Assistant allows instructors to create on-line vocabulary and grammar exercises for a beginner and intermediate language skill level. In addition, instructors can author teaching strategies and the student model.

When adding or editing an exercise, the instructor has two main tasks:
- create the student task
- list all the possible answers

The student task is a set of words and prompts that the student must use to complete the task. In the case of the Build-a-Sentence example, the student task lists the words that the students must use in their answer. The user of the authoring system can also add additional prompts like “simple past” to further restrict the student’s task, as illustrated in Figure 1.

![Image](image.png)

**Figure 1:** The ESL Tutor

Our previous studies have shown that ESL teachers who are inexperienced with both the authoring system and the ILTS, can develop one hour worth of learning material in about 2-3 hours. While this is a significant improvement over development times for authoring tools in other domains, the participants indicated they found some sections of the process difficult. In particular, they found it challenging to create student tasks which were varied, interesting and relevant. Significant time was spent thinking of relevant examples.

In order to alleviate this problem, and to decrease the overall development time for authoring learning material, it was decided to automate the process of creating the learning task.

The Task Generator

The goal of the Task Generator is to extract learning material from unedited texts. Unlike similar work by Kunichika et. al. (1998), the Task Generator creates examples from texts which already contain the target learning objective. Kunichika et. al. on the other hand, generate questions for reading comprehension from assertions existing in the text. The disadvantage of the Kunichika approach for the current task is that significant syntactic, semantic, as well as discourse information must be supplied - either automatically, or by the author.

This level of analysis is infeasible given the goals of our system. Firstly, our goal is to reduce the skill level and time required from the human authors. Secondly, from a computational perspective, one of the design goals for the Task Generator system is portability between languages. This is motivated by the fact that the system needs to be used by ILTSs from more than one language. Hence, in order to develop a system that is both usable and
portable, all of the task generation must be done by the system, and minimal linguistic resources should be used.

The Task Generator meets these goals. The user is required only to specify a particular learning objective, such as past tense, passive, or plural nouns, and to provide a range of texts which contain examples of the learning objective in use. Furthermore, the linguistic resources are restricted to a sentence boundary detector, a Part-of-Speech (POS) tagger, and a lexicon containing syntactic information. These resources are generally available for the more widely studied languages, and are what is minimally required to disambiguate the input text.

The overall architecture of the system can be found in Figure 2.

The first module of the system detects sentence boundaries, and separates the text into its constituent sentences. We use the MXTerminator system (Reynar & Ratnaparkhi 1997).

The next stage is the out-of-vocabulary (OOV) words filter. The ILTSs for which the learning material is being created perform significant linguistic analysis on the student input. Hence, all words in the task must be known to the ILTSs. The purpose of the OOV Filter is to remove sentences which contain out-of-vocabulary words.

The Part-of-Speech tagger assigns one of fourteen tags to each word token. The POS tagger is a Hidden Markov Model based on Church (1988). The tagger disambiguates the input so that the correct lexical information can be retrieved from the lexicon. Our lexicon is derived from the XTAG lexicon (Egedi & Martin 1994).  

The Learning Objective Filter removes all sentences which do not contain an instance of the specified learning objective. For each possible learning objective a Learning Objective Filter has been developed which specifies positive and negative constraints on the lexical entries that occur in a given sentence. For example, the filter for the Present Continuous learning objective specifies that the sentence must contain an auxiliary with a base form of 'be' and an additional verb in present participle form. It is also possible to specify a window within which the lexical items that match the constraints must co-occur.

The sentences remaining after the learning objective filter each contain at least one example of the learning objective. These sentences form the input to the Task Creator.

The Task Creator converts the sentence into one or more of the grammar-practicing exercise types used in our ILTSs: Build-a-Sentence, Fill-in-the-Blank, and Drag-and-Drop. The Format Specification file contains information about how the words in the sentence should be converted for each exercise type. In the case of converting a present continuous sentence into a Fill-in-the-Blank, the main verb is converted to base form, the auxiliary is removed, and the remaining words remain in their original form. This is illustrated in (1). In the case of converting the same sentence to Build-a-Sentence, a similar process is followed except that all words are converted to their base form, as illustrated in (2).

(1) But more than half also said they [save (present continuous)] for a dream vacation.
(2) but more than half also say they save (present continuous) for a dream vacation.

Evaluation

This section describes a recent evaluation of the Task Generator. The main aim in this study is to evaluate the accuracy of the system in producing learning tasks for the ESL Tutor. To this end, the accuracy of each individual component, as well as the overall accuracy of the system is evaluated. Since the OOV Filter achieves 100% accuracy (it is not a difficult task), this filter was excluded from the system for the purpose of the evaluation. This provided a wider range of input to the later parts of the system.

Procedure

The input to the Task Generator was 7,600 words from 13 texts that were selected by an independent analyst. The texts covered a range of subject areas from personal descriptions to family finances to net access for business travelers. Ten learning objectives were selected from the forty we have currently implemented. These were selected to include objectives for a variety of parts of speech, with an emphasis on the inflecting classes. The selected learning objectives are listed in Table 1. The input text was submitted to the system, once for each of the selected learning objectives.

Table 1: Learning Objectives Used in Study

Results

The performance of each system component can be found in Table 2. The accuracy of a component for a specific learning objective was determined by considering just those sentences that contained the learning objective. For example, the accuracy of the sentence boundary detector for the Passive learning objective was determined by evaluating all of the sentences that were identified as containing a passive construction. The percentages specify the percentage of sentences which were analyzed correctly by each component. The Correct column specifies the percentage of the created examples that are correct. The Total Produced column specifies the number of examples that were created for each learning objective - there is an upper limit of 150. Finally, the Total row provides the total calculated by averaging the original scalar values of each column (for reason of brevity original values are not provided in the table. They can be calculated from the information provided in the table). For example, in 99.5% of the tasks created, the Learning Objective Filter performed correctly.

Discussion

The results show that 90.8% of the examples produced were correct. In 8.2% of the cases, there was some error that was caused by one of the preceding modules.

By far the largest source of errors was the sentence boundary identifier. In 7.4% of the created examples there was an incorrect sentence boundary. This comprised 80% of the errors. A review of the data found that the detector we are using appears to rely heavily on periods and capitalization as an end of sentence identifier. In cases where periods do not frequently occur, such as at the end of headings, a sentence boundary was omitted, leading to...
problems such as (3). In addition, there were cases with a period and appropriate capitalization that were not identified as sentences. Hence, in order to increase our overall accuracy, an improved sentence boundary identifier is required.

Table 2: Results

(3) Effective vs. Ineffective One way to distinguish effective from ineffective employees is in how they act and react to the demands of their positions.

The remaining modules each achieved very high accuracy. The tagger performed extremely well, except in the case of the verb agreement category. In this case, the tagger occasionally incorrectly tagged a noun as a verb. One example is the input given in (4). In this case the noun Hikes was tagged as a verb. This is not surprising since the input is not a complete English sentence. This type of error accounted for three of the six tagging errors. In order to reduce this type of error it will be necessary to include filter mechanisms that exclude input items which are not complete sentences. The existence of an increased proportion of punctuation and capitals may provide sufficient indication of this.

The Learning Objective Filter also performed very well: the only source of error was with the singular pronoun filter. In three cases this filter incorrectly identified cases like (5) as containing an example of the singular pronoun it. In each case the actual word was an acronym. A solution to this problem is to consider capitalization as a factor in the learning objective filters. At present, the filters only place constraints on information that is present in the lexical entry for this word.

(5) The most significant case is that of Lois Fraxhi, an IT manager who was sacked for using the Internet during her lunch break to track down a bargain holiday.

The final source of error in our system is the lexicon itself. Firstly, the lexicon incorrectly identifies modest as a superlative adjective. An example is given in (6a). Secondly, the lexicon incorrectly lists the base form of lower as lower instead of low. An example in (6b). These two errors accounted for all of the five lexicon problems.

(6a) They tend to defer to others, are less likely to take risks, are modest superlative adjective] and cautious, and try to avoid conflict.
(6b) People with lower comparative adjective] dominance are congenial and cooperative.

2 This example also has an incorrect sentence boundary. The CALIFORNIA is a heading.
We are very encouraged by these results. With the exception of the examples influenced by the sentence boundary detector, the Task Generator is highly accurate. In particular, the shallow approach to analyzing the sentence has proved sufficient for the purposes of producing learning tasks for a specific learning objective.

Our analysis of the data indicated several areas for improvement. Firstly, the sentence boundary detector needs to be significantly improved. The detector needs to be able to deal with text in context i.e. text that includes components such as headers. Secondly, an additional module is required in order to filter sentences that have an unduly high proportion of capitals and punctuation. This should reduce the number of tagging problems. Thirdly, we need to update our language for stating learning objectives so that word capitalization can be used as a constraint.

Having established the reliability of the Task Generator, a next task is to integrate the system into our ILTS authoring tool. This will allow us to conduct studies with real users of the system. Our goal will be to establish to what degree the Task Generator affects the authoring process.

A further goal is to establish the portability of the system by porting it to German. While the language-specific resources must be replaced, it is expected that the rest of the system should need no modification.

Conclusion

This paper introduced the Task Generator, a component of an authoring tool for intelligent language tutoring systems. The Task Generator automatically creates learning content from existing texts. In order to ensure portability, the system is designed to require minimal linguistic resources. The current version of the system requires a sentence boundary detector, a POS tagger, and a lexicon with syntactic information. The results show these resources are sufficient to automatically produce learning content for a range of learning objectives.

References

Abstract: This paper summarizes a study conducted with Faculty of Education students preparing to teach Junior/Intermediate Visual Arts. The study investigates the potential and issues of computer-based systems to present and discuss theoretical material within a particular community context. The results suggest that active participation in threaded discussion is predominantly driven by reward motives such as grades, and that students do not normally participate beyond the minimum course expectations. Passive participation in the discussion areas such as browsing and reading was difficult to evaluate and document. Findings indicate that discussion tied to real-world experiences have a greater level of participation.

Introduction

A learning community is a group of individuals engaged intentionally and collectively in the transaction or transformation of knowledge. Building an online learning community is not an organizational problem — the problem is one of motivating participants to create a community and giving them an opportunity to do it (Schwier, 1999). Clark (1999) uses the apt term “growing” in place of “building” or “constructing” to emphasize the organic nature of this type of work. Research on online learning communities has established the significance of providing an appropriate structure for discussion. Once such structure is the threaded discussion database, which facilitates an ongoing exchange of topical information among students enrolled in a course. For this particular study, a threaded discussion database was created to support a thought-provoking and offline art project with the expectation that the addition would create observable differences in the responses of the community.

The Study

The community for this study consisted of 179 Junior/Intermediate, Faculty of Education students enrolled in a Visual Arts course as part of a traditional B.Ed. program. Each student had completed a three- or four-year undergraduate degree. The class list indicated that the sample group was divided into 107 females and 72 males. Thirty of the 127 students were Visual Art majors.

A Web browser was the only required interface for the students. The students interacted throughout the school year with three discussion databases using text format only. The first threaded discussion assignment, Readings Discussion, instructed the students to initiate a discussion related to one of the assigned readings. Each student was also responsible to read the postings by other students and to respond to at least one posting. The second threaded discussion, Ask an Artist, was compulsory only for the 30 art majors and was available to the non-art majors as a resource area, where they could ask the art majors and instructor specific questions to assist with teaching art during their practice-teaching sessions. The third threaded discussion, Stick Project, was set up as a crossover project with B.Ed. students taking a Language Arts class. The same level of participation was required for this project as for the Readings Discussion, a minimum of one posting and one response.

Findings
A minimal level of participation by the students was expected due to the heavy course load of the program and practice teaching sessions. The access logs on the server indicated the number of times the database was accessed, but provided no true indication of level of participation. The results, however, indicate a higher level of interest in reading rather than posting. The higher level of "lurking" to posting corresponds with the instructor’s observation that the majority of his students did not feel comfortable participating in threaded discussions. All students, regardless of their Visual Arts background, demonstrated a lack of confidence in the two databases that required participation for course credit. The students met only the required number of posts. In their messages, they expressed concern about whether their answers were right and appreciation for the examples of good submissions provided by the instructor. The instructor noted that the number of quality submissions exceeded his expectations for the Stick discussion, but not for the other two databases. A survey distributed to students indicates that the majority of them agreed that the Stick crossover discussion allowed more room for creativity and individuality.

Conclusions

- Threaded discussions should be structured to be very simple. One way to do this is to create multiple discussion areas; for example, one for each project in the course, or one for each week in the curriculum. The instructor should state clearly to students the protocol for using the discussion areas (minimum number of posts, participation grades, timelines, etc.).
- The ratio of one instructor to many students creates a situation where topics or directions can be overdone very quickly by the students and become stale. As part of the protocol for online discussion, the instructor should clarify for students that they should not contribute to a discussion thread unless they have something of value to add.
- Discussions on topics chosen by students – for example, related to overcoming the challenges of their course projects – are more lively and productive than discussions on topics required by the instructor.
- The workload on the instructor to provide more material online, monitor discussions, close topics, and provide fresh starting points is substantial compared to the traditional classroom. Universities should recognize this in their collective agreements and compensate accordingly.

Barriers in Using Technology

Burcu Tunca
The George Washington University
Washington, DC
USA
btunca@gwu.edu

Introduction:

Today's children are raised in a generation of "digital age" (Hruskocy et al. 2000). The new digital technologies provide faster links to the world and from agriculture to medicine, all areas are implementing technologies. Therefore, this age's children's future, employment is dependent on how much they can implement technology skills and transfer those skills into their content is becoming more and more important. In order to do this they depend on their teachers. That's why we have to look into the barriers in using technology.

It has been observed that the schools are trying their best on the hardware part by replacing the old machines with the new ones and even purchase more computers whenever they have the budget. On the other hand, it has been observed that technological readiness of America's teachers to use these new technological tools is very low. According to a 1999 National Center for Educational Statistics Study (in Haselbring et al, 2000), only 20% of all teachers feel very well prepared to integrate technology into their teaching. As Ertmer mentions (1999), although teachers recognize the importance of integrating technology into their curricula, they are limited. In the literature these limitations are called as internal and external barriers. Although the barriers are common in other studies, they are not always classified as Internal and External Barriers. However, I find that it would be a good idea to explain them under these two headings. Ertmer (1999), also mentions that training programs, recently, have incorporated pedagogical models of technology use as one means of addressing internal barriers. If pre- and in-service teachers are to become effective users of technology, they will need practical strategies for dealing with the different types of barriers they will face.

As mentioned above, the barriers are not always classified under the two headings in all studies but it is helpful to classify them as the “internal” and “external” barriers.

External Barriers:

Means and Olson (1997) describe external barriers as the types of resources like equipment, time, training and support that are missing or not provided adequately in teachers' implementation environments. External barriers to technology integration are described as being extrinsic to teachers and include lack of access to computers and software, insufficient time to plan instruction, and inadequate technical and administrative support (Ertmer, 1999). She also adds that teachers have to acquire technical skills needed to operate a computer. Dias (1999) also mentions the importance of external barriers. He says that the most common barriers include time, training, resources, and support. Teachers need time to learn how to use both the hardware and software, time to plan, and time to collaborate with other teachers. According to him another concern is training. Some educators do not have local training options available or the time to attend training. There is also the problem of lack of resources. Without computers in the classroom and appropriate software to support the curriculum, integration cannot take place. Support is critical as well. Lack of leadership, financial support, or an on-site technology expert sends many integration efforts into a tailspin. However, there is a very important factor that should always be kept in mind especially when dealing with technology and that is "time" and "change in time".

Internal Barriers:

Brickner (1995) defines internal barriers as the barriers that interfere or impede fundamental change. They are intrinsic to teachers and include beliefs about teaching, beliefs about computers, established classroom practices, and unwillingness to change (Ertmer, 1999). Kerr (1996) adds that these are rooted in teachers' underlying beliefs about teaching and learning and may not be realized by others or even by the teachers themselves for sometime. Internal barriers change fundamental beliefs about current practice, thus leading to new goals, structures, or roles (for example,
electronically conversing with an author to explore the cultural and political context of a story rather than writing a book report summary). Current literature shows that internal barriers are common among today's teachers (Hannafin & Savenye, 1993; Kerr, 1996; Riedl, 1995).

**Suggestions to overcome the barriers:**

Here are some suggestions that are compiled from different articles that I read:

- Professional preparation programs should continue to emphasize technology skills preparation within their preservice curriculum. Special attention should be given not only to use of computers in administrative tasks but should include how effectively use technology to enhance instruction. (Dorman, 2001)
- Faculty in schools or colleges of education preparing educators should integrate technology use within their professional preparation courses by modeling appropriate use of technology. (Hruskocy et al, 2000)
- Teacher candidates should be exposed to technology based curriculum materials and products within their preservice period. (Abdal-Haqq, 1995)
- Special attention should be given to field placements and internships to ensure students are placed in a technology-rich environment where supervising teachers are actually using technology in their classes. (Hruskocy et al, 2000)
- Experienced teachers may lack the formal training to feel comfortable using the computer in the classroom. Therefore, in-service programs featuring use of technology to teach about their content should be provided. Where possible, teachers should be given release time and support to develop technology skills. (Grooves & Zemel, 2000)
- Curriculum planners and product developers should consider innovative ways to enhance the learning about their content by using technology in creative ways. (Hruskocy et al, 2000)
- Technology enhanced curriculum products should be an integral part of a planned approach to learning about the content. This effort will assist teachers to use technology for instructional activities in addition to aiding with administrative tasks. (Dorman, 2001)

Most of this section comes from Byrom's article (1998): heightened abilities to collaborate in performing tasks He adds that designating appropriate assessment strategies helps teachers look for evidence of deeper understanding, statements of relationships, synthesis, and generalization of ideas to new domains. These kinds of strategies often include writing samples, student products, and portfolios. (Byrom, 1998)

**Conclusion:**

Technology integration into teaching is one of the goals of educators. However, teachers today face with various barriers as explained above. Although there has been some research done on barriers in using technology, the field still needs more research as technology develops so fast and the skills and the hardware that are used change so quickly as well. In order to catch up with the speed of this technological development, professional development training programs should always be kept up to date and be continuous. There is still need for study on:

- teachers' use of advanced education technology and barriers in using them,
- professional development and technical support strategies for enhancing teachers' effective use of technology

On the other hand, the biggest challenge for most of the teachers is to learn to use new technology tools and take major steps to change their classroom practices. (Ertmer, 1999) However, we can overcome these barriers if teachers are well prepared against them with effective strategies.

The Relevance of Haptic Experience in Remote Experiments

Jörg Tuttas Bernardo Wagner
University of Hannover
Learning Lab Lower Saxony (L3S)
Expo Plaza 1
30539 Hannover
Germany
tuttas@learninglab.de wagner@learninglab.de

Abstract: Experiments are an important part in technical education to improve understanding of the theoretical content. In the last years efforts have been made to provide access to real experiments via Internet (Aktan et al. 1996; Wagner et al. 2001). Unanswered is the question on the effects of learning outcomes, the problem solving process, the acceptance and the motivation of these non haptic experiments with their reduced focus of real world experience.

In this paper we describe the didactic concept of our remote lab and the evaluation framework for an empirical study which aims at examining the effects of the haptic component on problem based learning in remote laboratories.

The Remote Experiment

In our remote experiment for learners of process control at technical schools the learners have to develop and upgrade a program for an industrial controller (PLC) that controls a process engineering plant. In this process a fluid can be filled into the two tanks and heated or mixed in the reactor below.

The learners process the reaction of their program on the process through a remote controlled web cam. To access the lab devices the learners only have to run a web browser.

Didactic concept and task structure

The didactic concept in our remote lab course is orientated on problem based learning (see Norman 1991). The experiment is done in small groups of two or three learners. They are guided through the experiment and get additional information from a web based course. The course is structured in two parts. The first part is divided into three subtasks with increasing aspiration level. The second part is a thematic structured knowledge base of the content for explorative learning. Designed as a guided tour through the subject matters we address three different types of learners. The practically inclined learner may start with an example, the analytically inclined one with a description of the structure of a PLC-program. Learners who already have gained experience with PLC program development may choose the third, the quick path being offered.

In the beginning of the experiment the learners have to find an error in a controller program (remote diagnostic task). They have to read the data sheets of the actors and sensors in the system and understand their relation to the given program. They have to correct the program, upload it to the controller and examine the function of their solution at the plant by using the web cam (remote maintenance task). During their next steps they have to upgrade the program and include functions additional for a local operation unit (see figure 1) and a “notification of fault” function.

Evaluation Approach

To evaluate the relevance of the haptic experiences in our experiment we made a comparative approach, where the learners execute the experiment in three different settings (see table 1).
Setting | Description
--- | ---
Local learning setting | The conventional learning setting, where the learners and the experiment are in one room.
Remote learning setting | The group of learners are separate from the experiment.
Distributed learning setting | The learners are distributed and collaborating by synchronous tools like chat or video conferencing.

**Table 1: Variation of the learning environment**

All groups have the same devices (for the local group they were 'real', in the other two settings they were 'virtual' for the groups) and the same lab exercises. But only in the local learning setting the students had the full sense of impression of the lab devices and of the other learners.

**Figure 1: Local operating unit and Virtual operating unit**

**Evaluation Methods and Data Acquisition**

Our three different learning settings have one evaluative question in common: How far does a loss in haptic experience affect the outcomes of the learning process to be achieved? To measure the increase in knowledge we will carry out short pre- and post tests. To evaluate the quality of the problem solving process, we will observe the learners’ activities during the experiment by means of a self-developed evaluation tool that enables the evaluator to write down the activities of each learners’ group into a database. Additionally, we will analyze the server log data by another self-developed tool to trace information about the ways a group of learners took through the web-based course and for how long they stayed in each chapter. At the end of the lab exercise all learners will have to answer a questionnaire gaining subjective information about their acceptance and motivation during the experiment.

The collected data will give us the possibility to compare the outcome of the learning process, the structure of the problem solving process as well as the acceptance and motivation in the three settings.

**Conclusion**

Setting up remote experiments raises many questions in the field of education. One of the main questions is: How the loss of haptic impression change the learning effect. Special areas of interest are the acceptance, motivation, learning outcomes and quality of the problem solving process. Currently we are acquiring data in three classes with about 75 learners in vocational schools. Our aim is to find out if Remote Labs are a suitable way for problem-based learning compared to traditional experiment settings.

Evaluating the Effectiveness of Online Courses

Hakan Tuzun
Instructional Systems Technology Department
Indiana University
United States
htuzun@indiana.edu

Abstract: Evaluation is needed to justify the existence of online courses and to provide feedback on the performance of them. In this study, Kirkpatrick's 4-level evaluation model is proposed as a framework for the evaluation of online courses. The model and procedures are explained for collecting and analyzing data at each of the four levels for the ultimate purpose of the evaluation of online courses.

Introduction
Once the design, development and implementation of an online course are completed, it is time to evaluate it. Evaluation is needed to justify the existence of the online course and to provide feedback on its performance. Historically, educational perspective has treated the evaluation as the measurement of learning (Hawthorne, 1987). However, in the corporate environment, evaluation focus has been on the enhanced individual and corporate performance. Evaluations of corporate training have traditionally asked four questions. The purpose of this study is to evaluate the effectiveness of online courses by adapting these four questions asked in the corporate environment: 1) What the learners liked and disliked about the online course, 2) The amount of learning that occurred as the result of the online course, 3) To what degree learners have transferred the course attitudes, skills, and knowledge successfully to their jobs, and 4) What Return on Investment (ROI) have the learners' affiliates received due to participation in the online courses? There are various evaluation models, which can answer the questions above. Kirkpatrick's model will be used for this study, which is a widely used method of evaluating corporate training programs (Basarab & Root, 1992). Kirkpatrick developed a series of levels to use when deciding the type of data to use and the timeline for collecting evaluation data. In his model, Kirkpatrick calls for four levels. Levels 1 and 2 are formative and levels 3 and 4 are summative.

Methodology
Data Collection Procedures
Level 1: Reaction
A standard reactionnaire form completed by all learners will gather data to implement level 1 evaluation. All learners will complete the level 1 reactionnaire form prior to finishing the online course. The questions used on the reactionnaire will evolve from interviews with online course stakeholders and observations made by the researchers. Sample questions that might be included are: 1) How did the learners feel about the quality of the subject content, library services, the online learning process, and assessment tools? 2) How did the learners feel about the sequence of the materials? 3) How did the learners feel about the quality of online mentors' availability, answering questions, and knowledge of subject? 4) How did the learners feel about the course objectives as they relate to the learners' job requirements, and the applicability to the learners' job?

Level 2: Learning
The researchers will look for answers to the following questions at this level: 1) By learning objective, what skills and knowledge were acquired in the online course? 2) What amount of learning occurred after the online course? A pre-test and a post-test will be administered for the online course to evaluate the amount of learning gained from the online course in the short term. Online course developers will create the pre-test and post-test instruments.

Level 3: Behavior
Since the learners cannot apply what they learned until they have an opportunity, the measurement of transfer of knowledge, skills, and attitudes can only be done in the long-term. The researchers will look answers to the following questions at this level: 1) How many times have the learners applied course objectives on the job? 2) What are the reasons for not applying the behavior on the job? 3) How the online course impacted the learners' job performance? 4) What skills have learners had to learn on their own to perform a required job
behavior that the online course did not provide? To answer these questions, all learners will complete a post-course questionnaire three months after the course’s completion. The researchers will get additional information by interviewing the people around the participant such as immediate supervisors, subordinates, and peers.

**Level 4: Results**

For online courses, which don’t have tangible results and therefore a measurement in terms of dollars and cents is not possible, the researchers will observe the learners in the workplace. When performing cost/benefit analysis seems logical, the researchers will still observe the learners, but they will also use the causal model and ROI model to find out if it has been worthwhile to spend money on the online course. The researchers will look answers to the following questions when the causal model and ROI model are used: 1) What was the cost of online course for the learners’ companies? 2) What value the companies has received due to the online course? 3) What is the ROI from the online course?

**Data Analysis Procedures**

**Level 1: Reaction**

The researchers will summarize data from reactionnaires finding an average mean score for each item. Patterns will be detected in the open-ended questions.

**Level 2: Learning**

Statistics calculations such as mean, standard deviation, and t-score will be performed on pre-test and post-test scores for the online course. Using .01 level of significance, t-scores will be performed on pre-test and post-test results to see if the learning gain from online course is a true representation of learning. The percent of gain score indicates what percentage the participant has learned as the result of the online course. After gain scores are computed for each participant for the online course, the average percent of gain score for that online course will be computed. Item analysis of pre-test results will be performed to evaluate what learners knew before entering the online course. Based on this, recommendations will be made to modify course objectives and course content. Item analysis of post-test results will be performed to evaluate what objectives the learners could not master. Based on this, recommendations will be made to modify course content.

**Level 3: Behavior**

The researchers will compile the results of the questionnaires sent to the learners. To do this, data from questionnaires will be summarized finding an average mean score for each item. Patterns will be detected in the open-ended questions. The researchers will compile the results of the interviews made with the people around the learners. The interview records will be transcribed and analyzed to compare the behavior of the learners before and after the online course.

**Level 4: Results**

The researchers will analyze the observation records of learners to detect end results gained by the company. If the casual model and ROI model are used, the mean of sales/income for the experimental group and the control group will be calculated. The mean of the control group sales/income will be subtracted from the mean of the experimental group sales to find the value of training. This will be divided by the cost of the online course to find the return rate spent on each dollar. Due to lack of pure experimental design, the researchers will make judgments after the comparison of the data, and will not try to prove its statistical significance.

**Conclusions**

The data collection and data analysis techniques described above are generated based on the key characteristics and assumptions of Kirkpatrick’s evaluation model. The described procedure does not yet have a strong empirical foundation to support it. Empirical work is needed to understand if the proposed model works.

Instructor Support in Web-Based Instruction

Hakan Tuzun

Ozgul Yilmaz
Science Education Department
Indiana University
United States
oyilmaz@indiana.edu

Abstract: In this study instructor support problems related to the Web-Based Instruction (WBI) were identified after examining their experiences. It was found that the instructors need support in the area of hardware, software, design of the course, and handling student requests. In addition to this, it was also found that web-based course instructors will benefit from the knowledge management support, peer support, support for cooperation with school technology services, and web-based related research support. At the end, we propose a model for a support center for web-based course instructors.

Introduction

Using the Internet for different purposes has entered a revolution during last two decades. Especially, after the development of the hyperlink on the World Wide Web (WWW), the Internet has offered more user-friendly environments (Starr, 1997). Researchers indicated that WWW is not only a communication medium for e-mail and document distribution but it is also a place to learn (Lightfoot, 1999; Mioduser, Nachmias, Lahav, & Oren, 2000). With the combination of the specifically designed software and pedagogy, WWW can provide an educational environment that maintains the knowledge building approach to learning. These understanding, technological developments in communication and WWW have been used as new opportunities for delivering instruction online. Thus, web-based distance learning has emerged as an alternative approach to education in the last few years (Yellen, 1998). Especially for graduate students, universities have started to offer online courses (Barnard, 1997; Duchastel, 1997; Kearsley, Lynch, & Wizer, 1995). These practices in new educational agenda initiated some questions on researchers' mind. Support in web-based courses is one of these questions.

Researchers examined the support issue in web-based courses usually from the perspectives of distance education students. Paneitz (1997) made a research to assist community college personnel in the development of relevant student support services for web-based course students. She found academic advising as the most essential student service for students. Other essential student services were found as access to library and media services and counseling. Hudson (1999) equalized the progress of a web-based course with supporting the learner. The support for their adult learners included an on-site orientation at the beginning of each semester, a support CD-ROM developed by school's distributed learning office, student peer assistance through a help forum, teaching interns, and paid graduate assistants.

Lever-Duffy (1992) stated that a WBI program will not be functional without proper support. They indicated the support for instructors is a prerequisite for interactions between the instructors and the students. Their project recognized the need for support in four specific areas: technical support, technology training support, instructional design support, and staff support. Technical support included such tasks as network maintenance, hardware installation and repair, software installation and maintenance, and helping through an electronic help desk. A qualified technical staff specialized in each of these areas provided the technical support. Technology training support serves for two kind of audience: students and instructors. The technology training reduces the threat and interference of the technology for both kind of audience. Instructional design support is required to design web-based courses which differ from residential courses in the unique delivery style. Finally, the staff support facilitates the communications and trades between the department and distant student in terms of administration. Secretarial and clerical staff can handle information flow and clerical tasks.
Para-professional staff can assist instructors with student load. The research published by Lever-Duffy identifies the most detailed information to date related to the support of web-based course students and instructors. However, she did not provide information on how she has foreseen the support in four specific areas.

There are also some research papers in the literature that included minor information about supporting the web-based course instructors. For example, Kuchinke et al. (2001) received support from a technical support team consisted of six half-time staff with expertise in web design and development. A full-time academic professional directed the support team. While Friedrich and Armer (1999) developed a web site for a graduate course in statistics and measurement, an instructional designer/developer was assigned to each faculty member on a part-time basis to help with the technical aspects of the course. According to the authors, universities should support web-based course instructors by providing training to them. This training can inform the instructors about the types of technologies that exist and provide information related to the instructional design and development. Some studies mentioned lack of instructor experience in WBI as a problem (Lightfoot, 2000; Friedrich & Armer, 1999). Some authors recommended creating a permanent instructional design team and technical support team to overcome this problem (Ingebritsen, Brown, & Pleasants, 1997; Kuchinke et al., 2001). Ingebritsen et al. (1997) utilized a resource center for the development of their biology course on the Internet. The purpose of this center was 'to assist faculty in the development of on-line courses by providing technology resources, technical assistance and training'.

Motivation for the Work

The review of the literature reveals that there is not much information in the literature on the topic of supporting web-based course instructors. The purpose of this study is twofold: to present the support needs of the instructors in web-based courses and to develop a support center model. The results might help those actively involved in educational use of the Internet research, those participating in the development of web-based courses, and finally those who are teaching web-based courses.

Methodology

Research Questions

Is there a need for a support center for web-based distance courses?
What kind of support do web-based course instructors need?
What are the functions of a support center built for web-based course instructors?

Participants and Context

In this study, two instructors from a large mid-western university were interviewed. Instructors were selected with purposeful sampling. Since the nature of this study is qualitative, participants were selected according to their previous experience with the WBI to get deep and broad understanding about their support problems related to WBI. It was required for the instructor participants to teach at least one Web-based course. Instructors were the members of the same university, but none of the participants had a relationship through the courses.

Instructor1 was a non-native speaker of English and he was an Al in the Informatics department. He taught a web-based course three years ago. The students took this course within another country while the instructor was in US. The course was related with courseware design for computer mediated learning. It was at the graduate level and 10 students took the course. The course was offered in an instructional technology department. There was another instructor for the course.

Instructor2 was a native speaker of English and she was a faculty in an Instructional Systems Technology (IST) department. She had already finished the first nine weeks of her web-based course when the interview was conducted. Instructor2 taught 2 courses. One of the courses aimed to provide an introduction to the field and profession of instructional technology. The other course provided information on the instructional design process. Both courses were at the graduate level and they were part of an online master’s program. The courses were offered in an instructional technology department. There were 1 instructor and 10 students in the first course, 2 instructors and 18 students in the other course.
Data Collection and Data Analysis

Semi-structured interview questions were used to collect interview data. Interviews were conducted over a one month period. Each interview session was treated as an individually constructed discourse between the researchers and the participant. Both open ended and probing questions were used to get deep information. The study called for an in-depth understanding of the experiences of participants involved in WBI. Instructors' data were analyzed separately from each other. All data were transcribed from audiotapes for analysis. Then, researchers struggled to understand the context, discourse, and meaning behind the participant responses to determine the main areas about which respondents have problems with support in WBI. To increase the credibility of the study, participants' responses were coded by both researchers separately. Later, common themes accepted as the emergent categories. In addition, the data obtained from the literature was used for detailed interpretation of the results.

Findings

1. Is There a Need for a Support Center for Web-Based Distance Courses?

After the interviews it was clear that without adequate instructor support, web-based courses would fail. The instructor of web-based course, one way or other, will either find the required support for his problem, or there will be problems in the web-based course. This result is also aligned with Lever-Duffy’s (1992) findings in that support for web-based course instructors is a vital element for the success of the online courses. Both of the instructors indicated that they did not have a support center for the instructors of web-based courses. They both agreed that the lack of instructor support created major problems for their courses:

Instructor1: The biggest problem was the support problem. Since I was alone as the instructor, I had to arrange everything.

Instructor2: Every week there is a new problem, which really points to the fact that there is a lack of support for faculty for teaching online. ... Lack of support for faculty teaching in online environments is a huge problem.

Also, the instructors dwelled upon the importance of a support center for web-based courses:

Instructor1: Dealing with both the technical aspects of the course and content aspects of the course is an exhausting process. Personally, I prefer to teach in an environment where there is a support for non-teaching tasks. Because, giving feedback to students, getting together online, and grading the assignments are already very time consuming. If you add technical things on top of these, you are pretty swamped.

Instructor2: We need training and support for faculty teaching in an online environment. The combination of 3 issues, lack of faculty training, lack of faculty support, and a design process that lacks faculty buy-in, are the reasons for a lot of problems that are beginning to emerge [in our distance master's program].

2. What Kind of Support Do Web-Based Course Instructors Need?

The support needs of web-based course instructors will be summarized in the following categories: where to get support from, support for hardware, support for software, support for design of the course, and support for handling student requests.

2.1. Where to Get Support From

When the instructors got into problems and needed support to solve them, they tried several mechanisms. For example, instructor2 mentioned 11 instances where somebody came and supported her with different aspects of the course. These aspects included design support, and technical support. Below are 2 excerpts from the instructor2 on this issue, one for the design support and one for the technical support:

Instructor2: Even though the documentation was written, Dreamweaver was a brand new program for me. Thankfully, [the person who produced the course with dreamweaver] came in, spent about 15 minutes with me showing the basics to me. And that helped tremendously. And she was available during that period for a while. If I run into problems, she would allow me to call and [ask for support]. That whole process went fairly smoothly thanks to [this person]. That could have been worse.
Instructor2: The audio problem in PowerPoint was a problem that I don't even think design team could have perceived. It has taken all these weeks, just for [Person1] and [Person2] working together to figure out how to fix it.

Instructor1 had advanced technical skills. For that reason, he did not need much external support. However, he stated that the situation would be different for people with low technical background.

Instructor1: I didn't have many technical problems, but the reason for that is I have a good technical background. However, for somebody who has not as many technical skills as mine will suffer a lot from the lack of technical support.

2.2. Support for Hardware

Instructor2 indicated that she was not able to have a Macintosh computer (which she was used to using) at the beginning. Because of the lack of this, she had a lot of communication problems with the students. She had to provide feedback much later than her planned time frame.

Instructor2: I supposed to have a Macintosh computer [when I started teaching]. And there was a PC here, so I didn't have the right computer. Later I got a Macintosh computer but it was also having all sorts of problems.

2.3. Support for Software

One of the biggest time consuming tasks for the web-based course instructors is making the software feasibility analysis:

Researcher: Did you have any problems with software?
Instructor1: I didn't have a problem with using the software. I had to look for software functionally appropriate for the course. For example, the kind of chat software, and the kind of whiteboard software to be used during the course. There were several freeware software available, but I had to evaluate them to see their powerful and weak sides. I could test the software one-on-one with someone, but I had no idea what would happen when 10 student will be using the software.
Instructor2: Software was available only if I took the time to track it down. It would be nice to look beyond the tools that have been already used in the courses. I know there are better tools out there. But the time is limited to find them.

Learning new software also creates problems for instructors if they learn them while teaching web-based courses. They need support from the people who know these software:

Researcher: How about learning new software?
Instructor2: Yes, because I had to learn Dreamweaver and I did not have the application, so I needed to track down getting the application from one of my friends. Even though the documentation was written, it was brand new program for me.

2.4. Support for the Design of the Course

Instructor2 had to deal with the re-design of the course during the course delivery. This increased her task load for the course incredibly. To overcome the instructor related issues, she had to hire someone. Otherwise, she would not be able to keep up with the instructor tasks. She explained the design problems as the following:

Instructor2: ... The other big and huge problem was eliminating the design problems. ...So, you can go through the whole week then look how to fix it. That has been very time consuming for me. Probably more time consuming than any other thing that I have done for the course. I have been doing the redesign of the web pages and then going through and editing the lessons, and the visual parts of the lessons.

Instructor2: [The time spent for the preparation for the course is] absolutely unreasonable. I spent 30 hours every weekend just doing the revisions, so that lesson could be ready before Monday 8:00am. That even doesn't count the other times during the week that I spent on [the design]. It is taking an unbelievable amount of time.

2.5. Support for Handling Student Requests

Both instructors utilized support personnel hired for handling student requests:
Instructor1: On-site technical support for students was an important issue. Therefore, someone was arranged to support the students in the computer lab. For example, he showed people how to use the Paint Shop Pro software, and how to use the scanner. After the course was over, we concluded that such a support for handling student requests was important. Lack of such a support would increase the load of the instructor.

Instructor2: There are 2 distance master graduate assistants who handle all the administrative type of things. The instructor should only receive issues related to the content and the class. Graduate assistants handle any administrative tasks like books, registration, technical issues, all that are not supposed to be instructor’s problem.

2.6. Support in Other Areas

In addition to the five areas described above, it was also found that web-based course instructors either received support or would like to receive support in the area of knowledge management, peer cooperation, cooperation with school technology services, and web-based related research. Limited space prevents giving more information on these issues.

3. What Are the Functions of a Support Center Built for Web-Based Course Instructors?

A Support Center Model

Finding support when they are in need is the biggest problem for the instructors teaching web-based courses. Since they do not know what kind of problems they will have during the course, it is difficult for them to be prepared against these problems in advance. After analyzing the interview data, we came up with a support center model for web-based course instructors. This model is shown in (Fig. 1).

Figure 1: Support center model for web-based course instructors

In this model, we divided the support for the instructors into two categories: support for hard technologies and support for soft technologies. Support for hard technologies make up the nucleus of the model, because hard technologies are the essential elements of web-based courses. Hard technologies include the area of hardware, software, and network. These three essential elements provide the backbone, on which the web-based course system resides. All of these three elements have equal importance since lack of any of them will result in failure on the backbone. In sum, providing support for all of these three elements is essential. Although the model is open to development, we expect no major modification to the nucleus of the model in the near future.

The two circles around the center constitute the support for soft technologies. We define soft technologies as a combination of all elements that go outside the nucleus. The inner circle contains essential soft technology elements to be supported. These elements are support for design, support for orientation, and
support for handling student requests. When support for any of them is missing, there is a high possibility that the web-based course will fail. The dashed nature of the inner circle represents the fact that the model is open to development, and items might move away from the inner circle, or new items might be added to the inner circle. The outer circle contains non-essential soft technology elements to be supported. These elements are support for knowledge management, peer support, support for cooperation with school technology services, and support for web-based related research. It is useful to have support for these items. When support for any of them is missing, the web-based course will not fail. The dashed nature of the outer circle represents the fact that the model is open to development, and items might move away from the outer circle, or new items might be added to the outer circle. The two-way arrows also represent the openness of the model to further development. They show that soft technology support elements in the circles might become essential or non-essential or even obsolete in time. Or, new elements might be added as soft technology support elements. We think that the future modification and development of the model depends on the changing needs of instructors in parallel to the advancements and changes in Web-based course technologies, and also to the roles of instructors in web-based course environments.

Conclusions

For web-based course instructors, support should be provided on time and when it is needed. Hard technologies are the only way to communicate with students, which is essential for web-based instruction. If instructors have difficulty in obtaining the support on time, their communication with students can be disastrous. Students can easily drop the course just because of this. The designers of web-based courses, and especially the coordinators of web-based courses should understand that supporting the instructors is as important as supporting the students. The following phrase emphasizes the importance of this issue:

Instructor2: I probably had 100 times problems the students had.

The proposed support model for web-based course instructors provides a framework for supporting the instructors. It is up to the coordinators and designers of the web-based courses to implement the model formally. For example, the software support may be provided by a specialist or by an electronic performance support system (EPSS). Most probably, available resources will impact the form of the components of the model.

Returning the power to the users:  
The effect of computers that apologize

Jeng-Yi Tzeng  
Indiana University  
jtzeng@indiana.edu

Abstract: Believing that the essence of user-based design lies in the fundamental power structure between human and computer, this study examines the effect of computers that offer an apology to users whenever the users fail to accomplish what they intend to do. It is hypothesized that users will feel better about themselves and the program as well when the computers shift the responsibility of failure from users to computers. In this pilot study, a computer program was designed to play a revised “20 questions” game with four subjects, who were randomly assigned to 2 X 2 treatment groups (difficult question, easy questions, apologetic-feedback group, functional-feedback group). Users will receive either an ordinary functional feedback or an apologetic feedback whenever they fail to guess the answer. The tentative result supports the hypothesis, and the users will feel better even if they are aware of the hypocrisy of the apology.

Introduction

Nowadays, as “user-centeredness” becomes the golden rule for design, it is time to re-examine the power structure between human and computers. Unless the imbalanced status of power between computers and human can be reversed, a computer program will never be truly “user-centered”. The first and the most important step to change this imbalance is to have computers take the responsibility and apologize for its inability to accommodate users’ needs. In other words, while computers intend to be, and should be, designed as error-proof for users, computers should apologize for their inability to deliver this or whatever promises that they make and take the blame for a failed transaction between them and the users. Not only because it is the courtesy that runs our human society, but also because any design should be aimed at making users feel better about the program and themselves. Currently in the human-computer interaction literature, many studies have shown that instead of designing complicated program to have a computer act like a human and express emotions (i.e., Anthromorphism), we often project our emotion onto computers as if they were the counterparts at the other end of the emotional interactions (i.e., Ethopoeia). That is, we have the tendency to treat computers as social actors, a phenomena called “CASA paradigm” (Nass & Steuer, 1993; Nass, Moon, Fogg, Reeves, & Dryer, 1995). Following the idea of ethopoeia, this study tries to investigate the effect of applying one of, if not the, most powerful impression management tactic-apology-to the human-computer interactions. In this study, although computer’s apology is not due to violation of a serious felicity condition or a mere reflective locution for a perfunctory social interaction, it is about taking the blame of failure away from users’ shoulders in the hope of creating a stress-free type of environment for the users. However, the question is, do users actually care about whether computers apologize or not? If they do, what are the effects that computers’ apology will bring to the users? The following experiment was designed to answer these questions.

The Study

A computer game called “10 questions” was designed for this study. Similar to “20 questions” game, the computer had one noun (could be an object or an abstract concept) in “its mind” for subjects to guess. Instead of 20 opportunities, subjects had 7 chances to type a keyword to ask for feedback from the computer regarding whether or not the keyword is associated with the answer. Then they had 3 chances to guess the answer. To compensate for the lost of 10 questions, the computer will provide 3 hints at the very beginning of the game, after the 7th keyword guess, and before the last chance to guess respectively. For the first 7 keyword guesses, the keyword that subjects input would be matched with a pool of attributes that were related to the answer. Then the computer would provide a functional feedback like “Yes, ... can be associated with the answer”, or “No, ... cannot be associated with the answer” to provide a direction for subjects to think. After the 7 keyword guesses, subjects would have three chances to guess the answer, and only the exact word as the answer would elicit positive feedback. At this point, if the guess
was accurate, the computer would give a simple feedback such as “Great, ... is the correct answer”, then asked whether the subjects wanted to play another game or not. However, if the subject input an incorrect guess, two types of feedback would be provided: (a) a functional feedback to inform whether or not the guess was accurate (e.g., “Incorrect, the answer is not...” or “Correct, the answer is...”); or (b) apologetic feedback that the computer volunteered to take the blame for users' failure (e.g., “Sorry, ... is not the right answer. I apologize for not able to provide more useful hints for you to guess... your answers will be incorporated to the database for future improvement”). This apology not only contains regrets, but it also promises improvement to make it sounds more sincere. It is hypothesized that people who receive apologetic feedback would feel better about the program, their performance, or themselves. For this pilot study, a convenient sample of three female and one male doctoral students were recruited. All subjects use computers frequently to do their class assignments. One subject is a consultant in Educational Technology Service, and thus was more advanced in computer skills.

Findings

The following seven findings were obtained from this study.

1. Apologetic feedbacks may or may not have significant impacts on subjects' performance.
2. Apologetic feedbacks may or may not exert positive impact on subjects' self-evaluation of their performance.
3. Apologetic feedbacks may help subjects enjoy the program.
4. Apologetic feedbacks help to ameliorate subjects' negative feelings from the program.
5. Apologetic feedbacks make subjects feel better about themselves.
6. Subjects in apologetic-feedback group rate the program more favorably than those in functional-feedback group.
7. Even if they believe the program was flawed, the subjects still tend to blame themselves for their performance.

Conclusions

What the computer's apologies indicate is a shift of power that defines the "appropriate behaviors in human-computer interactions" from computers to users. While users' having this power is supposed to be the bedrock of the concept of "user-centered design", what most designers do are to thoughtfully take users' needs into account but still retain this power in their hands. Believing that giving this power back to users will enhance their satisfaction level with the program, this study shows that when computers volunteer to take responsibility for the users' failure, users not only feel better about the program and themselves, they also show more interests in interacting with the program again, even though those apology did not generate any improvement of their performance.

In addition, the question of whether the users are ready to ask computers to take responsibility for users' failure receives a negative answer from this study. Even after subjects had clearly identified the flaws of the program, they were still reluctant to ask computers to take the blame. While this may has a lot to do with their personality, this reveals is that users still feel helpless in the face of computers' failure, and they were overpowered by the computers because they felt they did not know computer enough to demand more user-centered treatment. When computers failed them, they even blame themselves for as a defense of the computers' failure, just as Postman (1992) predicted. Such a sense of helplessness in front of computer is the result of the reversed power structure that we are having with computer now. If users do not have the power to demand an action from the computer (as opposed to submit a request to computers), a design could never be truly user-centered.

Novice Designers of Online Learning: A Contribution to Principles for Instructionally Effective Online Learning Design.

Duan van der Westhuizen
Geoffrey Lautenbach
Department of Curriculum Studies
Rand Afrikaans University
South Africa
dvdw@edcur.rau.ac.za

Abstract: This paper reports on a study conducted at the Rand Afrikaans University in Johannesburg, South Africa. The study aims to determine to what extent novice online instructors can advance contemporary knowledge of instructional design in an online environment. Participants in the study were generally uncertified in teaching practice, but were faculty members in various disciplines and considered themselves as experienced face-to-face instructors. In addition, none of the participants have taught online before. The study showed that the participants had varied design needs, many which have not been anticipated by the expert course designers. It therefore appears that course design needs to be contextualised, and that novices can indeed contribute to design principles for online learning.

Context

The importance of instructionally designing (or educationally designing) online learning is widely reported in the literature (compare Alessi & Trollip, 2001; Driscoll, 1998; Horton, 2000; Kruse & Keil, 2000; Piskurich, 2000; Ravet & Layte, 1997). Investigative visits to higher learning institutions in Australia (1999 & 2001) and the USA (1998 & 2000) have shown that the majority of higher learning institutions employ trained instructional or educational designers for the design of print-based materials as well as for instruction delivered online. Furthermore, a scrutiny of the conference programmes of a variety of conferences (Ed-Media 1998 - 2001, and CAL 99) has shown that instructional design (ID) is considered to be an important factor in online learning.

It appears that many higher learning institutions worldwide are using skilled and trained professionals to design their courses. The Rand Afrikaans University (RAU) in Johannesburg is a modern, medium-sized institution offering courses for residential students as well as for distance learning students. During the last four years, several courses have been facilitated online, in a range of modes. Some courses have a limited, administrative presence, while others are fully online and integrated. However, RAU have not employed a single instructional designer for online delivery of courses. Courses are generally designed and developed by the presenters themselves. Many of these lecturers do not have teaching qualifications, and hold no qualifications in online teaching practice either. However, most of the lecturers who participated in this study consider themselves to be effective as instructors in the face-to-face situation, and believe that they have the ability to design effective online learning. They would argue that they have "natural" expertise gained from experience, and that they did not necessarily need "learned" expertise. Currently, there is limited evidence on how effective current online courses are. Van der Westhuizen (1999), Lautenbach (2000) and Cronje & Murdoch (2001) have reported on the experiences of lecturers and students at RAU. None of these studies however have attempted to measure the effectiveness of the design of the particular courses.

The expectation is that the expert design of online courses will realise effective courses. However, Dimitrova, Sharp and Wilson (2001) postulate that the evaluation of expert-based approaches are often unreliable as evaluators make subjective choices, and that the discrepancies between teacher ratings and learner ratings are not explained sufficiently. Furthermore, Tergan (1998) points out that checklist-based assessments of online courses do not adequately assess the efficacy of courses. It therefore appears that expert design of online courses may not necessarily imply instructionally effective online courses. The question is therefore whether it is possible for non-designers and novice online practitioners to meaningfully contribute to the expert design of online learning.

The Participants

Six novice online learning instructors were chosen to participate. Four of these practitioners had no formal qualifications in any form of educational science, and had little or no knowledge of pedagogy as a science. These practitioners taught Mathematics, Zoology (2) and Human Movement Studies. The other two participants had qualifications in education, and taught in the Faculty of Education. None of the participants had any training in instructional design.

Methodology

Participants were asked to explain how they envisaged an online environment that could facilitate the presentation of their subject field. The purpose here was to determine to what extent the participants could match their instructional needs with a) what they knew of the web environment and b) their expectations of what the online environment could offer. This initial "design" was referred to as the 'coarse design'.

Participants were then briefly introduced to online learning, and specifically to the WebCT environment (WebCT was used as the delivery platform). The learning resources that are facilitated by WebCT were explained and the application of the tool in an
online teaching environment was demonstrated. Participants, now having seen applications of the WebCT tools, were asked to amend and refine their original course designs. Specifically, they had to re-design the course considering different methods of content presentation and facilitation, tool application, learner activities, and also consider typography, the use of graphics and colour. The aim of this segment of the research was firstly to determine whether there were significant differences between the designs of those participants with educational training and those without. Secondly, an attempt was made to derive "novice design principles", and to find areas of commonality with design principles derived from literature and instruments for good online learning design (expert principles).

**Findings**

The study is a work in progress. The intercrossing of the "novice principles" and the "expert principles" showed some consistencies, although it was clear that the novices could benefit by exposure to principles of online learning design. Conversely, the novices contributed principles that were not encompassed by expert principles, although many of these proved to be contextualised. In the main, all participants required high levels of interactivity, visual representation of content and a sense of control over student activity. Some of the needs of the novice practitioners that were not anticipated by the expert designers, and that were not consistent with general principles are:

- A need to duplicate paper-based materials online so that students could manipulate text. Some practitioners required detailed content online.
- The use of metaphors was not required.
- The inclusion of visual "bridges" between objectives and the nature of the subject field.
- Most participants required a linear design.

Participants who had educational qualifications were more concerned with aspects of learner activity, visual design and assessment practices than those who were not educationally qualified. Their design of the learning experience appeared to be more structured. Clearer threads between course objectives, teaching method and assessment practices existed in their approach to the design of the course.

**Conclusion**

Generally, it was found that all participants had some "sense" for design principles, but participants with formal educational qualifications had approaches supported by pedagogical principles. All participants could apply the WebCT tools once they were made aware of the capabilities of the software. However, participants reported that they greatly benefited from exposure to principles for the design of online learning. The participants believed that the online modules were instructionally effective, but made suggestions for improvement. The intercrossing of the novice principles, the expert principles and the improvements suggested by the participant experience may therefore generate context-specific instructionally effective design principles.

Using Computer-Assisted Case-Based Instruction in Corporate Training

Nancy J. Vye, Katherine Burgess, John D. Bransford
Learning Technology Center, Vanderbilt University, USA

Chris Cigarran
American Healthways, Inc, USA

Abstract: This paper discusses a computer-based, corporate training program that was developed through a private enterprise/university partnership. The program was designed using a case-based instructional approach. At the core of the program is a set of multi-media cases depicting realistic situations and problems that trainees are likely to face in the workplace. A major goal of case-based instruction is to prevent “inert knowledge” by integrating content learning with problem solving. Case-based instruction provides learners with the chance to become familiar with the types of situations and problems that they are likely to encounter in the workplace, and to learn important content as necessary to help solve these problems. An overview of the theory of case-based instruction and the learning issues that it is designed to address, a demonstration of the computer program, and a discussion of the advantages of case-based instruction in corporate training settings is provided.

A recalcitrant problem in corporate, post secondary and K-12 education is the problem of transfer of learning. Educators have long lamented that learners often do not use what they “learn” in the classroom to help them solve problems outside of the classroom or in the workplace. Whitehead (1929) referred to this as the “inert knowledge” problem. Current research suggests that knowledge becomes inert when information is presented to learners as a set of discrete facts or procedures to-be-remembered (NRC, 2000). Under these conditions, learners do not understand when it is appropriate to apply what they have learned, and consequently, knowledge is not organized in memory in ways that will enable learners to later retrieve it to solve new problems. Furthermore, formal educational settings typically provide few opportunities for learners to practice applying new knowledge and skills. Without these opportunities, knowledge tends to be rigidly bound to the context in which it was learned.

A partnership of learning scientists from Vanderbilt University, disease management specialists from American Healthways Inc, and multimedia designers from Little Planet Learning, Inc have developed a case-based corporate training program, at the core of which is a set of cases depicting realistic situations and problems that trainees are likely to face in the workplace. A major goal of case-based instruction is to prevent inert knowledge by integrating content learning with problem solving (CTGV, 1997; Williams, 1992). Case-based instruction provides learners with the chance to become familiar with the types of situations and problems that they are likely to encounter outside of the classroom (in this case the workplace), and to learn important content as necessary to help solve these problems. When knowledge is used to solve related but non-identical problems, it becomes better differentiated. Consequently, learners acquire knowledge that is more flexible and adaptive for use in a variety of contexts. Learners are also generally motivated by case-based instruction presumably because they are more actively engaged in the learning process than in lecture-based classrooms. Case-based instruction has been used successfully—albeit on a limited basis—in K-12 and post-secondary education (Williams, 1992 for a discussion of use in legal, business and medical education). However, the use of case instruction in corporate training settings is undocumented and the use of a computer-based delivery system for case instruction is rare. Some exceptions to this are Vanderbilt University’s AMIGO project that is redesigning undergraduate instruction in bioengineering and the Cognition and Technology Group at Vanderbilt’s anchored instruction projects in middle school mathematics and early literacy (CTGV, 1997)

The training program to-be-discussed was developed for American Healthways, Inc (hereafter AmHealth). AmHealth is a leader in the field of chronic disease management, providing telephonic interventions to patients with diabetes, coronary heart disease and other chronic illnesses. The company employs registered nurses and dieticians to provide regular interactions with patients; clinicians educate patients about health issues, remind them about upcoming physician and lab appointments, and support them in making behavioral lifestyle changes.
that can improve their health status. Patients also can “call in” with questions and concerns. The new training program was developed in AuthorWare and is on CD-ROM. The cases consist of simulated phone conversations between clinicians and patients that provide new clinicians with integrated practice on computer and clinical skills. The program consists of 26 multimedia cases that the trainee uses over 15-days of training. The software also has content resources—in audio, video and graphic format—which are helpful in solving the cases. Additional resources are provided in print form.

Using cases for instruction requires a systematic approach to helping learners explore potential solutions. The software is designed to support a specific sequence of learning activities (see Schwartz, Lin, Brophy & Bransford, 2000 for more a detailed rationale of the learning cycle). Each case consists of: 1. A Multi-media Scenario involving a clinician. In many of the cases, the clinician is conducting a call with a patient. 2. A Challenge which is a problem(s) related to events depicted in the scenario. Sample challenge questions are “What might be your next steps in working with this patient?”, “What issues with medications might be discussed with the patient? Why?” and “What are the patient’s symptoms likely to be?”

Cases depict patients with acute and potentially critical health conditions and patients with more typical problems related to disease management and behavior change. After viewing each case, trainees: 1. Record their initial thoughts in a notebook, and 2. Examine resources related to the case. Recording their initial thoughts gives trainees the opportunity to articulate what they currently know about the challenge. Having people record their initial thoughts is extremely important. First, it is a “generative” (i.e., thoughtful) act. Learners are articulating and evaluating what they know in relation to the case at hand (and in the process may make knowledge gaps apparent, creating a “need to know” in the learner). The notebook entries also serve as a baseline or pre-assessment of what learners know about a case and how they approach it. The trainer and learners can use these entries to illustrate the growth in learners’ thinking.

After recording their initial thoughts, learners are given the chance to examine the resources related to the case. Resources consist of expert commentaries on the case, expository materials, and computer simulations. Trainees access resources as needed as they work through each case. Depending on their skill level learners may need to access only a portion of those available. In this way, case-based instruction can easily adapt to pre-existing knowledge differences among trainees—an outcome that is difficult to achieve in lecture-based training programs.

Case-based computer-assisted instruction in corporate training has several important advantages. As designed in the present context, the system is easily updated. Resources for training can be deleted and others added as medical information changes or is revised. In addition, it provides consistency in training that is often difficult to achieve when large numbers of individuals need to be trained. From a learning and motivation standpoint, the approach is engaging for trainees and provides opportunities for them to become familiar with the types of situations and problems that they are likely to encounter in the workplace, and to learn important content as necessary to help solve these problems.

Patterning Evaluation Models: Assessment in Support of Institutional Goals for Learning

Ron Wakkary
Technical University of British Columbia
ron.wakkary@techbc.ca

Karen Belfer
Technical University of British Columbia
karen.belfer@techbc.ca

Abstract: The aim of this paper is to demonstrate how evaluation models were developed and implemented in order to support institutional goals of an e-learning university. The paper will discuss the aim of assessment to support institutional learning goals, the benefits and challenges of this approach to assessment in e-learning, the use of pattern language to develop evaluation models, and the results based on implementation at the graduate and undergraduate levels of the TechBC.

1.0 Introduction

Quality assurance in learning at an e-learning university like the Technical University of British Columbia (TechBC) is critical due to the goals of innovation, the investment costs in an online curriculum, and the investment in organizational structures. In order to meet the goals and create the return on investment, the application of e-learning must be learning effective, cost effective, and scalable.

The role of assessment in this context is to validate (or invalidate) policies, methods, and ultimately, the outcomes. If assessment is in support of institutional goals, it is even more valuable toolset. As such it must be linked to the strategic goals of the learning institution in order to successfully implement e-learning.

Managerially, it is a toolset to ensure a cost and learning effective implementation of scalable e-learning. A key tool of assessment in addressing these issues is the use of evaluation models.

2.0 Supporting Institutional Goals

In the case of TechBC, the use of evaluation models is strategically shaped by the need to support institutional goals of effective learning, learner-centered learning, and the effective use of technology.

The mission of the academic program can best be described as creating an accessible and effective learning environment. The use of evaluation models strives to achieve and support the mission and goals.

3.0 Evaluation Models

3.1 Pattern Language

Christopher Alexander developed a powerful design tool and process known as “pattern language”, to help define environmental planning and architecture. It has evolved and has been applied to computer programming, human interaction, and organizational design (Coplien, 1995), as well.

We developed evaluation models within a pattern language design framework. Each model was described as a pattern, including elements of each pattern – such as name, description, application, how it works, example, and scenarios. We also provided the larger framework for the relation of patterns as “parent” and “child”.

In order to meet the goals of developing cross-disciplinary implementation of evaluation models, and certainly implementing their uses successfully creates a considerable challenge for “buy-in” and the required collaboration. Any development process, iteration and ongoing implementation required significant authorship roles by the learning staff at each stage. At TechBC, we modeled our approach to development and structuring of the evaluation models after Christopher Alexander’s “pattern language”. In addition, we benefited from the highly collaborative and inter-disciplinary culture of TechBC.

3.2 The Models

Evaluation models were created to address the need for a comprehensive document capable of supporting intended assessment practices. We identified pattern language as the design framework for the evaluation models applicable to TechBC’s modular learning structures and delivery models.

In addition to the components of a pattern, the evaluation models are accompanied by a “success criteria”, is drawn from past experiences. The goal is to adapt assessment a learning environment that benefits from effective curriculum implementation, effective management, cost-effectiveness.
Good instructional design is a significant enabler of effective learning (Belfer and Nesbit, 2001). Following a systemic approach to instructional design good pedagogical practices are embedded in assessment that is integral to learning and adhere to basic learning principles.

The evaluation models have these principles embedded, and therefore greatly support curriculum development, and ultimately move toward ensuring quality in the use of educational technology in learning.

4.0 Results

We have measured the success of the evaluation models by the degree to which assessment has supported institutional goals for learning, and derived the benefits of doing so.

4.1 Effective curriculum implementation

Key results for curriculum implementation is the achieving of coherency for the learner and exchange of best practices. Inter-disciplinary practice and collaboration were seen to be critical requirements. Similar to other implementations of pattern language, authorship by learning staff is critical. Faculty and learning staff were invited to re-define past practices as a pattern, or generate new ones. The results clearly support a goal of coherency for learners of assessment methods and the collaborative exchange of assessment knowledge and practice.

4.2 Effective Management

Key results for management are the scalability and portability of the programs. The name and description of each evaluation model tell a story and the means of assessment. Together with the details of each pattern, it is easier for learning staff other than developers to effectively deliver a course, even for the first time. The pattern language approach equally ensures the purpose each assessment activity and the goal in the overall scheme of learning activities is as evident as the evaluation method. In addition, evaluation models are linked to one or more delivery models, allowing for scalability to be a factor of learning activities and goals and not disciplinary content, i.e. the delivery and evaluation methods do not need to be re-written for new content.

4.3 Cost-effectiveness

A key result for cost effectiveness is the ability to effectively manage resources. Evaluation models have been developed to support a learning practice that is understood in discrete elements and as a team effort Therefore, modules identified for revisions, can be analyzed component by component. If the main concern of both learners and instructors in the assessment structure, the evaluation models provide an easy procedure to re-evaluate the assessment structure by choosing a new evaluation model, an not revisiting the module in its entirety.

5.0 Conclusions

We've argued and hopefully demonstrated that assessment must be linked as a management toolset to the strategic goals of the learning institution. This need is particularly critical to derive the benefits of e-learning. For administrators and learning staff, it is a toolset to ensure a cost and learning effective implementation of e-learning that ultimately supports scalability. We have focused on how a key tool of assessment in addressing these issues is the use of evaluation models.

A critical conclusion is the bridging of practice to goals requires buy-in, collaboration and participation in the design, selection, modification and adaptation of the evaluation models. A specific goal is that each module has a particular evaluation model that successfully prescribes assessment methods while establishing an organizational structure towards the process, making the process of assessment transparent and creating a common language for assessment as part of the learning culture.

Role with IT... the Evolution of Faculty and Faculty Support Roles and Responsibilities in the Rapidly Changing Climate of Educational Technology

Sarah Walkowiak, sarahwwpi.edu, Online Delivery Coordinator, Educational Technology Services, Instructional Media Center, Worcester Polytechnic Institute, Worcester, MA
http://www.wpi.edu/+IMC/ETS

Abstract: As digital technology becomes more widely integrated into the teaching and learning environment, particularly in distance learning, faculty members face new challenges. To thrive in this new teaching environment, faculty must simultaneously develop their pedagogical and technological skills. The process of technologically-based faculty development is often time consuming and difficult, especially for faculty who have less experience working with the nuances of instructional technology. To alleviate this problem at WPI, the Educational Technology Services team (ETS) was created as a functional workgroup under the Instructional Media Center. The mission of this group is to support and empower WPI faculty in the effective use of technology to enhance their teaching.

Introduction
Through the advancement of educational technology, an ever-widening variety of course material delivery and presentation options are available to faculty members. While this myriad of options can be exciting, it can also be frustrating and overwhelming. To alleviate this, and to create a knowledge base of standards and pedagogically sound best practices, we have expanded the services of our Instructional Media Center to include extended instructional support and design assistance. These services are provided by the Educational Technology Services (ETS) team, consisting of an instructional designer and director, a content coordinator, a graphics production coordinator, an online delivery coordinator and two technicians, one for video support and one for courseware support. The formation of this group and associated services provided, fueled an evolution in roles and responsibilities for faculty, staff and students at WPI in relation to teaching and technology.

Where We Have Been
As on most university campuses, there have been three consistent adoption levels for teaching with technology at WPI. These levels consist of a few early adopters, eager to try out new technology in their courses, intermediate adopters, using tried and true practices and basic adopters who prefer more familiar forms of technology or avoid it altogether. The early adopter role is often referred to as the “Lone Ranger and Tonto” approach to teaching with technology, offering grants to faculty members to fund software, equipment and a part-time graduate student. (Bates, 2001) For all levels of technological expertise, most faculty have received adequate hardware support but have received mixed levels of support in regards to incorporating the technology into their teaching. Faculty at basic and intermediate levels tend to become frustrated when something does not work, even with available support, so they tend to take fewer instructional risks in favor of a more stable teaching product. Most of our training in the past has focused on the technical side of teaching with technology, with instructional design issues handled separately or as a special interest of lone rangers. The need for more integration between instructional design and the use of technology is now understood by a greater proportion of the university at large, thus providing a foundation in the campus culture for emerging roles.

Evolution of Faculty and Staff Roles and Responsibilities
Through the process of providing extended instructional support, these roles have begun to shift at WPI along with the development of new responsibilities for each role. The “Lone Rangers” remain interested in new technology, but are freed from many of the technical burdens that can arise when exploring new technology alone. With this knowledge and research, we are able work together to implement best practices (instead of creating a project from scratch) while working within the context of supported university computing systems and resources. Thus keeping compatibility and scalability in mind and encouraging faculty collaboration on similar projects or combining efforts to expand on existing work. Our mission to technologically empower faculty has materialized through the execution of our instructional services and implementation of new training
materials, workshops and programs. We have created a supportive atmosphere to foster intrinsic faculty motivation at all levels of technological expertise by providing support staff, access to technology, faculty encouragement and incentives for implementing the technology. Extrinsic factors are supported by the assistance of our staff with technological projects and providing a channel for delegation of student technical support requests to the appropriate group on campus. (Irani, 2001)

Example: A Distance Learning Course

We have particularly noticed the emergence of new roles and responsibilities for faculty, staff and students in our distance learning courses which rely on technology for communication and course delivery. Each of our distance faculty members is partnered with an ETS course coordinator who manages the technical aspects of the course and assists with the development and assessment of course-specific materials. With this new partner, faculty are supported while re-tooling their teaching model as they learn to use technology more effectively. Throughout this partnership, the coordinator provides technical, pedagogical and moral support in weekly meetings and other communications. Several of our distance learning faculty are new to distance learning and the extra support helps to minimize the transition to a new teaching medium. This partnership creates an opportunity to build strong working relationships with the faculty and to fully understand how the media and technology are being applied in live courses. This added knowledge makes for a more efficient workflow, as each faculty member has one main contact and the coordinator becomes aware of each faculty member's individual style. Assessments become integrated into the curriculum as the coordinators work to improve student learning through course materials that are created. The students on the receiving end of our collective work find that with additional expertise behind a course, fewer technical glitches occur, and when they do, response time decreases as support requests are quickly routed to the appropriate place by the coordinator. Time and project management also play a key role in getting course materials delivered on time and without technical glitches.

Learning, Growth and Change

With new responsibilities for faculty, staff and students come growing pains – some faculty experience a more difficult adjustment to distance learning and new technology. A sense of loss of autonomy may be felt as the faculty move towards a learner-centric teaching model and as more people have a hand in course development. The process of working with a coordinator provides a forum for discussion of these issues and helps to alleviate any fears a faculty member might have. The experience of collaboration between the Educational Technology Services team and our faculty provides many opportunities for learning and growth for everyone involved. Our focus is on applying instructional design theory to these courses and learning along with the faculty. The faculty gain valuable technical skills and understanding while providing more effective learning tools and environments to their students. Faculty shifts from teaching in a lecture based mode to a more interactive mode provide a richer experience to the students, but also require students to take more responsibility for their learning.

Conclusions

As our group continues to evolve, we will pursue our mission of empowering faculty by encouraging our more experienced faculty to expand their technological skills and to share these skills and learning experiences not only with us, but with their colleagues. We have implemented multiple campus-wide workshops along with a Teaching Technology Fellowship program and are in the final development stages of an Instructor Certification in Academic Technology program that will serve this purpose well. Marketing materials and sessions to inform more faculty members and departments of our services are also planned, along with a collection of best practices that we have compiled in our first year as an online reference to help faculty get started with different media and technology types. The ETS group is beginning to see an actualization of technical change now happening at many institutions and looks forward to providing improved services and sharing our experiences.

From a simple PowerPoint™ presentation to a complete online course, technology now allows educators unprecedented freedom to create, modify, and disseminate their own instruction; however, this same freedom also offers unprecedented opportunities to create and disseminate ineffective or poorly designed instruction. Ineffective technology-based instruction often stems from neglect of the basic principles of effective instruction. This paper describes four non-technical tips educators can use to enhance the quality and effectiveness of technology-enriched instruction. They include (a) identifying instructional objectives, (b) understanding the target audience, (c) organizing the content, and (d) preparing for instructional delivery.

Introduction

It is no longer surprising to see P-12 teachers and college or university faculty with the technical ability to create multimedia-rich PowerPoint presentations, develop and maintain their own course Web sites, or, with no technical assistance, setup and operate a wide variety of computer-based equipment. As educators, we are rapidly becoming more technologically savvy. Fortunately, many of us are learning to embrace this change and are enjoying the unprecedented freedom technology offers us in our ability to create, modify, and disseminate instruction, however, this same freedom also offers us ample opportunity to produce ineffective or poorly designed instruction. In allowing us to personalize and package the instructional messages we convey to our students, technology also gives us much latitude to miss the mark, and that is precisely the issue raised in this paper. Perhaps we need to be reminded that, as we run to jump on the technology bandwagon, we must not forget to bring the basics of good instruction along with us.

Most of us have endured PowerPoint presentations with font sizes so small that we could not possibly read the information being presented or lectures by professional educators who stood with their backs to the audience as they read paragraph after paragraph from the information projected on the screen. In these and many other situations, technology, in all its capacity to enhance instruction, only served to impede the dissemination and reception of the intended message. It is with this in mind that we offer a few reminders on how, as professional educators, we can reduce the chances of getting blindly caught up in technology’s enticement and instead, capitalize on its potential to support effective teaching.

Identifying Instructional Objectives

In simple terms, objectives are specific descriptions of what we want the learner to know or be able to do as a result of instruction. Whether we are using PowerPoint in the classroom or delivering our instruction online, it is critical that we make the effort to identify specific instructional objectives, even if it requires a considerable amount of time. Surprisingly, many of us spend more time selecting background colors and clip art, digitizing video clips, creating endless lists of hyperlinks to online resources, or toying with any number of technology’s fun and often frivolous features than we do identifying and incorporating objectives into our technology-based instruction. While
technology's bells and whistles or its ability to expedite our productivity should not be neglected, our first priority should be to identify and incorporate instructional objectives in the design and development of our instruction.

Determining and writing good objectives is not always, if ever, a quick and easy process. Taking the time to determine instructional objectives, refining them, and then developing content and evaluation methods around them can be a very detailed and time-consuming process. This stands in direct contrast to the expectations we may have of technology and its ability to assist us in rapidly creating a finished product. While convenience and expediency are enticing attributes, as educators, surely we are not willing to trade them for quality and effectiveness.

Understanding the Target Audience

In a traditional setting, when teachers walk into a classroom to teach a lesson or deliver a lecture, they are in direct, face-to-face contact with their audience and can react, make accommodations, and modify the information they are presenting and the way in which they present it based on audience reaction and response. Trained educators know this ability can greatly improve the effectiveness of instruction. Unfortunately, technology, if we allow it to, can easily separate us from the learner.

As many of us have already discovered, our efforts to understand and accommodate our audience often tend to lead us away from the rigid and inflexible presentations that can be so instructionally ineffective and instead, toward the development of presentations that simply support the information we wish to convey. For example, rather than creating a presentation that contains slide after slide of the exact content being presented, forcing the instructor to follow the pre-developed content precisely, we instead find ourselves more often creating presentations that merely contain supporting electronic artifacts such as charts, graphs, maps, photographs, video clips, or a few talking points. By simply augmenting a lecture or presentation with technology instead of letting technology dominate it, we help create an instructional environment that is much more responsive to our audience.

Organizing the Content

The appropriate organization of content is crucial when conveying information or providing instruction. The clear articulation of the content order reduces the chance of misinterpretation or confusion by the learner while assisting him or her in establishing important and necessary associations between the elements that make up the content and between prior knowledge and current information. Fortunately, content organization is often made simple by the content itself. For example, the order in which a step-by-step task such as creating a new slide in PowerPoint is presented is very sequential and straightforward. On the other hand, some content is more open ended and much more complicated to organize. Imagine having to organize the content for a presentation on how to deliver a persuasive oral speech. This type of content could be effectively organized in a wide variety of ways.

It is in the delivery of this open-ended type of material that it becomes crucial for educators to give careful attention to the appropriate organization of content. Unfortunately, as we now find ourselves with the technology-enhanced ability to create our own instruction, we must often assume the responsibility of organizing our instruction ourselves. To do so effectively, we must have a strong understanding of the content itself, of our target audience's existing skills and knowledge, and of the desired learning outcome we wish to achieve. Based on these, we can begin to organize our instruction or information in clear and appropriate ways.

Preparing for Instructional Delivery

This is perhaps the simplest but most overlooked aspect of delivering effective technology-based instruction. Simply put, make sure everything works before getting up in front of your audience. Audiences or students are no longer tolerant of our lack of preparation and consideration when we don’t know how to operate equipment. In addition to being familiar with the operation of the equipment, we must also be familiar with our presentation and its content. Were not suggesting that hours of rehearsal and practice are required in order to deliver a polished and professional presentation, however, adequate steps must be taken to ensure that, as the presenter or teacher, we are familiar with what we are presenting and with the equipment used to present it. Anything less runs the risk of seriously jeopardizing the instructional effectiveness of our presentation. This is a big price to pay for failing to take a few extra minutes to make certain we are prepared.
On Using Data-Mining Technology for Browsing Log file Analysis in Asynchronous Learning Environment

Feng-Hsu Wang
Department of Computer and Communication Engineering,
Ming Chuan University,
Taiwan, R.O.C.
fhwang@mcu.edu.tw

Abstract: In this paper, we develop a tool for analyzing browsing log file based on data mining technology. The extracted knowledge includes the associative material clusters and the sequences among the material clusters. These findings enable teachers to study the dynamic browsing structure and identify some interesting or unexpected learning patterns, which in turn may provide decision lines for teachers to organize their teaching structure for better efficiency. Finally, application of the tool is conducted on a database collected from a web-based course in Ming Chuan University, Taiwan, to investigate its effectiveness, and some revelations are presented and discussed.

Introduction

In asynchronous web-based learning environments, teachers could conduct many kinds of educational activities such as material posting, homework assignment, group discussion, online testing and so on. However, the most prevailing issue in such a learning environment is that it is not easy for teachers to monitor students' learning behaviors instantly. Nevertheless, as compared with conventional CAI systems, web-based learning environments are able to record most learning behaviors of the students, and hence are able to provide a huge amount of learning profile. As a result, there is an urgent need of analyzing methods to discover useful information for improved instruction performance from the huge log database. Usually, web materials are divided into units of topics that are structured by some semantic relations among them (Barker, 1979). This study assumes that browsing behaviors of students in a web-based learning environment might reveal the true structure required of the material documents for being helpful to students. Therefore, this study proposes a browsing model to describe the useful browsing patterns, and develops a portfolio analysis tool based on data mining technique (Fayyad et al. 1996) to discover them from the browsing portfolio database. Finally, application of the tool is conducted on a portfolio database collected from a web-based course in Ming Chuan University, Taiwan, to investigate its effectiveness, and some revelations are presented and discussed.

The Document Browsing Model

In this study, the browsing model consists of two kinds of relations. The first is the association relation between document clusters and the other is the precedence relation among them. In the following, we present preliminary definitions that are related to the depiction of the browsing model.

Description 1 (Association Relation): For any documents \( p_1 \) and \( p_2 \), we say \( p_1 \) is associated with \( p_2 \) if and only if \( p_1 \) and \( p_2 \) are "frequently" browsed in a learning session without "observable" sequence between \( p_1 \) and \( p_2 \).

Description 2 (Sequence Relation): For any documents \( p_1 \) and \( p_2 \), we say \( p_1 \) precedes \( p_2 \) if and only if \( p_1 \) and \( p_2 \) are "frequently" browsed together and there is "observable" browsing sequence between \( p_1 \) and \( p_2 \).
Application and Discussion

This study applies the aforementioned tool in three web-based classes of the "Expert System" Course in Ming Chuan University, Taiwan. There are totally 172711 browsing records in the log database. Setting the minimum threshold of browsing time as 7 seconds, and the minimum support as 0.03, totally 22846 session records are left after the cleaning process and 960 browsing session records are attained after the transforming process. The total number of material documents is 96, and the number of sessions and average session length of each class are listed in [Table 1].

<table>
<thead>
<tr>
<th>Class</th>
<th>Number of Sessions</th>
<th>Documents</th>
<th>Average Session Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>A (Day Time)</td>
<td>349</td>
<td>85</td>
<td>2.9</td>
</tr>
<tr>
<td>B (Day Time)</td>
<td>334</td>
<td>85</td>
<td>3.1</td>
</tr>
<tr>
<td>C (On-Job)</td>
<td>277</td>
<td>80</td>
<td>3.4</td>
</tr>
<tr>
<td>Total</td>
<td>960</td>
<td>96</td>
<td>3.1</td>
</tr>
</tbody>
</table>

Table 1: The number of sessions and average session length of each class

To increase the reliability of the mining results, this study combines the session records of the three classes for the associative and sequential mining tasks. The result shows that 23 clusters are found with the largest cluster of size 3. Among these clusters, it is found that the "Theory" and "Demo Systems" categories are often browsed together, and "Demo System" and "Language" categories are also browsed together. These imply that the cross-reference usage of the materials is effectively achieved.

Most of the browsing sequences found meet the instructor's expectations. Nevertheless, some interesting sequence patterns are also found, including the sequence ((Backward-chaining ES), [Inference Engines]) -> ([CLIPS Language]), which reveals that about 20 to 30 percents of the students mistake the CLIPS language (a tool for designing forward-chaining expert systems) for a design language for backward-chaining expert systems.

Conclusions

This study develops a data-mining model and tool for analyzing the browsing portfolios in asynchronous learning networks. This study also finds that the amount of browsing records is still not large enough for more accurate mining results. This might be attributed by the fact that most students are prone to download all materials first for off-line browsing at home. Finally, more effective mining tools are still in lack for analyzing other kinds of portfolio information, such as the behavior of "thinking order" in web-based on-line discussions, and help to explore the relations among the various learning factors (efforts) and the learning outcomes.

A Knowledge Management Framework of Building a Technology Integration Community of Practice

Feng-Kwei Wang, John Wedman, Chi-Ren Shyu
School of Information Science & Learning Technologies
University of Missouri – Columbia
Wangfeng@missouri.edu, WedmanJ@missouri.edu, shyuc@missouri.edu

Abstract. Building upon a knowledge management framework manifested in the Nonaka's knowledge creation model, the Knowledge Innovation for Technology in Education (KITE) project, funded by US Department of Education, seeks to build a technology integration community of practice through a knowledge repository with case-based reasoning capabilities that allows to capture and disseminate the best practices and lessons learned of technology integration experiences by teachers and teacher educators. The project's overarching mission is to enable learning through sharing, communal understanding through storytelling, continuous exchange and creation of new knowledge, and collective problem solving within this technology integration community.

Introduction

As the face of American classrooms continues to change with rapidly increasing technological changes, greater diversity, and a projected need for 2.2 million new teachers in the next decade, teacher training institutions are faced with the challenge of graduating new teachers who will be adept at keeping pace with the technology explosion in the classroom. To increase the level of technology integration in teacher education programs, the Milken study recommended that researchers, professional societies, and education agencies should identify, study, and disseminate examples of effective technology integration on an ongoing basis (ISTE, 1999). Building upon a knowledge management framework, the Knowledge Innovation for Technology in Education (KITE) project, funded by US Department of Education, seeks to collect, organize and make accessible, and then disseminate technology integration knowledge of teachers and teacher educators with access to a practice-based collection of "how-to" resources.

Knowledge Management Framework

We believe the needs of teacher education programs described before can be addressed with the concept of knowledge management that has gained a wide acceptance in the business circle today. Knowledge management experts (Davenport & Prusak, 1997; Nonaka & Takeuchi, 1995) hold that an organization should actively locate, capture, and disseminate knowledge and expertise in a systematic manner to enhance organizational performance and innovation. In particular, Ikujiro Nonaka (1994), a prominent scholar in knowledge management, developed a model that explains how knowledge in an organization is created through a continuous process of knowledge conversions between explicit knowledge and tacit knowledge between explicit knowledge and tacit knowledge (Polanyi, 1966).

Explicit knowledge is formal and systematic in nature such as technical data, general principles, and standard operating procedures (Nonaka, 1994). Explicit knowledge can readily be elaborated, codified, and shared, and thus can be represented in books and databases and made accessible through libraries and online information systems. Tacit knowledge is practical "know-how" acquired through practice and experience (Leonard & Sensiper, 1998). Tacit knowledge approximates what Schön (1983) referred to as "knowing-in-action." Nonaka argued that "...tacit knowledge is deeply rooted in action, commitment, and involvement in a specific context" (p. 16). Tacit knowledge may require little or no time or thought when executed and can be so internalized that it is taken for granted.

As shown in Figure 1, in the context of technology integration, knowledge creation takes place in four modes of knowledge conversion. Socialization is "the process of creating tacit knowledge through shared experience" (p. 19). The socialization mode requires a field of interaction where practitioners share their experiences and perspectives through technology integration dialogues in the form of questioning, reflection, and feedback and through mentioning relationships between technology integration novices and experts. Second, externalization is the process of converting personal tacit knowledge into public explicit knowledge. Externalization is facilitated by synthesizing...
tacit technology integration experiences into explicit technology integration cases that allow practitioners to reflect their understandings and insights through interviews. These cases represent new experiences and perspectives which become transferable through case-based reasoning processes and functions in the knowledge repository. Third, combination is the process of converting existing explicit knowledge into new explicit knowledge. Combination implies that a community of practice should invest in a knowledge repository so that knowledge can be preserved, processed, and made available quickly without space and time boundaries. In other words, explicit knowledge can be "combined" upon the new experiences and insights gleaned from the practices of technology integration. Lessons learned and best practices can be compiled from the cases. Fourth, internalization is the process of enriching one's own tacit knowledge by internalizing explicit knowledge. In this phase, practitioners create a “field of action” that becomes the learning and working space in which they can reflect, practice and apply what they know and how they implement technology in teaching and learning. Internationalization can also take place by taking online technology integration courses.

![Knowledge creation as an ongoing cycle of knowledge conversion](image)

- **Socialization**
  - Bring in technology integration practitioners into the community of practice for sharing their experiences
  - Create online dialogue through sharing in forms of questioning, reflection, and feedback
- **Externalization**
  - Interview technology integration practitioners
  - Codify technology integration cases in the knowledge repository
- **Internalization**
  - Practitioners learn technology integration best practice cases
  - Participate in learning tasks of the online course
  - Study and test cases
  - Participate in dialogue with experienced practitioners
- **Combination**
  - Apply case-based reasoning
  - Refine new cases
  - Synthesize best practices
  - Develop online learning resources based on cases

Figure 1. Knowledge creation as an ongoing cycle of knowledge conversion

The knowledge management framework highlights the essential components of the KITE project that need to be developed, implemented, and evaluated. Building upon this framework, the project involves a consortium of 8 teacher education programs collaborating to create and diffuse technology integration knowledge. As the lead institution of this project, The University of Missouri-Columbia enhances and continues to support the ongoing development of the knowledge repository. Each partner institution hires knowledge scouts who are responsible for collecting, reporting, and updating technology integration cases in the knowledge repository; and work with local technology integration practitioners (teachers and teacher educators) as knowledge sources to capture their technology integration knowledge and experiences. The overarching mission is to build a k-16 technology integration community of practice through this knowledge repository that enables learning through sharing, communal understanding through storytelling, continuous exchange and creation of new knowledge, and collective problem solving.

Missouri-Specific Web-based Lesson Planning System

Feng-Kwei Wang, Guan-Yu Lin
School of Information Science & Learning Technologies
University of Missouri – Columbia
wangfeng@missouri.edu, gylqz6@missouri.edu

Abstract. Lesson planning is considered a critical but complex task to attain effective instruction. The traditional paper-based approach was found to be cumbersome and consequently detrimental in the willingness and effectiveness of teachers’ lesson planning. A Web-based lesson planning system combining instructional planning and calendaring functions to support Missouri’s education reforms was in the process of development and testing. Early usability tests proved the system to be positive in helping Missouri teachers plan their instruction. Some design issues were identified.

Introduction

The success of Missouri’s education reforms, to improve student performance as measured by the Missouri Assessment Program (MAP), will require new and different teaching and learning strategies that align curriculum and state standards using inquiry-based instructional strategies and infusing instructional technologies. Successful teaching and learning does not occur by chance. It relies on careful planning of instruction. Since lesson planning is considered to be critical to the success or failure of teaching and student learning, it is vital that teachers are competent in planning daily lessons that support Missouri’s education reforms.

Lesson planning is an essential but complex task (Borko & Livingston, 1989; Doyle & Holm, 1998; Johnson, 2000; Ornstein, 1997). Various theoretical models were developed to help teachers plan lessons (Eisner, 1967; MacDonald, 1965; Tyler, 1950; Yinger, 1980). While numerous studies exist to discuss lesson planning and its effects, the research on the effect of technology-based lesson planning systems is conspicuously lacking.

The use of technology to support lesson planning is not new. Several systems such as Computer-Prompted Instructional Planning System and Lesson Plan Maker appeared shortly after personal computers gained acceptance in early 1980s. Several studies have showed the positive effect of using personal computers to support lesson planning. Today, the advancement and prevalence of technology in schools makes it a very viable option for teachers to utilize in planning, sharing, and communicating instructional information. In particular, the Web allows teachers to create and access instructional plans without time and space boundaries. However, a search revealed that a Web-based lesson planning system combining instructional planning and calendaring functions to support Missouri’s education reforms does not exist.

Issues

While Missouri has undertaken a State initiative to support Missouri teachers as they integrate multimedia technology into inquiry-based, student-centered instructional practices (http://emints.more.net), most teachers are still using pencil and paper to do lesson planning. Major drawbacks of this paper-based lesson planning include:

- The process is very labor-intensive and cognitively arduous. The task becomes perfunctory to many teachers. They feel obligated to write out lesson plans only because it is required by the administration.
- There are no systematic prompts or built-in links to information that can guide the teachers’ lesson planning to focus on Missouri’s education reforms.
- Lesson plans are not accessible to colleagues or school administrators unless special requests are made. Consequently, sharing instructional information among teachers is difficult.
- Parents have no access to lesson plans and, as a result, must rely on other methods to know what their children are learning on a daily basis.
- It is difficult to modify the contents of lesson plans once they are written on paper.
- Paper is not very durable and thus, valuable instructional information can be easily damaged.
Implementation and Preliminary Results

To help resolve these issues in lesson planning, a Web-based lesson planning system is under development with "teacher friendly" tools. The objectives of the system are threefold. First, it streamlines the lesson planning process to align with curriculum and Missouri standards and provides guidance with checklist functions to help teachers focus on addressing Missouri's education reforms. Second, it preserves valuable lesson plans developed by teachers for dissemination and facilitates the sharing of lesson planning knowledge and skills among teachers. Third, it promotes better lesson planning results through sharing and collaboration and enhances communication between parents and schools, thus increasing parental involvement in their children's education.

This Web-based lesson planning system is a work in progress; consequently, only formative evaluation is available. To date, a preliminary working system developed in Lotus Domino has gone through several rounds of prototyping and usability testing to collect user feedback. Early indicators suggest the system will be particularly helpful in the areas of:
- searching and adapting existing lesson plans for other uses,
- communicating instructional plans with other teachers and students, and
- developing lesson plans to meet Missouri academic standards.

User feedback also reveals several issues that need to be resolved before the objectives of the system can be fully realized. Among them, the following two are most critical:
- The system has to be flexible to accommodate different instructional needs and processes of schools and teachers.
- Other non-technical arrangements such as training and support have to be in place to motivate teachers to use the system and to share their instructional plans.

Conclusion and future research

Preparing teachers for technology integration in their instruction and enhancing teachers' instructional quality are two important endeavors to advance K-12 education reforms. This initial phase of this project is to develop, implement, and pilot test the lesson planning functions. Later phases will include additional functions to support communication with parents via the Web and to scale-up the lesson planning model for statewide access and use, and to disseminate to a national audience. From a research perspective, this project will lead to a better understanding of:
1. How teachers plan instruction using technology?
2. How teachers share instructional information through technology, how technology can assist with instructional planning?
3. How the Web can serve as a communication means between parents and schools?

The on-going process of building the lesson planning system and preserving instructional plans in a sharable library enables teachers to better plan their instruction and share their instructional materials. As the system matures and the content grows, it will have the potential of improving instructional planning process and products of Missouri teachers and thereby advancing the entire K-12 education enterprise at Missouri.

Investigating Education Faculty's Perspectives of Their Experiences in a Technology Project: Issues and Problems Related to Technology Integration

Li Wang and Richard Speaker
Department of Curriculum and Instruction
University of New Orleans

Abstract: The ISTE (1999) stated it is important to study models that are making effective use and integration of technology in teacher education on an ongoing basis. The purpose of this study is to respond to this need by portraying three education faculty members after they experienced a federally funded technology-based project. Their practices, beliefs, and experiences are the focus of this study. Findings include 1) the range of previous experiences with technology varies dramatically, but all participants have used some computers for personal and professional tasks; 2) although actively learning to integrate technology and seeing positive impacts on their students, they do not believe that technology is the only tool for effective instruction; and 3) gender, age, social networking, access to current hardware and access to technical support remain issues needing consideration in the design of technology implementation in higher education settings.

Many educators today are facing the issue of integrating technology into their instruction. They no longer limit themselves to textbooks, chalk, and handouts to deliver course content because they are facing an increasing need to adjust their approaches to "teaching, preparing contents and delivering learning materials in accordance with" emerging technologies (Neo & Neo, 2001, p. 328). Some teachers have experienced great success in making effective use and integration of technology, but many teachers are still struggling with technology. This paper examines the beliefs and practices of education faculty regarding their integration and implementation of technology. In particular, what are the perceptions of their experiences after they participated in a year-long project to implement technology in their instruction?

Literature Review

Most faculty members have realized the positive impact that technology brings to students and believe that it is important to increase technology integration in the classroom. However, there is a significant gap between their beliefs and their practices. The factors underlying this situation include teachers' beliefs, fears of technology, reluctance to change, lack of access, and lack of technical and administrative support (Ertmer, 1999). Both external and internal factors may impede technology integration; external factors include access to technology, funding, and administrative and technical support, while internal factors are intrinsic to teachers, such as personal fear of technology, traditional teaching style, and reluctance to adapt (Ertmer, 1999). The internal barriers are often more difficult to identify and overcome than the external factors, because they are "less tangible" and "more personal and deeply ingrained" (Ertmer, p. 51), and these barriers can completely block implementation. Ertmer found that the focus on helping teachers integrate technology has been on grappling with the external factors but training programs have started to "incorporate pedagogical models of technology use as one means of addressing internal barriers" (p. 47). Ertmer also addressed the complexities of relationships between the external and internal factors and the strategies to overcome the two barriers to help faculty members incorporate technology into their classrooms efficiently.

What should faculty do?
First, before teachers integrate technology into the classroom, they should possess proficiencies with technology and develop a desire to apply technology in their instruction. This desire incorporates the premise that they have been provided with access to technology resources, technical support and training. Second, teachers should possess the knowledge of how to integrate technology into their classroom. Throwing a computer and software into the classroom is not integration. According to (Ertmer, 1999), successful integration involves careful evaluation of the curriculum and learning goals. Teachers should develop careful plans for improvement and assessment, and they should also be able to follow models that can help develop their own plans (Ertmer, 1999).

What can school/university systems do?

To help faculty members make effective use of technology and integrate technology into instruction, systems should provide proper and sufficient training and technical support. Only technology access combined with technical training, support, and assistance with using technology will serve as a significant motivation. Technology integration depends on facilities; however, other factors that influence integrating technology include faculty professional development and course-development time, which provide opportunities and time for teachers to concentrate on technology (ISTE, 1999).

Giving teachers sufficient time to plan students' technology experiences is one practice that facilitates technology integration. Teachers need to spend sufficient time planning how technology integrated is going to function most effectively, and determine the best practice to enhance students' learning outcomes (Walker, Ennis-Cole, & Ennis III, 2000). Teachers need to consider the necessary course content to be delivered in a normal class and to evaluate the impact that technology will have on teaching and learning (Lawler, Rossett & Hoffman, 1998; Walker, Ennis-Cole, & Ennis III, 2000).

Background of the Project

This project, according to Speaker and Dermody (Speaker, et al, 2001) is part of a $1.2 million grant from Preparing Tomorrow's Teachers to Use Technology (PT3), initiative of the U.S. Department of Education. The consortium, focused on strategically implementing technology in the classroom, is comprised of six partner schools working closely with two universities. The major purpose (Speaker, et al, 2001) is to make modern multimedia computer technology ubiquitous in content and methods courses, and field experiences for future teachers. Faculty and students in teams from the two institutions participate in the project and implement instruction using technology in their courses and field experiences with children in partner schools. This project (Speaker, et al, 2001) uses the model of teachers teaching teachers developed initially in the Bay Area Writing Project to produce teaching with technology. Over last two years, the project has involved 40 university faculty, approximately 100 university students as student technology mentors (STM), more than 2,000 other university students, and approximately 2,250 learners in 40 classrooms in 6 schools in the area. This project focuses on the training of both pre-service teachers and university faculty through summer institutes, as well as through numerous mini-session trainings, one-on-one tutoring and mentoring. These training courses cover a range of topics including web design, Internet in the classroom, presentation software, integrated curriculum, and video on the web (Speaker, et al, 2001).

Methodology

In this project, faculty members are categorized as Faculty Technology Participant (FTP), and student participants are categorized as Student Technology Mentor (STM). Each faculty member was assigned an STM to assist with teaching and preparation. Both FTPs and STMs attended a summer institute, in which they learned technology from invited teachers, students and faculty members who are using technology. These presenters share with their experience and demonstrate how they model technology implementation in their classrooms. Faculty and students completed individual projects using technology or completed a project on a cooperative basis. Processes began with a simple form to collect
some demographic information from three FTPs. After that, course syllabi, which faculty developed after they participated the summer institute, were analyzed. Based on the analysis and review of literature, we developed interview questions to delve deeper into the personal world of faculty members who are integrating technology into their classrooms.

Interpretivism, a “philosophy of science related to constructivist theory in psychology and to forms of research” (Willis, Thompson, & Sadera, 1999, p. 34), best suits this study. Interpretivists believe that it is difficult to find make valid generalizations about human behavior in social science due to the individual differences. Instead of making generalizations, Willis, Thompson, and Sadera indicated that interpretivism emphasizes understanding the individuals and interpreting them. What is true for one group does not necessarily stand true for another group since each group might be unique in certain ways (Willis, Thompson, & Sadera, 1999). The reasons to choose qualitative rather than quantitative design are manifold. First, our personal biases towards qualitative research present it as a flexible and non-restrictive method, which we can use to understand individuals' perceptions and processes. Second, our research question determined that this study should use qualitative design because the purpose of this study was to investigate the perspectives of education faculty members' experience in a technology project. This study was completed in a natural setting without the involvement of experimental and control groups. Third, since the number of faculty members who have participated in this project is relatively small, it is not possible to obtain a sample size to make valid and reliable quantitative generalizations. Fourth, ISTE (1999) suggests that future researchers should observe classroom activities, interview teachers, and analyze technology-based lesson plans to seek concrete evidence of effectiveness.

**Process**

Three faculty members, two female and one male, who had participated in the project gave consent to be interviewed. Each interview lasted thirty minutes to an hour. Semi-structured interviews were based on prepared a list of interview questions and audio taped. After transcription, the data were synthesized with demographic information, the electronic journals from the summer institute, and course syllabi to confirm the analyses. Transcripts and other data were coded as themes emerged. Follow-up interviews with member checking of the interpretations occurred after the initial data reduction.

**Findings**

There are some commonalities among the three faculty members and individual differences as well. The similarities and differences include previous experiences with technology, attitudes toward participation, beliefs and practices, technologies' impacts on students, and issues relating to gender, age, social networking, access to current hardware and access to technical support.

**Previous Experiences**

All three teachers had some experiences with technology prior to the participation of the grant project. Their experiences ranged from word processing and Internet browsing to PowerPoint presentations and web page design. Each had an office computer with access to a university local area network and e-mail. They had access to two computer labs in the building and supposed access to a faculty multimedia development lab which was usually locked, unavailable and unstaffed. Two of the faculty members mainly used computers for word processing, emails for communication and Internet browsing to search for information for their teaching and research. They did not develop web pages prior to the project. The third faculty developed web pages using HTML prior to the project and posted his course syllabi online and links for students to retrieve information about how to conduct research. He used some software similar to PowerPoint prior to the project in his classrooms.
Attitudes Toward the Participation

The three faculty members demonstrated satisfaction with the whole experience of the project. One is very happy to see her accomplishments in terms of products. The other two consider the project has provided a large variety of resources and support to motivate their learning, interests and rethinking of the goals of their instruction. “But I might argue that the project workshop in that summer was again the catalyst that recognize in my mind … (it) allowed me to recognize in my mind the limitations that … are associated with all the alternatives that I have available to me. The workshop did serve as a catalyst to at least allow me to understand what my needs were and how I could most effectively meet those needs, helping me because it forced me to rethink what I want to present in class.” (Dr. Swanson, male). Walker, Ennis-Cole, and Ennis III (2000) say that teachers’ positive experience in workshops and intensive institutes helps promote a sense of accomplishment or self-efficacy.

During their participation, each of the three faculty members was assigned one student technology mentor. All the three faculty members reported that their student technology mentors basically did not produce anything that they expected, due to mentors’ lack of technological competency and proficiency, and conflicts of time schedule for the faculty and the student mentor to work together. So the mentor relationships were not productive according to the three faculty members. “And then I was assigned a person who is still in the program. She knew less than I did. Well, she is a marvelous person, did subsequently take my literature class. We are still working on…um…she didn’t do much to help. I met her and she joined in. Whenever I ask questions, she would certainly attempt to figure it out or tempted to work on it, but basically I went to (person a). Every problem I have, I just go to (person a), who is not involved in the grant at all. He is a computer support person. I went to him prior to the grant and I continue to use him as the chief source. I did ask my mentor to do a couple of projects for me. I don’t want to give the impression that she is not completely compliant, willing, certainly she is and would independently go out and get her own help. I would ask her this is what I need in excel and later I would have it in my hands. And I wanted to have a powerpoint presentation made, and she did that.” (Dr. Bonnett, female).

Beliefs and Practices

All three faculty members believe that technology is not THE answer to instruction. The purpose of using technology is to enhance teaching and learning. Technology is a tool, and so if one particular type of technology gets in the way, faculty will not use it; instead, they will seek other alternatives to improve their teaching. These three faculty members take a strong critical/evaluative view of the functions of technology which they are implementing in their instruction.

It is not surprising to find out that faculty’s personal interest in technology is highly related to their motivation and adoption of technology. Therefore, the more interest one has, the easier it is to learn and incorporate technology into practice. Personal interest is also related to self-confidence and comfort. If individuals do not have an interest in learning technology and bringing technology into their classrooms, they will be reluctant to change practices and resist learning technology and technology infusion. When resistance exists, the level of confidence and comfort is crucial, influencing processes even though a faculty member may feel forced to bring technology into classroom to keep up with times.

After they participated in the technology-based project, the two female faculty members started to integrate technology into their classrooms. They developed their web pages for easy communication, information delivery and their own research. The male faculty member continually was working on his web pages to convert his website into a more non-linear site. He learned PowerPoint in the project and integrated it heavily into his classes.

Technology’s Impact on Students

All faculty members see technology as a positive impact on students’ learning. Through technology, students are no longer limited in their communication with peers and instructors. By using technology in their learning, students demonstrate enhanced learning outcomes in terms of activities and products. One faculty member mentioned teaching preservice teachers by modeling and requiring technology use in instruction so that preservice teachers can follow and integrate technology into their
academic activities and future classrooms. By watching how the instructors model the use of technology, students are able to use technology in their own academic activities and explore different learning resources. Dawson and Norris report (2000) that technology integrated into classroom by the instructor increased the possibility that preservice teachers transfer the computer skills into their classroom as compared to preservice teachers who learned computer skills in an isolated manner.

Issues

One interesting finding is that among the three participants, the male demonstrated higher motivation than female faculty members, and he is also the youngest (between 35 and 45; both female participants were over 45). He had already sought and received grants for further technology implementation in his courses. Ertmer and Hruskocy (1999) said the challenge that teachers face is to change the way they teach, which is often entrenched. In considering the idea of integrating technology into their instructional activities, many teachers find it difficult to confront their established beliefs about instruction and their traditional roles as classroom teachers. In addition, Becker (1994) reported that teachers’ practices incorporating technology are not only dependent on teachers’ personal interests in technological activities, but also highly correlated with gender, and this might be related to our culture, in which more males have patterns of personal interest that are “technical, mechanical, and numerical” (p. 311), which is consistent with having a deep interest in technology, specifically with computers. In this study, personal interest on an individual basis and gender basis has been identified as a major issue in promoting faculty members to use technology and incorporate technology into classrooms.

Other issues arise when faculty deal with technology. The two female faculty feel time is a problem because it always requires a large amount of time for them to deal with hardware and software. In Becker’s report (1999), he distinguished difference among exemplary technology uses between female and male teachers. Becker indicated that female teachers usually have higher demands on time. If faculty members are not allowed sufficient time to construct their lesson plans, they may find integrating technology into classrooms ineffective.

Another factor is the faculty member’s social network. The faculty member who is not very interested in technology and has experienced frustration mentioned that friends in some schools simply gave up whenever they encountered problems with technology, even without bothering to seek technical support. Presenters that this faculty member has met do not use Powerpoint to do presentations; instead, they use the traditional slideshows, so peer’s views and practices influence faculty members’ beliefs and practices.

In addition to requiring time, the male faculty member thinks it is important to update hardware so that it can meet the increasing needs. Faculty think that there are always problems with technology that they do not have sufficient technical skills to solve, so they are highly dependent on someone who is technologically savvy and has the expertise to deal with the situation. Faculty members feel that there should be someone to whom they can turn whenever they encounter technological problems. In this sense, technical support availability plays an important role in helping faculty members; it eases the pressures of learning new things and thus helps them integrate technology into their classrooms. Becker (1994) said available access to someone from whom teachers can learn or share experience with is very important in helping teachers incorporate technology.

Conclusions and Implications for Future Research

Three participants were involved in this study, two females and one male. Dr. Swanson and Dr. Bonnet are at their forties and fifties, while Dr. Greene is at her thirties and forties. Their teaching years of experience in higher education range from five to thirteen years. Although these faculty members had different experiences prior to the project, their attitudes toward participant, and beliefs and practices are undergoing changes as they use technology. They are either adding to their technology use or rethinking it, seeing the need to consider the technology as a tool through a critical evaluative lens. Issues continue to exist related to gender, age, access and currency of technology. Technologies have significant impact on
both teachers and students. They help both teachers and students reconceptualize their ways of working and thinking and strengthen the relations with the rapidly changing world. However, past studies show that teachers’ professional development has not “kept pace with the rapid changes in the quality and quantity of information technology” (ISTE, 1999, p. 1). Factors that impede effective use and integration of technology have been identified as both external and internal factors. Future research should be more focused on factors that influenced faculty’s use of technology and integration from studying both successful examples and unsuccessful examples, and these designs should balance gender and age.

Student Perceptions of Relative Advantages in Physical Versus Online Submission of Multimedia ePortfolio Projects in Graduate Coursework

Lih-Ching Chen Wang
Department of Curriculum and Foundations
Cleveland State University
2121 Euclid Ave
Cleveland, OH 44115, USA
l.c.wang@csuohio.edu

Abstract: This study will investigate student perceptions of two different methods of submitting multimedia class projects in a graduate educational technology course. All students will create a variety of multimedia files as standard course requirements. One group will be required to submit the projects physically, by directly providing to the course instructor paper or portable media containing the files. The other group will be required to submit the projects online, storing them in a central "ePortfolio" area on a class file server. Student attitudes and perceptions toward these two methods of project submission will be studied, along with their relative susceptibility to error and malfunction.

Introduction

Electronic portfolios are student portfolios which incorporate multimedia components. Wiedmer (1998) described a digital (electronic) portfolio as a learner's compilation of work growth in one or more fields which is developed and exhibited by electronic media. These media may include diskettes, Zip, Syquest, and Jaz drives; compact disk recordable (CD-R); local area networks (Farmer, 1997); and the World Wide Web (Kahtani, 1999). Electronic portfolios can reduce physical storage necessities (Moersch & Fisher, 1995), and encourage students to take more responsibility for themselves and perform better in self-assessment (Tancock & Ford, 1996).

Little research known to the author has yet addressed the use of a remote file server as a medium for creating or storing ePortfolios. Such a "remote ePortfolio" is accessible anywhere at anytime, and is defined for the purposes of this study as a multimedia portfolio created and maintained exclusively on a remote file server accessed by students using a computer network (including but not limited to the Internet).

With respect to remote ePortfolios, this project proposes four research questions. Each focuses on the difference between having students submit multimedia projects via portable media (e.g., papers; floppy disks; SuperDisks; Zip disks; CD-ROMs; etc.) and having students submit multimedia projects online to a central server. The four questions are: (1) Is there a difference in student attitudes toward these two methodologies? (2) Is there a difference in student perceptions of these two methodologies? (3) Which method of submission is more prone to errors? (4) Which method of submission is more prone to malfunctions?

Context

The study will be held in a graduate educational technology class taught at a midwestern urban state university during the Summer 2002 term. Approximately 40 graduate student participants, who are Prek-12 educators, from two sections of this educational technology course will serve as subjects. All students in both course sections will be required to create multimedia ePortfolios. All students in both course sections will be instructed in the use of a remote file server, and in the transfer of files to and from the server using FTP.

All subjects will encounter the same course content, learning activities, and instructor during the same term. The distinction between the control and experimental groups will be in the ways in which students are required to maintain and submit their ePortfolios. The control group will be required to maintain and submit...
their ePortfolios on portable media only, and the experimental group will do so using a remote file server (only).

Data Sources

At the beginning and at end of the term, subjects will complete a questionnaire dealing both with their attitudes toward and their perceptions of electronic submission of projects. The questionnaire administered at the beginning of the term will also collect information about students' prior computer experience and experience with online file transfer.

The first research question regarding attitudes (e.g., preference, satisfaction, etc.) and the second research question regarding perceptions (e.g., course delivery, knowledge and skills learned, etc.) will be addressed using data from these questionnaires.

The third of the research questions addresses errors (that is, human mistakes) in the project submission process. Students in both groups will be asked to record and report any mistakes or errors they are aware of during the process of creating, maintaining, and submitting their ePortfolios; the instructor will maintain an equivalent log.

The fourth of the research questions addresses malfunctions (that is, hardware/software malfunctions) in the project submission process. Students in both groups will be asked to record and report any software, network or equipment malfunctions they experience in the process of creating, maintaining, and submitting their ePortfolios. As with the third question, the instructor will also log such malfunctions.

An Analysis of Variance (ANOVA) model will be used to test the significance of the differences in students' attitudes, perceptions, errors, and malfunctions in multimedia coursework submission between physical (via portable media) and online (via remote file handling) ePortfolio formats. Students' attitudes, perceptions, errors, and malfunctions are the primary dependent variables while the method of ePortfolio submission (portable media vs. remote file handling) is the primary independent variable.

Educational Importance of the Study

The study is educationally significant because it is one of the few studies investigating the difference between coursework submission formats (physical vs. online) on student attitude, perception, error, and malfunction. Should an online format of submission prove to be both equally effective and equally popular, such ePortfolios can provide a cumulative multimedia record of student progress and outcomes which is continuously maintained and improved, as well as accessible to both the instructor and student from all locations around the clock.

Electronic Cognitive Apprenticeships: Building Students' Understanding of ID

Ling Wang
Hua Bai
Sung Hee Park
Purdue University

Abstract: This study explored how students' understanding of instructional design developed as they participated in collaborative learning activities in an electronic apprenticeship environment during a semester-long course. Novice and advanced learners analyzed a set of instructional design case studies. Novice learners also developed instructional design projects with feedback from the advanced learners. By engaging in joint case analyses and design reviews it is expected that both groups of learners will increase their understanding of the ID process.

Theoretical Framework

Literature shows that an apprenticeship environment provides students with opportunities to apply expert problem-solving strategies. Collins and his colleagues argued that cognitive apprenticeships, in contrast to traditional apprenticeships, could most efficiently occur in school settings (Collins, Brown, & Holum, 1991). In a cognitive apprenticeship environment, the goal is to make visible and explicit complex thinking and problem-solving strategies that experts use in particular domains. By combining six distinct teaching strategies, students can conceptualize their knowledge and use that knowledge in a variety of settings (Collins, Brown, & Newman, 1989). The six methods include: modeling, coaching, scaffolding, articulation, reflection, and exploration.

Along with these methods of cognitive apprenticeships is the concept called authentic activity—the use of ordinary practices of a given culture as a basis for learning (Brown, Collins, & Duguid, 1989). One promising approach to initiating authentic, contextual learning is case-based instruction.

Case-based instruction has been used in professional preparation programs to make a bridge between classroom and field. Recently case-based instruction was introduced into instructional design field (Ertmer & Quinn, 1999). The effective use of cases requires students to apply critical thinking to a problem situation to analyze the situation and recommend realistic solutions through better understanding (Ertmer & Russell, 1995; Shulman, 1992; Wright, 1996).

Flynn and Klein (2001) examined the role of group discussion in case-based instruction. Participants working in groups performed better while analyzing cases than those who worked alone. Other researchers (Griffith & Laframboise, 1997; Levin, 1995) found that, for experienced learners, discussion appeared to act as a catalyst for reflection based more on personal experiences than on theory and course content, while for less experienced learners, discussion appeared to allow them to clarify or elaborate their understanding and increase their perspective on the issues in the cases.

Simply stated, case-based instruction becomes more effective when learners at different levels work collaboratively in an apprenticeship environment. However, previous research focused more on the growth in novice learners' problem-solving expertise and their benefits from this learning experience. Few of them explored how advanced learners perceived the collaborative experience with novice learners. Therefore, it is important to examine how both novice learners and advanced learners perceive the benefits of case-based instruction in apprenticeship.

Purpose

This study examines the development of novice and advanced students' understanding of instructional design during one-semester in which they engaged in an electronic apprenticeship environment. To be specific, this study:

- examines the benefits to novice learners who participate in case-based collaborative problem-solving activities and instructional design project reviews in electronic cognitive apprenticeship environment.
- examines the perceptions of advanced learners who participate in case-based collaborative problem-solving activities and mentoring instructional design project reviews in an electronic cognitive apprenticeship environment.

Methods

Graduate students (n=20) at one Mid-Western university enrolled in an introductory instructional design course (classified as novice learners) and graduate students (n=11) from another Mid-Western campus enrolled in an advanced instructional design course (classified as advanced learners) participated in a semester-long study. Three graduate students from the latter group conducted the research. Qualitative data were gathered from discussion board postings.
revolving around case study discussions, instructional design project reviews, interviews, and an end-of-course reflection.

Throughout the semester participants analyzed and discussed 10 case studies via discussion board as part of their course assignments. During the online discussion, they will be in different case setup including role-play, small group discussion, discussion chain, etc. The novice learners also created an instructional design project and the advanced learners played the role of mentors to review novice learners' projects. The novice learners will also be asked to write a reflection at the end of semester. In addition, the researchers will interview the rest of the advanced learners with a semi-structured interview method. With their permission, the interview data will be tape-recorded and then transcribed.

A constant comparison analysis method (Guba & Lincoln, 1989) will be used to generate the categories and patterns from qualitative data. Specifically, discussion board postings and reflections will be analyzed to examine novice learners' perceptions of their benefits from this learning experience. The advanced learners' project review postings and interview data will be analyzed to identify the advanced learners' perceptions of the benefits from case-based collaborative problem-solving activities and mentoring instructional design project in electronic cognitive apprenticeship environment.

Results
Preliminary analysis of the data collected from the first two online case study discussions and the first instructional design project review demonstrates benefits of this collaborative learning approach to be perceived by both novice learners and advanced learners.

While there were no obviously different patterns found in the approaches to case studies between novice learners and advanced learners, the instructional design project review showed certain differences in participants' understanding of instructional design. For example, the novice learners were easily confused by miscellaneous details of the beginning two steps of the ID model, while the advanced learners considered the design steps in the whole process as a "big picture".

The analysis of the participants' discussion postings will continue throughout the semester. It is expected that the novice learners will demonstrate improved problem-solving skills and better understanding of instructional design through working collaboratively with advanced learners. In addition, it is expected that advanced learners will consolidate their understanding of instructional design through both mentoring novice learners' projects and applying their previous knowledge and skills to complex tasks in case-based discussions.

Implications
Although this study is limited by the number of participants and the inability to control the influence of other factors on students' perceptions, it has important implications for apprenticeship approach in building instructional design understanding. It is hypothesized that both novice and advanced learners benefit from collaborative learning in apprenticeship environment. It is usually considered that novice learners benefit the most from such learning experiences because they are more likely to make greater progress due to their low entry knowledge level. However, this paper hopes to demonstrate that advanced learners can also benefit much through authentic problem-solving activities and mentoring novice learners. Their collaboration further indicates that the cognitive apprenticeship provides an effective social context for understanding instructional design.

An Investigation of a Web-Based Learning Environment Designed to Enhance the Motivation and Achievement of Students in Learning Difficult Mental Models in High School Science

Shiang-Kwei Wang, Chia-chi Yang
Department of Instructional Technology
University of Georgia
United States
E-mail skwang@arches.uga.edu, chiayang@directvinternet.com

Abstract: A high school science teacher reported that the students have motivation and learning problems to understand the concept of fossilization. Working with the science teacher, a Web-Based Learning Environment (Web-LE) has been designed by a group of students in the Department of Instructional Technology at University of Georgia to enhance and sustain the motivation of learners in the context of secondary science education. The cognitive tool approach is employed to design the Web-LE to enhance the learners' cognition toward the scientific concept of fossilization. Several strategies for increasing students' intrinsic motivation will be involved in the Web-LE design. The goal is to find the practical approaches to design the online fossil course that should be shored up by the instructional theories including cooperative learning and the motivational theories. The high school teachers can use the Web-LE to aid the science subject instruction without purchasing software.

Introduction

This Web-Based Learning Environment (Web-LE) is being designed to explore the unique WWW features and utilize these elements to enhance and sustain the motivation of online learners in the context of secondary science education. The goal is to find the practical approaches to design the online fossilization course that should be shored up by the instructional theories including cooperative learning and the motivational theories. The high school teachers can use the Web-LE to aid the science subject instruction without purchasing software.

Background

The purpose of this research is twofold. First, the features of the WWW that increase and sustain the motivation of online learners will be identified through interviews with students, teachers, and experts. Second, using development research processes, a fossilization Web-based Learning Environment (Web-LE) that incorporates these motivational features will be designed, developed, and tested in the context of high school science.
The primary setting was a local private school located in a small city in northern Georgia. This school is equipped with well-organized computer technology including computer labs and wireless network. Students and teachers are used to the computer environment and equipped with high computer literacy. This research adopts purposive sampling method based on the specific purposes to work closely with the science teacher and students in a local school to promote learners' motivation and learning achievement. The participants are one male teacher and 16 10th grade students. The teacher is an experienced science instructor. The teacher encountered problems to convey the concept of fossilization to students, and has difficulty to motivate students.

The science teacher reported that the students have problems to understand the concept of fossilization. Fossilization is a result of complex combination of organism, ecological and physical burial. The fossil would be formed only under the correct situation. Students have to understand that how and why ecological and physical burial influence fossilization. The teacher couldn't find accurate or useful materials to help students visualize the process of fossilization. Some web sites introducing the fossilization contain only still images, pictures and texts, and the representations are not realistic enough or accurate to be employed in the classroom. The science teacher needs a tool that is realistic and accurate to explain the fossilization and provides opportunities for learners to consider the potential combinations of different decision. The learner will be able to identify situations that will cause fossilization. After evaluating the current available computer-learning environment, a Web-LE has been decided to be employed to carry the instructional contents.

Employing Web-LE as the cognitive tool

Owston (1997) indicated that the key to promoting improved learning with the Web appears to lie in how effectively the medium is exploited in the teaching and learning situation. The standard online tools mentioned above offer restricted choice to instructors seeking to offer experiences with complexity and dynamics of classroom experiences, and we need new tools to enable a variety of interactions (Hughes & Hewson, 1998). The advent of online interactive learning system enhances the interaction in the learning environment. Participants can interact with other participants to discuss the questions and concepts. With authoring tool (e.g., Macromedia shockwave, Flash, Authorware, JAVA), instructor can design the synchronous or asynchronous activities based on different goals and tasks. The features of open environment and immediate communication can be embedded in the application to enable collaborative learning strategies. The ability of these tools to carry interactive multimedia contents support design of situated learning strategies by simulation, problem solving or authentic activities (Leflore, 2000). The features of dynamic pages allow learners interact with contents directly to process the information individually. Learners will be benefited by the delivery of information with appropriate instructional design instead of presenting information in hypermeda structure and multimedia contents (e.g., streaming audio and video). Web pages can carry multimedia and access to the open environment. Learners can interact with content with pages (browsing, filling questionnaire ...), and the level of interactivity depends on how the designers design the web pages. With the features that the WWW provide, it makes Web the appropriate tool to carry the instructional contents.

Several doctoral and master students have been working together to design the fossilization Web-LE in the Department of Instructional Technology at University of Georgia under the guidance of two faculty members. The science teacher is the subject expert, who works closely with the team to verify the accuracy of the contents, identifies the educational problems and provides feasible instructional strategies. The system is developed by Macromedia Flash and combines with the online database with ASP and MS Access.

Instructional design strategies

Several strategies for increasing students' intrinsic motivation will be involved in the Web-LE. First, Lepper and Hodell's (1989) four characteristics of tasks that promote individual intrinsic motivation will be integrated into the instructional design.

1. **Challenge:** Engaging with the activities that challenge learners' abilities may enhance the intrinsic motivation. The premise is that the challenges of activity and skills of learner should be matched.
2. **Curiosity**: Curiosity can be achieved by using the technical events to attract the learner’s attention. Highlighting incompleteness or inconsistency is one technique to arouse the curiosity. Through the provision of unpredictable or random events may motivate learners to continue the learning processes.

3. **Control**: Learners’ intrinsic motivation may be enhanced if the activities can provide a sense of control over their learning performance.

4. **Fantasy**: Fantasy environment is defined by Malone and Lepper (1983) as one that evokes mental images of physical or social situations not actually present.

Second, Web has the capabilities to facilitate the communications among participants, and this feature provides the opportunities to carry out the cooperative and competitive strategies, whereas the open environment feature enables learners to publish their products or achievement and have people recognize their performance. The design of Web-LE will integrate the cooperation, competition and recognition strategies to facilitate collaborative learning pedagogy and stimulate interpersonal intrinsic motivation (Malone and Lepper, 1983).

The third strategy is to integrate multimedia objects into learning context. Learning with multimedia provides an effective alternative instructional strategy (Mathewson, 1999). From the motivational perspective, using medium to assist instruction indeed enhance learners’ interest (Freeley, 1982; Kramarski & Feldman, 2000).

Computer enables visualization of scientific concept and Internet enhances interaction among learners. The multimedia objects will be employed to represent the fossil concepts to enhance the intrinsic motivation.

**Overviews of the system**

**Instructional content**

How does a living thing become a fossil? Not all parts of animals and plants become fossilized. After completing learning the concept of fossilization with this cognitive tool, students will be able to identify conditions necessary for fossilization and construct possible scenarios for formation of fossils by manipulating the variables in the simulated processes. Fossilization is a rare event. The chances of a given individual being preserved in the fossil record are very small. Whether a living thing could become a fossil depends on three categories of conditions (organism, ecological status and physical burial), if an organism has hard part or not, if an organism gets buried quickly and the ecological situation, where an organism dies. It’s only possible that a living thing can become a fossil when these three conditions are met.

**System function**

![Flow chart of the fossil Web-LE](image)

Figure 1 is the flow chart of the fossilization Web-LE. When entering the Web-LE, learners will see the instructional page to explain the learning objectives and goals of the fossil unit. Learners have to input names and
login into the system. In screen a, learners can select different organism to observe the fossilization process. The dinosaur is the only available organism in the prototype. The description of this organism is placed under the screen (Screen 1). Learners can access to the online glossary to look up information if they have any questions. In screen b, they need to select the ecological status (Screen 2). In screen c, learners need to select physical burial. The combination of three decisions can decide whether the fossil will be developed. Simulation of fossilization begins when the decision has been made. The system will record paths that learners just made and help learners to identify the learning progress (Screen 3). After experiencing all twelve possible paths, learners will be able to identify the situations that can create fossils (online assessment).

The complete twelve possible combination including:
1. Organism
2. Ecological (3 conditions): temperate rainforest, tropical rainforest and tropical mountains

Learners can assess to online glossary to look up information about these conditions. With the communication tools that the Web-LE provides, learners can send e-mail to other learners and teacher. They can discuss questions with the bulletin board.

Media development

The primary audience is high school students who appeal to realistic graphics and animation. The science teacher also requests for the realistic representation of the fossilization process. Several endeavors are made to achieve the requirement. Referring the accurate images, the dinosaur is developed with accurate proportion and color. 3D software is used to develop the realistic landscapes and objects including ancient plants, volcano, lake and fossils. Macromedia Flash is the primary authoring tool because of its ability of integrating multimedia and the capability of optimizing media to enhance the speed of transmission.

Screens example

1. Screen 1: Select organism
2. Screen 2: Select ecological status
3. Screen 3: Begin simulation of fossilization
4. Screen 4: Use “my path” to record selections

Learners need to select organism in Screen 1. The description of this organism will appear in the text area. Learners should continue to select ecological (Screen 2) and physical burial conditions. When learners click
“submit” button, the simulation of fossilization will begin. An animation will appear to depict the procedures of fossilization. For instance, in Screen 3, learner chooses combination of “Brachiosaurus”, “Tropical Mountain” and “Lava Flow”. When simulation begins, the volcano explodes and the lava catches up the dinosaur to mantle its body. The fossil will be formed in this situation. In Screen 4, learners can assess to the communication tools (e-mail and discussion board). The function of “my paths” will record the paths that the learners have made and identify their learning progress.

Validation

The formative evaluation strategy is employed to make sure the content is accurate. The subject expert reviews the contents once a week and provides suggestion constantly. After the production is completed, the participants will be formed into one control group and one treatment group. Several instruments will be employed to exam the effects of the Web-LE on motivation, science and learning with Web-LE. The following interview with teachers and treatment group students will be conducted to probe their suggestions toward the Web-LE.

Expected Results

The expected results include: 1) effect of Web-LE on learning is significant difference between the control and treatment groups, 2) learners’ motivation toward learning science with Web-LE is significant difference between the control and treatment groups, 3) the previous two results can confirm the usefulness of the pedagogies and identify the motivational indicators, 4) identify the mental model of online learners. The Web-LE will be released online and all teachers and learners who are studying the similar unit can use it as a learning resource.

Future work

The fossil Web-LE contains twelve paths and each of them needs to be completed by March 2002. The online database is under development to record and preserve users information. We’re developing the communication tools including email and bulletin board to enable the interaction among participants. The science subject expert is helping us to design the glossary pages for learners to refer to. The glossary pages contain multimedia explanation about the units of fossilization (for instance, the various images of fossils and video clips of reconstructing fossils). The fossil project is one unit of the entire Geology and Ecology course in the school. The URL of the Geology and Ecology course is: http://128.192.78.9/science. Other units (geological time, radio dating, volcano and continental drift) will be designed after the fossil project to expand the web-site into a learning resource for science class in high school. The URL of the fossil project is http://128.192.78.9/science/fossil (the permanent URL will be activated after June 2002: http://www.itstudio.net/fossil).

The fossilization Web-LE is developed by Shiang-Kwei Wang, Chia-chi Yang, Wan-Ting Huang, Beaumie Kim, and Dr. Hill under Dr. Reeves and Dr. Hill’s supervise. We appreciate Jack Kridler’s contribution to this project as a subject expert.
If You Build It, Will They Come? Helping Instructors Change Their Role

Jenny Wang-Chavez, Greenfield Coalition, Wayne State University, USA, chavezj@focushope.edu
Diane Schuch-Miller, Greenfield Coalition, Wayne State University, USA, schmild@focushope.edu

Abstract: The study examined three engineering courses that were offered in the Fall 2001 at Greenfield Coalition in order to facilitate the changing role of instructors. These three courses, as other Greenfield courses, with its learner centered instructional strategies and technologically enhanced activities, were designed to have the instructor function more as a facilitator, mentor, and coach rather than the typical stand-up instructor. This study documented the instructional strategies and learning activities that helped instructors transition from a traditional standup instructor to a “guide on the side.” In addition, this study identified factors that affected the successful implementation of instructional strategies and technology and also suggested ways to assist instructors to implement technologically enhanced and learner-centered strategies.

Introduction

The high demand to produce knowledge users and problem-solvers requires that instructors play the role of coach, mentor and facilitator rather than director and disseminator of knowledge. This demand calls for change to traditional teaching. As instructors are introduced to new instructional strategies and tactics that force them to function as a “guide on the side,” it is essential to study the effect that such strategies and tactics have on the traditional instructor and to identify ways to assist instructors making this transition.

The purpose of investigating the usage of instructional strategies and technology was to identify: instructional strategies and learning activities that facilitate the transition from a director & disseminator of knowledge to that of a coach and resource; the factors that might affect the successful implementation of new instructional strategies and technology; as well as ways to assist instructors implementing technologically-enhanced and learner-centered strategies.

The courses investigated, Arts in Action, Engineering Economics, and Tool Design and Construction, are required courses for all candidates enrolled in a degree program through Greenfield Coalition (GC). GC courses are designed based on the belief that students will learn faster, and will become more effective problem solvers if engineering education and practice are integrated, and students actively participate in their learning.

Data Collection and Analysis

Eight instructors were invited to participate in this study. Five of them returned our survey and participated in a focus-group interview. All but one of them has been teaching for more than 6 years. The survey and interview focused on the use of instructional strategies, instructor’s perception of teaching, assessment methods, barriers to adopt Greenfield courses, and types of support that instructor will need to fulfill their role as a facilitator.

Survey data were tabulated by the question items. Qualitative data were coded into indexed categories and subcategories. Through iterative comparisons of these categories and subcategories with the guided research questions, key issues and themes were generated.

Findings

The survey and interview data indicated some trends in using instructional strategies and technology.

Using instructional strategies

All participating instructors were aware of the instructional strategies used in the three courses being studied. All instructors rated lecture as an effective teaching method, and they all used student discussion as well as...
required student participation in class. Four instructors described their teaching as engaging and interactive. Four out of five instructors used such strategies as case studies and projects and they all viewed them as effective teaching methods. Three instructors thought that students achieved listed objectives. Two instructors required students to work together. One instructor used online interactive problem solving and additional WWW resources. One instructor used student input to determine course content. In assessing student learning, there is a combination of traditional tests and quizzes, and authentic evaluation such as projects, case studies, and peer evaluation.

Instructional strategies rated as “well and will work well” to help the instructor transition from traditional knowledge disseminator to facilitator, mentor or coach include: instructor playing role of coach, having resources available to students all the time, doing more hands-on, using real world problems or examples, using authentic tools, facilitating group discussion, using interactive activities, what-if questioning, and projects.

Using technology

In class, instructors use more traditional media, such as whiteboard, LCD projector, and audio-visual equipment. Outside of class, instructors use more new media such as computer and Internet resources. Other than traditional media, only two of five instructors indicated incorporation of technology in their teaching. Instructors indicated a desire to use technology more in the future. One instructor hoped that technology-enhanced strategies would help him reduce his reliance on lecturing. Another would like to have a course that is “plug and play,” and portable. Yet another would like to explore the possibility of providing real time feedback using technology.

Factors affecting the successful implementation of instructional strategies and technology

Instructors raised some issues regarding the adoption of the role of facilitator. These include: student and instructor readiness, and administrative support. Three instructors felt frustrated with students not taking responsibility for their learning. Also, one instructor was puzzled with the value of teaching if the instructor was not there to “instruct.” Yet another felt that his role as a facilitator may be criticized by peers and administration.

Technological constraints, which include the infrastructure, technical support, and reliability issues, discouraged instructors from adopting technologically-enhanced instruction. Additionally, some classrooms did not have enough computers to use, or did not have adequate Internet connections.

Implications and Conclusion

From our limited sample, we noticed that instructors used a combination of instructor-centered and learner-centered instruction. While lecture is the predominant mode of instruction, instructors began to incorporate strategies that required students’ active participation, such as real world problem solving and hands-on projects.

Below are suggestions that we believe would enable the greatest ease in the adoption of the GC paradigm:

- Demonstrating course materials and the use of instructional strategies and technologies at partner universities to promote wider use.
- Conducting faculty development workshops to help faculty adopt student centered strategies.
- Planning and implementing an ongoing technical support system.
- Encouraging academic Directors and Deans to promote instruction that is learner-centered, technology-enhanced, problem-based, and reality-based.

Moreover, we feel that the issues faced by GC are not unique or new. The findings verify that if you built it, they (the instructors) may not come. Although instructors were aware of the instructional strategies and agreed that online materials were good, the barriers prevented them from fully implementing the activities. Three things need to take place before instructors can fully adopt facilitator’s role and endorse student’s responsibility for learning: instructor readiness, support from administration in terms of a reward system (recognition toward tenure, etc.) and the assurance that ongoing technical support will be provided and be considered a priority.

Yes I Can: Teachers Developing Interactive Classroom Activities Using Digitized Resources

In cooperation with the Education and Research Consortium of Western North Carolina, teachers from WNC public, private, and charter schools as well as undergraduate pre-service education majors are participating in a pilot program which enables educators to utilize through the Internet the millions of resources held by the Library of Congress (http://www.loc.gov). The educators chosen to participate in the project are on the leading edge of the development of a classroom technology program that is expected to become a national model. The pilot program exists at Montreat College as well as 4 other institutions that are a part of the Education and Research Consortium of Western North Carolina.

The focus of the project is to provide pre-service and in-service teachers the tools and instructional skills necessary to integrate technology into the teaching and learning process. The objectives for the four year program are as follows: a) To demonstrate a Library of Congress American Memory Fellows Program pilot that teaches teachers how to utilize technology and digitized primary resources in their classroom instruction (http://memory.loc.gov) b) To train pre-service and in-service teachers to use primary resources in their class instruction c) To further validate the American Memory program with a broad group of K-12 teachers in local settings and d) To demonstrate and evaluate a training program that can be exportable to other communities.

Participants selected to participate in the Adventure of the American Mind program (http://aam.montreat.edu) are required to complete a one-year program that includes three phases. The first phase is a three-day Summer Institute that introduces the laptop which is provided for each participant by the program and immerses the participants in the basics of using PowerPoint. Phase II is a graduate level course, Multi-Media and the Internet in the Classroom(http://aam.montreat.edu/ED504). This course runs for fifteen weeks, 3 hours each week and yields 4.5 CEU's and 3 graduate credit hours. The participants learn how to integrate technology into their classrooms and schools, how to build interactive projects in PowerPoint, and how to engage students in the learning process to build higher level and critical thinking skills. The final phase of the program is the Mentoring Phase. Following the train-the-trainer model, participants act as mentors as they take the skills and techniques and skills from Phase I and Phase II and share them with colleagues. The mentoring may be either in one-on-one or group workshop setting. After successfully completing all phases of the one-year program, the participant earns permanent ownership of the laptop.
Weekly in-class activities for the teachers were designed to enhance their use of and understanding of electronic resources. Journal articles broadened participants' knowledge of ethical and practical issues relating to the integration of technology into classroom activities. Participants were required to respond to the articles on-line in a threaded discussion. Group discussion in class highlighted major issues that arose during the threaded discussion. Mechanics of designing presentations including downloading and uploading graphics and music as well as the esthetics of presenting information on-line were presented in class. Lab time was available for individual practice during each class. As a final product, participants presented an interactive PowerPoint-based lesson that each would use in the classroom. The presentation was accompanied by a unit plan which included state and local course objectives for the grade and subject level taught.

On-line assignments were also a part of class requirements. One class activity required students to read articles on-line and post responses related to the application of the information from those articles. Another assignment was for participants to locate exemplary lesson plans that integrate technology into the lesson. They entered the URL for the lesson plan, a summary of the plan, and an evaluation of the plan into the class database. All of the class work was designed to enhance the participants' skills and informed practice as they formulated lessons and philosophies for their specific classroom needs.

The growth from novice to confident developer of creative and innovative lesson plans was facilitated by opportunities for participants to develop relationships with others in the class. During part of each class, participants worked in a group. Rotating the members in the groups each week gave the opportunity for participants to interact throughout the semester with each member of the class. In addition, a portion of each class period was allocated for mentoring. Pre-service teachers were assigned a hypothetical "class" which included the characteristics of each student. The pre-service teacher education students then visited the classrooms of the in-service teachers who taught the same grade level. The classroom visits enabled the pre-service teachers to develop strategies and appropriate classroom activities for their "class." Reciprocally, the pre-service teachers mentored their in-service partners in technology skills.

The final component of the class was its instructional team. During each class meeting a curriculum specialist, an instructional technology specialist, and a technical support specialist provided input. These three instructors were available on-line or by telephone during the week as well as during class to assist teachers in their learning process.
Mitigating Risks During the Transition to Fully Automated Exams:

Edgar Weippl
Software Competence Center Hagenberg, Hauptstr. 99, A-4232 Hagenberg, Austria
edgar.weippl@scch.at

Abstract: In this paper we present a strategy how traditional in-class exams can be substituted by computer-based exams. Exams obviously involve security issues; for instance, the aspect of availability is of great concern to students whereas teachers expect integrity of the results. Under no circumstances will students tolerate exams being lost while they take them or will teachers use a system where exam answers can be changed after the exam. The stepwise migration strategy from traditional paper-based to computer-based exams proposed in this paper has multiple benefits: (1) advantages of migration are perceived at every stage by all stakeholders. (2) Fall-back options exists that may be used if problems occur. (3) Paper-based backup used to cover legal uncertainties. (4) Instructors can independently decide when to migrate to the next step.

1 Introduction
During the transition of a conventional examination system to fully automated Web-based tests, day-to-day business processes should only be briefly interrupted. We therefore show how we use a stepwise migration strategy to eventually establish a fully automated Web based examining system that allows students to take exams almost anytime.
Our main contribution is to show how to setup a stepwise migration strategy that minimizes organizational interruptions. Moreover, we emphasize an approach where moving to the next step is always perceived as advantageous by all stakeholders.

2 Multi-Step Approach
Before an exam can be generated automatically a database of exam questions and answers has to be created. Despite a still limited application at Austrian universities we found that multiple-choice exams are well accepted by students. We propose to use questions with five options each, of which exactly one answer is correctly. An exam comprises approximately twenty questions with five possible answers each; thus the probability of a student passing the exam by chance is very low.
Once a database of approximately one hundred questions has been compiled we recommend proceeding to the first step and using automatically generated exams for in-class test.

3 Practical Experience

In this section we will present the tools we developed supporting the aforementioned stepwise migration. The main purpose is not to promote our solution but to show that every transition by itself requires only little development effort and the time between migration steps can be scheduled to match scarce resources of developers and faculty.

3.1 Database

The application presented in this section works with any ODBC database; we tested it with mySQL (www.mysql.com) and Oracle (www.oracle.com); as the current installation is mainly used by students to generate practice exams mySQL suffices as database. The drawback of mySQL is that concurrent write accesses to the database are slow; however, write accesses are only necessary for real exams.

3.2 Exam Creator

Teachers can specify what an exam (e.g. Test01) looks like by selecting different rules. For instance, the teacher wants that the exam contains 3 question that satisfy the condition mathStat=1. There are 48 questions that satisfy this criterion.

The rationale for choosing this complex specification is that all the teachers in the department prefer typing conditions (that can be quite complex) to limited GUIs. The green numbers on the right indicate how many questions really satisfy the condition. If an illegal condition is entered, a '0' highlights that no questions are available.

Each question has two mandatory values assigned: required time to complete and level of difficulty. An exam is composed of randomly selected questions that satisfy the aforementioned restrictions. For each exam a minimum and maximum time and difficulty are also specified. The sum of the values of all questions that are randomly selected should lie within the specified ranges. A tool helps teachers and checks how many randomly generated exams satisfy (green dots inside the shaded area) the time/difficulty bounds and how many do not (red dots outside of the shaded area). If there are a lot more red dots than green dots the generation of an exam might be slow because only “green” exams are really generated for students. “Red” exams might be too difficult or require too long to solve.

This user interface is used by faculty and staff in step 1 and 2 to automatically create paper-based exams.

3.3 Web-based Practice Exams

A very simple Web server allows publishing practice exams on the Web. It suffices to copy a small executable file which subsequently serves as a Web server. The advantage is that installation is very easy and even teachers without special IT knowledge can install and maintain the server without the help of IT staff. Students enter the system with a Web browser and can select an exam. Thereafter an exam will be automatically generated and both the questions and answers will be available to the student.

Students benefit considerably from practice exams since they can continuously assess whether they reached their learning goals [Woit and Mason 2000].

3.4 Computer-based Exams

From step 3 on a simple program is used by students to enter their answers. The focus was obviously placed on a simple design. After pressing 'OK', the student is asked whether she wants to hand in the exam or continue editing it. When she decides to hand in, a paper copy of the exam and the answer sheet is printed.

4 Conclusion

In this paper we explained how a multi-step approach can be used to minimize risks when introducing computer-based exams. The key issue is security and the option to “fall back” to previous steps if problems occur. Moreover, as every new step brings benefits to the stakeholders, the chance of successfully completing the project, i.e. of going all the way to step 5, is high.

The Transition from Computer-Based Training to eEducation

Edgar Weippl
Software Competence Center Hagenberg, Hauptstr. 99, A-4232 Hagenberg, Austria
edgar.weippl@scch.at

Abstract: Navigation is one of the key aspects of eLearning environments that can make a difference when comparing new forms of learning to traditional ways of learning. In this paper we elaborate on the experience we gained while developing an eLearning solution and highlight the relevant issues giving screenshots.

1 From Computer-Based Training to E-Education

During the past few years the Web has fundamentally altered many people’s work life. Businesses were transformed into e-businesses and the buzzword ‘e-commerce’ is now ubiquitous. There is, however, an industry that only gradually adopts these new technologies - teaching. Despite the fact that universities have significantly contributed to the development of the Web, it is still not fully used to improve academic teaching.

It was only last year that the term eLearning was defined by Lennox [Lennox 00] as “the use of e-business technologies to speed the flow of business information and knowledge from creator to learner in a highly personalized, on-demand fashion”.

In this paper we will present two decisive factors for Web-based training (WBT) software in the context of e-education. We will focus our report on offline education, as real time communication (except chats) is not yet sufficiently reliable due to low bandwidth Internet access in most European rural areas. Moreover, one of the main advantages of WBT software is being able to study according to one’s own schedule. Even if online communication was available, a large offline corpus of knowledge would be required too - just like textbooks are used in today's courses to support traditional in-class teaching. The techniques presented in this paper can help to organize the electronic equivalent of textbooks.

Compared to textbooks, correspondence-based distance learning programs and first generation computer-based training software, WBT offers many advantages. Two of them which we consider most important will constitute the main focus of this paper: First, navigation is no longer limited by serially flipping through pages and second, interactive examples are far more likely to actively involve students while studying. Throughout this paper we will give examples of how these features have been successfully implemented [Weippl 99] in WBT software called Teach/Me [Lohninger 99].

Dating back to the hype of the term “eCommerce” eLearning is widely used in different ways; for instance, [LineZine] understands eLearning ranging from “the convergence of the Internet and learning, or Internet-enabled learning” to “the use of network technologies to create, foster, deliver, and facilitate learning, anytime and anywhere” or “the delivery of individualized, comprehensive, dynamic learning content in real time, aiding the development of communities of knowledge, linking learners and practitioners with experts.”

[ELeamers Glossary] defines e-learning as any form of learning that utilizes a network for delivery, interaction, or facilitation.

According to [Learning Circuits Glossary] “E-learning covers a wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms, and digital collaboration. It includes the delivery of content via Internet, intranet/extranet (LAN/WAN), audio- and videotape, satellite broadcast, interactive TV, and CD-ROM.”
2 Interactive Navigation

Based on the knowledge of how students learn, it seems obvious that the way of presenting knowledge and the options offered to navigate or access it, are essential for successful teaching. It is a commonly known fact that WBT offers the possibility to design teaching material that can be accessed in a non-linear way. However, a brief scan through existing course material reveals that a large number of today's courses are not designed for efficient navigation which is needed for learning. This is why it is essential, that when designing the navigation structure for WBT software one always has to keep in mind that the ultimate goal is to effectively convey knowledge.

In this section we will first discuss theoretical issues that are essential for designing ways to navigate WBT content. We will then continue by discussing various forms of navigation. Finally we will elaborate on the forms of navigation best suited for different targets of learning.

2.1 Learning Process

When studying, people usually create an internal representation of the topic they study. A cognitive map, i.e. a form of visualizing content structure, can aid in this process. Cognitive maps are two-dimensional representations of knowledge structures. They are based on the assumption that the relationships between ideas or concepts can be uncovered due to semantic proximity; that is, semantically related ideas will appear close in geometric representations of cognitive space whereas unrelated concepts will be separated by a greater distance.

Fenker [Fenker 75] states three assumptions about cognitive maps: First, information about a topic is organized and interpreted on the basis of a set of dimensions which represent organizational features of the topic. Second, these dimensions can be represented in n-dimension geometric space. Third, there are many relationships that can exist among concepts. Similarity, degree of association, and the extent to which one concept implies another are examples of these types of relationships. That is, the nature of the semantic relationship is implicit in the relationship but has to be interpreted.

During the learning process cognitive maps can be used to assess how well students have integrated recently acquired knowledge and whether they can position it within existing knowledge. The student draws a concept map representing his current knowledge; areas not well linked to other parts of knowledge may be identified and indicate the necessity of further studies.

Acquiring new knowledge, i.e. transforming external to internal representations preserves certain aspects of the representation, mainly the topology [Steiner 88]. Cognitive maps do not seem to be a full and continuous representation of the information stored in mind. They are fragmented and distorted on an individual basis. Since they change dynamically they cannot be easily copied onto an external representation. Each time an individual tries to output the interior cognitive map containing specific knowledge, it looks different. This implies that there is not only one 'correct' spatial representation of relations between topics.

Although the definition of cognitive maps varies in the literature, there seems to exist an agreement that cognitive maps are an appropriate way to represent relationships between different entities of knowledge [Driver 92], [Gergen 92], [Spiro 92], [Galsersfeld 92].

Some details seem especially important in the context of this paper. Certain points of interest and paths between these points are learned (i.e. external maps are internalized) when studying new concepts. Using those paths, the overall context of the knowledge can be understood easily because students can look at topics in the vicinity of those paths to find related concepts.

The first step in the process of teaching is that the attention is drawn to points of interest, i.e. important topics. Learners perceive these points of interest either because they are highlighted on the cognitive map and can therefore be easily spotted or due to their Importance. In a second step points of interest that are close to each other are used as starting or end points of paths. Knowledge of these paths seems to be more or less knowledge of starting- and endpoints and orientation in the map. This "learning of paths" is what can be achieved by using "Guided Tours" in a Knowledge Landscape, which will be discussed in greater detail in the next section.

2.2 Navigation Metaphors

Initially most CBT programs implemented the behaviorist paradigm. Since the days of behaviorism seem to have passed an increasing number of approaches in CBT try to adopt constructivist methods (overviews can be found in [Jonassen 93], [Brandt 95]).
Freeman [Freeman 96] tried to integrate the constructivist paradigm into a course enabling teachers to use the Internet for distance learning. Having taught the necessary basics, she gave the participants the opportunity "to build up their own internal knowledge base."

The visualization of a given field of knowledge should leave it up to the students how to explore the data, how to structure the contents, where to set priorities and to decide which chapters they consider as related. However, in order to avoid the experience of not knowing what to learn and not being able to structure the presented data, presenting some pre-defined structure to start with is useful.

The modes of navigation offered by Teach/Me [Lohninger 99] go far beyond those of other textbooks. Pohl et al. [Pohl 95] have identified four main difficulties when creating educational hypertext. First, authors are used to structuring text in a linear or hierarchical way like in printed textbooks. Second, the texts are often too long and do not have enough words highlighted e.g. by bold typesetting. Third, scientific publications as well as textbooks have long argumentative strains that support one final solution for a certain problem. These parts have to be read in a fixed order determined by the author. Fourth, a large number of short texts may be confusing, especially if they are not suitably structured. This can result in the well-known phenomenon of 'Lost-in-Hyperspace'. Two of these issues, i.e. hierarchical text structure and potentially confusing hyperspace navigation can be addressed by providing multiple forms of navigation through WBT content. We will now present four different approaches to navigating hyperlinked textbooks.

2.2.1 Table of Contents

The oldest form of navigation through written information is the table of contents. It is still widely used in today's hyperlinked WBT. This is mainly due to the fact that everyone is familiar with this form of navigation. Most authors think that sequentially structuring content seems to be an efficient way. However, the fact that researchers and authors like a hierarchical-linear structure is to a great extent because it is the structure they have always used.

Despite the advantages offered by the navigation interfaces discussed later in this section, WBT courses should always include a table of contents because everyone expects it and knows how to use it.

2.2.2 Keywords – Indices

Similar to the table of contents, an index is a form of navigational interface commonly found in books. Nonetheless, software may offer a much greater flexibility. First, searches for keywords can be more expressive by using Boolean expressions. Second, by displaying an indexed expression in its context before actually opening the page users can quickly scan through a large number of matches. Compared to paper-based indices that sometimes refer to ten or more different pages for a single keyword the quicker access in a Web-based textbook is certainly an advantage.

2.2.3 Hyperlinks

Hyperlinks are commonly used to navigate through hypertext. Today's Web is linked by only one link type that can represent different forms of how a linked text is related. Rada [Rada 91] distinguishes three fundamentally different forms of links. (1) Sequence links connect pages in a linear sequence. Using 'Next' and 'Back' links helps especially first and second year undergraduate students to access all pages relevant for a lecture. (2) Outline links refer to pages that contain overview. (3) Reference and citation links point to pages that describe topics in greater detail.

When designing WBT software we recommend to clearly indicate (e.g. by a particular icon) the kind of link; this helps students to decide whether they want to follow a link or not. Figure 2, for example, shows two different links; one opens an interactive example to illustrate concepts explained in the HTML page, whereas the other link starts a calculation tool with preloaded exercises so that students can apply their newly acquired knowledge.
knowledge landscape

To provide a good overview and easy navigation we have chosen to visualize the textbook with the help of a Knowledge Landscape. A mountain in the landscape represents each page of the underlying textbook. The formation of the Knowledge Landscape is governed by two general rules: (1) In the 3D version, fundamental chapters, explaining basic concepts, are visualized by high mountains, whereas more specific lessons are displayed by smaller mountains. (2) The placement of the mountains is made according to the similarity of the contents of the corresponding lessons. Thus highly related texts are placed next to each other. The positions of the mountains on the 2D surface are computed automatically. This approach allows easy non-linear and non-hierarchical access to originally hierarchically structured documents.

Static objects in a landscape, whether they are real or virtual, have unique fixed positions in the spatial three-dimensional space. We all have experienced the exploration of unknown and the navigation in known territory since early childhood. Thus we are used to remembering the relative positions of objects in our environment and we can easily find objects again, even if they are not in our direct line of sight. Despite the fact that there is not only one ‘correct’ spatial representation of relations between topics we offer only one Knowledge Landscape as novice users may easily be confused if they are confronted with more than one spatial representation.

2.3 Learning Targets

In this subsection we will have a closer look at five learning targets and we will examine which forms of navigation are best suited for each of them.

2.3.1 Training – Drill and Practice

Drill and Practice training was one of the first applications for computer-based training. The computer was the perfect tool to teach highly standardized procedures such as preflight preparations for an aircraft’s cabin crew. A major component of these simple CBT programs is testing the students’ knowledge. Objective tests and quizzes are among the most widely used and well-developed tools in higher education. Each question assumes a simple answer that can be evaluated either as correct, incorrect, or partly correct. According to the expected type of answer, questions are often classified into eight types. There are four basic types: (1) yes/no questions, (2) multiple-choice/ single-answer (MC/SA) questions, (3) multiple-choice/multiple-answer (MC/MA) questions,
and (4) fill-in questions with a string or numeric answer. More advanced type of questions include (5) matching-pairs questions, (6) ordering-questions, (7) pointing-questions – the answer is one or several areas on a figure – and (8) graphing-questions – the answer is a simple graph. Also, each topic area may have specific types of questions [Brusilovsky 99].

If CBT software is developed for drill and practice, the most important navigation tool is the table of contents. It gives students a clear outline of what will be covered. There is no need to support learning or understanding additional topics as the whole learning process is highly predefined. Referring to the example of training cabin crews, the CBT software does not need to help students understand which preflight checks a pilot would have to make.

2.3.2 Gaining an Overview
Especially in a professional working environment it is very important to be able to quickly gain an overview of a topic and to identify the main concepts. We think that this learning process is best supported by a combination of the Knowledge Landscape and a keyword search. The search results are highlighted in the Knowledge Landscape and one can therefore locate the main concepts and their relation with certain keywords.

2.3.3 Understanding In-depth Knowledge
Teachers generally agree that students must actively process and make sense of available information in order to gain an in-depth understanding of a topic. Therefore, expert teachers use many different techniques to ensure the active involvement of students. For example, classroom teachers rely on a number of visual cues from their students to enhance their delivery of instructional content. A quick glance, for example, reveals who is attentively taking notes, thinking about the lecture or a difficult concept, or trying to make a comment [Willis 93]). In contrast, pupils studying with WBT software may lose attention without anybody noticing.

One way to increase the probability that learners actively process information is to require answers to small quizzes and the use of interactive examples (see Section 3). Another option is to engage them in the process of exploring the knowledge domain. A knowledge landscape can be both motivating to navigate through and convey insight into how concepts are related. As understanding the connections between various topics is essential for gaining in-depth knowledge, the knowledge landscape is an important tool supporting this process.

2.3.4 Reference
Students often keep good textbooks as reference. Mainly because they have spent a considerable amount of time and effort to study the book, they are able to understand concepts they do not remember well very fast again. Therefore it is essential that good learning material is also designed to be used as a reference. Obviously, an index is the most important navigation interface for finding the required information. However, as indices are by definition word-based and not content-based one might miss highly related concepts, particularly if different domain experts use different terms for the same concepts. As the Knowledge Landscape is computed content-based and does not rely on keywords only, it can uncover such relationships.

2.3.5 Adding or Updating Content
The content of WBT software has to be periodically updated to ensure that it meets the demands of a changing syllabus. As most WBT projects are maintained by more than one author it is very difficult to make sure that links to all related topics exist— even if the author is required to set links to topics written by others. The Knowledge Landscape can support authors in finding relevant relations and it helps to ensure that the hypertext navigation structure, i.e. links, is built properly.

3 Conclusion
Navigation can be considered to be one of the decisive factors in determining whether eLearning software really supports the learning process of students. It is no longer limited by serially flipping through pages; we showed how Knowledge Landscapes can be used to provide another (flat) view of hierarchically organized content. The option to interactively manipulate the landscape increases the chance of actively involving students while
studying. Throughout this paper we gave examples of how these features have been successfully implemented in existing WBT software.

Abstract: Current courseware is often tightly coupled with a specific e-learning system for its access and presentation. We identify the system components and their interaction in creating, publishing, accessing and executing platform independent learning content. We present a system model aimed at using inexpensive off-the-shelf components to supply the core functionality while being ready to integrate flexible and powerful content management and e-learning support systems in future.

Introduction
In April 2001 12 German universities have started the project "WissensWerkstatt Rechensysteme" (engl. 'Knowledge Factory for Computing Systems') targeting the development of multimedia learning modules in the field of technical computer science. It was an essential task to find a suitable system to create, store, combine, and deliver these modules. Despite of the massive amount of teaching/learning support systems on the market as well as reports about selection criteria and evaluation results of e-learning platforms [B01], it was difficult to find a suitable platform. The scalability of the planned 150 modules (as discussed in [LT02]) will result in 18 potentially different variants per module. Thus our system needs to handle up to 2700 module variants in total, each of them referring a large amount of media objects (such as images, audio, video, animation, ...). Efficient construction of multiple variants and output formats is supported best by XML technology. That's why the platform needs to be able to handle XML-based content and output construction according to our specification. Furthermore the system should support and control the distributed development, evaluation and continuous maintenance of the modules by workflow and source control / versioning tools.

Based on these requirements we evaluated 13 Systems (among them Blackboard, WebCT, WBT Topclass, Lotus Learning Space, Time4You). None of the examined systems satisfied our core requirements [W01]. Since no financial and personal resources for system development are available within our project, it was necessary to develop a cost effective yet extensible concept of establishing a suitable access and management platform.

System Concept Requirements
Looking at existing e-Learning platforms the major problem is that most of them impose dependencies on content and system functionality. Following dependencies can be identified:

- **System component dependencies**: Modern e-learning platforms integrate functions such as authoring, asset/course/user/access management, content configuration/retrieval/presentation/execution. These functional components are often tightly coupled. As a result it is hard, for example, to integrate a new publication subsystem or personal learning environment.

- **Data format dependencies**: Many of the current e-learning systems organise and store the course structures tightly coupled to the specific functionality of the system. The courses are not platform independent. Packaging standards such as LTSC and SCORM [AD01] are forced to take up a rather abstract point of view on learning objects [K01]. The necessary platform-independent model of the fine grained internal semantics of e-learning content is topic of current research [K00] [K01] [SKF00] [LT02].

As platform independency of the developed content is one of the core requirements of the WWR project our strategy is to avoid data format as well as system component dependencies by applying content management concepts such as separation of specification (XML - code) and publication of course content (html, pdf). Of course there are more than content engineering related aspects to providing e-learning content (retrieval, online access, personal learning environment). These components are further objects in our system model.

System Model and Implementation Stages
Based on the requirements analysis of the WWR project we developed a system model identifying the dataflow between its major components: authoring environment, publishing environment, distribution platform, personal learning environment (fig. 1). We organize the implementation of this system model in 3 stages:

**Stage 1: Exploiting XML's authoring potential.** In this phase we use XML-technology to simplify the authoring process of multi variant content [LT02]. The source as well as the output documents (html, pdf) are constructed locally (using XSL transformations) and uploaded on a central repository facilitating source control / versioning. The system will adopt standard web server/browser software to support retrieval, online access, download, off-
line access and basic communication functionality (feedback). Additional output filters for integrating our content into the project partners' local e-learning systems will be implemented successively.

**Stage 2: Exploiting XML's publishing potential.** A central content management system (CMS) will be adopted as part of the distribution platform to organize the content production and publication workflow. The publishing subsystem – in stage 1 implemented locally as part of the authoring environment – will be transferred to the central distribution platform. As output objects will automatically be rebuilt whenever changes to source files are released consistency and timeliness of the output documents are guaranteed. Ideally the CMS will even support live publishing driven by the recipient's request (personal script/course).

**Stage 3: Exploiting XML's run time potential.** The learner will be offered a dynamic personal online/offline learning environment as an additional subsystem. The learning environment will render the native XML content adaptively according to the learner's profile, preferences and learning situation, and will integrate personal content (annotations) as well as runtime data from interactive components (experiments, self tests).

**Conclusion**

As we specify our learning content in an open, platform independent format and decouple the functional components authoring, publishing, distribution and personal learning in our system design we are able to adopt standard components in central areas (document management and distribution) while keeping the system flexible and extensible in areas of current research and development. The next steps are the research of suitable components on the market and their integration into an overall system.

Towards a Discipline Based Reflective Thinking Process for K-12 Students and Teachers Through On-line Discourse and Action Research
Elizabeth Wellman, Ed.D.

Introduction

The California History-Social Science Project, a legislatively-mandated professional development program is administered out of the University of California, Office of the President. The Executive Offices are based at UCLA, and oversee seventeen local sites across California. CH-SSP's mission statement includes: a commitment to improving the teaching and learning of history-social science by strengthening disciplinary content knowledge for all students as outlined in the California History-Social Science Content Standards; enhancing instructional strategies in the teaching of history-social science to promote accessibility to the discipline; promoting collaboration across grade levels, kindergarten through university; and enhancing teachers' use of technology as an integral part of the instructional process.

As part of meeting this mission, CH-SSP engages teachers in action research on the use of technology-based discourse tools to support the development of a discipline based reflective thinking process, which promotes student ability to engage in historical thinking and understanding. This action research project grew out of a previous project in 1999 and 2000 in which teachers explored the uses of technology in K-12 history classrooms and developed lessons plans for statewide distribution. Although we felt that the work which emerged from that project was of a high quality, we did not feel teachers were exploring the issues involved in technology and the classroom at the depth that we were interested in. We modified the program in two ways. Instead of asking teachers to generate lesson plans, we asked them to engage in action research in the classroom. We felt this methodology was more likely to get teachers to think about their teaching in a reflective manner. The second change we made is we focused much more, although not exclusively, on online discourse tools. The reason for this was from the previous program – the teacher in that program expressed interest in the use of these tools in the history classroom. So, in 2001, twenty-six teachers from across California conducted research in grade 3-12 classrooms with diverse student populations, low performing and ESL students. The collective results of these research studies was surprisingly uniform. Students, particularly low performing and ESL students, engaged in significantly higher levels of discourse than in the traditional classroom; and they were either learning to engage in or engaging in discipline based activities ('doing history'). The interaction of these two – discourse and activities – lead to higher levels of historical thinking and understanding, as reported by the teachers. This result was only true when the teachers provided scaffolding in the form of discourse supports.

Purpose/Theoretical Perspective

The primary purpose of the professional development is to engage and support teachers to investigate instructional methods that support students' development of historical thinking and understanding through a discipline based reflective learning process, and to investigate using technology to support the instructional methodology in ways that could not be done without technology.

Fundamental to how we approach the professional development is our approach to history. We approach the teaching of K-12 history as a discipline as opposed to a subject (Stearn, 1993). As part of practicing history, historians engage in discourse about the discipline and in discipline based activities. We reflect this in the K-12 classroom. Discourse in the History/Social Science classroom supports students in externalizing thinking and in creating cultural supports for thinking (Bain, 1998). Discourse interacting with discipline based activities provides a basis for students to 'do the discipline' and engage in higher levels of thinking and historical understanding. For this to be successful, teachers must provide social assistance (scaffolding) to the learners to support the necessary competencies through which the historical thinking and understanding can emerge and be internalized (Vygotsky, 1978). There are many kinds of scaffolding that can be used. Technology based tools, and concomitant teacher supplied supports, are one kind of assistance (Salomon, 1988), which we focus on.

We model this approach with the professional development. We approach the teaching of history as a discipline. We engage in discourse with cultural supports to externalize the teachers' thinking. We use an action research model as it is an ideal vehicle to manifest this. Action research provides for inquiry through
reflection, it brings the unconscious to a conscious level (Schon, 1993). The teachers’ understandings can emerge and be internalized. And, once again, among many forms of scaffolding that are used, technology tools are used support this.

Interaction between discourse and action research are therefore, central to this professional development approach. We see discourse as a creative process in which a shared understanding is created (Bohm, 1996). To engage in discourse is to engage in both disciplines – history and education. It is reflective and iterative in nature. It involves social assistance and the use of tools. Scaffolding is provided by the professional developers (facilitators). Tools are non-electronic (small group discussion, writing) and electronic (email, bulletin boards, chat, threaded discussion, databased discussion, electronic annotation).

Action research is also a process. It is a way to engage with classroom teaching and bring more of it to a conscious level (Hopkins & Antes, 1990). It is reflective and iterative in nature. Reflection encourages the challenging of ones existing theories and preconceived views of teaching (Kettle & Sellars, 1996). Action research involves social assistance and the use of tools. As with discourse, scaffolding is provided by facilitators (coaches) and tools are both non-electronic and electronic.

As elements of both of these processes we engage in reflection, collaboration and inquiry.

**Professional Development Model**

We see our professional development model as a system of people, practices, and technologies. The human activities are served by the technology (Nardi & O’Day, 1998). Its parts consist of facilitators, teachers and students; the practices of discourse and action research, in the disciplines of history and education; and the supporting technologies.

Teachers participate in online pre-institute discourse activities, then spend three days at UCLA starting the research process (see below). Back in the classroom, they implement their action research. Finally, they write up their results for dissemination. In total, this is a five to six month commitment.

The action research process consists of six overlapping stages

- First, they question their assumptions about the disciplines. Through online discourse before the institute and in person discourse during the institute, the hidden assumptions that we all have are brought to the surface.
- Second, they pose a problem (research question). They will discuss these with the other teachers and give other teachers feedback on their problems.
- Three, as each teacher focuses on one problem, one aspect of their teaching, the plan for the solution should emerge (research plan) and worked out collaboratively.
- Four, they will implement the action research plan in their classroom.
- Five, both qualitative and quantitative data will be gathered by all teachers, analyzed and shared with peers to assure the highest level of reliability and validity possible.
- Six, the process and the results of the action research are documented, peer reviewed and disseminated.

The first three stages of this process are the most difficult for the teachers. Once they have a plan of action, implementing and following through on the plan has not posed too many problems. Because of this, and based on the research from the 2001 group, a proposed discourse/action interaction process has been developed as a scaffolding tool for the teachers through the action research process. This tool is used by the facilitators and can be used by the teachers in their own classroom. It is considered a tool-in-progress. With each iteration of professional development, it is anticipated that the tool will change in response to the teachers input and their experiences in the classroom. It is described in more detail below.

Other tools that both support the professional development and are the focus of the action research are primarily online. Blackboard was used as an online environment and we will be using it again. Within Blackboard, email, bulletin boards, threaded and non-threaded discussion, chat (and archived chat), posting
and annotation of documents, the development of individual pages, and annotated links and resources all provide discourse tools for the action research.

**The Discourse/Action Interaction** (see diagram at end of paper)
As part of their action research, teachers are asked to engage in instruction which leads to students engaging in a discipline based reflective thinking process. Although we believe that there are a number of major components to this process at a minimum discourse, visual thinking and experiential thinking - at this time we are focusing on discourse. As professional developers we are asking our teachers to engage in the same discourse/action interaction and discipline based reflective thinking process. We believe it is crucial to this professional development program that the teachers engage in the same kinds of learning activities we are asking them to use with their students. We will go over the discourse/action interaction we are using as it would be applied in a K-12 classroom, and then we will discuss how this differs for the professional development program.

When we are considering the role of discourse in a discipline based reflective learning process, we focus on four major areas. The students should engage in a continuous discourse/action process where discourse leads to action which leads to discourse and so on. So discourse and the activities are two of the areas. The third area, teacher provided supports, reflects the teacher's role in the students process. The teacher supplies a number of scaffolds or supports to the acquisition of the reflective learning process. All of these three areas feed and support the fourth area - the student reflective process. So, students develop a reflective learning process through the interaction of discourse with activities and the judicious and considered use of supports from the teacher.

In their action research, the teachers focus more specifically on the kinds of discourse, the kinds of activities, how technology supports those and an exploration of what teacher provided supports seem to provide the most assistance, in what context, to which students. This past year the focus was on chat rooms, threaded discussion groups, bulletin boards and database based discussion. Generated by the teachers, they focused on the questions outlined below:

- Do these tools provide greater opportunity to engage in discourse? Does this result in historical thinking and understanding?
- Do the students engage in more discourse with the technology tools? Are they more motivated to engage in discourse? Does the type of discourse that technology provides facilitate deeper historical thinking and understanding than other forms of discourse?
- Does the technology interfere in any way with the discourse process?
- What does the teacher have to provide in the form of scaffolding tools to facilitate optimal discourse?

We have used the results of the teachers' work in these areas to expand on the four major areas in discourse/action interaction. Some work has been done on the area of online discourse tools. This has been summarized by Sherry (2000) in a thorough article available online. We have drawn from many of the ideas in this article and combined it with our experience with our teachers to structure an approach to thinking about discourse in the classroom. We ask our teachers to first consider the structure of the discourse which currently exists in their classroom. Typically this will reflect a teacher asks question, student answers question, teacher provides feedback format with some minor variations. It will also typically involve only 10 - 15% of the students and virtually no ESL or low performing students (from our teachers). We proposed going in the direction of teacher questions, students question, students answer, students/teachers support/share and students/teacher comments where these may not occur in any particular order. The teachers' role in this form of discourse is to support the student to create, share, negotiate, interpret, expand, justify, question, summarize, clarify, predict, extend, and so on. As the students expertise increases, there can be more of a focus on framing questions appropriately, expanding on valid propositions, students being open to critical review of their point of view, students sharing understandings, working towards a common understanding, common knowledge construction, and so on. The environment should be constantly evolving, yet be organized.

There is room for teachers to focus action research questions in nearly every area of the discourse/action interaction.
interaction. In particular, every teacher eventually gets around to exploring what kinds of teacher provided supports will best facilitate the discourse. As most of the discourse occurs in an online environment, the teacher support questions are not just about supporting discourse, but on how to use the technology to best advantage to support the discourse. These questions can range from - when do you use chat or threaded discussion? To what cultural implications are there to the introduction of technology on this scale in my classroom? This last question came up in post-research musings by the teachers last year. We will be tackling it in a more focused way with this years program.

The activity area of the discourse/action interaction involves discipline based activities - activities that are relevant, and authentic. These activities can be multidisciplinary, interactive, exploratory, performance based, involve advance skills, etc. These activities should interact with discourse activities in such a way as to enhance the development of both the new discourse process for the students and the process of developing the skills to ‘do the discipline’.

As teachers think about the discourse/action interaction and develop their research questions, they will be themselves engage in discourse activities in the online environment. Here is the challenge for our facilitators. Many of these teachers do not have a well developed discourse process. We must provide the appropriate scaffolding to support these teachers in engaging in the process that they will be working with their own students to develop. Our research, other than reporting on the teachers’ results, is to develop these scaffolds as the project progresses, and evaluate the results. The discourse/action interaction is one such scaffold. It is self-referential in this way – it scaffolds the teachers to help them scaffold their students by also using the discourse/action interaction.

Examples and Results from 2001
Teachers approached the implementation of the research in a number of different ways. The following three examples are illustrative of the projects as a whole.

At a high school near San Diego, CA, the participating teacher had a history class of 36 primarily ESL and low-performing students. He took advantage of a school with a block schedule to spend a 1.5 hour block for this class in the computer lab in a chatroom on Blackboard. All the students were still in the same room, but discussing history in a chatroom. This step alone allowed 100% participation from the students (instead of 15% in a traditional classroom). He then followed this discourse up with a 1.5 hour activity where the students wrote about their ideas. A higher level of historical thinking was evidenced in their writing. The most promising result however, were the gains made over time in the ability to write in English for these ESL students.

At a middle school near Riverside, CA a participating teacher used threaded discussion to supplement the classroom activity. At first, without adequate teacher supports, participation was poor and the level of the discussion was low. He instituted several teacher provided supports, such as more detailed instructions on writing entries, and he provided immediate (24 hours) and explicit feedback to the students. The results were an increase in participation (not quite 100%) and more thoughtful contributions. He found that a particularly useful byproduct of the use of the threaded discussion was his ability to diagnose and address misconceptions and preconceptions much more quickly than he could in the classroom.

At a middle school in Santa Monica, CA, a participating teacher developed her own database for student responses to open ended ‘thought’ questions on history. As each student responded to the question, they could also read the responses other students had entered. They can then respond to other students, develop arguments, which combine other student’s points of view, or refute a student’s point of view. She provided both discourse and content supports within this environment. Both motivation and participation increased dramatically over the traditional method. She was surprised at the level of participation from students who literally did not participate in any other way. She also found unexpected gains with her ESL students in their writing skills.

The following results were seen in every teacher’s research study.
For teachers:
• The development of and use of discourse supports embedded in the classroom environment (technological and non-technological) was critical to promoting optimal engagement in the
technology-based discourse activities.

- Increased opportunity to diagnose and correct misconceptions.

For students:
- Motivation to participate in technology-based discourse activities was much higher than to participate in non-technology discourse activities.
- Non-technology discourse activities were positively affected, both in the level and amount of participation.
- Low-performing students showed the greatest gains in both participation and understanding.
- English as a Second Language learners benefited significantly. Their interest in participating, their ability to express ideas and their writing skills all showed more than expected gains.
- Students who had previously excelled at non-technology based discourse were the least enthusiastic.
- Nearly 100% of students voiced their opinions, received feedback and responded to others’ opinions.
- A significant percentage of students used historical thinking and understanding including citing historical fact, comparing differing primary sources, questioning others’ interpretations, and citing each other.

In addition, many teachers had results from their research that weren’t addressed in the other research studies. These included:
- Students did not adhere to ‘clique’ boundaries when using technology-based discourse tools.
- Students were using the tools to expand discussions beyond the classroom.

Discourse is an important methodology in History/Social Science classrooms. The traditional forms of discourse are the classroom discussion and the small group discussion. Teachers find that both of these forms are limited. The teachers who participated in this research believe that less than 15% of their students participated in these. The research these teachers conducted indicates that the use of technology-based discourse tools seems to increase both the participation in (to nearly 100%) and the level at which students are engaging in historical thinking and understanding. This increase gives the teacher a solid foundation on which to make the change from history as a subject which teachers teach and students take, to a discipline, where historical thinking and understanding are core processes.

This year, by providing more support in the form of the discourse/action interaction, we hope that teachers will be able to form more focused questions than they did last year and concentrate more specifically on issues such as the appropriate use of various forms of teacher provided support for different students (ESL and low-performing, in particular) different technologies, and different pathways to the development of a new discourse process for the students.

Conclusion

This is an action research project. As such, it has yielded rich information on the use of discourse and the use of technology to support discourse for the advancement of student historical thinking and understanding in History/Social Science classrooms. It is the intention of all the teachers in this project that action research on these issues, and on the issues that these studies brought up, be continued. It is also the hope of all the teachers’ that a more formal treatment of these issues will be pursued within the professional community.

Abstract: We have developed SASK (Socratic ASK), a domain-independent architecture for implementing Socratic dialogs to foster deeper student reflections on well-defined tasks. In SASK we have built the Dialysis Mentor, a program that uses Socratic questioning to improve student performance and learning in an undergraduate biomedical engineering lab. Small usability tests and a pilot run in the actual lab suggest that Dialysis Mentor and SASK systems in general can improve the value of pre-defined learn-by-doing task experiences. We are now working on improving our SASK Mentors and building authoring tools for them.

SASK Mentor Project: http://www.cs.northwestern.edu/~riesbeck/sask/

Introduction

Dr. J. Walsh's Biomedical Engineering Laboratory course at Northwestern University includes a dialysis lab session in which students characterize how well an artificial kidney (a dialyzer) transports water, urea, and salt across its membrane. Students work together in groups of two or three for several hours on this lab. This lab typically uncovers a number of important gaps in student understanding, ranging from simple trouble using the lab devices, to misinterpretation of key measurements, to performing actions contradictory to the basic goal of the experiment. Dr. Walsh handles such problems not by telling the student what to do, but by asking a few penetrating questions, such as "What are you trying to do here?" followed by "What variables are you controlling?" These questions cause the students to quickly discover for themselves gaps in their understanding of the task. Without such attention, students tend to rush through their lab. Many fail to produce any useful results. Even those who do, likely miss many opportunities to reflect on their thinking while they are doing their lab work. Such reflection is known to increase students' ability to transfer their learning to new settings and events (Bransford et al. 2000).

This Socratic technique is facilitated by broad knowledge of the domain and how one's students best learn that particular domain. Often people with such expertise are a scarce resource. Most graduate assistants lack broad domain knowledge as well as experience in teaching it Socratically. Hence, groups in Dr. Walsh's lab would often wait 20 minutes for his guidance before they could make any progress. Sometimes groups had wasted time doing something unfruitful and would have to continue the lab during the next class session. Even worse, sometimes a group would get too much information from a graduate assistant and finish the lab without gaining the understanding Dr. Walsh had hoped they would.

Our project goal was to provide an artificial mentor (We use the term "mentor" instead of "tutor" because tutoring implies a teacher-centric, drill and practice activity. Mentoring implies that we are trying to provide a student centered, apprenticeship, inquiry activity.) capable of providing a service similar to that Dr. Walsh provides, at the time students need it. A Socratic system makes students active learners, leading them
to debug their own thinking and knowledge, unlike alternatives such as Frequently Asked Questions (FAQ) lists and other systems that encourage passive learning.

The Project's Development

The Dialysis Mentor

The SASK engine and the Dialysis Mentor (DM) application were developed in summer and fall of 2001, using Java for the engine, XML for the domain content, and QuickTime for Java to play videos. When students start DM, they first see the "Overview" interface (Fig. 1), where they can watch a video of Dr. Walsh's lecture on the dialysis lab, and read a transcript of the lecture.

Students then switch to the "Lab Mentor" (Fig. 2) to interact with the program. This interface includes an annotated diagram of the laboratory set-up for reference (upper left), a dialog transcript (lower left), and, most importantly, a dialog interaction panel, upper right. In future, we plan to include video clips of Dr. Walsh speaking to the students in the role of the Dialysis Mentor.

The conversation panel was the key interface challenge, specifically the part where students answer questions such as "What are you trying to do?" On one hand, the interface had to avoid overly influencing or constraining what students say. What students say is the key window to their underlying misconceptions. On the other hand, an empty text box where anything can be written is both impossible for current programs to understand and intimidating to students.

Therefore, we use a mixed button and template approach. Simple answers with no variable content, such as "We're still thinking," are buttons. More complex answers with variable content are buttons that bring up structured "fill in the blanks" templates similar to web forms. For example, clicking on "We're trying to measure..." brings up a template of the form "We're trying to measure <empty text field> and control <empty text field>." (Fig. 3). The students can write anything they want in the text fields. This semi-structured approach lets students choose what to say and how to say it, but the program only has to deal with short phrases in well-defined contexts. This interface approach was successfully used in Creanimate, a program that used a question and answer dialog to help children learn and think about zoology (Edelson 1993).

Figure 1: Overview Mode

Figure 2: Lab Mentor Screen

BEST COPY AVAILABLE
Figure 3: After students choose "We're trying to measure..."

The program's behavior is specified in the Dialog Graph Document, represented in XML, that contains all the Dialysis Mentor's questions, response options, and template patterns for selecting follow-up questions. The current DM graph has 89 utterance nodes and 153 edges (rules that link student responses to DM utterance nodes) in it. Figure 4 shows part of a small part of that graph in outline form. Student responses with underlined elements are template patterns, the other responses are buttons. This fragment Socratically asks students to test their assumption about what controls what, which will lead them to discover a mistake in their thinking.

Mentor's current goal: Students seem to know the main goal. Lead student to realize that varying the flow does not help the goal

Mentor: Remember that when you do an experiment you want to vary only one thing at a time. Then you graph Ultrafiltration (U) over Transmembrane Pressure (TMP). Do you think you will see a relationship between Ultrafiltration (U) and flow rate(s)?
Students: Yes
   Mentor: What controls the Ultrafiltration (U), TMP or flow rate(s)?
   Students: The flow rate
   Mentor: How do you know U is not controlled by the TMP?
   Students: I do not know
   Mentor: Please set up your experiment so you can tell me what controls U, TMP or flow rate.
   Students: TMP directly controls U based on the equation you gave me.
   Mentor: That's the theory we presented. You must use the lab to prove that TMP controls U and not flow rate. How do you change only TMP?
   Students: ANY OTHER ANSWER directly controls U based on the ANY OTHER ANSWER.
   Mentor: Please set up your experiment so you can prove what controls U, TMP or flow rate.

Figure 4: Partial Graph of Dialysis Mentor's Task Dialog Graph Document

Background
Socratic Intelligent Tutoring

A classic early Socratic intelligent tutoring system was WHY (Wenger 1987) created by Dr. Allan Collins. Collins analyzed the dialog between students and Socratic tutors and developed a theory for the implementation of a Socratic-tutoring program, including a set of 24 production rules to improve WHY's pedagogical component (Collins 1977). We used some of these rules as a formal way to understand Socratic techniques. For instance, the partial graph in Figure 4 is an example of Collins's Socratic Rule 15: "Request a test of the hypothesis about a factor".
ASK Systems

ASK systems are a form of multimedia based on the metaphor of having a conversation with an expert, or a group of experts. An ASK system presents a user with a set of initial top-level questions. When the user selects one, the ASK system responds with an answer, either in video or text. In addition, the system displays a set of follow-up questions relevant to the answer given. The user can pursue one of these follow-ups, which will lead to a new answer and a new set of follow-ups, or return to an earlier answer and follow a different path (Cleary 1995). A number of ASK systems in a wide variety of domains were developed by the Institute for the Learning Sciences at Northwestern University, and later commercially by Cognitive Arts Corporation. The success of ASK systems in a number of domains leads us to believe that static dialog graphs are sufficient to provide performance and learning support in well-defined tasks.

Validation
Usability and Pilot Testing

A small usability test was performed with a biomedical engineering undergraduate student. We videotaped the student doing the dialysis lab under Dr. Walsh's tutelage. Her interactions were typical of those in the actual lab, and was used as a seedbed for the initial dialog graph. Several months later, we videotaped her interacting with the first version of the Dialysis Mentor. This test revealed a number of phrases that needed to be added, as well as some new dialog branches. It also showed that it was very easy for certain DM responses to lead the student to treat the system like a multiple choice guessing game. This was particularly true when the DM's immediate follow-up to a student response strongly implied that the response was incorrect or unwise. To avoid this unfortunate phenomenon, some follow-ups were changed to avoid immediate implications of any judgment. This made the dialogs more Socratic.

The Dialysis Mentor was then used in Dr. Walsh's dialysis lab in October 2001. Fifty-two biomedical engineering undergraduates were involved in two sections, a morning section and an afternoon section. Each section had nine groups of two to three students each. The DM logged all interactions for later analysis. Some interactions were video taped. A few weeks after the use of DM in the lab, 47 students completed a survey regarding their experience. Although the test in general is considered a success, preliminary analysis of the data revealed or emphasized issues for future research. In particular, Table 1 categorizes the DM's responses by whether the intended follow-ups to student responses were taken.

"Missing phrase in task dialog graph document" meant that the DM had a relevant dialog branch internally, but did not recognize that a student response should take that branch. "Wait too long" meant that the DM told students that it would wait for them to do something but waited an improperly long period of time. "No existing branch" meant that the DM's dialog graph didn't include a relevant branch for the student's response. "Appropriate action" meant that the DM selected the dialog branch that we had intended for a given response.

Chart 1: Student Opinions on the Helpfulness of the Dialysis Mentor

The following chart shows the results of the conceptual assessment question in the same survey. Answers to the question “What parameters should one vary when quantifying the hydraulic permeability and what parameters should one hold constant?” was scored by first noting who answered correctly to what parameters should be varied and then who answered correctly to what should be held constant. 9 students (19.15%) were incorrect about what to vary and 12 students (25.5%) were incorrect about what to control. 6 students (12.77%) were found incorrect about both parts of the question and 9 students (19.15%) were partially correct. 32 students (68.09%) answered the question completely correct.

Chart 2: Student Responses to Conceptual Assessment Question

Future Work
Social Interaction and Interpretation Issues

Videotapes of the pilot tests show cases where a student group was at a loss for an answer to a question presented by the DM. When Dr. Walsh asked the students to pretend he had just asked them the same question, the students quickly came up with an answer. When they entered that answer into the DM, it was usually handled properly and the dialog progressed. In other words, students treated questions from the DM differently from the same questions from Dr. Walsh.

There are several possible explanations for this phenomenon. One is the difference between text and speech. Questions that are clear when spoken often become ambiguous in text form. Another factor is the difference in social relationships between a computer program and a faculty member. When a faculty member like Dr. Walsh says “Think about it. I’ll ask you again in 5 minutes,” students stop and think. When a lowly computer program like the DM said the same thing, students often do whatever they can to get around the delay, including restarting the program. Since getting students to stop and think is the main goal of a SASK system, overcoming this difference in response is a critical research problem.

For these reasons, we are planning to use video clips of Dr. Walsh asking the questions, in conjunction with the text version. The addition of audible speech may improve DM as a pedagogical agent and improve students’ retention and problem-solving transfer abilities (Moreno et al. 2001). It may also
increase students feeling like they are talking to Dr. Walsh, or someone like him, therefore reducing the
differences in their response patterns.

We also need to make sure students do not guess at answers, because this is antithetical to learning.
Guessing happens when students believe they can tell if their response choice was correct or not, based on
the system's first follow-up. That makes it easy for students to try each response and see what happens.
Therefore, we need to minimize two kinds of initial follow-ups: negative "no, because..." follow-ups, and "I
do not understand, please rephrase" follow-ups. The latter happened approximately 25% of the time in the
DM, either because of missing phrases (3%), or missing branches (22%). Fortunately, avoiding bad follow-
ups is mostly a matter of expanding and refining the Dialog Graph Document.

Authoring Tools and Internet Accessibility

Another area of future design research will be the development of the authoring tool for dialog
graphs. The Dialysis Mentor's XML files were authored with a text editor. Even with an XML editor, this is
a tedious and technically complicated activity. We plan to design an authoring tool so that teachers such as
Dr. Walsh can build the dialog graph document themselves. Of particular interest will be the development of
"dialog sequence templates," based on Collins' Socratic rules and other useful dialog patterns we have
discovered while designing the Dialysis Mentor.

Using Java Servlet technology, we also have a preliminary web interface to the SASK Mentor to
ease deployment to many sites.

Conclusions

Overall, our SASK Dialysis Mentor has the potential to be an effective tool for improving students'
learning experiences. We look forward to furthering its development and making other SASK Mentors for
other learning environments and domains.

Rejuvenating the Social Foundations of Education Course Using Digital Technology and the Case Method

Keith Whitescarver
School of Education
College of William and Mary
United States
mkwhi2@wm.edu

Abstract: This conceptual essay examines theoretical and methodological problems associated with teaching the Social Foundations of Education course and provides a framework on how to overcome these difficulties. Foundations of Education courses are notable for both their volume and the ambivalence with which students and instructors regard their role in preparation for teaching. The ambivalence is held because foundations courses generally suffer from instructors unknowingly devising incompatible goals for the course while the multidisciplinary nature of the course frequently leads to intellectual incoherence. One way to overcome these deficiencies is to have students acquire an “ironic” understanding using the case method. Case studies that use digital technology make this approach even more powerful because digital technology provides students with a cognitive tool that encourages the profound knowledge necessary to attain ironic understanding.

This conceptual essay examines theoretical and methodological problems associated with teaching the Social Foundations of Education course and provides a framework on how to overcome these difficulties. A staple of teacher education since the 1930's (Cohen 1999; Lagemann 2000), Foundations of Education courses are notable for both their volume and the ambivalence with which students and instructors regard their role in preparation for teaching. The ambivalence is rightfully held by both because foundations courses, from their inception, have suffered two significant shortcomings. First, instructors unknowingly have devised incompatible goals for the course. Second, the multidisciplinary nature of the course frequently leads to intellectual incoherence for all concerned.

As a teacher of Foundations courses, I have struggled with overcoming these embedded course deficiencies. Over time, I came to a realization that the course needed a new goal. I borrowed from Kieran Egan (1997) the idea of having students acquire an “ironic” understanding. Due to the multidimensional representation possible with cases, attaining ironic understanding is enhanced when case methods are employed (Merseth, 1996). Most recently, I have begun to supplement paper copies of case studies with digital technology and believe that the enriched learning experience provided by such an approach makes the case study method even more powerful. Digital technology provides students with a cognitive tool that encourages the profound knowledge necessary to attain ironic understanding.

Many instructors of foundations of education courses have grappled with ways to overcome the incompatible goals and the intellectual muddle of the course. An effective way to resolve the paradox is to create a course that seeks a new goal using new intellectual tools. Vygotsky (1978) argued that people make sense of the world using mediating intellectual tools. Intellectual development, then, is dependent not only on psychological stages, like those described by Piaget, or on the knowledge we accumulate, but also relies on the intellectual tools that society makes available. While Vygotsky focused on oral language, or sign systems, in his formulation, other intellectual tools are available. Using these tools in innovative ways can refashion the social foundations of education course.

For me, the way out of the teaching dilemma presented with a course that has at its core incompatible goals is to radically change the student outcome desired. Guided by the insights of Kieran Egan (1997) on the larger purposes of schooling, I seek to assist students in acquiring an ironic understanding of schools and teaching. Briefly, irony, as we know it today, is tied to a belief that the truth long sought in the western intellectual tradition is illusionary. In place of certainty, irony provides for the centrality of reflexiveness in thinking. Ironic understanding, then, leads to the removal of a commitment to
simple truth of general schemes. The sophisticated ironist, instead, enjoys extensive ways of understanding and recognizes the value of a varied spectrum of perspectives.

Fostering multiple perspectives is at the heart of the articulate ironist. Gliding from perspective to perspective is valued and becomes second nature in such a person. The ironist applies the varying perspectives to make sense of their experiences. A teacher might ironically note, for example, that a new school policy designed to improve math performance in fact creates a wider gap between high math achievers and low achieving math students. A better identification of the problem and a clearer solution is then possible. One must take care, ironically enough, to make sure that the disciplinary incoherence of the social foundations course is not replaced with incoherence arising from seeing events with different perspectives. The value of a case study approach to teacher education is that while cases offer multiple perspectives, they are at the same time grounded in a specific narrative context. General theoretical principles flow from an array of possibilities that build on one another. Out of what seems to be chaos comes not only insight but also orderliness.

Emerging digital technology is allowing the case study method to develop into an even more powerful tool by permitting cases to become more contextually grounded. More specifically, an interactive course web site that supplements the text of a case with multimedia presentations and links to other data sources allows great flexibility in student construction of knowledge. To illustrate this, I shall borrow a metaphor from the world of art museums. Elizabeth Valance (1995) refers to a “public curriculum” inherent in the orderly images found in art museums. This public curriculum consists of the images displayed; the order in which the images are placed; the information provided for visitors; the tours, lectures and workshops and other programs offered to the public; and the publications produced. The curriculum is randomly accessed by visitors and is readily available to anyone who comes to the museum. All visitors, however, study” the curriculum on their own and make sense of the images in endless varieties of ways. While visitors may understand the curriculum in a variety of ways, the curriculum is deliberate. Images are arranged in some order (usually by culture chronology but such need not be case) with or without helpful labels. Some images are quite accessible to all but others are difficult, and visitors may even view an image with hostility. Visitors will frequently confront a museum worker with some sort of refrain along the lines of, “Is that really art?”

Similarly, a well-designed course website will be accessible and challenging. Depending on how images, text, video and audio are arranged, one can create different learning environments and attempt to frame relevant issues in key ways. Arranging course materials using digital technology into generative topics allows for students to respond to the realities of classroom practice and educational policy-making in multiple ways. What cannot be controlled, of course, is what students learn. The goal, instead, is to provide as many avenues as possible to allow students to make their own connections and to form their own categories. Like a well run art museum that helps novice visitors find accessible entry points into the world of art, an interactive website can assist the novice teacher into gaining access to the profession of teaching.

EduBeans: Efficient development of interactive instructional exhibits leveraging a multi-layered, component based framework

Simon Wiest, Andreas Zell
University of Tübingen
Wilhelm-Schickard-Institute for Computer Science, Sand 1
72076 Tübingen, Germany
wiest@informatik.uni-tuebingen.de

Abstract: While Java based applets have become commonplace in web based training, their development is still costly. We present a framework that uses the JavaBean component model in a layered approach using several abstraction levels to facilitate the reuse of development infrastructure. A reference implementation was successfully employed in teaching audio signal-processing to computer science students.

Introduction
Interactive exhibits constitute one of the major advantages of computer-based instruction. While dedicated authoring packages allow for high-quality animation, non-trivial domain specific functionality is hard to implement. On the other hand, all-purpose programming languages make way for sophisticated domain specific functionality at the price of considerable overhead for animation. Platform independence, built-in capabilities for audio-visual output, and its enormous installation base has made Java (applets) increasingly popular in the educational field. Unfortunately, the absence of software frameworks hindered code reuse; missing configuration options restricted applets to only one context. A need has emerged for a software framework, allowing reuse of interactive educational assets on a component level.

Christian (2000) successfully developed a set of generic physics related applets, named Physlets, that can be scripted and customized by the educator using JavaScript. While this considerably broadened the scope of possible uses, these applets are not intended to be used e.g. in conjunction with third-party APIs. Integrating software components into more complex projects requires well-defined interfaces between these components. Sun Microsystems introduced therefore the JavaBeans specification (1997). Praehofer (1998, 2000) and Benes (1999) presented two JavaBeans based frameworks helping to teach simulation based on the discrete event system specification formalism. In the field of image processing, Hanisch (1999) demonstrated an efficient approach to assemble applets by wrapping the Java Advanced Imaging API into JavaBean components.

A multi-layered, component based framework
Although JavaBeans have proved to be well suited for the creation of educational exhibits, there has been little reuse and exchange between different content authors. This astonishes, because the promise of reusability is one of the major drivers of component-based development. We identify missing access to only partial functionality of the existing bean-based exhibits as the primary reason for this: While they are built from components, they behave as monolithic entities. Therefore we introduce a framework, named EduBeans, that (1) employs the JavaBeans component model and (2) introduces a new abstraction layer hierarchy into the applet creation process and (3) provide a reference implementation of a web-enabled bean builder tool, the EduBeanBuilder.

JavaBeans component model
JavaBeans™ is the component model for the Java language endorsed by Sun Microsystems. Any Java class can act as JavaBean as long as the code follows a set of design patterns that expose semantic information of the component’s properties. This information can be extracted by application development tools, referred as bean builders and displayed in a graphical user interface (GUI). Bean builders call the same methods to modify the internal state of a bean as a programmer would do in her source code. Therefore, a prospective user can familiarize herself with the properties of a certain bean using a GUI before employing the bean programmatically.

Abstraction layer hierarchy
Although there have been successful attempts to create JavaBean based educational software (see above), reuse and adaptation to other domains had to take place in a rather binary fashion: Either adopting the complete infrastructure or rewriting it from scratch. Differentiating several layers of abstraction in the building process facilitates a partial reuse of the code base. With increasing concreteness from level 1 to 5, these layers address different target groups: level 5-4 are geared towards the learner, level 5-3 towards the subject domain expert (teacher), level 2-1 towards the experienced Java framework developer. Table 1 depicts the layer hierarchy.
Table 1 abstraction layer hierarchy used in framework

<table>
<thead>
<tr>
<th>Abstraction layer</th>
<th>Support offered by framework</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 instance configuration</td>
<td>applications can be configured using localized text, images, specific experiment settings etc.</td>
<td>file: madonna.wav, file: mozart.wav, ...</td>
</tr>
<tr>
<td>4 application assembly</td>
<td>domain specific beans can be combined to form larger applications or &quot;macro&quot; beans</td>
<td>feature extraction, time segmentation, ...</td>
</tr>
<tr>
<td>3 subject domain</td>
<td>functionality can be extended by inheriting from existing classes or wrapping third-party APIs</td>
<td>image processing, audio processing, ...</td>
</tr>
<tr>
<td>2 interaction paradigm</td>
<td>paradigm specific communication mechanisms are provided (e.g. data push / pull in filter chains)</td>
<td>DEVS network, filter chain, ...</td>
</tr>
<tr>
<td>1 component interface</td>
<td>components can be employed in web-based bean builder tool or JavaBean compliant IDE</td>
<td>JavaBean</td>
</tr>
</tbody>
</table>

The most abstract component interface layer (level 1) purely requires that JavaBean compliant classes are used. This important assertion allows the use of components in IDEs and web-enabled bean builders. The interaction paradigm layer (level 2) provides support for typical interaction mechanisms from the subject domain. Our reference implementation uses a source-filter-sink paradigm. Other paradigms include structured algorithms or DEVS networks. The subject domain layer (level 3) contains domain specific beans. Authors can create sets of related beans, leveraging the interaction paradigms provided by layer 2. The application assembly layer (level 4) determines the connections between the beans from the subject domain into larger applications or "macro" beans. Usually the author will assemble these applications as preset demonstrations, but this can also be delegated to the learners as an exercise task. Finally, the instance configuration layer (level 5) configures applications by loading set-ups for specific experiments.

EduBeanBuilder

Most Java IDEs can load and display JavaBeans. But there are also situations in which detailed information on the inner workings of a bean is not necessary or even disturbing. We therefore extended a bean builder provided by Sun Microsystems Inc. into the web-enabled EduBeanBuilder. It allows launching pre-configured applications consisting of multiple beans in a web browser as well as providing an empty workbench onto which domain specific beans can be placed and "wired". The state of the applications can be serialized easily into an XML stream (Java Community Process, 2001), which is exploitable in educational settings.

Case study

Computer science students had to be trained to participate in the development of a Java audio signal-processing package. This software applies several cascaded filters on an audio input signal. Because this approach maps to the source-filter-sink paradigm provided in level 2 of our reference implementation, extending the existing code base to make it JavaBeans compliant allows the integration of the actual signal processing code into instructional applets. This avoids re-implementing functionality in "toy" classes solely for educational purposes. The students’ feedback was very positive, especially because the chosen approach helped the students to bridge the gap between learning abstract concepts and applying implementation-level programming skills.

Conclusions

The presented EduBeans framework proved very useful in the development of interactive instructional applets. The JavaBeans component model allows using the same code base for demonstration purposes as well as "real world" tasks. At the time of writing the framework offers support for generic JavaBeans by the EduBeanBuilder on level 1, a source-filter-sink paradigm on level 2, audio processing functionality on level 3 and includes various assembly and configuration examples in level 4 and 5. The next development is oriented to extending the package with other problem domains and completing a comprehensive documentation.

Software Agents, Activity Theory, and Mentoring - A Preliminary Model

Kay Wijekumar
School of Information Sciences and Technology
The Pennsylvania State University Beaver
United States
kxw190@psu.edu

Abstract: This paper is a report on the preliminary approach to creating a software agent based mentoring system for women in the Information Technology domains. It outlines the data collection and analysis methods and the proposed approach to the creation of the mentoring software agent.

Introduction

Mentoring has been widely used in educational and professional settings to help students become part of a community of learners, novices adapt to new work environments, and professionals advance their careers, however, current mentoring techniques are limited in scope (AEA, 2001; Super, 1984). This approach has been frequently used to encourage women and minorities to enter computer science(CS) and information technology(IT) degree programs and the workforce (CMU, 2001). The current approaches use other professionals, professors, advanced students, and members of the community to do the mentoring. While these mentoring programs have been effective on a small scale there are two issues with them (Lynem, 2001). First, there is already a shortage of women and minorities in the CS and IT fields, those few people can be overburdened with the need for mentors. Second, the mentoring depends heavily on the individual's ability to mentor a newcomer and rarely are there any guidelines or tips available on how to mentor.

The Approach

In order to create a more widely available mentoring system we are beginning a unique project to create an Activity Theory analysis of two IT projects that will be used to create a Software Agent based mentoring system. This system will be used in preparing students to enter IT internship programs as well as entering the IT workforce. In collaboration with two major software companies we are conducting an Activity Theory analysis of the design environment and will analyze the data to create a framework to program software agents. These agents will act as the mentors from the software companies to students in the Information Sciences and Technology program and help them learn about what they can expect when they go on an internship or join the workforce.

Preliminary Framework

Activity Theory (Engeström, 1991) is used as the theoretical framework for data collection, analysis, and programming of the software agent. It conveys the complexity of real world activity systems in manageable chunks. The data representation in the software agent will be done using multiple techniques including video, images, animated agents, and text. The retrieval of the data will be using production rules (Anderson et al., 1995), and Latent Semantic Analysis (Landauer & Dumais, 1997). The agents will have a natural language interface (Person et al., 2001), synthesized speech (Cowley & Jones, 1992), and facial expressions (Link et al., 2001).
Conclusions

Software agents are currently being used in many areas like Physics Tutoring. Current applications of these agents include Physics tutoring (Graesser et al. 1999; Van Lehn, 1999), learner feedback (Negroponte, 1997), promoting reflective thinking (Baylor, 1998), teaching biology (Moreno, 2001), and psychological counseling for families with terminally ill children (Johnson, 2001). The software agent technologies have also been used to provide workplace simulation (Work Sim) in schools (VanLehn, 2001). This approach is unique in the data collection method using Activity Theory and its application as a mentoring environment.

Making Web-based Academic and Student Services Section 508 Compliant: Whose Job Is It, Anyway?

Shahron Williams van Rooij, Ph.D., C.D.E.P.
Director, Product Marketing
Datatel, Inc., USA
E-mail: svr@datatel.com

Abstract: Over the past few years, institutions of higher education have been rolling out a variety of Web-based services to their constituents. Registration, faculty grading, transcript management, general ledger inquiry, student advisement, and other critical service functions are available online to students, faculty, administrators, and alumni. But the rollout of online services is usually evolutionary, built on the tools and technologies available at the time. Online services launched prior to Section 508 must now be re-evaluated and re-worked, further stretching an institution's human and financial resources. This paper documents how an information management system vendor made those critical service functions accessible to all of its clients' constituents and provides a checklist against which to assess any information management system vendor's Web products.

Introduction

Section 508 is a statutory section of the 1973 Rehabilitation Act and was signed into law by President Clinton in 1998. Section 508 requires that electronic and information technology developed, procured, maintained, or used by Federal agencies—including Web sites—be accessible to people with disabilities, unless an undue burden would be imposed on that agency. Section 508 was enacted to enhance the ability of Federal employees with disabilities to have access to and use of information that is comparable to that provided to others. Similarly, by procuring accessible electronic and information technology, Federal agencies would be able to provide members of the general public with disabilities with information that is comparable to that provided to others. What constitutes comparable access under Section 508 is described in Subparts B, C, and D of the Access Board Standards issued in December, 2000 by the Architectural and Transportation Barriers Compliance Board, an independent Federal agency promoting accessibility for individuals with disabilities.

The scope of Section 508 is limited to the Federal sector and does not apply to the private sector, nor does it generally impose requirements on the recipients of Federal funds. However, states receiving assistance under the Assistive Technology Act State Grant program are required to comply with Section 508. Moreover, many institutions of higher education are committed to providing access to all their constituents, regardless of Federal guidelines. For example, in the State of California, the commitment to accessibility has been formalized into official policy to provide electronic access to the community colleges.

Institutions have already begun the task of checking their own Web sites for compliance. Some institutions have used Bobby, an automated accessibility checker offered by the Center for Applied Special Technology (CAST). Bobby functions like a spelling checker, to diagnose accessibility problems. A user can type the address of any Web site, and Bobby will respond with a review of the site, indicating areas of concern and suggestions for improving accessibility, or else awarding the site with a Bobby Approved badge for passing its test. Bobby rates accessibility based upon general requirements it looks for in the source code, such as alternate text for all images. The Bobby tool is also available to download, so that Web authors can use it to run accessibility tests on their own hard drives during the process of site design. However, Bobby Approved does not mean Section 508 compliant. The Web developer must still implement the proper code to make the site compliant with Section 508 requirements.

Another tool is InSight/InFocus, developed by SBB Technologies. InSight scans an institution's Web site and flags areas that could cause problems for disabled users, and InFocus fixes the flagged areas. The Equal Access to Software
The EASI initiative also assists institutions with compliance issues through workshops, consulting services, and a resource-rich website.

The Challenge

What makes compliance checking somewhat painful is the lack of a single, agreed-upon definition of compliance. The Electronic and Information Technology Access Advisory Committee (EITAAC) standards provide sixteen specific items for Web accessibility. The Web Content Accessibility Guidelines 1.0 produced by the WWW Consortium (W3C) define three priority levels, ranging from compliance of a specific piece of software on a specific operating system with specific assistive technology devices, to accessibility on a variety of applications, platforms, and assistive devices.

Web-based academic and student services present a particular challenge for Section 508 compliance. The data sources for these services reside in the institution's information management systems, such as the Student Information System, Financial System, Human Resource System, and the Fund-Raising System. These enterprise-wide administrative application software systems are usually licensed from a vendor/manufacturer, with system maintenance, upgrades, and enhancements provided by the vendor. Vendors that provide pre-packaged Web workflows for academic and student services are responsible for testing its software for Section 508 compliance and making the necessary program changes. Because institutions pay the vendor an annual fee for system upgrades and maintenance, it is the job of that vendor to make the changes required to comply with Section 508, at no additional cost to the institution.

A Vendor-Client Partnership

Working in partnership with four client institutions in the forefront of universal Web accessibility – Springfield Technical College, The College of Southern Maryland, Dallas County Community College District, and Oakland Community College – Datatel, Inc., a leading provider of information management solutions for higher education, launched an in-depth assessment and redesign project to produce WebAdvisor 2.0, a robust Web-based self-service solution that meets strict Section 508 compliance standards. Different institutions have different system configurations. For that reason, the project required testing on a broad and complex variety of configuration combinations. Testing was performed on all platforms: Windows 95, 98, ME, NT, 2000, XP, and MAC. Browser testing was conducted on Internet Explore 4, 5, 5.5, and 6, as well as Netscape 4, 4.7, 6, 6.2, and on Opera, Lynx, and Mosaic. Various computer brands and types were tested, as were various HTML versions. Assistive devices, including JAWS, ZoomText, Window Eyes, and other screen readers, were used in the testing process. The objective was to take into account various disabilities, such as blindness, low vision, cognitive, and physical disabilities.

Some of the technical changes made to the Web product were:
- The addition of ALT tags to images and image maps, enabling screen readers to "read" the images in words
- Skip links, enabling the visually challenged to skip the navigational bar
- Clear and unique field labels
- Style sheets that follow the Section 508 HTML templates
- Shortcut keys
- An accessibility description page
- Tags for combination and Submit buttons
- Linear tables for ease of use

In a statement of accessibility compliance published in July 2001, Nu Visions Unlimited, Inc., an independent testing and auditing firm certified WebAdvisor 2.0 as compliant with the World Wide Web Consortium Level A Accessibility Guidelines and Section 508.

Partnering with Your Vendor

When working with your vendor, an excellent starting point is the 16-bullet checklist provided by the Access Board. The checklist covers layout, look and feel, navigation, the use of color, and other criteria set down in the Section 508 guidelines. Once compliance testing of the Web product has been completed and the areas for improvement identified, a development plan with major milestones, accessibility testing and verification, along with clearly defined roles and responsibilities for both client and vendor, should be crafted. The Web product should integrate seamlessly into the
institution's overall Web presence. However, it should be flexible enough to enable some colleges within the institution — law, medicine, etc. — to have their own look and feel, if desired.

Thanks to a solid vendor-client partnership, WebAdvisor 2.0’s compliance with Section 508 was a key milestone for Datatel, because it has a far-reaching impact on the ability of Datatel’s clients to serve all of their constituents, including those with disabilities. In making Web-based academic and student services Section 508 compliant, the vendor does most of the work. But the success of the undertaking is the job of the vendor and the client institution working together.

Web Based Learning Support for Experimental Design in Molecular Biology

Tinri Wilmsen, Ton Bisseling
Department of Molecular Biology, Wageningen UR, The Netherlands
Tinri.Wilmsen@mac.mb.wau.nl, Ton.Bisseling@mac.mb.wau.nl

Rob Hartog
School of Technology and Nutrition
Wageningen UR, The Netherlands
Rob.Hartog@users.info.wau.nl

Abstract: An important learning goal of a molecular biology curriculum is a certain proficiency level in experimental design. Currently students are confronted with experimental approaches in textbooks, in lectures and in the laboratory. However most students do not reach a satisfactory level of competence in the design of experimental approaches. This paper describes the development of a web-based application, which supports the learning of this design skill. The application consists of an activating part and a library part. In the activating part, the student is presented with a biological question that must be solved experimentally. Therefore, the student has to make a set of coherent choices, execute steps in an experiment and interpret the experimental results. Furthermore, a DNA sequence has to be analyzed with web-based databases. The library consists of learning objects that present essential background information. A test with a small group of students yielded very promising results.

Introduction

The Food and Biotechnology (FBT) program aims at the creation of a rich body of digital learning material for university curricula related to food science and biotechnology. The FBT program was initiated at Wageningen University in September 2000. The program focuses on web based learning support for those learning goals where digital learning material is expected to have a clear added value. One of the FBT projects aims at the development of digital learning material for molecular biology. This paper describes the first stage of this project.

One of the important learning goals of a molecular biology curriculum is a certain proficiency level in designing an experimental approach. This involves the application of different techniques. Students are usually capable of understanding how these different techniques work, but they have difficulty in combining them in a useful way and in judging whether they are suitable to find an answer to a particular question. Moreover, students often do not realize that experiments are performed with biological systems. Consequently they do not use their knowledge of biology when designing experimental approaches, even though this is essential for the design of a useful approach. This lack of applying biological knowledge can also be observed during the analysis of experimental outcomes.

The indicated problems in experimental design may be inherent in the current educational setting. Currently students are confronted with experimental approaches in textbooks, in lectures and in laboratory courses. Each of these formats has its own drawbacks. Textbooks do describe many experiments and approaches, but this is not sufficient for students to learn to choose techniques and to schedule operations. One of the problems is that students usually focus on the mechanisms behind techniques, thereby losing sight of the uses of such techniques. In a lecture, more weight can be put on the actual designing of experimental approaches. It is however very hard to involve more than a limited number of students individually in such a way. Furthermore, the students that do get involved, can hardly get personal feedback due to considerations the lecturer has to take of the other students as well as the time allotted for the lecture. In a laboratory course finally, students have little freedom in choosing and scheduling operations. Moreover, they become preoccupied with the practical skills they still lack, such that the overview of even the specific experimental approach is lost. Thus the teaching of more general aspects of designing experiments is practically
impossible. The possibilities of computer based learning support may offer a solution to the above problem. Apart from the well known argument that computer based learning support makes it possible to activate each student individually and generate personal feedback, many of the experimental results in molecular biology experiments are photographs or sequences and can thus be represented digitally. Moreover, the processing of results in molecular biology experiments requires computers and web access. Recently, many DNA and protein sequences have become available in web-based databases. In current molecular biology research, using these databases becomes increasingly important for the design of experimental approaches and the interpretation of experimental outcomes. Therefore, learning to use information from databases was added as new learning goal to an undergraduate course. For an effective use of the available data, database searches have to be performed and the data have to be integrated with biological knowledge and knowledge about molecular biology techniques.

Thus web-based learning support should improve the following skills:
- designing a basic experimental approach by selecting and combining suitable techniques;
- performing a database search;
- integrating information from biology, techniques and database searches.

These skills can only be improved when sufficient background knowledge can be used. Knowledge that the students have not mastered yet, has to be presented as well.

The material has to complement the lectures. As the lectures may change from time to time, the material should consist of modules that can be combined flexibly. It should also be possible to use these modules independently from the lectures.

In this paper we describe the development of the first module including the results of a first evaluation. The paper finishes with a discussion of the methods we applied to teach the skills mentioned above.

The Global Structure of the Site

To offer students the opportunity to practice the necessary skills, they are offered a case (see demo site) in which they have to design an experimental approach to solve a real (but basic) biological problem. Thereby the theory is placed in the proper context. This may be favorable for retrieving the theory from memory in a similar context (Anderson 2000), but this also makes its relevance more apparent, which may motivate students (Keller 1987). The background information that is needed to successfully go through the case is available to the students just when they need it. This just-in-time information presentation is, among others, recommended by the Four Component Instructional Design model (van Merrienboer 1997), which gives guidelines for teaching complex cognitive skills. Some background information may be needed several times, when going through the case. To be able to offer this information from one place, we constructed a library (see demo site) that contains all necessary background information. This library consists of independent self-explanatory learning objects. Because of this setup, it is possible to study only a selection of the learning objects and no specific study order is required. In case a student prefers this, he could also study all background information before starting with the case. The library also ensures that students with varying amounts of prior knowledge can in principle complete the case.

The Light Induction Case

In the light induction case the student has to isolate a gene that is induced in plants upon light exposure and analyze its DNA sequence. The student is guided through the case by multiple-choice questions to prevent him from getting lost and frustrated. Sometimes a choice between different techniques is offered. In this way the student is stimulated to actively think about the possibilities of the techniques, which is essential for the design of an experimental approach.

After choosing a technique, the student is immediately confronted with the experimental result. This result has to be interpreted in order to find out whether applying the technique was indeed useful. Thereby it is essential to take biological aspects into account. This is illustrated by the screen dump from the demo site shown in figure 1. This shows the screen the student sees after choosing to analyze differences in mRNA concentrations on an RNA gel on which total RNA is loaded. This choice has led to a useless result because mRNA cannot be visualized with this method. This is partly due to the fact that mRNA, the RNA that needs
to be studied, forms only a minor fraction of total RNA. Thus, it is necessary to use knowledge about biology to decide whether the technique is useful. The student will discover that the technique was not useful after selecting a band for analysis.

This format in which students are confronted with a result that they have to interpret has several advantages. Firstly, students probably remember better whether a technique is useful in a certain context when they discovered this themselves than when this would have been told. Secondly, if students do not use their biological knowledge, they are confronted with the consequence. This probably makes a stronger impression than when this is pointed out during a lecture. Thirdly, a picture of an experimental result contains implicitly much information about the precise use of a technique. By interpreting the results, students are stimulated to focus on and give meaning to these results. These include results of techniques that were not useful and that are usually not shown in a textbook. As people tend to have good memory for meaningful interpretations of an image (Anderson 2000) and easily make inferences from them (Larkin et al. 1987), the students are in this way again stimulated to remember the precise use of a technique.

Sometimes it is also necessary to interpret the result in order to continue with the procedure.

The gene can eventually be obtained by applying a method that is called "differential screening". This method was chosen for several reasons. Firstly, the problem is an example of a very common research question in molecular biology. In many instances, genes that are specifically induced under certain conditions have to be identified. Even though differential screening is a relatively old method it was chosen because it clearly illustrates the problems involved. Moreover, more advanced methods are still largely based upon the same principles. Therefore, understanding the differential screening method may facilitate the understanding and proper application of technologically more advanced methods, based on an analogy process (Anderson 2000).

![Light Induction](image)

**Figure 1.** Screen dump of a screen a student see after selecting a technique. To be able to interpret this result, the student needs to use biological knowledge. Only after interpreting the result correctly, it becomes clear that this technique was not useful in this context.
After isolating the desired gene, the DNA sequence of the gene has to be analyzed (see sequence analysis section at the demo site). The first sequence to be analyzed is not complete, as is usually the case in practice. Another reason why this partial sequence is offered is that the student has to discover for himself that it is not complete. Therefore, experimental findings have to be combined with knowledge from biology. The student has to perform an additional experiment to obtain the complete sequence. This sequence has to be analyzed by performing a database search. To perform this search it is again necessary to actively use biology knowledge as well as knowledge about the applied experimental techniques.

The interactive part of the case is followed by a summary. This summary contains overview pictures as well as information about why applying a technique in the given context was useful or not. The summary contains in principle all necessary theoretical information. Thus, the interactive part should support the training of extra skills, whereas the theory can be found in the summary.

Finally, a number of multiple-choice questions are implemented which serve as a self-test.

The Library

The library contains background information that is necessary to go through the case, so that the material can in principle be used by students with varying amounts of prior knowledge. The library contains information about techniques, database searches and processes that take place inside cells. As mentioned before the library contains independent and self-explanatory learning objects.

The explanation of a technique consists of 2 to 6 movies, because of our positive previous experiences with these types of movies. Figure 2 gives a screen dump (see demo site) of the introduction page for the technique, which is labeled DNA gel. The page contains pictures that give an impression of the content of the movie. The student can click on a picture in order to start a movie. The movies do not take more than 2 minutes. They consist of spoken text supported by photographs, annotations and animations. As stated before, it is essential for designing experimental approaches to know the different purposes of a technique. Therefore, this is stressed in the first movie. The second movie explains the principle of a technique.

![Figure 2. Typical introductory screen for a technique in the library. Pictures give an impression of the content of the movies. A student can click on a picture to start a movie. Questions are available as well.](image-url)
The explanation of some techniques also highlights specific steps of the technique to give the student an idea of its complexity and scale. A movie showing a typical experimental result is sometimes added as well, which makes it easier for the student to interpret results himself later on. The written text and the still images of each movie are available. Extensive experience with the use of movies at Wageningen University has shown that some students prefer to view the text when the pace of the movie is too slow for them. The written text is also better for students who just want to scan through the theory quickly (Hartog et al. 2000), for students whose mastery of the English language is insufficient to understand the audio and in situations where there is no sound available. Beside the movies, each learning object contains a couple of short questions to let the student internalize the newly acquired concepts. In case of similar techniques, movies that explain identical steps, are actually identical. If applicable, this is clearly indicated.

The learning object on the database search contains some text to explain the background and a simple simulation. In this simulation a search can be performed in controlled circumstances. When the student follows the instructions given on top of a page, he stays within the simulation and gets new instructions. It is however also possible to leave the simulation and find out what happens when another strategy is followed. This learning object also contains some multiple-choice questions.

The learning objects dealing with the biology background contain schematic drawings, tables etc. in which the most important information is summarized. These objects serve to refresh the student’s memory and are not meant to teach them new information.

Evaluation Results

So far the material was evaluated with a group of 6 volunteers. This evaluation was carried out to identify ways to improve the site. By testing the site with a small number of users, most usability problems should become clear (Nielsen, 2000). The students first had to give an indication of their prior experiences and they had to make a short test. Next, the students worked in pairs through the site. Finally they performed a post-test that was similar to the first one and completed an evaluation form. The students judged the site on average with an 8.7 on a scale of 1 to 10. Thus, the students were very enthusiastic. Reactions on the evaluation forms include:

- "The overall impression is very positive. By performing a virtual experiment you become able to understand techniques, but more important, learn to combine different techniques to come to a good result."
- "I think it is a good idea showing some films because this helps to imagine the practical work and not only the theoretical explanation. And then, the possibility of listening the explanation is very appropriate because, in this way, it is not so tiring reading the whole text from the computer screen."

The evaluation also yielded ideas for improvement. Most importantly, students had problems to perform the database search. Therefore, the above mentioned simulation was added to the library. Further minor improvements include the addition of a clarifying figure, the reformulation of some feedback and the removal of a number of spelling mistakes.

An important test result is, that each student applied the concept of differential screening sufficiently well after studying the material whereas only one student already managed to apply this concept before studying the material. Furthermore, in the post test the students had to design an approach to solve a (basic) biological problem that was different from the problem they solved at the site and that required a different approach to be solved. The students performed better in the second test than in the first test, even though the problem was slightly more difficult. Overall, the results were encouraging.

Final Remarks

A web based application, which supports learning experimental design in molecular biology has been developed. The web site has been evaluated by a small group of volunteers. Currently the demo site is accessible worldwide for review. The site will be used in Wageningen in the course "gene technology" in spring 2002.

The ultimate goal will be that students can design experimental approaches in new, unfamiliar situations. The application confronts the students with situations and experimental results, which force them to actively use their knowledge of biology while designing a new approach. It is expected that applying their knowledge,
while working with molecular biology techniques will eventually become habitual. The web site teaches to design an experimental approach addressing a new question in molecular biology in three ways. Firstly, the differential screening method that students use in the case, can be used to address similar biological questions. Secondly, the differential screening method can also serve as a schema when designing an analogous, technically more advanced approach. Finally, the application forces the student to focus on the precise use of each technique in multiple ways. It is essential that the student becomes very much aware of what the use of a technique exactly is. Thus, it should become easier to design new approaches using the same techniques. Moreover, students will probably gradually learn to focus more on the use of a technique when studying new ones in the future. This may even lead to a better performance for designing approaches that consist of these new techniques as well. Currently, several additional cases are being developed, covering the production of transgenic organisms. The research is progressing towards a qualitative simulation environment that will present the consequences of a student's choice in terms of experimental results based on programmed rules. The number of different options will be almost unlimited in the perception of the student. On the one hand this offers the students a more realistic situation and more opportunities to test their own ideas, but on the other hand students could easily flounder and show unstructured behavior (de Jong et al. 1998). The main challenge for the future will thus be to embed the simulation of experiments in an environment that guides and supports the students.

The Role of Group Development and Facilitative Teaching in Online Courses

Jean Wilson, Instructional Development and Support, University of Kansas, Lawrence, KS lpwilson@ku.edu

Abstract: In an effort to engage online students interactively, distance-learning guides emphasize group-based instructional strategies and the use of Internet communication tools in online instruction. Although some of these guides include a general discussion of group development and facilitation strategies (see, for example, Palloff & Pratt, 2001, p. 125), none provide a concise, step-by-step approach to group facilitation for instructors who may be unfamiliar with these strategies. Using Lacoursiere's model of group development, this article will present an overview of the application of group development models and group facilitation in online courses, one that can provide instructional designers and instructors a practical framework for maintaining meaningful interactivity and group cohesion in online learning.

Research in distance learning emphasizes interactivity, especially learner-to-learner and learner-to-instructor interaction, as a key to engaging learners and achieving learning objectives in online courses (Moore, 1989; Hillman, Willis, & Gunawardena, 1994; Wagner, 1994). Accordingly, instructional designers and developers incorporate instructional strategies such as group projects into course design and encourage the use of discussion boards and e-mail in course implementation. But these provide only the technological opportunity to interact; they do not necessarily provide the motivation to do so. Group facilitation can help motivate students to interact but in order to be used effectively instructors must have at least an introductory knowledge of group development. Drawing from the observations and models of group development, this article presents a step-by-step approach for the application of group facilitation strategies in online courses.

Group Development and Online Learning

Researchers of group development use models to study the behavior of groups and maintain that groups are usually better able to accomplish a given task if group leaders use facilitation skills to help the group establish a sense of cohesion. In this way, understanding group behavior provides a framework for group leaders so they can learn which specific interventions may help foster and maintain this cohesion throughout group development. Although Tuckman's model is the best known (1965), Lacoursiere's group development model (1980) may be more helpful for instructors and designers who have never been exposed to group development because it demonstrates the relationship of morale to productivity, suggesting that group cohesiveness may affect the achievement of learning outcomes. According to Lacoursiere's model, there are five stages of group development: Orientation, Dissatisfaction, Resolution, Production, and Termination, with each stage characterized by measurements of morale and productivity. Lacoursiere's developmental stages are presented briefly below, along with suggested online facilitation strategies for each stage.

In the Orientation stage, group members have high expectations about the task they are undertaking but lack the requisite skills to fulfill the task. Members experience anxiety over the purpose of the group and group roles and are highly dependent on the leader. Overall, orientation is marked by high morale but low group work. During this stage, the instructor should initiate low risk activities such as icebreakers, help group members gain key technical and content skills, and clarify group roles and purpose. It is important that the instructor establish communication protocols and behavioral norms. Finally, the instructor should maintain a high presence, use a conversational tone, and role model risk-taking through personal disclosure to encourage students to do likewise (Cutler, 1995).

During Dissatisfaction, group members experience conflict between their initial expectations and the reality of the group and its task. Morale drops but work increases as group members attain the necessary skills to undertake the task. If conflict is mostly low-level frustration, the instructor can continue to help clarify group goals, reminding the group that conflict is a natural byproduct of the process that can be productive if managed successfully. If conflict is highly charged and personal, the instructor should contact members privately and
consider more formal conflict resolution strategies. Generally, the instructor should maintain a high presence, be directive, and act quickly to address and resolve any negativity. Interventions in this stage are highly variable and situational.

In the Resolution stage, reality is accepted and reconciled with expectations so there is decreasing negativity. Morale and work both increase. The instructor can begin to let go, but it is important that students know he/she is still active and a content resource for them. For example, in online discussions the instructor might deflect questions, redirecting them back to the group or to specific members of the group. In addition, the instructor should summarize and refocus discussions if they digress. As the group begins to develop cohesiveness, he/she can initiate higher risk activities such as peer-to-peer critiquing.

In the Production stage, the group is working well, is satisfied with group member relationships, and group members have positive feelings. The group is now able to work autonomously so the instructor can step back and allow the group to function independently, but he/she should remain ready to intervene if group cohesion begins to impede work on the task, for example, if the social interaction threatens to impede learning objectives. Since morale has regained some ground and group members are more skilled, this is a time that the instructor might introduce discussions around controversial topics, or some similarly challenging activities.

Termination is characterized by a sense of loss and concerns about completion. Group members either pull together to finish with positive results or disintegrate early, impeding group work. Although morale is fairly high, it may dip if the group begins to break apart. The instructor should use closure activities to bring the group to completion on a high note. This can be done formally with traditional activities such as posting final projects and evaluations, or informally, for example, through discussions about completed learning objectives.

Conclusions

The ideas presented above are a simplified overview of group development and facilitation. In reality, both are highly dependent on the context of both the group and the task, and they can be quite complex. By understanding the stages of group development, faculty may become better able to determine which facilitation strategies will help develop group cohesion and provide the motivation for online interaction. Learning group development will help faculty see the context for facilitation strategies they may already be using, for example, icebreakers and communication guidelines. Finally, introducing group development in the planning and implementation of online learning may help instructors see that they have dual roles in online teaching, that of the traditional content expert and that of a group leader. Meaningful and productive online interactivity depends on the successful deployment of both roles in a learner-centered instructional context.

Abstract: There is a noted shortage of educational resources to help people facing terminal illness. Completing a Life is an interactive multimedia CD-ROM and web site developed to address this issue. Many content and design challenges were addressed during development. The resulting product includes a carefully crafted interplay of content, navigation, interactivity, and look-and-feel to create an approachable, empowering resource for a subject that is emotionally difficult for most people to address. Completing a Life serves as a model for medical education, combining personal stories with task-based information contained within a virtual environment.

Introduction

Modern medical science allows people to live for prolonged periods, even with the onset of a terminal illness. This has led to an increase in the issues related to end-of-life care. Given that the subject of dying is often viewed as taboo in our society, frequently individuals do not talk openly about it with their health care provider or are not "ready" to do so when the opportunity presents itself (Yang, 2000).

The major goal of Completing a Life is to give a comprehensive overview of a subject that is emotionally difficult for most people to address and to do so in a way that is comfortable, reassuring and instructive. The project took on the complementary task of opening up the users to make them receptive to the information. If we could achieve this, it was our hope that Completing a Life would give users control over a situation in which they may have felt none before, resulting in a sense of empowerment. In the case of users with an advanced illness, this empowerment would provide the ability to take charge of their lives for the time they have remaining. In the case of users who are friends or family members, this empowerment should give them access to much needed information to answer their questions and help them empathize with the needs and desires of the patient.

Objectives

To achieve these goals, the core team, composed of three content experts, two multimedia designers, a writer/researcher, and an artist, spent much time investigating and brainstorming to arrive at the following objectives:

- Educate users on end-of-life issues not readily available elsewhere;
- Identify and organize the content to reflect the tasks faced by the target audience;
- Design navigation that empowers users to find and explore the information to address their own personal questions and concerns;
- Communicate the information in a clear, inviting tone without being authoritarian;
- Develop a look-and-feel that is welcoming and comforting while maintaining the emphasis on the content itself;
- Integrate stories of others facing similar issues to create a "virtual" support group;
- Create a multimedia product that is viewable, printable and accessible on the majority of modern computer systems, while still being innovative in its design.

In order to achieve the desired objectives, several content and design challenges had to be identified and resolved.
Content and Design Challenges

Completing a Life (see Figure 1) was developed through a process of iterative design. User involvement was an integral part of this process. Focus groups helped define and structure the content. Prototypes were tested on the target audience to help determine an appropriate writing style, effective navigation, and a welcoming look-and-feel.

Content Research
The first task in the development of Completing a Life was to determine what resources were currently available for patients and families and what information was needed. We conducted focus groups with health care providers, hospice workers, religious figures and family members of the recently deceased and interviewed content experts to aid in this process. Printed material, videos, Internet-resources and information gathered from discussions with support groups were also examined. This research provided us with the foundation to begin the iterative process of gathering, writing, and structuring information. It also led to the creation of a list of resources that would ultimately be highlighted throughout Completing a Life as additional support materials that users could seek out.

Information Architecture
The organization of content was very important in making the project approachable and useful. After much discussion and consideration the decision was made to divide all the content into three major areas: Taking Charge, Finding Comfort and Reaching Closure related to the tasks our target audience generally face. Each of these tasks contains several topics. Each of the topics contained several levels of subtopics. This hierarchy defined a logical structuring of a complex information space and ultimately became the basis for the primary navigation.

Navigation
Completing a Life is built on a user-centered model. Reflecting awareness that not every user will want to or be ready to investigate all the content, the navigation allows users to develop their own paths, exploring the information they want when they want it. This user initiated nonlinearity, coupled with a variety of secondary hyperlinks throughout the content, was designed to keep the user actively engaged in the content, which studies have shown promotes learning (Brandsford, Brown, & Cocking, 2000).

The navigational hierarchy parallels the information architecture. However, we did not want to overwhelm the user with too many choices onscreen at one time. Therefore, the hierarchy was compressed. Several subtopics were merged together to limit both the number of subtopics for each topic and to limit the maximum depth of the hierarchy. Further, it was decided to display only the depth of the hierarchy and the current topic’s immediate subtopics at any one time. Overall, the visual design of the navigation orients users to their location in the information space and promotes active exploration and discovery of subtopics, while providing an immediate method to navigate back through the hierarchy.
Writing Style

Given the delicate nature of the subject matter, we knew that how the content was presented was just as important as what was actually said. We experimented with a variety of "voices" in the writing style. It was decided to use a "voice" that spoke directly to the person facing the terminal illness. This approach supported our goal of empowerment. The tone was positive, friendly and experienced. It was appropriate for family members and health care workers who, as informal testing demonstrated, had no problem empathizing.

The writing also had to adhere to the nonlinear accessibility of the content. That is, since a user may have arrived at the page via a direct hyperlink from another part of the product, we could not assume that the pages were read in any particular order. Therefore, each page of information had to be written to make sense on its own.

Reading Comprehension

The content was written in a concise manner. This kept the information straightforward while minimizing the amount of vertical scrolling. We consulted with a literacy and reading expert to improve accessibility of content and keep the material at an upper elementary school reading level. It was also decided to supplement the onscreen text with an optional audio narration that made the content accessible to visually impaired users who represent a high percentage of our target audience. And, since listening comprehension is higher than reading comprehension, it further reduced literacy barriers (Lynch, 1988).

Look-and-Feel

The look-and-feel of the project was a major concern. We wanted to present the content in an approachable, comfortable fashion. Early in the development several artistic styles were prototyped. After some user testing and feedback from other multimedia designers, we decided to go with a watercolor style because we felt it conveyed the sense of softness and delicacy of the subject matter.

The visual metaphor we decided upon was that of a back porch overlooking a lushly vegetated yard. The visual metaphor links the four primary locations in the original watercolor scene to the four primary content sections in the product. The porch represents the location of the personal stories, as people often sit and talk on porches. A gazebo with a table and chairs represents the Taking Charge content. A comfortable looking tree swing represents the Finding Comfort content. And a bench overlooking a calm pond represents the Reaching Closure content. The metaphor between the visuals and the content was very subtle and intended only as a subliminal cue as the user browsed the content, not as a navigational metaphor.

User testing verified the watercolor style and visual metaphor were effective. However, we found some users did not respond to the look-and-feel positively or negatively. They were, in fact only interested in the information itself. For this group, we added a listing of Topics to be used to navigate directly to the desired information.

Personal Stories

A defining element of the project was the integration of "personal stories." Personal stories are told firsthand through video interviews. The interviews document the real-life experience of people who have confronted advanced illness in one way or another. Rather than use actors and scripts, it was decided that true stories told by those who were experiencing a life threatening illness were much more powerful and effective. However, the process of finding and interviewing candidates willing to tell their stories was challenging. It was found that there was a limited time between the point when individuals were ready to share their stories and when they were still in a physical state suitable to be interviewed. Our team had to work closely with hospice and a variety of doctors to help identify appropriate candidates. The team also had to respond quickly when a candidate agreed to be interviewed.

An effort was made to include interviews from a diverse group of individuals to increase the likelihood that the user would identify closely with one of them. Fifteen interviews were conducted. However, several of the interviews were not included in the final product. The primary reasons for exclusion were either the individuals were not ready to discuss issues related to completing their lives or, because of their advanced illness, they were very difficult to understand and follow. Ultimately, nine individuals were included in Completing a Life, representing multiple demographic groups, illnesses, and personalities.

Overall, there are more than three hours of interviews in Completing a Life. Each interview was arranged in the same task-based categories as the content: Taking Charge, Finding Comfort and Reaching...
Closure. Within each category, the user can watch segments of the interview. Therefore, a user can listen to the parts of the stories that are interesting and relevant to them.

These video narratives illuminate many of the topics addressed in the content sections and are extensively cross-linked with that content to enhance the user’s interactive multimedia experience. Links to topics relevant to the individual’s story are available below the video interviews. By following the link, users can explore the topic in more depth. In addition, content pages have links to related personal stories.

Page Design
At the beginning of the project in 1999, Web usage statistics showed that over 80 percent of monitors were at least 800x600 pixels in size (Nielsen, 2000). Given that this percentage would assuredly increase over time, we designed the pages within Completing a Life for viewing on 800x600 pixel displays or larger. This allowed for optimal layout of navigation and content with no horizontal and minimal vertical scrolling.

Following Jakob Nielsen’s premise that “navigation is a necessary evil that is not a goal in itself and should be minimized” (Nielsen, 2000), we kept navigation to a minimum. The average page in Completing a Life has less than 25 percent of its real estate dedicated to navigation. The largest amount of real estate is dedicated to the content. Ample space is also given to “white space”. White space is used to segment the page into meaningful areas that the user can quickly identify.

The pages were designed to be conducive to printing. Most individuals, particularly the elderly who represent a sizeable portion of our target audience, find it difficult to read a large amount of text on the computer screen. Further, we have found that users often enter an “information gathering” mode in which they browse through the content rapidly skimming it. When they find something of interest they often prefer to print it to be read in detail at a later time so they can continue in their information gathering. They also may want to print content to share it with others who do not have computer access readily available. For these reasons, we avoided such page design features as frames and popup windows.

Delivery
Despite the recent downturn in the dot-com industry, Internet use is still on the rise, especially among home users (Roberts & Crump, 2001). The so-called “digital divide” between those who have access and those who traditionally do not, including the ethnic minorities, rural populations, and the elderly, is rapidly shrinking (Fox & Rainie, 2000; Eng, Maxfield, Patrick, Deering, Ratzan & Gustafson, 1998). Today, one of the most common uses of the Internet by consumers is to obtain health information (Fox & Rainie, 2000; Horrigan & Rainie, 2002). With this in mind, we developed Completing a Life with Web-enabled technologies. However, we did not want to limit our audience to those with just Internet-access. Therefore, we utilized only client-side technologies that do not require a server. This provided us the flexibility to deliver the product on the Internet, within Intranets, such as local hospitals’ networks, or on CD-ROM.

The design of Completing a Life demanded cutting-edge multimedia technologies. Audio, video, animation, interactivity and the ability to print complex medical forms could not be handled by HTML alone. Flash, QuickTime and PDF were chosen to address these multimedia needs. These technologies have become de facto standards on the Web. They are available as free downloads and work identically on both Macintosh and Windows platforms. Further, a high percentage of typical Web users already have these technologies installed and configured on their machines. For those without the required technologies, Completing a Life guides users through the download and installation process.

Another delivery decision was to target broadband connections rather than slower phone-modem connections. This choice was made for several reasons. First, broadband availability is on the rise. It is estimated that 1/3 of household Internet users and 2/3 of business users will have a broadband connection by 2002 (Rose & Warren, 2001). Second, it was our goal to produce an engaging, rich multimedia experience. It would be very difficult to do this with the bandwidth that a 56K modem provides. Third, we wanted the personal story videos to convey the personality and emotions the individuals expressed in their interviews. This would not be possible with thumbnail-size video at slow frame rates and poor audio quality.

The site was made available on the Internet in October 2001. Broadband users can access the content in real-time with little or no wait time. Modem users can access the content. However, in most cases, they may have to wait for the multimedia elements to load. We also made the product available on CD-ROM for those wanting immediate access without broadband connections and those without Internet connections altogether.
An Evolving Model

Combining Personal Stories with Medical Information

In Breast Cancer Lighthouse, personal stories were shown to be an effective approach to creating a “virtual support group” (Greene & Heeter, 1998). Easing Cancer Pain extended the personal stories model by linking from medical information in the product to related segments of the personal stories. This was found to “humanize” the information by tying it to the individuals' actual experiences (Greene, 1998). In Completing a Life, this interlinking of content with the personal stories was enhanced to go both ways. That is, personal stories segments also linked to content related to the issues being discussed in the stories. This added validity to the personal stories. Further, it provided “just-in-time” information as users heard topics discussed within the personal stories.

Virtual Environments

Another hallmark of the model developed in Breast Cancer Lighthouse was the use of a virtual environment to disseminate the medical information. In the product, information was tied to locations on an island. In one area the user could walk along a beach, by navigating with a mouse. On the beach, they were introduced to women who have survived breast cancer. The user could click on a woman to share in her personal story. In another area of the product, the user could walk along a garden path, containing a variety of signs. When the user clicked on a sign, they were presented with information about the given topic. A similar navigational metaphor was employed in Easing Cancer Pain. The user navigated along a path at a virtual retreat grounds, locating information in kiosks found along the path. Personal stories were told around a campfire. The virtual environments were shown to create a relaxing mood among users, increasing their receptiveness to learning (Greene & Heeter, 1998).

The information space in Easing Cancer Pain was much more complicated than Breast Cancer Lighthouse. Testing found that some users had a difficult time making meaningful associations between the information and the virtual locations; this lead to some disorientation when navigating. The information space in Completing a Life, containing a wide variety of topics, was even more complex than Easing Cancer Pain. Therefore, rather than using a virtual environment as a direct navigational metaphor, we decided to employ a more traditional, hierarchical menu system to navigate the information. However, a virtual environment was utilized as a visual metaphor to achieve the benefits found in Breast Cancer Lighthouse without the confusion found by some in Easing Cancer Pain.

User Testing

An evaluation study of a target group of 50 patients has begun in an inner city hospital setting. The study seeks to determine if people facing life-threatening illnesses are comfortable using computers as a way to learn about end-of-life issues and if our project objective of creating a comforting, empowering, easy to use product is obtained. To date, a small group of chemotherapy patients, three men and six women with an average age 62 years, have participated in the study. While this sample is small, the preliminary data has so far validated our approach.

After viewing the CD-ROM, five patients said they were very comfortable using the computer to learn, three were somewhat comfortable and one was not comfortable. All the patients felt comfortable with the information found in Completing a Life. Two of the patients said they felt somewhat more empowered to talk with their physician about end-of-life issues. Another indication of empowerment was three of the five patients that did not currently have an Advance Directive said they were somewhat likely to complete one after spending time with the CD-ROM. Overall, six of the nine were interested in spending more time with the CD-ROM and seven said they would recommend it to others. All of them found the CD-ROM to be somewhat easy to very easy to use.
Summary

Completing a Life represents a model for a kind of medical education that did not exist before interactive multimedia. It delivers a wealth of learning resources in a form that is not intimidating or overwhelming and that places control of the learning experience in the hands of the learner. It also brings the power of multimedia to bear in the use of the personal stories whose immediacy and emotional resonance add meaning and accessibility to the material.

The development of Completing a Life demonstrates the tight interplay between content and design in educational multimedia. To achieve the desired learning goals, the content and design challenges must be addressed simultaneously and harmoniously.

E-Learning, Semantic Web Services and Competency Ontologies

Darrell Woelk
Elastic Knowledge, USA
dwoelk@elasticknowledge.com

Abstract: This paper describes a proposed system for competency-based just-in-time learning that uses competency ontologies and semantic web services to deliver learning objects to learners. A competency ontology is a semantic description of the competencies needed in order to participate in the business processes of a company. Semantic web services are web services with semantic descriptions that enable people and software agents to more efficiently identify services that can provide the proper learning objects.

1. Competency-Based Just-in-Time Learning

A goal of corporate e-learning is to increase efficiency and effectiveness by identifying precisely the training that an employee needs to do their job and providing that training in the context of day to day job activities of the employee. (Fig. 1) illustrates the flow of activity to implement competency-based just-in-time learning services in an enterprise environment. In the lower right hand corner is a representation of a couple of the business processes of the enterprise. In the upper left hand corner are the ontologies that capture knowledge about the products, organizations, competitors, etc. of the enterprise. A competency ontology is included that captures the competencies that an employee must possess to participate in specific activities of the business processes. The lower left hand corner illustrates the learning resources such as learning objects, courses, email, etc. Each of these learning resources has been manually or automatically linked to various parts of one or more of the enterprise ontologies to enable people and software agents to more efficiently discover the correct learning resources. The upper right hand corner illustrates the learner profile for an employee that contains preferences, experiences and assessments of the employee's competencies. The box in the upper middle of the figure is a competency gap analysis that calculates what competencies the employee lacks to effectively carry out their job responsibilities. This calculation is based on what the employee needs to know and what they already know. Once the competency gap has been identified, a learning model is selected either manually or automatically. This establishes the best way for the employee to attain the competency and enables the system to create the personalized learning process at the lower middle of the figure. The personalized learning process may be created and stored for later use or it may be created whenever it is needed, thus enabling dynamic access to learning objects based on the most recent information about the learner and the environment. The results of the personalized learning process are then returned to the learner's profile.

![Figure 1: Competency-Based Just-In-Time Learning](image-url)
2. Advanced Technology Support

Each box in the business processes and the personalized learning processes in (Fig. 1) is an activity. These activities might be implemented as existing legacy applications or new applications on a variety of hardware and software systems. In the past, it would have been difficult to integrate applications executing on such heterogeneous systems. But the development of a set of technologies referred to as web services (W3C 2002) is simplifying this integration. The most important of these technologies are SOAP, UDDI and WSDL. IBM, Microsoft and others are agreeing on these specifications. SOAP is a technology for sending messages between two systems using XML for representing the messages and HTTP as the most common transport. UDDI is a specification for an online registry that enables publishing and discovery of web services. WSDL is an XML representation used for describing the services registered with a UDDI registry. Vendors of enterprise applications such as ERP and CRM have announced support for web service interfaces to their products.

However, UDDI and WSDL have limited capability for representing semantic descriptions of web services. The World Wide Web consortium has initiated an effort to develop specifications for a semantic web (W3C 2002) where web pages will include semantic descriptions of their content. The US Defense Advanced Research Projects Agency (DARPA) Agent Markup Language program (DAML 2002) has focused on the development of a semantic markup language DAML+OIL for web pages that will enable software agents to understand and reason about the content of web pages. The program has also developed a markup language for web services called DAML-S (Ankolekar 2001) that enables an improved semantic description of a web service. The e-learning industry has developed metadata standards for describing the semantics of learning objects (IEEE 2001). The Advanced Distributed Learning Lab has developed an XML representation of this metadata as part of the Shared Content Object Reference Model (SCORM) specification (SCORM 2002). The system in Figure 1 requires a representation for business processes so that competencies can be mapped to activities in a business process and a representation of personalized learning processes to enable integration of the learning processes with business processes. There have been attempts to standardize the representation of business processes (WFMC 2002). There are now efforts underway to standardize on a process representation for web services.

A few commercially available e-learning products use competency hierarchies to capture the skills necessary for various job types. The competencies in these hierarchies are then mapped to courses that can improve an employee's competency in a certain area. There is no industry standard representation for these competency hierarchies and they do not capture the rich semantics of competencies. The concepts, relationships and processes of an enterprise can be captured in a set of enterprise ontologies. Ontology representation and reasoning systems are available (Lenat 1995) and the DARPA DAML program has also done significant research on the representation of ontologies. Intelligent software agents can be used effectively in a system such as the one described in (Fig. 1). There has been research into the use of software agents for discovery of information (Woelk 1994), collaboration planning and automation of processes (Tate 1996) and numerous other applications (Bradshaw 1997). This research is now focusing on the use of software agents with web services (Hendler 2001). These agents can proactively search for learning objects both that are needed to meet dynamically changing learning requirements.

Abstract
For three years, the Technology and Learning Team (TLT) has supported the campus at University of Colorado at Denver (UCD) with integration of technology in instruction. In this role, TLT works with UCD faculty in the use of a variety of technologies for instruction, research, and service. TLT brings a holistic or integrated approach that stresses pedagogical considerations over technical ones. A 5-part support model describes this approach for technology integration at the UCD campus. Skill development, community building, product development, support, and vision casting comprise the five elements of the model.

Faculty Support at UCD Campus
Since its inception in 1999, the Technology and Learning Team has grown in member numbers and collective experience. With that experience comes the knowledge that access to technology for faculty is not enough for successful integration. It requires a team effort, with diverse skills, and a focus on multiple areas of support. TLT brings a holistic and integrated approach that stresses pedagogical considerations over technical ones. A 5-part model describes this approach for technology integration. Skill development, community building, product development, support, and vision casting comprise the five elements of the model.

TLT team supports faculty in 5 areas:
1. Skill development
Purpose: to develop the technical skills of faculty. This was provided individually and collectively through workshops on a variety of topics including Blackboard, eCollege, PowerPoint, Dreamweaver, NVIVO, and Inspiration.

2. **Community building**
   Purpose: to bring faculty together to share their experiences, challenges, successes, and war stories. This was accomplished through show ‘n tell meetings, workshops, websites, and a common faculty technology lab.

3. **Product development**
   Purpose: for TLT members to develop products that were experimental and/or required advanced technical skills. Examples include website templates, CD-ROMs, website design, and graphic creation.

4. **Support**
   Purpose: to stress pedagogical considerations over the needs of the technology. Support included one-on-one consultation and participation in departmental task force meetings. TLT contributes graphic design considerations, potential technical solutions, estimated costs, and implementation issues.

5. **Vision casting**
   Purpose: to lead technology integration on the UCD campus. This means that TLT sought out the latest technology and tested its limits, researched what other campuses were doing, found good examples, participated in conferences, and conducted needs assessments.
Faculty Support Model

- Blackboard & eCollege
- PowerPoint
- Dreamweaver
- NVivo
- Inspiration

Skill Development

- Hybrid groups
- Fellows projects
- CD-ROMs
- Learning new technologies (Zoomerang, "Freebies")
- TWT Conference
- Needs assessments
- Electronic portfolios

Vision Casting

- Show 'n tell meetings
- Websites
- Hybrid workshops
- CUOnline

Community Building

- Web templates
- CD-ROMs
- Website designs
- Graphics

Product Development

- One-on-one consultation
- Graphic design
- Good examples

Abstract: This paper describes the development of Master—a computer-mediated tool for learning and research in probability reasoning. The objectives of this software are 1) to explore how levels of interactivity and dynamism of representations in probability influence levels of dynamism in student mental models of probability and 2) whether levels of dynamism in mental models influence probability reasoning. We expect that there is a relationship between levels of interactivity and dynamic movement of representational resources and flexible and dynamic mental models that allow for better reasoning about probability. Hence, we are developing a computer program to investigate this issue. Not only will Master support learning in probability, but it will also help us investigate whether and how dynamic and interactive representations are more influential than others in improving probabilistic thinking.

Introduction

Many studies have been conducted to investigate the effects of computer animations in different instructional environments (Chipman, 1993; Park, 1994; Schank & Cleary, 1995; Snir et al., 1995). Dynamical, graphical representations are considered to be effective modes of depicting information in instructional technology environments. Mental model theory offers a useful lens for examining how and why dynamic representations lead to better reasoning ability. Dynamic representations could be instigating development of dynamic mental models, allowing for better reasoning about probability.

Park and Gittelman (1992) suggest that animation is more effective and efficient than static graphics and help students form useful mental models about the system structure and troubleshooting procedures. Mayer (1997) claims that well designed visual representations allow students to simulate the system mentally. Gentner and Stevens (1983), examining how analogical comparisons influence thinking, and Schwartz and Black (1996), studying using analog imagery as the paradigm to investigate mental models and reasoning, discover that imagery serves as the basis for depiction, which allows for simulation and reasoning. Kaplan (2001) found that dynamically suggestive visuals of system components encourage students to form mental depictions, allowing for mental simulation, thus leading to improvements in reasoning. Russell and Corter (in prep) examined the uses of visual devices in probabilistic reasoning. The experiment revealed a significant relationship between drawing an outcome tree and determining a correct solution.

Statistics is not often presented in visual or dynamic formats. A problem-solver would have to generate mental movements in their minds themselves, perhaps scaffolding their thinking by creating an external representation of the problem. Many students of statistics either generate an inefficient representation or are not able to generate a mental model. We've designed Master to provide multiple visual representations of probability to not only support learning in probability, but help us investigate whether certain representations are more influential than others in improving probabilistic thinking. Furthermore, Master is designed for graduate students studying statistics towards the fulfillment of their research requirement. It helps students comprehend abstract concepts of statistics through visual representations and authentic tasks in a computer-mediated environment. By adapted to online settings, Master will be also available for distance learners.
Master – Software Design

The objectives of Master are to explore how levels of interactivity and dynamism of representational resources in probability influence levels of dynamism in student mental models of probability and whether levels of dynamism in mental models influence reasoning. Master presents probability problems in five representations – Standard Text (ST), Static Visual Displays (SVD), Static Visual Displays with Motion Cues (SVD-MC), Dynamic Visual Displays (DVD), and Interactive Dynamic Visual Displays (IDVD). Comparisons among representational use will allow us to make several discoveries. First, we would like to find out whether an external representation that is visual and dynamic encourages students to visualize the problem dynamically and have higher levels of dynamism in mental models. To explore this possibility, we can compare learning with the standard problem format to learning in a static visual format or a dynamic visual format. Second, we will be able to determine whether all forms of dynamic displays are equally conducive to generating a more effective mental model. It is possible that a more dynamic mental model, which is more conducive to reasoning, is created by the generation of the dynamism in the mental model. This leads us to examine whether static visual displays with motion cues which encourage mental movement would be superior to dynamic visual displays because static visual displays with adequate motional cues support students to think in higher degrees of dynamism. Third, we believe that a student constructs information dynamically when he/she manipulates an object. We expect that software which requires students to manually move objects would be better than software which automatically moves objects for them. Comparison of Interactive Dynamic Visual Display, which allows students to manipulate screen objects, to Dynamic Visual Displays will further reveal whether we should be moving representations for students or encouraging students to make mental movements.

An Example – If a pair of dice is rolled, find the probability of a match or getting a sum of 7.

Event A: Getting a Match = \{(1,1),(2,2),(3,3),(4,4),(5,5),(6,6)\}
Event B: Getting a sum of 7 = \{(6,1),(5,2),(4,3),(3,4),(2,5),(1,6)\}

5 & & & & & & \\
6 & & & & & & \\
\end{array}

Master moves two tables together. Users will see the animation and the overlapping color effect.
The screen design is similar to the DVD screen design. Differently, in IDVD, users are able to manipulate these two tables and then observe the overlapping color effect.

Research Expectations and Implications for the Future

*Master* research permits us to make the following investigations while promoting probability learning. We believe students will develop more dynamic mental models and be able to solve probability problems better if the information is either presented or encouraged to develop in higher levels of interactivity and dynamism. We expect students in Dynamic-Visual-Display group will demonstrate more dynamic mental models and better reasoning than students in the SVD group. We expect all students presented with visual representation will form stronger mental models and develop better reasoning strategies than students learning in a standard text format. We suspect that software which requires students to manually move objects would allow students to build greater dynamism in their mental models than the software which automatically moves objects for them. Thus, we expect that students in the IDVD group will demonstrate more dynamic mental models and better reasoning than the students in the Dynamic-Visual-Display group.

As stated by Park (1998), that static graphics with adequate motional cues representing the dynamic aspects of the task would accomplish results similar to those of animation. We are not certain of the comparison of levels of dynamism in mental models and learning performance of the students in SVD-MC group, Dynamic-Visual-Display group, and IDVD group. If the result shows that the students in SVD-MC group actually do better than the students in Dynamic-Visual-Display group or in IDVD group, it could lead us to consider that static visual displays with motion cues could support students to conceive a problem through generating mental movements themselves, which promotes students for better probability reasoning and improves probabilistic thinking.

*Master* research will reveal how representation influences reasoning about probability. Results will provide evidence for how to design software for teaching probability and suggestions for how to design educational technology in general. In development of *Master* we framed the basis of our designs in the way people think versus the way the technology looks. Basing our instructional technology research questions from the perceptive of how the mind is working led to the development of new media representations. The overall goal is to initiate further studies in diverse disciplines, and discover a tool that is flexible and adaptable enough to promote multi-representational displays across disciplines.

Tension between knowledge and competence in second language acquisition (SLA)

« Skills oriented learning » is the new buzz word in SLA. In many language classes, comprehension and oral expression are now the core didactic activities, instead of the “outdated” knowledge oriented activities. This phenomenon can be observed in all levels of education (from primary to university) and, consequently, in computer assisted language learning (CALL) software.

1. The need in SLA to focus on knowledge
The raised interest for skills training is especially profitable for starting language learners, who have great interest in being “sub-merged” in the new language, because their knowledge base is very small. Things are different with intermediate and advanced language learners, whose learning problems cannot be resolved by more skills training. Those learners present two kinds of problems. The first phenomenon is known as the “ceiling” problem (Gass & Selinker, 1994, Second Language Acquisition: An Introductory Course Lawrence Erlbaum, Inc): it is the incapacity of language learners to move from an intermediate level to an expert level. The second phenomenon is linked with errors: research shows that intermediate level language learners keep making the same mistakes, persistent, difficult-to-correct errors. This is known as “linguistic fossilisation”, demonstrated by Germain and Séguin in *Le point sur la grammaire* (1998, Paris : CLE International).

2. Tools for knowledge building and deepening
Knowledge is generally divided into three types : cultural knowledge, literacy knowledge and grammatical and lexical knowledge. In this context, the grammatical and lexical knowledge is at stake. Exercises are crucial in this component of the language learning process (Hulstijn 2001, *Intentional and incidental second language vocabulary learning: A reappraisal of elaboration, rehearsal and automaticity*, In P. Robinson (ed.), Cognition and Second Language Instruction (pp 258-286). Cambridge: Cambridge University Press, 2001). Second, it is important to mention the "pedagogy of errors" which does not consider errors as ending points obstructing the acquisition of a language, but, on the contrary, as an interesting symptom of the “interlingua”, characterizing any learning process. Finally, a third set of findings relates to the ratio which exists between task and transfer. Thus, Solomon and Perkins (1989, *Rocky roads to transfer. Rethinking mechanisms of a neglected phenomenon*. Educational Psychologist 24, 113-142) noted that the more complex the cognitive assimilation of a task is, the more language learning and the transfer of knowledge to competences will have succeeded. One of the most complex tasks is undoubtedly translation.

To make profitable use of these assets, we need relatively complex applications that confront learners with the differences between their mother tongue and the foreign language and that formulate an adequate response to the errors generated by the contact between languages.

3. And what about keeping a place to new technologies in the choice of learning tools ?
It is true that, today, there is already (lexical and grammatical) knowledge oriented software, but most of it presents some considerable disadvantages. They are generally limited to closed activities (such as multiple choice questions) that activate only a minimum of high level cognitive processes. Another disadvantage is that the generated exercises are almost exclusively of the “structuro-global” type, i.e. the only objective is to memorize forms, mostly by repetition (drill). Furthermore, feedback is crucial in language software. To be effective, feedback must be personalized. It must refer as much as possible to the input of the learners. In other words, it must provide feedback to the errors committed by
the learner and not with the errors that he or she could possibly make. Moreover, the feedback must be intelligent: it should explain the observed rule, show why the answer is not correct and thus allow the learner how to avoid the same mistakes in the future. Finally, to prevent learners from memorizing their mistakes, feedback must be immediate.

4. IDIOMA-TIC: a concrete tool
IDIOMA-TIC is a language learning software developed at KULAK by a team led by prof.dr. Piet Desmet. It is both an “authoring tool” and a “language learning environment”: it allows a (language) teacher to create exercises that can then be presented to learners. Idioma-tic is composed of two modules: an input module and an output or learner’s module.

The first module is made for the input of exercises and tests. Input is user friendly and requires very little time, thanks to some system functions, like the intelligent encoding of answers and the reuse of input.
From a technological point of view, the number of question types has been reduced to three. But, actually, each of these three types allows to create various and very different exercises. We more concretely distinguish multiple choice, fill-in-the-blank or correction and translation exercises.

A navigation tree is provided (or created by the teacher) to attach the exercises to. By attaching the exercises to several “branches” of the tree, the author allows learners to consult the Idioma-tic database in various ways. The student can then choose freely between exercises sets according to themes (like exercises on "On a journey", or “Family and relations”), to the grammar (grammar in general or specific grammatical problems), to specific languages domains (like legal or business language) or to lexical difficulties (such as homonyms and expressions) etc. The tree facilitates also the exchange of exercises among colleagues.

The majority of these exercises created are translation exercises and corrections or fill-in-the-blanks, exercises which support by their half-open character the transfer of knowledge to competences.

In the case of the fill-in-the-blanks, students can make two attempts before being confronted with the correct answer, which is not the case for the multiple choice exercises where the correct answer already appears after the first attempt. In the case of the translation exercises, the number of attempts is theoretically unlimited: after each incorrect answer, the system indicates which words do not correspond to the possible answers. The student decides himself on the number of attempts he makes.
For the three exercises types, the teacher can provide hints. A hint is presented in the form of an asterisk. Student who want to see the hint just needs to click the asterisk.

For the moment, correction of exercises always uses the comparison (matching) method, which implies that the authors of the exercises must provide all the possible correct answers. Currently, we are evaluating the analysis (parsing) method. We expect this method to be able to give more accurate feedback to unpredicted errors.

Let us note finally that the errors made by students are automatically saved by the program, so that the learner can repeat the exercises which he had not answered correctly. The exercises qualified by the learner as stumbling blocks can also be remade.

Please refer to http://impuls.kulak.ac.be/idioma-tic
Information and communication technologies are obviously much more than a delivery tool. They are definitely changing the way we teach and learn. Whatever direction these changes will take, teachers and educators will be at the heart of it and thus should have the opportunities to take part in this revolution from the start.

A generic model—The TAMID Model—for the professional development of in-service teachers has been developed for this purpose by the Open University of Israel (Yaffe, 1996, 1998, 2002). This model focuses on teachers as professionals who are obliged, not only for knowledge and expertise in subject matter and didactics, but in the new technologies. They have to master them not by learning on them, but by using them for their on-going professional needs.

TAMID is based on the Internet as the leading technology and distance teaching strategies as the core methodology for teachers development. It operates simultaneously as a Virtual School for teachers, and as their Professional Club. In this way it is offering teachers an innovative framework for professional growth which facilitates and encourages continuous learning and proper preparation for teaching in the classes.

As a virtual school TAMID offers to the teachers on-line distance-learning courses in a variety of Curriculum-based topics and a variety of educational means: Text, video, audio, face-to-face meetings, satellite lectures etc, are used to deliver on-line courses.

As a professional club TAMID offers the teachers on-going access to experts from the open University and other Universities, presenting them with authoritative, expert advice on the various subjects relevant for their teaching. In addition TAMID provides the teachers with a framework for peer discussions and cooperative construction of a bank of activities and ideas, the help of an information specialist and access to new updated and relevant information.

A typical on-line TAMID course usually includes:

**F2F Meetings:** Dedicated to enrichment lectures, workshops and hands on activities.

**The Courses Web Site containing relevant materials:** reading materials, bibliography, current news, a bank of class activities and ideas, discussion groups etc.

**Assignments:** Relevant to the course's goals and to the teachers' needs.

**On-line Discussion Groups:** for ongoing discourse with the course's tutors, with colleagues and with academic experts for the exchange and the dissemination of information, ideas and other enlightening information, which can be integrated into teaching.

TAMID is operating since the last year as a joint venture with the Center of Educational Technology (CET) and the Ministry of Education. Six communities of teachers are presently active in this program: Science teachers, Democracy and Civic education teachers, English teachers, History teachers, Reading skills, and teachers who focus on New Pedagogy. Each of the communities has its own needs for professional development and its own learning environment and training agenda, however the underlying model remained basically the same.

Within this framework, different models of on-line courses aiming to facilitate professional growth of teachers have been developed and examined:

A. "Teaching Together But Apart". Teachers in this program selected a specific subject for teaching in their classes during the time of the course, (Astronomy and Civic studies were the candidates in this case study), and constantly reported to the course's web-site on progress, success and difficulties encountered in the classroom. The teachers taught their own program to meet their pupils' needs, and the conditions in his classroom. However they enjoyed the benefits of belonging to a group of peers similarly engaged, and of receiving professional expert information, subject-related aid, support and much empathy.
B. Teachers as Developers. In this model teachers developed, along with the guidance and support from distant experts, sets of Internet-based, learning activities for their students.

C. Pedagogy of Science Education. Using the network to discuss theory and practice of Science Education.

One of the main advantages and specialties of the TAMID model is the direct and ongoing access to University Faculty who act as the academic experts of the teachers' center. They are responsible for the academic aspects of the on-line courses, for the academic control of the teaching materials delivered to the teachers and they are giving the teachers an academic backing on subject matter issues.

These aspects of faculty involvement in teachers development will be demonstrated by examples from two fields of teaching: Astronomy and Microbiology. Those two fields are putting special demands on the teachers as they are both:

1. Rapidly changing and call for regular updating of knowledge.
2. Conceptually difficult for the students and teachers might need help in their teaching.
3. Widely represented in the news and over the Web and call for classroom discussions as well as for an expert's eye.

Another aspect of the accesses to experts is the asking and answering of questions. It is a continuous, evolving process that involves, on the students' side, the overcoming of social barriers ("my ignorance displayed for all to see"). The type of questions may vary from requiring factual information to asking for additional explanations and may range from purely subject matter to general pedagogy. On the expert side, answering requires the adaptation of a different writing and teaching style. Answers should not relate only to the subject-matter per se, but should also reflect a broader view of the course content, the school curriculum and the classroom application. Answers should always include the broad aspects of the topic involved and ideally would become a resource for the course participants to use.

An additional aspect of being an on-line expert is the ability to update and involve teachers in the latest scientific information available that is relevant to subjects they teach in schools. Images from spacecrafts, reports of new discoveries in the genome project, on-line articles and publications in major journals are all bringing "out-of-the-oven" materials. Summaries, explanations and experts' "did you know that" approach enable the teachers to feel that they are being brought up to date in all the important scientific discoveries. While most of the text books used in schools are usually a couple of years old, the contact with on-line experts of various fields helps the teachers to keep abreast of the rapidly changing knowledge that they must transfer to their pupils. The ability to receive immediate replies from a reliable experts helps the teachers to encourage their students to ask "any question hey can think of" knowing that even if they will not be able to give the right answer on the spot, they will be able to return with an answer from a first class experts within days.

By using concrete examples from the teachers' center we will demonstrate how this model of linking the teachers to faculty is actually working, and put forward some of the questions that we are facing: What are the added values of such contacts? Who benefits from them? What are the conditions for a fruitful connection? what are the expectations of the "connected experts"? What are their obligations? How to choose an on-line expert, what should be his profile? And what are the implications of these option within the formal educational framework?

Our underlying premise of these models, which has been confirmed over the past six years, is that teaching individually yet together with a group of colleagues and with support from experts, is potentially more meaningful, more interesting and more enjoyable both to teachers and to their pupils.

We believe that this new paradigm for Teachers' training which is in high relevance to teacher's work and offering strong connections to colleagues and experts, is highly advantageous, and most suitable for the professional growth of teachers.

Digital Video as an Educational Tool in Distance Education

Edna Yaffe, Boaz Marmelstein, Alit Epstein, Meira Privman, Shoham-Center for Technologies in Distance Education, The Open University of Israel

Abstract: Video films have pedagogical strength as they can provide instruction through sound, motion, and visuals. However, the volatile nature of live distance lessons as well as the rigidity of analog and linear video has limited its effective use for teaching and learning. Digital video, allows for a shift from a linear and passive mode of use, to a modular, and interactive mode. The Open University of Israel (OUI) has developed simple user-friendly tools and interfaces, which hold the promise for more effective teaching and learning. Several different formats of using digital video will be demonstrated in this presentation and discussed in the light of their pedagogical potential for Distance Learning.

Introduction

Video has special strengths. It usually contains a combination of motion, sound and visuals and is thus particularly suitable for teaching and learning. It is accepted that video can help students envision new ideas, help them perceive the reality around them, and increase motivation for learning. Moreover, video can serve to capture lectures and lessons for later distribution and use.

Video indeed has been used for many years as a teaching tool at all levels to transmit and describe processes, events, objects, experiments, ideas etc.

The Open University of Israel (OUI), which is a distance learning institution, has been using video almost from its start. Academic video films are quite commonly sent to students as part of the learning package. In addition, interactive video lessons are transmitted via satellite to classes all over the country to convene first class lessons to all students. These lessons are recorded for students who could not attend the live satellite lesson. However, both modes have severe weakness that limits their contribution to the learning process. Analog videos are linear, non-interactive, and expensive to produce and distribute. Analog video-films do not encourage active learning neither interaction with the learning materials, which is so important for learning. On the other hand, interactive video is volatile and fades away after the lesson is completed.

Digital video has many advantages in regard to teaching and learning. Payne, H (2002). It is easy to produce, to index, to segment and to distribute, and might encourage active and interactive learning. Digital videos can be used for sessions of varying length and different settings. Combining digital video, the Internet and other media opens up a new avenue for teaching and learning. (Storm 2001)

During the last year the Open University of Israel has been utilizing digital video, combined with suitable software and a user-friendly interface, which have been developed at the OUI. These videos serve not only to convey the learning material, but also to add a human face to the teacher-student communication along the course, through the web-site of the course. This human face, called by others intimacy and immediacy was found to be positively connected with students’ motivation and cognitive learning (LaRose, R. & Whitten, P. (2000), Rodriguez, J. I., Plax, T. G., & Kearney, P. (1996).

Thus a set of tools is embedded with the video into the students working space which enables the student to search the video, move between topics, add personal annotations, and bookmarks, and move using hyperlinks to other resources.

Several different formats of using digital video in distance teaching will be presented and discussed:

Digital Video Formats

The following families of video formats are tested at the OUI at present:

Long Video Lessons, are produced as substitutes of the live face-to-face lectures or tutorials. The face-to-face encounter and dialogue between the expert and the student has, since the beginning of education, been a central feature in the learning process. Besides the imparting of knowledge by the expert, a "live" encounter can, at its best, produce productive intellectual brainstorming, in-depth thinking and inspiration and offer a personal example and social support for the learning process.

However the "live" encounter has also inherent limitations. They are limited by time and location which is problematic for distance learners, and they are volatile. Once delivered they are gone. The aim of the video lessons is to overcome these limitations.

Teaching Clips are short video segments (1-10 minutes long). Most of these are short "talking head" clips of a faculty member discussing some aspect of his course or just greeting his students. The main purpose of these clips is
to convey elements of intimacy and immediacy to the teacher-student communication along the course through the web-site of the course.

**Video-Rich Multimedia Lessons** are complex constructs containing an integrated combination of video, text, graphics and animations, tools for active learning annotations, bookmarking, links to discussion groups etc.

All types of video might be used in a single program.

The digital video with or without the Web-based materials can also be stored and distributed on a CD-ROM. Then Internet users could also employ the CD-ROM and Web material in an integrated way.

In our presentation we will demonstrate this formats and discuss some of options for what the video media might look like in the educational framework. We will also sort out and analyze families of products that might prove both valuable and viable (as evidenced by extensive, long term use).

By using these formats, it is possible to engage the student in active learning. Students can annotate, summarize and search through a video film, construct their own path of learning

From the instructor's point of view, digital video technologies enable simple production of video lessons, which can be connected simply to other media (text, Internet, multimedia). The tool also allows instructors to prepare interactive questions and assignments pertaining to the film watched.

From the students point of view digital video can be used as a self-study modular and interactive resource. Linearity is broken by allowing immediate access to relevant sections in the film by clicking on the list of segments. Attaching annotations provides for reflection on important points in the film.

We believe that integrating digital video into teaching, according to the formats that will be described in our presentation, can improve teaching and learning, and will affect students' motivation attitudes and achievements. Several experiments are planed aiming to evaluate the various formats of digital video that have been developed. The evaluation plan and considerations will be discussed elsewhere.

Primary results show that students are very satisfied with the integration of video elements into the teaching package. In particular they expressed satisfaction of the possibility to return to recorded live lessons and used them mainly to prepare for final examination. Satisfaction was also noticed whenever short video clips containing greetings, explanations and clarifications were integrated into the courses' web-sites.

We believe that the shift from analog to digital video and the rapid changes in information technology, which supports video hosting and distribution, are about to intensify the use of video in education.

Storm, J. Young, Clive. (2001), Developing A Steaming Video Methodology. On-Line EDUCA BERLIN,
Abstract: Education is moving towards revenue generation from such channels as electronic learning, distance learning, and virtual education. Hence, learning technology standards are critical to the sector's success. Existing learning technology standards have focused on various topics such as meta-data, question and test interoperability, and others. However, it is believed that the meta-data standards play an important role in the success of electronic learning. This is due to the fact that meta-data is the standard for learning objects; which is the main concept that allows interoperability and reusability to occur. Although bodies or consortia such as IEEE LTSC (Learning Technology Standards Committee), IMS (Instructional Management System), and others had developed the meta-data standards, there is concern about the features embedded in the meta-data standards. It is believed that to achieve a more meaningful learning process, a learning object needs to comprehend more than technical features. Features such as pedagogic, community, and context are important, as they will provide a more far-reaching description of what the learning object is about. Thus, the objective of the research is to obtain the detail elements of the meta-data standards and enhance it by inserting the necessary elements related to the above features. The learning theories such as Instructional Design Theory, Constructivism Instructional Design Theory, and Design Potential Approach were used to derive the elements associated to the above features. The results of this study are in the form of elements, which can be embedded into the existing standards.

Introduction

The key to make e-learning successful is depending on the thriving of learning object design. This is due to the fact that learning object is the core concept of electronic learning where it is regarded as the basic ingredients that allows flexibility, customisation, and interoperability to take place. With the use of learning object, recombination of material at any level may occur thus increases the value of the content and facilitates the competency-based learning. The learning object definition abound: Learning object is any entity, digital, non-digital which can be used, reused, or referenced during technology supported learning (IEEE Standards, 2000); Learning object is any digital resources that can be reused to support learning (Wiley, 2000).

We propose the following working definition: Learning objects are discrete, focused, interactive digital entities, which can be used, reused, searched, referenced to support the learning process.

Realising the importance of learning object, various consortia such as IMS, IEEE LTSC, ARIADNE (Alliance Of Remote Instructional Authoring And Distribution Networks For Europe) and others had made an effort to develop the learning object standards or better known as meta-data standards. The standards derived by these consortia define the conceptual structure for meta-data. Most of these standards provides the technical overview of what learning object should contained and aspects of how meta-data should be structured. For example, IMS defines the conceptual structure for meta-data where its information model was based on a structure of defined elements that describes or catalogues the learning resource. The model was formed on a
hierarchy manner and has nine main components, which are (IMS, 2001): general, lifecycle, meta-meta-data, technical, educational, rights, relation, annotation, classification. Each of this main component has it's sub-components. For example, the general component has the identifier, title, catalogentry, language, description, keyword and others as it's sub-component. The structure of the meta-data information model is given below (IMS, 2001):

Figure 1: Root to leaf tree view of meta-data

Most of the other standards had similar edifice like the above; although some might have a slight different structure depending on the primary goal of the standards. ARIADNE (2001) for example, is more focused to the educational needs.

Looking at the structure and its sub-elements it is apprehend that the standards are more focused towards the technical aspects of the learning object. Although the standards had put emphasis on the pedagogic portion; where they have the educational and pedagogic elements but little was given. The prominence was more towards describing the interactivity type, intended user role, age range, difficulty level, context, learning time and others. Less emphasis was given on how a learning object may assist effective learning, how it may provide the specific community users and how it may impart the context of instructional use of the object. Apart from that, there is lack of description regarding the learning activities surrounding the learning object and the support for the reuse of the object within specific instructional context (Recker, 2000). These short-comings are the basis that initiates the work.

**Current Work.**

The work carried out is focusing on how elements such as context, pedagogy and community can be embedded into the learning object standards. Recker (2000), Wiley (2000), Boyle (2001), Suthers (2001), and others had carried out similar work, which shows the importance of having context and pedagogic aspects attached to the meta-data structure. However the details of each element and examples of what can be included into the standards were not given. The aim of the study was to provide details of the elements that need to be attached to the meta-data standards in order to make them more efficient. The work used a comparative approach which involved looking into several learning theories to derive the elements related to context, pedagogy and community. The elements derived are then compared to the existing elements in the standards to see whether the standards had the procured elements. The method carried out in this research is as below (figure 2).

The elements mentioned are believed to be important as without context, learning object is nothing more than a clip art item, it can be misleading, confusing and utterly meaningless (Longmire, 2000). Gillroy (2001) had stated that learning is fundamentally both social and experiential.
Therefore to make learning more pleasurable, the focus should not only be on content but also on the organisation of learning experience. As a result the pedagogical process becomes the most important factor in the design of learning. To have a full understanding on why these elements are believed to be important we need to look at the basis of each element.

**Context**

Context is a difficult term to explain: basically it means the environment in which the learning unit is situated. It portrays the situation from the learner’s point of view. It is an abstract representation of the relevant environment. It then guides adaptive action in that environment, i.e. what type of learning actions to undertake (Boyle, 2000). The context consists of the framing of content along with associated interactivity and it is important in making learning happen within activity rich, interaction rich and culturally rich social environments (Afonso, 2000; Boyle, 2000). Hence in order to construct learning context, it is believed that it will involve content structuring, interactivity, compositional framework and usage of content. As mentioned without context, learning objects can be confusing, misleading or utterly meaningless. Therefore it is important to have context embedded as one of the elements in the learning object.

**Pedagogy**

Pedagogy means the science of teaching or educating children and is used as a synonym for teaching (Oxford Dictionary, 2002; Wave Technologies, 1996). It is the approach that the teacher/tutor use in constructing the courses to aid cognition through different learning styles. Consequently it embodies teacher focused education. In the pedagogic model, teacher assume responsibility for making decisions about what will be learned, how it will be learned and when it will be learned (Connex, 1996). Pedagogy is important as it shows and directs on what can be learned, how to learn and when to learn. As a result this needs to be included in the learning object as it will help the learners to appreciate the learning process, to be able to use the learning object effectively, to mark the choices of content structuring. With pedagogy embedded in it, it is believed that the learning object can be customised to the individual needs.

**Community**

A community is a group of individuals who have common values, norms and meanings, a shared history and identifications within a particular culture. The bonds that exist between communities are believed to go
beyond the instrumental into the realm of affection and exclusive (Gillroy, 2001). Consequently it is significant to have a community feel when using the learning object in order to make the learning process more effective.

Looking at the above facts all the components (context, pedagogy, community) are believed to add value to learning object and it will help to make learning through electronic medium more successful. It would greatly enhanced the educational use of learning objects which are presently pedagogically limited (Cowley, 2000) and context limited (Gillroy, 2000; Boyle, 2000)

Outcome

The learning theories, which were used in the work were the Instructional Design Theory - Dick and Carey Systems Approach Model For Designing Instruction (Dick et al, 2001), The Constructivism Instructional Design (Jonassen, 2001) and the Design Action Potential Approach (Boyle, 1998). The theories were chosen due to the fact that they are the basic theory to the design of instruction in the computer environment and each of them takes a different approach to model the instruction. Dick and Carey ID Theory for instance provide a system approach model for the design, development, implementation and evaluation of instruction. The theory is less complex than the others such as theories by Reigeluth (1999) and Jonassen (1997) to name a few. On the other hand, the Constructivism Instructional Design uses the constructivist conception, which is believed to be the learning theory behind a learning. The Design Action Potential Approach uses an ‘action potential’ approach distinguishing it from the other theories. It provides a method for formalising scattered knowledge without constraining individual design decisions. Each of these theories was then looked into and analysed and the elements related to the above elements were extracted. Below are the elements extracted.

Table 3: Constructivism Instructional Design Elements

Each of these elements are then looked into and compared to the existing standards. This is accomplished by giving definition to each elements and examples. The next step taken is by matching up the definition and the examples obtained to the similar sub-elements in the standards. Some of the elements are already existed in the standards but it is believed that it needs further clarification. For example:
Example 1:

*Current work:* The type of learner element - This element is the classification of the learner. It is to distinguish specific type of learner for a specific type of learning object. Example: beginner/ intermediate/ expert

*Existing Standards (IMS, IEEE and ARIADNE):* The intended user role element - This element is described as the principal user for which the learning object was designed. Example: teacher, author, manager and learner.

It appears that although the same type of element were designed for learners there is different definition to it thus providing different examples. The standard bodies might want to consider another feature, which could be added to the existing standards that might resemble the current work type of learner element.

Example 2:

*Current work:* Related cases and information resources that support understanding of the problem - This element is the access to a set of experience that the learner can refer to as this will provide the learners with a set of experience to compare to the current learning object

*Existing Standard (IMS, IEEE and ARIADNE):* The existing standards do not embed this element.

Example 3:

*Current work:* Information about the learner - This element is the information about the learner, who may access or use the learning object. It is consider that each learning object has it's target users and the target user's needs to have certain educational levels and prior knowledge before they are able to use the learning object. Thus the learner information must be described in terms of prior knowledge needed and skills required.

*Existing standards (IMS, IEEE and ARIADNE):* The closest element that can be compared to is the intended user role element. The intended user role element - This element is described as the principal user for which the learning object was design. Example: teacher, author, manager and learner.

From the above examples, it is clearly shown that although the elements might share the same designation; definition differs between them, hence providing different types of examples. It is realised that the definition and the example play a crucial role for each element. This is to provide a clearer picture of the element and allows a thorough comparison to be carried out. Further analysis is also needed for the meta-data standards in order for it to comprehend the pedagogic needs therefore making the learning object more useful and more meaningful to the learners. Apart from that, from the work carried out, it is apprehend that there are more elements, which needs to be added to the meta-data standards. If all of these elements were taken into consideration and be added to the existing standards, learning object will be able to reach it’s maximum value; where it does not only make electronic learning a reality but it also allows learning to take place efficiently.

**Conclusion**

There are more features apart from technical, which needs to be considered when deriving the meta-data standards. Features such as related cases, types of learners, problem manipulation and others need to be considered as to achieve a more comprehensive learning object structure. By adding these elements, which belongs to the context, pedagogy and community elements into the existing standards, it will certainly make the learning object more meaningful to the learners in the future.

Integration of Laptops into a K-12 Learning Environment: A Case Study of a Science Teacher in the Middle School

Chia-chi Yang
Department of Instructional Technology
University of Georgia
United States
E-mail chiayang@directvinternet.com

Abstract: This case study identifies the feasible approaches to integrate laptops into a science learning environment in the middle school. The observation of learning activities and teaching strategies took place in the 8th grade science classroom with seventeen students for five class periods and the data from teacher’s opinion gathered by interview. The results report the strategies the teacher used with laptop in the classroom including problem-based learning, project-based learning, collaborative learning, hands-on activities, and have students to use laptop as a cognitive tool. With appropriate strategies, laptop can be used as a cognitive tool and enhance the possibility of shifting teacher’s role from a lecturer to a facilitator. Integrating laptops into classroom should consider the following issues: make use of laptop as cognitive tool, employ constructivism approach, provide curriculum support, manage logistics of classroom, and reduce distraction.

Pervasive computing can enable learners, teachers, and parents to have continuous access to computing technology. By taking the advantage of portable technologies such as laptops to establish a pervasive computing environment, students can be empowered to learn with technology anytime, anywhere. Recognizing the potential benefits of pervasive computing, a coeducational, independent, college preparatory day school in the southeastern region of the United States has worked for two years to integrate laptop computers into middle grade core subjects (language arts, social studies, math, and science) with a wireless networking infrastructure.

Information technology has been shown to motivate students and, computer-assisted learning can make a notable addition to learning and understanding science concepts but its value will lie in apt use and this will depend upon teacher judgment and expertise (Rodrigues, 1997). Successful implementation of technology in an education setting requires more than merely providing resources and a hospitable environment. Collaboration among the participants is an essential feature of the formula. Collaboration in itself does not lead to success in achieving change if those involved do not embrace a shared vision or a perceived need of technology implementation. Moreover, integrating technologies with education requires a reconceptualization of the classroom environment and the teaching and learning strategies employed therein (Woodrow et al., 1996).

Aware of the laptop successes and challenges documented at other schools, the technology leaders at the school used in this study contacted external evaluators to conduct a long-term evaluation of the use of portable technologies in their school (Hill, et al., 2001). The findings of the evaluation from the last two years indicates that even though teachers were enthusiastic about using laptop into their classroom, some of them felt frustrated because they perceived a need for more practical strategies about how to integrate the laptop into the learning environment. As a component of the overall evaluation project, this study sought to: 1) identify learning activities that use the laptop, and 2) identify the strategies the teacher uses during the learning activities in the learning environment to integrate the laptop.
The description of the problem

During the Spring of 2000, the school offered a series of workshops (known as 20-Minute Modules) to prepare middle school teachers and administrators to participate in a wireless laptop learning environment. While the workshops were useful, several suggestions were offered during the teacher interviews at the end of the year. One teacher suggested that the technology training and the strategies of teaching learning should be separated. Another teacher mentioned a need for personalized training to match her/his curriculum. Yet another teacher stated they needed training on technology integration. While training received to date has been useful, it appears that the teachers are still trying to figure out the feasible approaches to integrate the new portable technology into the learning environment.

One area that holds particular promise in terms of technology integration is science computer applications in science education could include word-processing reports, using data-loggers, spreadsheets, databases, simulations, multimedia and the Internet, for data collection and analysis (Rodrigues, 1997). For example, by allowing pupils to carry out complex calculations and present the results quickly and easily, they are able to concentrate on the important scientific principles underlying their work rather than on the tedium of the number crunching that can so often get in the way of understanding (Carson, 1997). In addition, modeling could be used for investigations and multimedia authoring for communication information. For example, by creating a dynamic computer model of the thing to be studied, and manipulating that model to changes and new influences, student gain a sense of how the thing itself works (Carter, 1998).

Research design

Based on the many opportunities of integrating the laptop into the science learning environment, this study sought to develop a strategy to help teachers systematically and successfully integrate the laptop in the middle school to enhance student learning. This study focused on one classroom of one eighth grade science. Students and the teacher have their own laptops and they can access to the Internet anytime, anywhere with their laptops. The classroom context is a science class covering ecology, earth science, and physics. The class meets five days a week during the semester. Participants study astronomy unit when the researcher doing observation. Seventeen 8th grade students from the same classroom of the science teacher were selected to participate in this study. The majority of the students received their laptops two years ago and are computer literate. (note: some students are new to the academy so have not had their computers for two years) The teacher has 7 years experience of teaching science and two years experience of using the laptop into the learning environment.

The design of this study is a case study, utilizing qualitative research methods because the researcher wants to generate data rich in detail and embedded in the context. According to Stake (1994), in the intrinsic case study, no attempt is made to generalize beyond the single case or even to build theories. However, as Jennifer Mason puts it:

*I do not think qualitative researchers should be satisfied with producing explanations which are idiosyncratic or particular to the limited empirical parameters of their study...Qualitative research should [therefore] produce explanations which are generalizable in some way, or which have a wider resonance (1996:6).*

Purposive sampling guided by time and resources is a positive answer to the question of how we can obtain generalizability. Purposive sampling allows us to choose a case because it illustrates some feature or process in which we are interested (Silverman, 2000). As Denzin and Lincoln put it:

*Many qualitative researchers employ...purposive, and not random, sampling methods. They seek out groups, settings and individuals where...the processes being studied are most likely to occur (1994:202).*

The researcher focused on a single case by purposive sampling because unique qualities of the learning environment can promote understanding, inform practice for similar situation and allow access. Due to identify
the teaching strategies the teacher employs in the learning environment, on-site observation of the activities with the laptop and interview with the teacher are selected.

This study gathered the qualitative data by two primary methods: 1) conducted observation in the classroom to see how the middle school science teacher integrates the laptop into the learning environment and the reactions of students with observation protocol, and 2) an interview with the middle school science teacher to gather detailed information about the experience. Other sources of data were also used to inform the results of the study; including surveys from the overall evaluation effort and informal discussions with the overall evaluation team.

Data analysis

The researcher used descriptive statistics to include frequency of activities occurred in the learning environment and activity structure. The data from field observations were analyzed based on the categories in the observation checklist. The interview session was recorded on audiotape. The transcribed teacher interview protocol was compared with the data drawn from observations and surveys. The interview was analyzed by the inductive approach and themes were identified. The data of surveys done by the external evaluation team from the last two years of the four-year longitudinal evaluation about the science teacher's view on teaching and learning, computer use for teaching, and the descriptions of his teaching and learning environment were synthesized with the data from observations of actual using the laptop in the learning environment. The teacher's self-description of the experience was gathered from the interview.

There are some limitations might limit the validity and reliability of the results of this study. First, the observation time was limited due to limited personnel; the researcher was not able to participate in each science. Second, any possible generalization of the results is limited to the middle school in science. Third, the results may not apply to the teacher who is not equipped with the high computer literacy because the teacher in this middle school has been through training in using a laptop.

Results

The case study revealed some interesting results. One key to successfully integrating the laptop into learning environment is how the strategies are being employed. In this study, the strategies the teacher used with the laptop included problem-based learning, project-based learning, collaborative learning, and hands-on activities. The teacher also had students using the laptop as a cognitive tool, representing their knowledge with some application such as creating a Webpage, or a PowerPoint presentation, or spreadsheet graphics. Most of the strategies that the teacher used also clarified the result of literature review (Wiesenmayer & Koul, 1998; Woodrow et al., 1996; Scanlon, 1997; Devitt, 1997) including the value of an inquiry-based approach, project-based activities, collaborative learning, and using a variety of resources available through the Internet to integrate technology.

Another key to successfully integrating the laptop appears to be the role of the teacher. The teacher's role changed from that of a lecturer and transmitter of knowledge to that of a facilitator, guiding students to take advantage of opportunities to develop their inquiry skills; from being a conclusion-drawer to becoming a curriculum planner and initiator, while using the computer and other resources to provide science information (Levine & Donitsa-Schmidt, 1996). The particular advantage for science educators is that there is a teaching point to be made in using a collaborative context for science learning, stressing that scientists usually work in teams and that science is a social activity (Scanlon, 1997).

Yet another key to successful laptop integration is the curriculum support to come up the ideas about how to integrate laptop into the learning environment. Between grading and making test and keeping up with their
lessons, there is no time for teachers to be able to sit and look for valuable and valid resources. Providing resources that will assist teachers with generating the ideas is important, as is providing time to tryout and revise the ideas.

Classroom logistics is another key in successful integration of the laptop in the learning environment. Even though they have wireless Internet connection, the laptop still needs a power cord to operate. Currently, the cords are all over the floor and create challenges for moving around the classroom. Set up or the learning space needs to be considered.

A final factor revealed in this study relates to student attention. Students can configure laptops with their own personal interest. For instance, they can setup different wallpaper for desktop, install fancy screensavers and entertainment applications. While important, these can also become sources of distraction. Balancing personalization of the tools while maintaining a focus on use for learning is another key factor to the successful integration of the laptops.

Implications

The data gathered suggests a number of recommendations that are applicable in the learning environment with laptop. Implementation of these strategies may assist with the successful integration of the laptops.

1. **Make use of laptop as cognitive tool:** Using software like spreadsheet, PowerPoint, image processing, web construction and multimedia authoring tools enable student to create charts, graphics, presentations, projects, and websites easily. They can use these tools to represent and construct their knowledge toward concepts and enhance their cognition. Therefore, laptop can be used as a cognitive tool (Jonasson & Reeves, 1996) with appropriate strategies and enhance the possibility of shifting teacher's role from a lecturer and transmitter of knowledge to a facilitator.

2. **Employ constructivism approach:** Learning and instructional practices in science classrooms should be flexible and form a constructivist learning environment. (Levine & Donitsa-Schmidt, 1996). To enable a constructivist learning environment and switch the structure from teacher-centered to learner-centered, teacher should provide students chances to construct their own knowledge representations with laptop.

3. **Provide curriculum support or formal channel to share instructional ideas:** Teachers don't have enough time to develop appropriate tools for laptop in each unit is a problem for integration. Laptop just becomes a tool to replace pen and paper. Having someone who is good with computers and laptops, understand teaching techniques, pedagogy and familiar with curriculum to design the ready-to-use activities as resources for teacher to adapt is a strong need to implement the laptop environment. Or create an official website for sharing valuable resources that can provide teachers a channel to access to all kinds of tool for specific units.

4. **Logistics of classroom:** Although the learning environment is wireless for access to the Internet, laptop still needs cord to get power because kids seldom remember that they have to recharge laptops everyday. Ideally there would be enough plugs under every desk in the floor or a desk with plus. Considering the arrangement of desks, plugs, and cords before using laptop in the classroom is a primary work.

5. **Reduce distraction:** students can configure laptops with their own personal interest; for instance, install fancy screensaver and entertaining applications. They may miss the lecture and put attention to these distractions. Teacher may needs to set up classroom rule to prevent students browsing unrelated information in class.
Conclusion

Bringing wireless laptop into learning environment has some strength. The capability of accessing to the Internet anytime anywhere and being portable extends the learning environment beyond the boundary. This advantage makes the learning environment turns into classroom, lab, library, and the authentic context based on the instructional goals without the physical limitation. Carter (1998) indicated that in the ecology class, students enter the full ecological context, doing it as a biologist or ecologist would, gather data and convene to discuss the data and patterns, formulating conclusions and new questions about the ecological relationship in the environment that supports it. This kind of real experience is most powerful, because the learning is situated in the most authentic context possible. Moreover, teacher can collect ready-to-use tools for laptop from the Internet and share that easily with other teachers. Teachers perceived Internet as a major tool for teaching collaborative and investigative practices of science and scientists and they also became aware of the possibilities and the problems created by both the nearly unlimited quantity of information available on the Internet and the limited quality and relevance of much of that information (Wiesenmayer & Koul, 1998; Jackson et al., 1997). Students can seek information on the Internet and email peers to share their knowledge and accumulate resources collaboratively. Besides, with the laptops in the classroom, it saves lots of time because they don’t have to go back and forth between media center and classroom.

The strategies of integrating laptop into learning environment depend on the feature of learners and subjects, learning goal and objectives. There is no reason that laptop should be involved in each activity. Teacher should use laptop for meaningful purposes. For example, for middle school kids, it’s better to use mixed up strategies with and without laptop because it’s impossible to ask kids sit in front of laptop all day even these tools are excellent. The ideal situation is not over and not under use. It has to be integrated but there still things have to stay, not total transition. Finding a balance in use and house remains a challenge for further research.

Asynchronous On-Line Discussions:
Facilitating Critical Thinking Skills in Distance Education

Ya-Ting Carolyn Yang
Department of Curriculum and Instruction
Purdue University
United States
yangyc@purdue.edu

Abstract: In distance education, students and instructors rarely meet face-to-face and interactive discussions are infrequent, if they take place at all. Such challenges make it difficult to model thinking skills or guide students through the thinking process. An asynchronous online forum is a promising tool to cope with this problem. This paper reports an ongoing project that examines the effects of asynchronous online forums on critical thinking and overall learning performance, and also probes students' overall perspectives toward the effect and function of using asynchronous discussion forums in the context of distance education. The research design, participants, instruments, and data analysis of this project are described.

Problem Statement and Research Objective

A primary function of education is not only to help students build knowledge base but to teach and develop their critical thinking skills as well. In many cases this occurs through class discussions (Bloom, 1956; Newman & Wehlage, 1993). Yet, in distance education, learners are separated by distance and/or time from the instructor and their peers; discussions are often hindered since students and instructors rarely meet face-to-face. Besides, since the population of distance learners tends to be older or have career/family obligations, learners have less flexible time and fewer opportunities to engage in the class discussion with each other synchronously. If collaborative inquiry tasks are assigned, it is difficult, if not impossible, for the instructor to facilitate interaction, monitor collaborative discussions and critical thinking in a distance. Such challenges make it difficult to model thinking skills or guide students through the thinking process.

Asynchronous online forums (i.e., text-based computer-mediated communication tools) are promising tools that offer an opportunity for interactive discussions independent of time and place, and also provide an opportunity for the instructor to moderate such discussions (Duffy, Dueber, & Hawley, 1998). However, like face-to-face discussions, online discussions can deviate from intended pathways, and facilitators need to continually monitor the discussion and provide input at appropriate moments. Instructors need more guidelines from educational researchers about integrating electronic collaboration and communication tools into their classrooms (Bonk & King, 1998). Some studies have compared the effectiveness of online forums to face-to-face forums; however, verbally based face-to-face forums and textually based asynchronous forums make direct comparisons difficult (Anderson & Kanuka, 1997). In essence, the core issue should be whether asynchronous discussions supplement instruction to facilitate more interactive discussions, foster critical thinking, and/or enhance overall student learning performance. The question, "Are asynchronous online forums effective in higher education?" still remains largely unanswered.

The purpose of this research project is to examine the effects of asynchronous online forums on critical thinking and overall learning performance and, in addition, to probe students’ overall reactions and perspectives toward the effect and function of using asynchronous discussion forums in distance learning environments.

Research Design

The research design is a pre- and post-test quasi-experimental design. The independent variable is the use of the structured asynchronous online forum. Students in a control group class only use their regular communication mode (via e-mails) to ask their instructor or peers course-related questions. Students in an experimental group class will use an asynchronous online forum (threaded discussion bulletin board) as a...
supplement to their Web-based classes; a series of discussion topics will be posted on the class bulletin board and facilitated by the instructor. The students taking BMS 235, an undergraduate distance learning course at Purdue University, in spring 2001 are the subjects in the control group; the students taking BMS 235 in fall 2001 and spring 2002 will be the subjects in the experimental group. There are two dependent variables examined in the study: students' learning achievement and attitude. The first dependent variable is the learning achievement of the students that is measured at two levels—declarative knowledge and critical thinking skills. Declarative knowledge refers to the concepts, principles, issues, and facts presented in a learning situation. It is measured as the scores on the four quizzes and two exams on course content. Learning in terms of critical thinking is measured via California Critical Thinking Skills Test, class discussions on asynchronous online forums, and essay questions that go beyond declarative knowledge acquisition and involve analysis, synthesis, reasoning, interpretation, and induction. The second dependent variable is students' attitudes towards asynchronous online forums, class discussion, and the course in general. Students' attitude has been defined as scores on the attitude pre-and post-course Likert-type surveys developed by the researcher. The interview questionnaire will also be administered to probe students' attitude toward the study.

ANOVA will be performed to justify whether there is a difference among the subjects in terms of age, educational backgrounds, attitudes toward asynchronous forums and the course, and knowledge of content at the beginning of the class. The dependent variables, including students' learning achievement and attitudes toward the course and the asynchronous online forum, will be analyzed using a one-way ANOVA at the end of the class. In addition, the qualitatively analytic procedure that organizes the data, generates categories, themes, and patterns, and searches for alternative explanations for the data is adopted to analyze the data from the interview questionnaire to generalize themes regarding students' perspectives about the study. In order to pilot test the efficacy and reliability of the proposed research design, BMS 236 class in summer 2001 was used as a pilot study for the experimental group.

Implications of Results

The importance of class discussion has been highlighted by a host of research studies; to move students beyond assimilating inert facts into generating better mental models, teachers must structure leaning experiences that highlight how new ideas can provide insights in intriguing, challenging situations (Dede, 1996). This research speculates about how an increasing important tool— asynchronous online forum, can afford educators great pedagogical opportunities to reshape distance education. It is our anticipation that asynchronous online forums are the means that afford students the time for thoughtful analysis, reflection, and composition as their discussion of an issue evolves and that allow instructors to mentor and evaluate the critical thinking skills exhibited during out-of-classroom discussions. It is this potential of asynchronous online forums that we find so exciting. However, the actual impact and effectiveness of the asynchronous forum as a supplement to distance instruction is still insufficiently researched. Thus, this research project will identify and experimentally examine asynchronous online forums in a constructivist paradigm, and provide useful information as to the overall reactions and perspectives of students toward the effect and function of using asynchronous discussion forums in the distance education environments.

Instructional Strategies for Web-Based Bulletin Boards to Stimulate Interaction and Improve Student Learning Performance in Distance Education

Ya-Ting Carolyn Yang
Department of Curriculum and Instruction
Purdue University
United States
yangyc@purdue.edu

Abstract: History has shown that interaction is an essential component in the learning process. Integrating interaction into a traditional classroom is relatively easy; however, moving that interaction into several time zones is much more difficult. Web-based bulletin boards (WBBs) are promising tools that offer such an opportunity for interactive discussions and collaboration in distance education. Thus, a set of theoretically-based instructional strategies for the instructor will be developed to help promote active interaction and help students make the most use of WBBs. The proposed instructional strategies for WBBs will be implemented in experimental settings to evaluate for their effectiveness.

Numerous studies (Romiszowski, 1988; Schaffer & Hannafin, 1993) have provided evidence that interaction may be the missing link in a successful distance education course. Computer-mediated communication (CMC) has been utilized to fill this gap for the past two decades to increase interaction between learners and the instructor and among learners. CMC can be used to facilitate both synchronous (real-time) and asynchronous (delayed time) discussion. Asynchronous discussion, such as e-mails, listservs and electronic bulletin boards are usually viewed as least costly, most flexible, and effective ways to facilitate discussions in today’s distance education. Students can read, follow, and participate in discussions as they wish. They can exit and reenter as their schedules allow without missing conversation or an opportunity to contribute their ideas. However, researchers, such as Jonassen (1996), have indicated that many technology-based innovations have failed because they were not properly implemented and, without due care, this trend will continue into future. No matter how high our expectations are for computer-supported collaborative learning, only the careful development and implementation of these tools will help us realize the full potential of the technology (King, 1998).

Recently, the increasing popularity of the Internet and the incorporation of conventional CMC and the World Wide Web (WWW) have begun the ongoing renaissance to enhance human to human interaction in the field of distance education. Due to the development of hypertext, the WWW has become the most popular and user-friendly way to distribute multimedia contents. Considering accessibility of diverse resources from the Web with asynchronicity and cost-efficiency, I have selected the Web-based bulletin boards (WBBs) as an instructional tool to improve interaction and distance learners’ academic performance. In addition, based on the suggestions of many researchers and educators, such as Klemm (1998) and Jonassen (1996), who have experienced using WBBs to facilitate their instruction, a set of guidelines and instructional strategies to help instructors stimulate more interactive discussions, cope with the unsolved challenges using WBBs, such as information overload and lack of social presence, as well as enhance overall learning performance in WBB environments for distance education will be synthesized and developed. Based on the theory of constructivism, the proposed instructional strategies will include:

a) How to prepare students with an asynchronous discussion tool they will be using. For example, the instructor can provide students with thorough handouts and training on the use of the discussion tool, clarify student roles in class discussion, and remind students to focus on ideas, not on personal attacks as well as to show tolerance for divergent points of view.

b) How to break the ice, set a tone and create a relationship with students as a class.

c) How to encourage students’ participation in discussion. For example, strategies to encourage student involvement may include:
Motivating students that thinking hard is a meaningful goal not only for this course but for their future life and work as well. Their productions will be taken seriously by the instructor, and their efforts be rewarded by the educational system and society in general (Jonassen, 1996).

- Emphasizing the importance of online discussions by appropriately weighting their value (e.g., the percentage of the overall grade that the discussion is worth).
- Holding high but realistic expectations for students.
- Posting or disseminating important information, such as quiz results, homework solutions, or exam preparation hints, only on the WBB. This may increase the frequency for students to visit the WBB and, thus, may increase the chances for students to look at, contribute to or respond to the online discussion more frequently.
- Making the instructional activity relevant and interesting.
- Avoiding leading questions or yes/no questions. The instructor should ask more "why" or "how" questions, leading students to try to figure out things for themselves.
- Providing immediate feedback.
- Listening attentively and acknowledging student contributions. Give students some indication of how well they have contributed to the class discussion and how to improve (via private e-mail). Rewards can be as simple as saying a student's response was good, with an indication of why it was good, or mentioning the names of contributors: “Cherry's point about pollution really synthesized the ideas we had been discussing” (Davis, 1993; Willis, 1993).

- Providing a variety of learning activities since variety reawakens students' involvement in the course and their motivation.

- Modeling critical thinking skills by asking students Socratic questions.
- What available teaching activities are that can catch students' attention or reawaken students' involvement in the course and their motivation to actively participate the online discussion. For instance, role playing, case studies, debates and study questions that explore the main topics of the course content are all instructional activities that can be incorporated into almost any distance learning course to encourage intellectual discussion and provide opportunities to apply what students have learned.
- What instructor's role is as a facilitator in online discussion.

The actual impact and the gain of student learning performance by using the proposed instructional strategies have not been realized yet. Thus, the above proposed instructional strategies will form a framework from which to build an analysis of the actual use to facilitate interaction for distance learning courses at Veterinary Technology Distance Learning Program at Purdue University. After this pilot study, appropriate modification will be made and then the use of WBBs with the modified instructional strategies will be experimentally tested to investigate the impact and the actual gain of student learning performance as well as the overall reactions and perspectives of the instructor and students toward the effect and function of using WBBs in the context of distance learning courses.

A Case Study for Promoting Collaboration on Online Project-Based Learning

Young-Sun Yang
Department of Educational Technology
Kwandong University, Kangnung, Korea
E-Mail: vsvyang@kwandong.ac.kr

Abstract: The interactive mechanism of the internet allows learners to interact with teachers, other learners, and contents while it facilitates teachers to interact not only with learners but also with other teachers who teach the similar or related courses and conduct online teaching. The study attempts to analyze teaching strategies for planning collaborative learning and teaching through a case of online project-based learning in inter-universities. The study also attempts to observe the degree of students' learning experience, collaboration and participation with their expectancy and satisfactions on the collaborative online project-based learning.

1. Introduction

In last several years, online education has become an accepted means of teaching and learning in higher educational institutions, and more and more universities use computers to improve learning and instruction by connecting to the resources and by communicating with others. The interactive mechanism of the internet and the Web allows teachers and students to share ideas and to access information and resources with a much broader community than would otherwise be possible. Through the Web learners can interact with teachers, other learners, and contents more actively and effectively. As the same manner, this interactive mechanism encourages teachers to interact not only with learners but also with other teachers who teach the similar or related courses and conduct online teaching. This collaborative interactivity of teachers with the internet can be taken place between or among universities in the mode of intra or inter-universities by sharing ideas in preparing courses, developing course materials, and operating, managing, and evaluating courses.

This collaborative way of teaching would improve the quality of teaching and learning and consequently expand new opportunities of education. When the Web extends learning beyond classroom walls to learning communities, the students can work in inter-group as well as intra-group, and the roles and concepts of teaching and learning are restructured. According to Pea (1994), there are two alternatives to the transmission model of communication. Teachers and students alike are transformed as learners by the process of communication. Through such collaborative discourse within the learning community, active leaning occurs more and knowledge is constructed through more interactions.

The interactions can be actively employed especially in the project-based learning activities by formulating an efficient communication system for group interaction, since project-based learning requires interaction among other students in order to accomplish the group project. In the project-based learning, learners generally involve in identifying the problem and information they need, locating corresponding information needs, and extracting and organizing relevant information from a variety of sources into productive uses through group communications and activities. On the same time, teachers engage in planning a collaborative course by setting the topic of the project, designing the materials and learners' activity, and managing and evaluating learners' progress.

Based upon this assumption, this study attempts to analyze teaching strategies for designing and operating courses, methods for successful collaborative teaching in the Web environment, and suggest new potentials on the view of collaborative teaching, especially for project-based learning with the internet. Also, this study explores the issues in students' learning experience, collaboration and participation along with their expectancy and satisfactions on the collaborative online project through observing an electronic survey.
2. Background of the Study

Structure of Interaction in Collaborative Learning and Teaching

In online learning environments there are usually three kinds of interactions that take place: learner-content interaction, learner-instructor interaction, and learner-learner interaction (Moore & Kearsley, 1996). Learner-content interaction is the interaction between the learner and the information presented that should lead to knowledge acquisition. This interaction relies on the knowledge base that the learner has built from prior learning experiences and on the ability of the learner to interact with the content presented. Learner-instructor interaction is a vertical interaction dependent upon the ability of the learner and the instructor to communicate. At this type of interaction, the instructors provide support, and encourage the learners. Learner-learner interaction is the horizontal interaction between learners. Students learn in a self-directed way, but at the same time they interact with other students by communicating information and ideas so as to increase their participation and enhance their motivation and learning.

These types of interactions in online learning environment are taken place by the instructors focusing on learners. However, for the sake of instructors the interactions can be made with other teachers or outside experts as well as with learners or a group of learners (Yang, 1999). Therefore, the forth type of interaction occurred in collaborative learning is the interaction between instructors. This allows learners to have interaction with not only learners in his/her schools but also learners in other schools or communities. The instructors are connected through shared teaching objectives or contents whereas the groups of learners are connected through the shared problem of the project.

When the collaborative teaching is conducted between instructors, more interactive collaboration has made in the whole teaching and managing process including planning, implementing, and evaluating. The collaborative teaching covered all types of interactions among students and instructors, instructor and instructor, and students and students. Teachers can share their syllabus, lectures, students' task, activity and practices, and students' progress on discussion.

Such a collaborative teaching is not happened before in traditional classrooms. General availability of multimedia and communication tools, such as e-mail, bulletin boards, conferencing systems, whiteboards, chat rooms, and videoconferencing make a great impact to educational curricula, learning materials and instructional practices and are adapted for collaborative learning and teaching. In addition, the learners in online learning environment have become more heterogeneous, and learners' social or cultural background and own interest are divergent so that they tend to receive information actively with more interaction and feedback.

Elements of Collaboration in Learning and Teaching on Project-Based Learning

Collaborative learning emphasizes the mutual engagement of learners in the learning process rather than on the sole efforts of individual to reach a common group goal. Therefore, on project-based learning the final products are evaluated based on collaboration and represent a synthesis of the whole. Some of the main advantages of collaborative learning are that it encourages active and constructive learning and encourages deep processing of information, as well as evoking critical thinking, reasoning and goal-based learning (Bernard et al., 2000). Collaborative learning requires less teacher-imposed goal structuring and includes the process of sharing the learning task, combining expertise, knowledge and skills to improve the quality of the learning process, building or consolidating a learning community (Slavin, 1995).

In a collaborative learning setting, the emphasis is placed on the interactions as common understandings are negotiated and developed across differences of knowledge, skills and attitudes. Motivation to participate and confidence, together play an equally important role if benefits are to merge from the experience. Moreover, participants need to assume a variety of functional roles as interchanges progress and involve question answering and explanations that are open to challenge and justification (Bernard et al., 2000). To conduct collaborative online learning successfully, it is crucial that the learner feels part of a
learning community where learner's contributions add to a common knowledge pool and where a community spirit is fostered through social interactions.

**Problem Description**

The objectives of the study are to identify instructional strategies and support system for project-based learning using the Web and to examine factors for collaborative teaching process. The study examines and exemplary case of more effective and efficient collaborative instructional methods in inter-universities. The process of online project includes not only the identification of the problem, the time of accessing information needed for the project problem, but also collaborative learning and teaching strategies such as preparing courses, creating social climate and sense of community, encouraging students collaboration, and using support mechanism. Accordingly, questions are asked in terms of how much the students learn from online experience, how well they collaborate and participate in the project, how much they are expected and satisfied at collaborative online project-based learning activities.

**Learning Community and Environment**

Students were junior majoring educational technology or curriculum education, and taking a distance education system and new media course. Students of two universities worked in small groups, and two universities located in 4 hours driving distance were involved in online project, sharing their knowledge and collaborating to perform context-dependent tasks.

The task was developing a model for distance learning, and it is loosely structured in individual activity. The instructors provided the topic upon which each group develop own specific model for distance education, monitored the pace of group task, provided the steps for successful completion, guided the enabling objectives for completing their final group report. Meanwhile, instructors did not interrupt discussion itself while providing supports and facilitating guide.

**Students Survey and Analysis**

The survey was held at the end of course and the survey was consisted of items including the followings:

- Did the collaborative online project experience enhance understanding of distance education?
- Were your communication skills improved by the collaborative online project learning?
- Were your problem-solving skills improved by the collaborative online project learning?
- Were collaboration well taken place through learning in your group?
- What was the most significant factor to interfere your collaboration?
- When collaboration was not occurred, how did you handle it?
- Did you participate actively in collaborative online project?
- Were you satisfied at participation of other members of your group?
- What did you expect of collaborative online project before it started?
- Do you want to take another online project course if you could?
- What mechanism did you use most for collaboration (e.g., bulletin board, chatting room, etc)?

Additionally, messages were analyzed based on the electronic bulletin board discussion in order to observe which students play leadership most and facilitate team project, monitor other students' thoughts and opinions, put together the process and results of collaboration work.

**3. Teaching Strategies for Online Project-Based Learning**

Some of strategies for online learning in general are reviewed with collaborative learning and teaching, especially in project-based learning settings. The process of project-based learning with the internet is generally composed of online questions and answers, online report, online discussion by using the bulletin board, e-mail, and newsgroup etc. In the project-based learning, the students learn by problem solving process based on the given problem of the project. For example, teaching strategies such as reflection and summary of what students earn from project, and small group activity in the class which
are often used in the traditional class can be more effectively occurred in online learning space when collaborative interaction mechanism are applied. Recently, educational environment and learning process are moved toward the performance centered evaluation, portfolio, cooperative learning task. Teaching methods and strategies for collaborative teaching between or among teachers in project-based learning through the Web were examined by some exemplary case studies. The based framework of teaching process is based upon previous research including Bernard et al. (2000).

Preparing courses

In online learning, students' data as like as traditional classroom settings can be collected by questionnaires, pre-tests through e-mail or electronic questionnaire. In collaborative teaching, it is crucial to plan collaboratively including class scheduling, students grouping, project topic, select of technologies for communication, and organization of the group and leaders. In online project-based learning, it is especially important to select project problem that reflects social issues or debates so that learners can start from the issues the discussion for identifying the problem, specifying the problem and find the solutions, and synthesizing the results of discussion and represent them effectively. Also, it is important for improving the collaboration between instructors to put agreed efforts on the whole process from planning instruction to evaluation. To receive and minimize differences between sites, the value or culture on each other's site should be considered in advance.

The methods of preparing the online courses are as follows: conducting a learning needs assessment, establishing learner profiles, organizing informal face-to-face or online "getting acquainted" activities, teaching and modeling collaborative behavior and skills that are expected of students, providing tutors and students with all technology training required, and scheduling the process and completion of project.

Creating a good social climate and sense of community

Developing and maintaining a positive social environment and creating a community of learners are considered to be essential. Learning collaboratively is basically a social process that must be encouraged and nurtured.

The methods of achieving the community are the follows: providing a social space in the conferencing system that allows for easy and free access to other students and the instructor, assigning students to collaborate, posting introductions, information folders, and other self revealing items like photos of participants, making the environment as democratic as possible to encourage the involvement of everyone, providing a restricted space that is unavailable to the instructor for students to converse among themselves, providing adequate levels of tutor support, initially, that gradually gives way to increased responsibility on the part of students, and arranging for at least one live meeting such as face-to-face group encounter for participants to get acquainted.

The advantage with using a face-to-face audience first is that the additional direct contact makes it easier to modify procedures and instructions than when it is done solely online for the first time. When the online students are taught through face-to-face at the same course, this can be more easily met. The effects of face-to-face group encounters are examined in inter-university project-based learning.

According to Harris (2001), virtual communities are no longer a place-based concept, but formed around issues of identity and shared values. Electronic personalities require internal dialogue, semblance of privacy, deal with emotions using text, and create mental pictures of others, and in online learning we need to personalize communications to create a sense of presence. Harris suggested the community-building steps as follows: define group's purpose, create distinctive gathering place, promote leadership, allow for range of member roles, create and facilitate subgroups, and allow members to resolve their own disputes.

Encouraging collaboration

True collaboration can best be realized only when instructors view themselves as facilitators and guides rather than lectures or experts. The degree of instructor involvement is also an issue. As Brown and
Palinscar (1989) suggested "scaffolding", the tutor began by providing high levels of support to all groups and students, but as students started to demonstrate independence and cohesiveness, the tutor support was faded gradually.

The methods of encouraging collaboration are as follows: using small groups, using nickname for each group made by group members, selecting group leader and rotate leadership in turn, assuming instructor's role as a facilitator, modeling desired collaborative behavior, using facilitating techniques, substituting visual social cues with verbal cues, and promoting positive interdependence.

In online collaborative learning, instructors use facilitating techniques such as 'weaving' to steer discussions and 'go around the circle' to ensure maximize student participation. Promoting positive interdependence among online team members reinforces collaborative online learning by introducing a legitimate need to collaborate. To give collective rewards and distributing needed resources across group members is fostering a healthy interdependence.

It is important for students to need to be prepared for a collaborative online experience because it is not assumed all learners possess the prerequisites for skilful collaboration. When messages are analyzed based on the electronic bulletin board discussion, some contend strong leadership, and facilitate the team project, monitor other students thoughts and opinions, put together the process and results of students.

Using support mechanism effectively

Land & Green (2000) pointed out the need for external support mechanisms that help learners develop strategies for effectively learning with project-based environments. Encouraging goal setting and reflection during the learning process is important. Supports of extensive teacher-student conversation in complex learning situations facilitate gradual changes in understanding.

The methods of using the support mechanism are as follows: matching medium to instructional objectives, using technology that is accessible to all participants, making use of internet features, e.g. discussion forums, chat rooms, etc, and using a metaphor that relates to learners' experience.

The teachers provide the topic upon which each group develop own specific group task, monitor the pace of group task, provide the steps for successful completion, guide the enabling objectives for completing their final paper. Meantime, teachers do not interrupt discussion itself while providing supports and facilitating guide. Minimum support can be given as necessary in mechanically, individually by personal using e-mail to the learners those who do not participate well.

4. Results of Case Study and Conclusion

The students survey showed that their experience on collaborative online project would enhance understanding of distance education overall and provide adjustment skills in other collaborative works. The students responded that their communication skills and problem-solving skills were improved by the collaborative online project learning. More than 70% of students were satisfied at their active participation and other members' participation in groups. In open questions in the survey, students pointed out the factors that interfere their collaboration and the way they cope with them. In addition, the types of mechanism used most in online community were discussed.

Collaborative teaching with the internet, with its expanded interactions, has a great potential in designing and managing courses more effectively and efficiently than ever. The interactive mechanism of the internet and the Web allows teachers and students to share ideas and access information and resources with a much broader community. The interaction between instructors occurred in collaborative learning was emphasized in which instructors can have interactions with other teachers or outside experts as well as with learners or a group of learners while learners have interaction with not only learners in his/her schools but also learners in other schools or communities.
Strategies for online learning in general were analyzed with collaborative learning and teaching, specially applied to project-based learning settings including preparing courses, creating a good social climate and sense of community, encouraging collaboration, using of support mechanism. Furthermore, to identify the students’ learning experience, their involvement in the process of collaboration and participation as well as students’ expectations and satisfaction level, a survey was conducted at the end of the course and analyzed. The findings and results of study would provide implications for other settings and suggest for further studies.

As a conclusion, it is still difficult for teachers to construct a collaborative learning activity in online teaching because the web features was not developed collaborative teaching and the web itself do not support collaborative learning and teaching. Therefore, we need to refine collaborative teaching strategies for various situations, and by using technology support the process of collaborative learning and teaching.

Extending Educational Access Through Hand-held Devices

B. H. Yin and V. Tam
Department of Electrical and Electronic Engineering
The University of Hong Kong

ABSTRACT

The University of Hong Kong has been critically aware of the need for students to gain “access” to their instructors at various times and from various locations. In a sense, education may be enhanced and communication accomplished while the student is “roaming”. Through University sponsorship, a project to utilize PDA Hand-held devices for accessing a Web-server is under implementation. Questions are asked and answered; course materials are downloaded to the PDA. Educational “access” is thereby extended.

I. Introduction

The Hand-held Devices for IT Education (HHIT) project was initiated at the University of Hong Kong in late 2001. The goal of the HHIT project is to promote students’ learning outside their classroom, anytime and anywhere. Through this project, learning materials, lecture notes and tutorial exercises are made easily accessible to students by means of their hand-held devices. Students can review course material anytime and anywhere, freed from the physical boundaries of the classroom.

II. HHIT Design

2.1 Palm Platform

Students prepare and compose their FAQs on the Palm and forward them for eventual communication with Web servers via communications interface conduits. These requests are maintained and managed in their hand-held devices. The Palm platform is comprised of two software elements: Creating a new FAQ and Reading the FAQ. This includes the database management software to permit the 2-way interchange with the Web server. The Palm-FAQ interface, showing the software components and the necessary conduits to interface with the Web server, is shown in Figure 1.

2.2 Web Platform

The Web platform is the primary interface on the receive-and-response side to the students’ FAQs. Instructors receive and inspect messages composed by the students. They, in turn, compose messages including clarification requests and responses to the FAQs. These are forwarded via software operating on the Web platform to complete this two-way interchange.

The Web platform consists of FAQ Reader and FAQ Writer components. It provides for the receipt and presentation of
FAQs to the instructor as well as the composition and re-transmission of replies to the originating student. The identity and
directivity of the FAQ to the originating student is preserved and the instructor has an on-going dialogue with him.
The overall flow of Web FAQ interfaces with the Palm database is shown in Figure 1.

III. HHIT Implementation

3.1 Palm Platform

Our Palm FAQ system is divided into 3 sub-systems:
- Palm Application Subsystem: the Create Question and View Question functions in our FAQ system on the Palm.
- Conduit Subsystem uploads the question created by student to the instructor via the PC Desktop and the Web and
downloads the corresponding instructor response.
- Server Database Subsystem stores the record of the FAQ and does further processing

Students create a new FAQ according to their subject studied and their area of concern. The title and content of the new
FAQ is inserted via Palm entry keys. The system prompts the student to supply all missing fields until the entry is
complete. Students can temporarily save the question, or complete the writing and formulation of the FAQ on their
handheld devices at their own convenience. The completed FAQ can then be directed to the corresponding instructor and
is stored in the FAQ database. The student performs the HotSync on his/her desktop PC which forwards the FAQ to the
ultimate HKU Database Server via the conduit interface. This generates an e-mail to the instructor. The HHIT system
prompts the student through a series of screens to insert FAQ requests for instructor responses (Figure 2).

3.2 Web Platform

The Web Platform of our FAQ system is divided into 3 sub-systems:
- Web Server applications consist of the software which provides user requests and then sends them to the server for
querying the database or processing data.
- Web Browser applications are those programs with JavaScript, which are downloaded to the client computers to
provide different services, e.g. navigation menus.
- System Database stores the record of the FAQ and does further processing. The database should be common to both
Palm and Web.

Figure 2. HHIT System Main Screen
3.3 Database

The databases interact with the programs through a Java Database Connectivity (JDBC) - Open Database Connectivity (ODBC) bridge as Java Server Pages (JSP) is used to write server related programs. It requires the bridge to connect the Java DB engine to Microsoft DB engine due to the development of Java programs on a Windows environment.

Figure 3 shows the relationship between Web platform subsystems.

![Figure 3. Relationship between the Web Platform Subsystems](image)

When a user makes a client request on the browser, the request is sent to the Web server for processing. All data processing and request handling is done on the Application Server Machine. The JSP engine will change all the custom tag extensions and custom Java classes or JavaBeans to JDBC driver and other data access technologies to their control codes. Database queries can then be made to the database server by using the "open" schemes of JDBC to make a bridge with Win32 ODBC.

There is no applet or JDBC driver to download to the client. The browser using the Web application is not required to support Java at all. The JSP has full control over how many JDBC connections are made to the server; the client never makes direct JDBC connection to the server. This solution can work readily through a firewall; only standard HTTP is used between the Web server and the client.

IV. Future Plans and Improvements

PDA Hand-held devices offer a new hardware platform with numerous opportunities for developing future applications. New, important and useful, functions such as multicasting to allow all students in the class to read someone’s questions, and Chat-room via the Palm for each class, are planned for implementation. The use of wireless technology to set up Webcast in the classroom to enhance teaching, and Search Engine on the Palm to enhance learning, is projected. Scheduling and eForm, will reduce the paperwork associated with our educative practices. We have identified the following capabilities for our future implementation:

1. **Multicasting, and Chat-room**: Students designate questions as unicasting or multicasting. A Chatroom is established.
2. **Webcast**: Students download Palm version notes for the lesson; instructors send a quiz or other learning materials.
3. **Search engine on Palm**: Students and instructors input a keyword to search any topics of interest, or learning materials.
4. **Scratch graphics for Questions, and eBook**: The scratch graphics function converts graphs into Palm displayable format. The eBook function allows users to download useful materials in Palm version.
5. **Two-way scheduling**: Students and instructors download their timetables/events or schedule the many facilities.
6. **eForm**: eForm permits students to download required forms from desktop and then beam it back.
7. **Short message services (SMS)**: SMS (short-message service) via PDA to send messages about the seminar, course or other announcements. We set up a BEAM point for those with PDAs to get the messages/announcements beamed.

Many other extensions for our HHIT project exist subject to limitations on the amount of available resources and the current advances in networking and wireless communication technology.

V. Summary

The HHIT initial capability and its inherent growth offer a new dimension to the instructor-student relationship. The University of Hong Kong is seeking to incrementally empower the education-teaching process. By facilitating student access to their instructor on an “anytime-anywhere” basis, the education process becomes a more natural part of the student’s everyday life and activities. Finally, the textual and graphic nature of their interface encompasses the sum total of their requisite interaction. The University of Hong Kong will seek to disseminate and technically transfer this capability.

**Acknowledgement**: The authors acknowledge the contribution of James K.M. Tsoi and Ray Y.C. Tsang, IT Programmers at The University of Hong Kong, for their programming efforts applied to this project.
WebQuests for Reflection and Conceptual Change: Variations on a Popular Model for Guided Inquiry

David L. Young

Brent G. Wilson  
Brent.Wilson@cudenver.edu

Information and Learning Technologies Program  
University of Colorado at Denver  
United States

Abstract WebQuests have become a popular form of guided inquiry using Web resources. The goal of WebQuests is to help students think and reason at higher levels, and use information to solve problems. In this paper we present modifications to the WebQuest model drawing on primarily on schema theory. We believe these changes will further enhance student reflection and deeper conceptual change through the use of WebQuest activities in the classroom. The revised model is illustrated in a makeover of a sample WebQuest.

WebQuests have become a popular form of guided inquiry using Web resources. The goal of WebQuests is to help students think and reason at higher levels, and use information to solve problems. Thousands of teacher-authored WebQuests are currently available on the Web for use in different subject areas and at all educational levels. Teachers may thus choose to incorporate WebQuests developed by others, or they may develop their own WebQuest as a way to get their students reasoning at higher levels.

Dr. Bernie Dodge of San Diego State University first created the WebQuest model in 1995 (Dodge, 1995). Though he and Tom March articulated a fairly specific model and created many example WebQuests, there is now an even wider range of activities that fall under the WebQuest umbrella. Of course, the WebQuest model is a subset of the larger class of guided inquiry activities in use today. Other guided inquiry activities contain instructional strategies that are not a part of the WebQuest model, e.g., stronger reliance on a case as a resource; higher levels of guidance toward reflection. In this paper we propose modifications to the WebQuest model drawing on primarily on schema theory. We believe these changes will further enhance student learning through the use of WebQuest activities in the classroom. We also discuss ways to help teachers integrate WebQuests successfully into the overall curriculum.

The WebQuest Model: Evolving Over Time
There is no strict format for WebQuest design, and this flexible structure is one of its most appealing attributes (Dodge, 1995). Most WebQuests have the following elements:

1. An introduction that sets the stage and provides some background information. The introduction can be likened to an instructional set that stimulates prior knowledge and prepares students for new learning.

2. A task or problem to be addressed. This problem-solving task is at the heart of the WebQuest. The task is like the problem in a problem-based learning unit--It is the challenge or conflict to be addressed in the WebQuest activities. Dodge has provided additional assistance to educators attempting to create the WebQuest task through his online training materials. His "Taskonomy" helps educators envision a wide array of possible WebQuest tasks (Dodge, 1999).
3. A clear description of the process learners should go through in accomplishing the task. It is here that collaborative teams are formed and roles for each member of the team identified. Specific guided activities are often included in the process.

4. A set of information sources needed to complete the task. Since the WebQuest itself is delivered as a webpage, these resources are most typically Web-based, though widely available print or video resources can be identified for student use as well. Some WebQuests provide a common list of resources used by all members of the team; others identify information sources based on team member role.

5. An open-ended evaluation system for products created by students as a result of their problem solving. It is recommended that rubrics be used for the purposes of evaluation (Pickett & Dodge, 2001).

6. A conclusion that brings closure to the quest, reminds the learners about what they've learned, and perhaps encourages them to extend the experience into other domains.

A number of sites serve as portals or clearinghouses for WebQuests, allowing teachers to search for resources in their areas, including:
Blue Web'n (http://www.kn.pacbell.com/wired/bluewebn/),
The Matrix of Examples (http://edweb.sdsu.edu/webquest/matrix.html), and
The WebQuest Collections (http://edweb.sdsu.edu/webquest/webquest_collections.htm).

Many of the more innovative WebQuests will include unique design elements. Some developers have offered formal variations on the WebQuest model. March (2000), for example, has made modifications to the original WebQuest structure. Spartenburg (2001) presents a model for CyberInquiry projects that, at once, are more open and more linear in progression than WebQuests. Rather than seek out information from prespecified locations, CyberInquiry students conduct more open searches as part of a clear line of inquiry.

Schema Theory and Guided Inquiry
WebQuests can be seen as part of a broader movement within education that was heavily influenced by the paradigm shift away from behaviorism and toward cognitive psychology in the 1970s and 80s (Mayer, 1992). Schema theorists of that era advocated an approach to education that valued deep conceptual change over simple behaviors (Norman, 1976). Following this schema-based approach, students use their existing knowledge to make predictions and address problems (Posner, Strike, Hewson, & Gertzog, 1982; Strike & Posner, 1985). By engaging in a number of inquiry and problem-solving activities, students undergo a conceptual shift that leads to new schemas and ways of seeing the world—as well as specific procedural skills for dealing with that world. At beginning, middle, and end of problem-solving activities, students reflect on their changing schemas and their growing understanding. Math and science have been particularly fertile areas for schema-based curricula because new schemas can provide the hooks for making the computational details meaningful and stable in memory (Perkins & Simmons, 1988).

STAR.Legacy is a promising instructional model developed by Vanderbilt's Cognition and Technology Group that is based on conceptual-change principles (Schwartz, Lin, Brophy, & Bransford, 1999). The basic framework is an inquiry cycle with repeated opportunities for reflection and prediction. STAR is an acronym for Software Technology for Action and Reflection. The authoring tool, currently in prototype form, is intended to support the development of multimedia units for encountering and solving authentic inquiry challenges through small-team collaboration and research activities.
In a website overview, Sean Brophy provides a succinct description of the STAR.Legacy approach (see http://peabody.vanderbilt.edu/ltc/brophys/legacy1.html):

The learning cycle begins with the presentation of a challenge in either audio or text format. Then students are asked to reflect on the challenge and to "Generate Ideas." Once they've articulated their thoughts, they listen to "Multiple Perspectives" from various experts. These experts provide hints about things to think about when solving the problem. However, these hints do not provide a specific solution to the problem. This allows users to compare their naive first impressions with the experts to help them notice their lack of differentiated knowledge.

This initial sequence is similar to a WebQuest, but takes things a little slower. Students are asked to use their existing knowledge to think about the problem and generate some initial ideas. They are then exposed to other points of view about the problem. All of this precedes formal inquiry using outside sources.

Now they are prepared to engage in a process of "Research and Revise." This stage of the learning cycle organizes resources into meaningful learning activities designed to help them focus on issues related to the initial challenge.

This is like a WebQuest's process activities, with students using various Web resources to learn more about the subject.

Once they feel they've learned enough they can go to "Test your mettle." Here they engage in a set of activities that helps them explore the depth of their knowledge. The goal is to create assessment situations that help them evaluate what they do not know so they can return to the "Research and Revise" section to learn more.

This cycle of "testing mettle" and returning to resources is more elaborate than the WebQuest model and requires a more fully developed instructional unit.
Students progress to the "Go Public" stage after proving to themselves that they understand the content well enough to express a solution to the challenge.

Students "go public" with their solution, but they also "look ahead and think back." The reflection involved in the process—from beginning stages using limited knowledge, to final stages at the conclusion of inquiry—creates greater opportunities for students to undergo conceptual change rather than simple incremental addition of new facts. As Brophy explains:

This cyclical process of active research and reflection on the process provides an excellent opportunity for students to generate their own understanding of the content knowledge.

A Variation on the WebQuest model

STAR.Legacy units require more comprehensive resources and design than most teachers are able to include in a WebQuest. Even so, WebQuests can do more to encourage reflection and active use of knowledge. Our project incorporates elements of the STAR.Legacy model to create a more schema-based approach to WebQuest design (see Fig. 2 below).

![Diagram](image)

**Figure 1:** A four-stage reflection process can be triggered by an outside assignment or by continuing work of an individual or team.

This cycle of reflection can be prompted by an external challenge, as in WebQuests, or by the natural and continuing interests of team members. We see this reflection cycle as a variation on the Star.Legacy and K-W-L models of inquiry learning (Ogle, 1986).

Specifically, the WebQuest model is revised at two main points:

1. **What Do You Think?** following the task. Students need opportunities to test and use their initial understandings before engaging in specific search activity. We suggest that once students have been introduced to the Task in step 2 of the WebQuest, they be given a chance to propose possible solutions to the problem based on their current knowledge and understandings. What Do You Think? requires team members to pool their initial knowledge concerning the topic of research, and to present that knowledge as a basis for inquiry.

   There are specific advantages to adding this step. First, by allowing students to articulate possible solutions to the task or problem, both students and teacher can identify students' existing knowledge.
Second, this first pass at a solution provides a benchmark against which students can compare their conceptual growth over the course of the WebQuest. Third, the collaborative discussion that occurs as students share their ideas allows them to understand the thinking of the other members of their team (van Zee & Minstrell, 1997). And finally, it may become apparent to the teacher, based on the solutions generated at this stage that one or more steps of the WebQuest activity need to be revised. For example, it may be discovered that the information sources identified in step 4 of the WebQuest are inadequate. Or, a teacher may uncover that the task itself needs to expanded or narrowed to make the job of problem solving more meaningful to students.

2. Share and Compare. Students also need time to debrief and reflect with others as they complete WebQuest activities. The Conclusion step of most WebQuests often seems to be an afterthought rather than an essential component. We believe that this step should allow students to take an active role in assessing their conceptual growth throughout the course of the WebQuest experience. This could be easily done by comparing and contrasting the final team solution to the problem or task with their initial attempts at problem solving articulated in the new “What do you think?” step that we have added earlier. Share and Compare provides a structure for the public sharing of research findings, then feeding those findings into further inquiry questions.

Public sharing of findings allows all students in the class to experience the solutions offered by each of the teams. This opens up opportunities for large-group analysis of the solutions and further opportunities for conceptual development. Active sharing will also allow the teacher to help link the understandings and knowledge that students gain from the WebQuest experience to the rest of the curriculum for the course. This linkage back to the curriculum is an oft-neglected aspect of WebQuest use.

A Modified WebQuest
To illustrate how a typical WebQuest can be modified for increased reflection, we have conducted a makeover of a WebQuest preparing 5th grade students for a field trip to Southern Colorado (see http://ouray.cudenver.edu/~dl0young/adam/html_files/ for the revised site). In this WebQuest, students study a site they will visit and prepare inquiry questions relating to that site.

Three pages are added to the site to increase support for reflection and conceptual change: Teacher Page, What Do You Think? and Share and Compare. The Teacher Page presents the learning objectives for the site and suggestions for appropriate use. The Teacher Page also presents the four-stage model (see Fig. 2 above). As part of the What Do You Know? activity, students brainstorm together to pool their initial knowledge about their site. In the Share and Compare page, students submit their research questions and are prompted to review and compare questions from other teams. Once the teams have contributed questions, the whole class, working under the teacher’s direction, can decide how to use the questions as they physically visit the geographic sites. Alternatively, the visits can be conducted virtually, with similar kinds of sharing and reflection activities.

Contextual Use of WebQuests
It is important to remember that WebQuests are not isolated instructional activities. Instead, they are intended for use within the larger context of course objectives and curriculum. Encouraging greater reflection by active students will increase the likelihood that they will successfully link the activity back to the principles and ideas of the curriculum. Achieving this connection between specific activities and general principles is a challenge for education. We see WebQuests as powerful tools to help meet that challenge.

In some instances, a WebQuest may be used as the instructional set for a larger unit of work. In other instances, it may be a culminating activity. Because the ability of students to think and reason at higher levels varies widely, a teacher may elect to implement a particular WebQuest in different ways from class to class. In fact, a teacher's first administration of WebQuest will most likely vary significantly from their later use of the strategy. In general, we need to examine closely how teachers choose to incorporate WebQuests into their everyday activities.
The Need for Continuing Research

The rapid rise of the WebQuest as an educational practice has outstripped the research community’s ability to provide a solid theoretical foundation for its use. This is no different than other technologies that rise rapidly into use. The many approaches to WebQuest design further complicate efforts to study the impact of these interventions. We see this dynamic and diverse state of affairs as a healthy condition that now provides a fertile opportunity for research of various forms.

We have proposed modifications to the original WebQuest model. The key issue for research, however, may not be finding the perfect model but, rather, finding ways to help teachers make best use of these models in their teaching practices. We intend to continue studying how teachers make use of models and frameworks, and how they adapt these frameworks to their own purposes and conditions. Over time, we hope to better understand conditions and strategies that will help students develop higher-order reasoning skills.

Abstract: This qualitative study explores the potential impacts of one application of the Internet—on high school-level English, including 29 students and an instructor. Based on the findings, the researcher concluded that the Internet could motivate student learning and provide students with a less stressful environment to write down their opinions and thoughts freely on the Internet, but the Internet alone could not improve student English writing in terms of grammatical proficiency. Recommendations were made for maximizing the educational benefits, and minimizing the limitations, of using the Internet in the Internet English classroom to develop the confidence and writing ability of students.

Introduction

With the rise in the popularity of information communication technology among the younger generation, there is a pressing need for the integration of technology in education and for further study on domain-specific effects. Obviously nowadays English is the mostly used language in cyberspace. This need is particularly acute for the domain of teaching/learning English as a second language because of the features of the Internet and the abundance of English learning resources freely available on the Internet. Currently, for example, more and more websites intended to be free English virtual learning and teaching environments for listening, speaking, reading and writing have been sprouting up on the Internet over the past few years.

The emerging applications of the Internet in educational settings have energized learning (Ian, 1999; Lee, 2000; Krajka, 2000; Gerald, 1998). The Internet has the potential to provide a new learning environment that has rich digital textual, graphic, audio, video and other interactive features for the language learning approach as well as for culture (Muehleisen, 1997). The Internet is considered a key-factor in enhancing the learner's motivation for both language learning and linguistic proficiency (Lee, 2000). In recent years, language teachers are exploring ways in which information communication technology can be employed to make language learning more effective and motivating for students (Kern, 1995; Vallance, 1998; Bricknall, 1999; Donaldson & Kotter, 1999; Wible, et al., 2000). According to Muehleisen (1997), reasons for using the Internet in the English classroom are as follows:

- Learning to use computers provides a strong intrinsic motivation for learning English;
• The Internet places English in an international contexts;
• Internet projects are interactive;
• Facilities for using the Internet are often readily available.

On the Internet, students have the chance to communicate and collaborate with other remotely distributed classmates, peers, or teachers by using e-mail. Communication over the Internet can help learners create, analyze, and produce information and ideas more easily and efficiently. Research shows that by using network computers, students can be empowered by the capacities of the technology and become better problem solvers and better communicators (Frizler, 1995; Belisle, 1996; Al-Kahtani, 1999). The communicative potential of Internet-supported classes has recently become the focus of much attention in the fields of education and research (Kern, 1995; Warschauer, 1997). With the integration of information communication technology in language learning, new kinds of activities, such as electronic communication via e-mail or chatrooms, have also been developed to help students (Liao, 1999; Kokkas, 1999). Different modes include synchronous and asynchronous interactive e-mail, Webchat, MOOs, IRC-multimedia activities, Web-based reading, and task-oriented activities. Each mode fosters a different kind of linguistic competence, and calls for various skills (Negretti, 1999; Liou, 2000; Oliver, 1996). Meanwhile, teachers also face many challenges (Singhal, 1997). Such contexts have been shown to facilitate students' willingness to participate in discussion, as evidenced in the increased volume of language output.

This Study

The study employed both qualitative and quantitative methods. The researcher used a multi-method approach to document and evaluate the process of integration of the Internet in the English leaning settings, including the collection of their electronic data from chats, discussions, dialogues and email exchanges on the Internet, observations of their online classroom activities, formal and informal interviews with the instructor, and a post-class questionnaire.

Specific questions explored in the study include the following:
1. Can students learn the functions of the Internet via the English language and significantly improve their English e-talk on the Internet?
2. What are the benefits or difficulties with the use of Information Technology in the teaching of English as a Second Language?
3. What are the issues and challenges that arise in the integration of the Internet in English learning contexts?

The research project was conducted at a vocational high school in the northern part of Hsin-chu city. The course was geared to intensive study and was named Internet English; it was offered by a young male English teacher. The goal of this course was to use various methods to facilitate students' Internet usage by way of English writing. A two-hour on-line lecture plus a computer session was held on Tuesdays in a computer lab where thirty Personal Computers were set-up and networked. In the lab the teacher lectured on some introductory aspects of the Internet
and its functions and at the same time demonstrated its uses and gave students opportunities for practice using English and exploring the Internet. In addition to the weekly lecture and computer session, the after-class activities and assigned tasks were required of each student. The online lecture was divided into four sections, with each section focused on one of the following topics: the World Wide Web, Newsgroups, Email and MOOs. To carry out the after-class projects and assignments, the students, therefore, needed to connect to the Internet and search for the required materials in response to the teacher's weekly questions and, meanwhile, they were required to use English to communicate with the teachers as well as with the other classmates. Moreover, all of the students needed to write “letters” to email pen pals in other countries such as Japan, U.S.A., and Korea and address several topics posted by the teacher.

The participants in this study were 29 third-year high school students: 22 females and 7 male students plus the young male teacher. The course was conducted in two semesters: autumn/fall semester, from September 2000 to January 2001 and spring semester from February 2001 to June 2001. The results reported here are mainly based on the data for the first academic semester of the project, from autumn 2000 through spring of 2001.

Findings

Overall results of the use of information technology in the class

The teacher used an open-ended question to solicit student overall response to the use of the information technology in the class. This question was, “Do you think Internet English can really improve your English? Tell me why.” Most students thought the Internet was an interesting and useful tool in their Internet English class. Statistical data indicate that nineteen out of the twenty-three students (19 out of 23, 82.16%) held positive attitudes toward this class, while three out of the twenty-three (3 out of 23, 13%) had negative attitudes and one gave an irrelevant answer (1 out of 23, 4.4%). The benefits they gave varied and included the following: 1. Being able to practicing typing (5 students); 2. Learning more English (4); 3. Being more motivated in learning new vocabulary (4); 4. Being able to learn more about the computers (4); 5. Communicating with others using Emails and making friends from other countries (4); 6. Looking for information on the Internet and enhancing reading comprehension by reading materials on the Internet (3); 7. Meeting people (2); 8. Talking on line (1); 9. Being able to correct mistakes instantly (1). Negative reasons included 1. Not liking the Internet (1); 2. Too much vocabulary resulting in learning pressure (1); The fast-paced schedule of the class (1).

Students' English learning/improvement in terms of the use of the advanced technology

After reviewing thoroughly the in-depth qualitative data from student discourse and based on the interview data with the teacher, the researcher concluded that the Internet could motivate student learning and provide students with a less stressful environment to write down their opinions and thoughts freely on the Internet, but the Internet alone could not improve student English writing in terms of grammatical proficiency. The most common mistakes students made in their e-writing could be categorized into the following six groups: 1.) Spelling mistakes; 2.) Not
capitalizing a proper noun; 3.) Incorrect word combination; 4.) Single and plural disagreement; 5.) Incorrect phrases; and 6.) Grammar errors.

Throughout this study, the qualitative data from sentence analysis indicated that students did not really improve much in their grammar usages in making sentences, but the students could express themselves freely on the Internet. Each correct sentence was almost of the same length, since longer sentences were more likely to contain more grammar mistakes. Results from this study suggest that most students welcome computers as a powerful tool to be integrated into English learning. The use of computers and computer networks does not seem to pose concerns for most of the high-school students. Student could benefit a lot from the use of the Internet for many different reasons, including greater volume of English utterances rather than the grammatical proficiency. This study indicated that integration of information technology in the Internet English facilitates the creation of a virtual environment that thus transforms learning from a traditional passive experience to one of discovery, exploration, and excitement in a less stressful setting.

However, data collected from formal and informal interviews with the teacher and observations indicated that the teacher, although he was very familiar with the computer functions and was active and enthusiastic in the integration of information technology in the English class to maximize the learning effect, seemed to feel more concerned about classroom management in the virtual classroom setting. He was further occupied with technical assistance in handling computers, troubleshooting problems, and seeking logistical support from staff to help organize digital data generated in the pedagogical settings. In general preparing a network session plus taking care of the after-class online activities demanded up to three to four times the class time that a traditional session required. The author hopes that the paper provides some insights toward a better understanding of high school student use of the Internet in English classes in Taiwan. More studies on how to improve student grammar through English writing practice on the Internet should be strongly encouraged.

Acknowledgements

The author wants to express her sincere gratitude to the students and teacher involved in this study. Without their support this project would not have been possible.

Group Dynamics in a Synchronized Computerized Competitive Learning Environment: the Effects of Anonymity and Proximity Factors

Abstract: The present study set out to investigate whether the negative effects associated with face-to-face team competition can be mitigated with the support of networking technologies where opponents' identity or proximity can be manipulated. Results indicated that subjects in the face-to-face team competition condition rated statistically significantly less favorably on inner-group processing than those in the decreased proximity and anonymity conditions. Data analysis on student perception toward classroom climate revealed that subjects in the anonymity condition rated statistically significantly more favorably on classroom climate than those in the other two conditions. The results of this study tend to lean toward the position that to promote effective interactions within learning groups and to cultivate more regulated classroom climate, networked team competition where opponents are not identified may be the preferred instructional strategy to adopt.

Introduction

Competition has been suggested as a means of enhancing the motivational appeal of educational activities, and as a way to foster learner involvement and excitement in the activity (Butler & Kedar, 1990; Clinkenbeard, 1989; Malone & Lepper, 1987). Adding an element of competition between individuals or groups is widely believed to be a motivational-enrichment strategy in play, work, and education (Deci Betley, Kahle, Abrams & Porac, 1981). Despite the fact that competition is encouraged as an appropriate goal structure in the form of various academic contests to motivate people to perform to the best of their ability, the negative side effects of competitiveness on learning has provoked discussion and suspicion. While empirical bases claim that competition has negative effects on learning, past studies were primarily conducted in traditional classrooms involving face-to-face situations. For example, Festinger (1950) found that defensive reactions are more commonly aroused in face-to-face competing groups. Results from Hammond and Goldman (1961) yielded that small face-to-face competing groups was less favorable for group process. High school students in Garibaldi's study (1976) perceived less effective communication within their dyads in face-to-face team competition situations.

Gleaned from the literature on media effects and human factors in telecommunications, face-to-face and mediated interaction differ in many psychological significant ways; nevertheless, evident for such differences on group dynamics have only been examined in decision making situations for small group interaction (Er & Ng, 1995; Jessup, Connolly & Galegher, 1990; Jessup & Tansik, 1991; Valacich, Dennis & Nunamaker, 1992). The effects of face-to-face versus networked team competition where opponents are identified or not on group dynamics in academic learning environments have yet to be explored. Within the limitations imposed by the laboratory conduct of experiments it is rarely possible to examine the issue up till the advent of networking technologies. Thus, the present study set out to examine the effects of anonymity and proximity feature of computer telecommunications on group dynamics within competing groups.

A number of questions could be examined within this context. For example, would face-to-face and networked team competition generate different atmosphere of competition, which, in turn, construes different group dynamics within the learning groups and the overall classroom climate? More specifically, would close proximity in face-to-face team competition situations be less favorable for group process? In other words, would face-to-face competing groups suppress inner-group information exchange and sharing due to the fact that competitors sitting next to them might overhear their answers to the posted questions and that what their
competitors exhibited during the game will distract them from concentrating on the task at hand? Might opponent proximity, physical separation and/or loss of identification provoke different defensive reactions and behaviors among competitors, which, as a consequence, engender different classroom climate? The data yielded from this research can provide informative and practical suggestions regarding the suitability of embedding elements of anonymity and/or physical separation among competing groups for real-time game-based competitive learning environments.

Methods

Participants

Three classes from the fourth-grade level of one primary school in the southern part of Taiwan were selected. In total, 103 fourth-graders (ages 6-11) participated in the actual study for three instructional sessions in three consecutive weeks. All students in the participating classes had been taking computer literacy classes for two years, and possessed a fundamental knowledge of computer hardware operations.

Learning systems

A synchronous computerized competitive learning system, called Joyce, was devised for the study. Joyce with its origin dated back from 1972, in essence, adopts a board game format that allows learners practice answering multiple-choice questions with competing opponents simultaneously face-to-face or via network (Chang, Yang, Wang, Yu & Chan, 2001). Various functions and rules including shortcuts, funny questions, random number, bump, spaces move control, and icon selection were built into the system to increase its intrinsic motivational values to the user (Yu, Chang Wang, Han, Chan & Liu, 2001).

The main interface of the Joyce system (see Figure 1) is divided into six parts. Part 1 Question Area presents the item stem and four alternatives through a pop-up window. Part 2 Feedback Area provides information on players' responding status, for instance, who has not keyed in their answers to the question yet, and the correct answer for the question, etc. Part 3 Dice Rolling and Combination Choice Area. After answering each question correctly, a simulated dice will give a random number from one to six. After two questions answered correctly, students can determine the number of steps that the icon can move on the board via three different combinations of the two numbers. Part 4 Route Map. There are 31 stops in each round. In addition to general questions, which are related to a specific subject matter and instructional topic, five funny questions and four shortcuts are included in the route map. Part 5 Icon Window allows the player to choose and change the icon to represent him/her to move around the board game. Part 6 Win/Loose Status Window shows the number of games won by both sides of the competing parties. When the player wins a game, he/she will be promoted to a higher step up the ladder.

![Figure 1: Joyce Learning Environment](image)

Multiple-choice questions corresponding to large class instruction on social studies and natural science in the
participating school were built in the system for the purpose of this study. Specifically, “Folk custom and life of Taiwan” was taught in social studies. “Omnipresent water,” “Underwater creatures” and “Photosynthesis” was taught in natural science. All test items built in Joyce were drawn directly from textbook publisher’s test banks and student study guides. Sample items included, “Which ethnic group in Taiwan like to express their feelings using lyrics and songs during leisure times (Hakka, Fukien, Ya-Mei, A-Mei)? Which one of the following does fish use for breathing under water (skin, gills, lung, scale)? What color will the water with a weak base indicator change if you blow CO2 into it (from blue to transparent, from blue to yellow, from transparent to yellow, from transparent to blue)?”

Treatment Conditions and Experimental Procedures

To examine anonymity and proximity factors in synchronized computerized team competition environments, three different team competition modes were derived in the study. Considering normal arrangements for computer literacy instruction for fourth graders at the participating school, which is two students per computer, in all treatment conditions students were randomly re-assigned to groups of two to compete with their randomly assigned opponents for the duration of the study.

In Treatment A (the face-to-face team competition condition), pairs of students were competing with their randomly assigned opponents sitting next to them. In Treatment B (the decreased proximity condition), names of the competing teams were announced before the activity but competing teams were intentionally displaced away from each other while interacting in the game via networking technologies. To examine the effect of proximity, competing teams in Treatment B were sitting at least 15 feet away from each other in the computer lab. In Treatment C (the anonymity condition), competing teams were not identified throughout the experiment. Pseudonyms were randomly selected from a list prepared for the study for each dyad and used to log in the system. Pairs of students were competing with unidentified opponents via networking technologies.

To avoid teacher’s effect, one elementary school teacher was trained to implement the study. An instructor’s manual delineating all the procedures and directions to participants was developed to standardize the experimental procedures. To further secure that experimental procedures were accurately carried out during the study, a training program was provided to the implementer prior to the actual study. Each classroom was observed by the investigator to verify that all experimental conditions were implemented appropriately to ensure experimental fidelity throughout the whole study. In addition, two pilot studies were conducted to ensure that the learning system was operating accordingly and the experimental procedures for each of the treatment conditions was adequately and appropriately implemented prior to commencement of the study.

In the present study, students participated in three instructional sessions in three consecutive weeks. The study was conducted during computer literacy classes in the school’s computer laboratory. In the first session, ground rules for participating in the activity, including "Being on time?, "Staying in your seats?, "Raising your hands before posting questions?, and the purpose of the learning activity (i.e., to have student practice answering questions to the instructional content just covered in whole class instruction) were announced and explained via classroom broadcasting system. Various features and the operating procedures of the learning environment were introduced and demonstrated before having students compete answering social science questions with their randomly assigned opponents.

At the beginning of the second session, the ground rules and procedures for running Joyce were reviewed before having students compete answering natural science questions on the system with their randomly assigned opponents on computers for the next 35 minutes.

At the beginning the third session, before having pairs of students compete with their randomly re-assigned opponents for the next 15 minutes on social science and natural science questions, the teacher quickly reviewed the basic procedures involved in operating Joyce. Subjects were given a questionnaire to be completed individually afterwards.

Measurement Instruments

A post-experiment self-report questionnaire was disseminated to students to be completed individually. The questionnaire consisted of "Student Perceptual Impressions of In-group Processing," and "Student Perceptual Impressions of Classroom Climate."
A number of scales from previous research were adapted to make the items better fit the experimental task and target population used. Specifically, Yu's (2001) "Perceptions of the Communication Process Within One's Own Dyad" was adopted for "Perceptions of In-Group Processing" Xiang's (1979) "Classroom Environment Scale" and Li's (1980) "Learning environment Scale" was adopted and adapted for "Perceptions of Classroom Climate." Semi-structured interviews with six students purposefully selected from the target audience and expert reviews were undertaken during scale development to ensure validity of the measurement instruments.

The questionnaire consisted a total of 24 Likert-scale items to collect data regarding whether anonymity and proximity influenced in-group processing and classroom climate. Nine items was included to test the hypothesis relevant to in-group processing. Sample statements included, "My teammate and I discussed our answers to the posted question in order to reach consensus; when my teammate had trouble understanding the rules of the game or the question posted, I assisted him/her during the activity." 15 statements were included to test student perceptual impressions of classroom climate. Sample items included, "During the activity, almost all students can keep silent; during the activity, class order is usually out of control; Most of the participants are focused during the activity."

Each statement was rated on a five-part discrete scale, with corresponding verbal descriptions ranging from "strongly disagree" through "disagree," "no-opinion," "agree," to "strongly agree." To counteract possible response set tendencies, both positive and negative statements were included in the instrument. The questionnaire was scored according to the number of "strongly disagree," "disagree," "no opinion," "agree" or "strongly agree" responses a student selected. Each response received a weight of 1, 2, 3, 4, or 5 respectively. Scoring on the negative statements was reversed so that negative and positive responses could be summed and averaged with higher scores reflecting more positive attitudes. The internal consistency reliability (coefficient alpha) for each of the scales on the post-experimental questionnaire calculated after the actual study was .8681 and .7438, for in-group processing and student perceptual impressions of classroom climate, respectively.

Results and Discussion

The means and standard deviation (SD) values for student perceptual impression of inner-group processing and classroom climate for different team competition modes were listed in Table 1. Collected data were analyzed using the analysis of variance technique on each of the two dependent variables followed by Scheffe multiple comparison tests when a significant main effect is found.

Table 1: Descriptive Statistics of Different Team Competition Modes on Student Perceptions of Inner-Group Processing and Classroom Climate

According to the data analysis conducted on student perceptions of in-group processing the study found a statistically significant effect for different team competition modes, F (2,100)=5.326, p<.01. Scheffe multiple comparison tests revealed that subjects in Treatment A (the face-to-face team competition) (M=32.2647) rated significantly less favorably on inner-group processing than those in Treatment B (the decreased proximity condition) (M=37.5143) and Treatment C (the anonymity condition) (M=36.2353) at .009 level, and .067 level, respectively.

Data analysis on subject perception toward classroom climate yielded a statistically significant effect for different team competition modes, F (2, 100)=15.065, p<.001. Scheffe multiple comparison tests further revealed that subjects in Treatment C (the anonymity condition) (M=56.6176) rated significantly more favorably on classroom climate than those in Treatment A (face-to-face team competition) (48.3824) and Treatment B (the decreased proximity condition) (M=47.4571) both at .000 level.

The present study compared the effects of three different team competition modes, i.e., face-to-face, decreased proximity and anonymity team competition, upon in-group processing and classroom climate. Data from the present study support our proposition that anonymity and proximity are more favorable for group process.
Distinguishing aspects of telecommunications media, that is, anonymity and proximity, did have an influential mediating effect on human behavior in present study. Students participating in the physical separation and anonymity competitive conditions perceived themselves to be focusing more on information sharing and exchanging as compared to the face-to-face team competition condition.

It is suggested by social psychologists that nonverbal information transmitted in a face-to-face situation may involve visual cues that distract the participants from formulation of their own arguments (Short, Williams & Christie, 1976). With competing teams unidentified and dispersed, cooperating pairs tended to encourage attention to the content of a message and task at hand rather than to the nominal characteristics of the face-to-face interacting parties, which may distract from that (Maxx, 1999). In other words, anonymity and reduced proximity minimize the in-group process losses associated with face-to-face team competition situations and induce more task-related interaction and effective communication within groups.

The present study also found that networked competition where competitors were anonymous rated significantly more favorably on classroom climate than those in other two treatment conditions. That is, pairs competing with unidentified competitors tended to rate lower toward statements on the subscale like: It was loud and noisy during the activity; The atmosphere during the activity makes it hard for me to concentrate; during the activity, class order is usually out of control, etc.” as compared to the face-to-face and physically dispersed team competition modes. That is, with competitors identified, the atmosphere exhibited in the classroom seems to be noisy, out of order, unmanaged, and unregulated no matter variability of competing group proximity.

Conclusions

The capabilities of communication and computer technologies offer interested parties the opportunity not to be identified and be physically separated from each other while interacting with each other within the system. The purpose of this study is to examine the effects of competing group’s anonymity and proximity, two important components manipulable with the support of networking technologies, on group process of cooperating dyad. Data from the present study found that anonymity and decreased proximity of competitors is conducive to effective in-group processing and information-sharing behaviors. The results of this study tended to lean toward the position that to promote constructive interactions and to enhance regulated classroom climate, networked team competition where opponents were not identified might be the preferred instructional strategy to adopt, as compared to face-to-face team competition. Gleaned from the results from the present study, it is recommended that designers of competitive game-based learning systems are well advised to include the feature of anonymity in their system to support student learning.

This is the first empirical evidence investigating the potential of network team competition on group dynamics with the support of networking technologies. Future studies with longer duration of experimental time, different age group subjects, content areas, interaction tasks and dependent measures of learning outcomes may be needed to extend the scope and extent of the generalizability of present study. Finally, the present study involved pairs of participants competing with each other in objective-type question-answering practice. As group process are more complex than dyadic ones while engaged in problem-solving questions, further studies involving various group size and different question types might make finer distinction so as to make practical recommendations regarding the particular situations in which anonymity and proximity could be used for the enhancement of learning outcomes.

ABSTRACT
The World Wide Web can serve as a complete learning and educational environment and poses new challenges. Testing and assessment are value-added services in a learning process, which aim at evaluating and measuring the outcomes of learning experiences. Developing tests in an instructional efficient and effective manner is a difficult task, especially when this is implemented over the web. In this paper we describe the main features and functionalities of a web-based testing system that deploys state-of-the-art technologies providing the instructors and learners with a powerful web-based testing environment.

1. INTRODUCTION
1.1 Background
An increasing number of researchers and practitioners have been motivated to discuss and develop Computer based and Web-based testing systems, in recent years. These kinds of systems should provide certain basic instructional functionalities like other web-based learning and education systems (Overbaugh, 1994). On the other hand, instructors must recognize the need to design assessment appropriate to the medium. The component of the assessment in an online learning environment is of great importance. Assessment is an integral, ongoing aspect of learning, which is about gathering, analyzing, quantifying information about learner performance. Comparisons with traditional assessment methods suggest that the use of computer and web-based techniques may improve the overall performance of learners (Bocij and Greasley, 1999). The major benefit of computer-based assessment appears to be the improvement of task-focus. If performance increases and completion time for the test decreases, then computer-based assessment enhance the ability of learners to focus on questions and recall relevant information (Bocij and Greasley, 1999).

2. DEVELOPMENT OF THE SYSTEM
2.1 Goals, motivation and basic concepts
Our work and development effort focuses on answering the following question:

➢ How can we provide instructors, teachers, trainers or testing authors the capability to construct tests dynamically over the web in an efficient and effective manner?

The main focus is on the user that has the responsibility to create tests, no matter if he/she is a teacher, instructor (subject matter experts), testing author/designer etc. Additionally two other questions raised our motivation to develop this web-based testing system:

➢ How can we provide them (instructors, testing authors etc.) the capability to review the tests’ results whenever they want and receive feedback in a manner that will help them to adjust their learning material and courses?

➢ How can we motivate the learners (test takers) and provide them with options for receiving more customized feedback?

As far as it concerns the basic concepts, feedback is main concept of our system. Providing feedback is crucial for the orientation and motivation of the learner. In the web-based testing system we developed, a learner is free to choose whether he/she wants to receive feedback while he/she is executing the test. Furthermore a learner is provided with the option to receive his/her own results report either in a text format, or a graphical presentation, pie charts, histograms etc. according to his/her preference and learning style (Honey and Mumford, 1992). Rich feedback is provided to the instructors also through the reporting capability of the system, which keeps tracks of learners' performance and progress. This kind of feedback is of great importance since it helps the instructors to evaluate the success of a learning experience and adjust the learning objectives, courses and learning materials to the level of learners' performance. Additionally, addressing issues like plagiarism and cheating is of high importance in testing environments and these concepts have been taken into account while designing the system. This system has been developed towards summative assessment: Careful design of summative assessment is an approach that can reduce plagiarism. More specifically in selected response type of assessments (Rovai, 2000),
the construction of a large pool of items can be of great importance in order to produce tests that will be unique for each learner and to reduce cheating or plagiarism (Howard, 1995) (Carnevale, 1999a). Timed tests can also decrease the opportunity to cheat (Rovai, 2000).

2.2 System Architecture
Following the 3-tier Architecture model with a thin client, we use relational database technology for the database layer, Java and Java Server Pages for the application logic, and html and JavaScript technology for the presentation layer. A common browser (Microsoft Internet Explorer 4.0 or Netscape Navigator 4.0 or newer versions) is the minimum requirement for the client.

2.3 Basic System's Modules
The system we developed consists of the following four basic modules:

1) User Management Module: It is the module that enables the administrator of the system to specify the instructors and learners as well as the subjects/topics and groups of learners, respectively. This module also includes: i) the management of roles and ii) security issues

2) Authoring Module: It is the module that enables the instructors to construct their own questions and questionnaires (tests), as well as to manage and modify the question pool. This module is about authoring, storing and selecting questions and tests. The main user of this module is the instructor, or testing author. The types of questions supported by the system are the following: 1) True or False, 2) Multiple Choice, 3) Multiple Response, 4) Text Question, 5) Fill in The Blanks, 6) Ordering, 7) Matching and 8) Composite.

3) Testing Delivery Module: It is the module that is responsible for the execution of the tests by the learners.

4) Reporting Module: It is the module that gives both the instructors and the learners the capability to view the results of the tests that are related to them.

3 PILOT TESTING
3.1 Introduction
The evaluation of the system has been carried out in real environment conditions using a selected sample of educators and learners. The objective of this process was to combine the outcomes for the usability and the functional evaluation in order to assess the acceptance of the system by its users, acquire further suggestions concerning its functionality, as well as remove technical obstacles. In order to evaluate every aspect of the system, a distinction between two orthogonal parameters has to be made:

- **User Interface Parameters**, that identifies the level of acceptance of the User Interface (UI) by the users.
- **Functionality Parameters**, measuring the level of compliance of the system with the user requirements, upon which the system development was based.

3.2 Methodology
Usability is considered as a basic parameter of the quality of a system and it was a basic component of the system's evaluation. Particularly in the case of developing software for learning and educational purposes, there is a clear need for the system to become "invisible" allowing the learner to focus at his/her learning tasks. Usability testing has taken place in laboratory settings. The researchers involved in this work conducted experiments with real users. As already mentioned, the testing places were three university laboratories; the testing duration was 2 hours maximum per subject and the experimenters were the system designers. The purpose of this test was to record the reactions and responses of potential users of the system regarding mainly the ease of use, system's potential marketing application and its improvement possibilities. For the testing process a sample test was designed containing 20 various type questions such as open, dichotomously, multiple choice, multiple answers etc. These questions were related to general knowledge questions as well as Marketing and Computer Science specific. These questions were imported into the system comprising the test data for the testing process. The results obtained lead the researchers into formulating specific suggestions for the improvement of the system. It should be clear that before starting the testing session, all users attended a 30-minute introductory presentation of the system functionality and were shown the testing sessions content. The rationale for the latter is that users would become accustomed to the questions mentioned above and as a matter of fact, to be more focused to the measured tasks and user interface elements, during the real testing sessions.

3.3 Preliminary Evaluation Results
As part of the evaluation process, we designed and distributed to the users a questionnaire that has been devised for the evaluation of the system. The questionnaire consists of several sub-sections, each dealing with different aspects of the system: the design of the GUI, the performance of the system, the system’s ease of use, the state of the documentation and other issues that a user may be able to identify. For the purpose of the evaluation we have already established 6 evaluation indicators, and we are trying to approach the systems evaluation from these various perspectives. For each indicator we are presenting the results of the system evaluation:
Apart from the users’ response to question A6, which is related to the ability provided by the system to the user in order for the latter to avoid making mistakes, the judgment of the users regarding the general issues of the system, is positive with a large percentage of the subjects replying very positively or partially positively.

The judgment of the users related to dialogs, forms and menus is again positive with a large percentage of the subjects replying very positively or partially positively. In the question “Can the keyboard be used to control the program as extensively as with the mouse?” the response of the subjects was rather negative, whereas regarding the question “When accessing a form, is there a logical grouping of the various choices on the form?” it was probably not clearly understood from the subjects probably due to formulation.

The results of the questions related to user interaction and convenience present a great fluctuation. Many negative responses have been recorded regarding the speed of the system, progress notification and short key availability.

Apart from the users response to question “Are error messages categorized by, for example, a certain subsystem of the program, by an error code or some kind of keyword?”, the judgment of the users regarding errors and error messages of the system, is positive with a large percentage of the subjects replying very positively or partially positively.

The results of the questions related to Help and System Documentation present particularity since there is a high percentage of not answered questions. This is possibly due to the fact that users haven’t used the help system sufficiently or that this component is not easily accessible or usable. Most received answers were positive apart from the questions related to the provision of examples in the help system and a printable version of it.

The overall assessment and evaluation score of the system expresses a generally good opinion of the users. The majority of the answers are above average level, whereas a high percentage is between 7 and 8 out of 10 (Very Good).

</table>

FUTURE WORK AND IMPLICATIONS

Next steps in our research include the development of the next version of the system by taking into account users' feedback derived from the pilot testing. Further use of the system and the preparation of a large-scale experiment in educational settings (universities and training organizations) have been planned for usability testing purpose. Future enhancements concerning next versions of the system will include:

a) The addition of question types that require multimedia features and
b) The integration of the testing system with other learning systems such as Learning Management Systems etc.

Finally, another important issue to be taken into account is interoperability and the conformance with standardization efforts such as IMS-QTI (IMS-QTI Specification, 2000), etc.

Case Study: Cognitive Flexibility Theory and the Evaluation of Repurposable Learning Activities

Purpose: The purpose of this study was to examine the re-purposability and reusability of “learning activities” used in two courses within the domain of cognitive psychology and explored the role of Cognitive Flexibility Theory with respect to instructors’ use of learning activities.

Introduction: The main purpose of this study is to investigate the role of Cognitive Flexibility Theory in the development of learning activities for use in online course in the domain of cognitive psychology. Cognitive Flexibility Theory emphasizes the flexible reassembly of preexisting knowledge to fit the needs of new situation. (Spiro et al, 1987) We believe that it is important for instructors of courses to be cognitively flexible when developing and re-purposing learning activities for their courses. In order to attain cognitive flexibility, instructors must have a working mental model of the actual domain, which leads to the re-purposability of the learning activities. Mental models provide “an explanation of why procedures work.” (Black, 1992) It is “an image of the different parts and objects of a mechanism together with procedures for transforming these parts and objects to form a mental simulation.” The focus of this study is on the cognitive flexibility exhibited by the instructors rather than the students of the courses.

A learning activity can be as simple as a graphic or as complicated as a whole curriculum. The granularity of a learning activities can be broken down into two levels, a Fundamental Information Object (FIO) or a Combined Information Object, (CIO). An FIO is defined as a unit independent of context. For example, a single graphic of a gear would be considered an Fundamental Information Object. An FIO has the highest degree of reusability. (Wiley, 1998) A CIO results from combining several FIOs. This results in added context but lower granularity. For example, several gears put together with a direction arrow and a question asking in which direction will the last gear turn is a CIO.

The goal is to create Generative Instructional Learning Activities that allow for the repurposing of learning activities. A repurposable object is developed when an FIO is taken from a CIO and repurposed for a new CIO. Not all FIOs can combine together to form a meaningful CIO. An analogy of this would be similar to how atoms combine to form molecules. Not all atoms are able to combine together. Furthermore, certain atom combinations lead to changes in the overall structure of the molecule. We believe that FIOs should not be repurposed for all domains. In order to do so, the creators of the learning materials must be able to be cognitive flexible when developing the learning activities.

Case Study: Two graduate courses in the domain of cognitive psychology were used in this study. The study was conducted after the semester ended. The first course, Theories of Human Cognition and Learning focused on theories of Cognitive Psychology and related empirical results. Cognitive Psychology includes such topics as memory,
learning, comprehension, problem solving and attention. The second course, Cognition and Computers, focused on applications of theories and results from artificial intelligence and cognitive psychology to try to improve uses of computers and related technologies in education. Separate instructors, with similar backgrounds in the field of cognition and learning, taught the courses.

Both instructors created learning activities specifically for their respective courses. Once the learning activity was created, it was stored in an online distance learning platform to which both instructors had access. As the instructors were creating their modules (CIOs), they could look online at the other instructor’s course with the intent of gathering learning activities that could be re-purposed for their own use. The learning activities were created as the semester progressed and either instructor could check to see if new objects had been added. There was no enforced structure of looking, nor did the instructors discuss uses and implications of these objects between themselves.

Discussion: The fundamental question was whether the re-purposing of these objects was feasible and if instructors were able to be cognitively flexible. Although the focus of the courses differed, reciprocal exchange of learning activities was prevalent. For example, one instructor created a CIO learning activity with specific instructional intent, which included images, lecture notes, journal article readings and a learning activity. The other instructor used the images (FIO) to create another CIO with a different learning purpose. Thus, through this re-purposing of the learning activity, the second instructor was displaying cognitive flexibility.

Because there was no active communication between instructors, and the sharing of learning activities occurred naturally, we believe that the instructors demonstrated cognitive flexibility when designing their own learning modules. The instructors indicated in interviews that they were able to be cognitive flexible in their development of the materials because they were both familiar with each other’s courses and understood the original purpose of the learning activity. The results point to a need for further evaluation of learning activities a feasible instructional design tool as well as a measure of instructor cognitive flexibility.

Implications: This study is important because it demonstrates a successful case for collaborative instructional design. Both courses were enriched because the instructors were able to draw upon common resources and still develop unique learning activities for each course. This also allows instructors to become more productive with the development of their course materials and cuts down on redundancy of effort. Another implication of this case study points to a deepening of content knowledge and reasoning of instructors because in order to be cognitively flexible with the learning activities themselves, instructors must know how and when to use the objects appropriately. If the instructors are more knowledgeable about the content and are cognitively flexible, they can pass on this knowledge to their students more readily.

Abstract: The fundamental ideal that access to education and information as one of our basic human rights must not be neglected in the electronic information age. This ideal however is not being met in the area of postsecondary web accessibility. This study surveyed 350 postsecondary institutions in Canada to see their level of web accessibility using the Centre for Applied Special Technologies accessibility tool, Bobby. It was found that 14.9% of postsecondary institutions surveyed met the priority 1 checks as established by the World Wide Web Consortium (W3C) Web Accessibility Initiative (WAI, 1999), and only 1.7% were free of both priority 1 and priority 2 errors. The specifics of these errors however, reveal that with the recognition of the issues for those with disabilities and the web, they can be easily addressed.

'The power of the Internet is in its universality. Access by everyone regardless of disability is an essential aspect.' - Tim Berners-Lee (WAI, 2001)

The fundamental ideal that access to education and information as one of our basic human rights must not be neglected in the electronic information age. With many facets of our society's information taking a digital form, the Internet has become the primary source of information for many, including those with disabilities. Applications such as the World Wide Web, video conferencing, and email provide disabled people with the potential to participate in, and contribute to, education in a way that would never have been thought possible ten years ago (Booth, et. al, 2000). Many people with disabilities today use a variety of assistive devices to participate in the digital world. Screen readers, Braille embossers, screen magnifiers, and voice recognition technologies give some disabled people the ability to render electronic information accessible. But even with the use of such devices, there is no guarantee that they will be able to access the information. Poorly designed Websites, no matter what assistive device is used, will continue to hinder the user from deciphering and accepting the message and information contained within. Since the end-user cannot count on either standard technology or other enabling devices to ensure access to information on the Web, the onus is on the Web developer to deliver the message in such a way that allows everyone to benefit (Canada, 1998). Approximately 4.2 million Canadians and approximately 7.4% of the post secondary student population have some type of disability; it is mandatory that information on the Web is accessible to them. University and College Web pages serve as the gateway for many student activities such as checking grades and class schedules, even down to the simplest task of finding phone numbers. It is in the best interest of the institution, students, and prospective students, that all information is made available and accessible. This goal however, must at present be an institutional initiative, as the guidelines and laws in this area are yet to be established in Canada.

Canada currently has no laws governing the accessibility of electronic and information technology. Although Section 5 the Canadian Human Rights Act does protect citizens against any discriminatory practice in the provision of goods, service, facilities, or accommodation customarily available to the general public.
There is no federal legislation that governs Web accessibility. There are, however, guidelines established by the Public Service Commission of Canada and the Treasury Board of Canada Secretariat.

The Treasury Board Secretariat, a federal government agency whose mission is to help the Government of Canada manage its human, financial, information and technology resources, established The Common Look and Feel for the Internet (Canada, 2000), a set of standards and guidelines. These guidelines, based on the World Wide Web Consortium (W3C) Web Accessibility Initiative (WAI, 1999), were approved on May 4, 2000 with the goal of having all government Websites meet both priority 1 and priority 2 checkpoints by December 31, 2002.

The Employment Equity Positive Measures Program Directorate of the Public Service Commission of Canada is an independent agency responsible for safeguarding the values of a professional public service: competence, non-partisanship and representativeness. In conjunction with the Adaptive Technology Resource Centre at the University of Toronto, they have developed the Universal Internet Access Project (Adaptive Technology Resource Centre, 1996), which aims to provide information and research on ways to enhance the provision of accessible information on the Internet. The project has created tools for Web site evaluation and guidelines for Web accessibility.

Although Canadian agencies, both are based on the W3C's Web Accessibility Initiative (WAI, 1999) which aims to provide accessibility of the Web through five primary areas of work: technology, guidelines, tools, education and outreach, and research and development (WAI, 2001). The Web Content Accessibility guidelines as recommended by the W3C in May of 1999, have become the defacto standard for the identification and resolution of Web accessibility issues, and serve as the basis for the development and authoring of accessible Web resources. These guidelines also serve as the basis for the post secondary Web accessibility studies and Web accessibility evaluation tools, such as Bobby (Center for Applied Special Technology, 2001).

A number of U.S research studies have been conducted using Bobby as a Web accessibility validation tool. Although these studies range in focus from distance education to library Web information, all found a large gap between the actual and ideal for Web accessibility. The research has shown that the current status of university, library, and distance education Websites are fraught with accessibility obstructions. At the very best, the accessibility figures fall between 30% and 40% (Schmetzke, 1999). In a study that evaluated the accessibility of a random sample of Web pages of 400 prominent colleges and universities in the U.S., Rowland and Smith (2000) found that only 22% had front pages that would receive Bobby approval. In a follow up study by Walden, Rowland and Bohman (2000) the number rose to 24%. In a similar study, Schmetzke (2001) examined the Web pages of 219 post-secondary distance education institutions and found that 15.1% were free of major accessibility errors. The trend continues with 21% accessibility for a study on the accessibility of Web sites of 80 college of communications and schools of journalism (Guthrie 2000), and 27% of 89 special education program homepages (Flowers, Bray and Algozzine, 1999).

These studies show that there is a need for the identification and evaluation of Web accessibility issues at the post secondary level. These types of studies however, are not evident in the evaluation of Canadian post secondary institutions. Therefore, this study evaluates the accessibility of post secondary Canadian institutions top-level or entry level Web pages.

Evaluation tool

Bobby is a free application developed by the Center for Applied Special Technology (CAST) that analyzes Web pages for their accessibility to people with disabilities (CAST, 1998). It analyses Web pages based on the Web Content Accessibility Guidelines 1.0 as proposed by the World Wide Web Consortium's (W3C), Web accessibility initiative (WAI, 1999). Bobby establishes three levels of priority errors based on the checkpoint's impact on accessibility:

- **Priority 1.** Priority 1 errors are those that seriously limit a page's accessibility. Every effort must be made by the developers to ensure that these errors do not exist. Satisfying this checkpoint is a basic requirement for some groups to be able to use Web documents.
- **Priority 2.** Priority 2 errors are those that the Web content developer should satisfy. Otherwise, one or more groups will find it difficult to access information in the document. Satisfying this checkpoint will remove significant barriers to accessing Web documents.
• **Priority 3**. Priority 3 errors are those that a Web content developer may need to address. Otherwise, one or more groups will find it somewhat difficult to access information in the document. Satisfying this checkpoint will improve access to Web documents (WAI, 1999).

Bobby checks for all three priority errors in its evaluation. The number of each priority error in each page is displayed in the tool and the specifics of these errors are displayed in a summary report. There are a number of errors however, that cannot be detected in the automated process. For this, a list of user checks is generated that the user must manually go through while evaluating the site. In order to be recognised as a Bobby "approved site," which is equivalent to WAI Conformance Level A designation, the site must have no priority 1 errors. This includes both priority 1 errors detected by Bobby and the manual user checks. It is highly recommended however, that all Priority 2 checkpoints also be satisfied, when evaluating sites, since WAI Conformance Level AA is now frequently required by U.S government agencies and others (CAST, 2001).

For this study the downloadable version of Bobby 3.2 was used to evaluate the pages and generate a summative report. Priority 1 and Priority 2 errors were summarized for this study.

**Research Methodology**

A list of 357 post-secondary Websites were identified from the Canadian Information Centre for International Credentials (CICIC, 2001). This list, based on information supplied by the ministries and departments responsible for education in Canada, is the only Canada-wide list of all postsecondary institutions recognized by the competent governments in Canada (CICIC, 2001). Seven of these were excluded from the study due to sites under construction, duplicate sites, and those links that were down at the time of the study. Of the remaining 350 sites, 166 are universities and 184 are colleges. Each URL from the list was viewed and the URL was changed if it did not represent the top level information page for the institution. For example, if the site provided a splash page with the option for an English version or French version of the page, the English version was chosen to represent the top level information page.

The list of sites were imported into Bobby for evaluation. Priority errors were evaluated within each site and the summative report was generated. The results from this report were then entered into an Excel spreadsheet for analysis.

While Bobby did identify items that require manual user checks before approval can be granted, most studies of a great number of sites (e.g., Rowland & Smith, 2000; Walden, Rowland & Bohman, 2000) do not perform these manual checks due to the time constraints of evaluating the source code of all these sites. These checks however must be done in order to display Bobby approval.

**Results**

Table 1 summarizes the results of the Bobby examination. Of the 350 post-secondary sites evaluated, Bobby found that only 14.9 % (n=52) of the University and College top-level Web pages were free of priority 1 errors. Within this group only 8.7 % (n=16) of the college Websites and 21.7 % (n=36) of the university Websites were error free.

<table>
<thead>
<tr>
<th>Number of Sites (n=350)</th>
<th>Colleges (n=184)</th>
<th>University (n=166)</th>
<th>Total (n=350)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bobby Approved</td>
<td>16 (8.7%)</td>
<td>36 (21.7%)</td>
<td>52 (14.9%)</td>
</tr>
<tr>
<td>Free of Priority 1 Errors</td>
<td>16 (8.7%)</td>
<td>36 (21.7%)</td>
<td>52 (14.9%)</td>
</tr>
<tr>
<td>Free of Priority 2 Errors</td>
<td>24 (13.0%)</td>
<td>15 (9.0%)</td>
<td>39 (11.1%)</td>
</tr>
<tr>
<td>Free of Both Priority 1 and Priority 2 Errors</td>
<td>3 (1.6%)</td>
<td>3 (1.8%)</td>
<td>6 (1.7%)</td>
</tr>
</tbody>
</table>

Table 1: Canadian Post-Secondary Website Evaluations
The most common Priority 1 errors identified in the evaluation were contained within three categories: images without alternative text 69.4 % (n=243) and image map hot spots without alternative text 19.1% (n=67) and not giving each frame a title 16.9 % (n=59). Other priority 1 errors that were found were, not providing alternative text for applet’s 2.6% (n=9), not providing alternative text for all image-type buttons in forms 1.4% (n=5), and not having each frame referencing an HTML file 0.9% (n=3).

It is also worth noting that only 1.7 % (n=6) out of the 350 sites passed both Priority 1 and Priority 2 errors, which is required to meet the Common Look and Feel for the Internet guidelines (Canada, 2000).

Discussion

The finding that 14.9% of Canadian University and College initial Web pages would be classified as a Bobby approved site, which is equivalent to WAI Conformance Level A standards, is significantly lower than similar to findings for prominent US university and college initial Web pages (Rowland & Smith, 2000; Walden, Rowland & Bohman, 2000). This means that over 75% of college and university sites in North America contain errors that seriously limit their accessibility to the disabled. Universities and colleges recognize that the Web is one of their most important methods of communicating with their potential clientele. One can imagine that a university or college president would be terribly embarrassed if the front page of their site displayed a “broken graphic” image, or contained a broken link. There would undoubtedly be a very sharp message to the University Webmaster that this should be fixed immediately and that it shouldn’t happen again. This is exactly what the disabled person encounters when they encounter a page with a Priority 1 error.

It is unlikely that any organization would intentionally alienate 7% of its clientele. It is more likely that post-secondary administrators and Webmasters are unaware that their Web sites are being read (or not) by the disabled, and what they must do to make them accessible. We charge that a post-secondary initiative be established to raise the awareness and educate administrators and the public about equal access to information. Guidelines for post-secondary institutions should reflect this goal.

Conclusion

Bobby 3.2 was used to examine the accessibility by the disabled of the front pages of the universities and colleges in Canada. Approximately 85% of these pages were found to contain Priority 1 errors and more than 95% contain either Priority 1 or 2 errors. This is totally unacceptable. The Government of Canada has set December 31, 2002 as a goal for having government Websites free of Priority 1 and 2 errors. While it is not mandated, it would appropriate for post-secondary institutions to set a similar goal. While it is likely through ignorance, there is a long way to go before we meet these standards. We need to take action to bring this issue to the attention of senior administrators in University and colleges to raise the awareness and prompt immediate action.

A RDF Implementation Model for Personalized E-Services Composition in Adaptive E-Learning Systems

Xiaokun Zhang and Peter Holt
Centre for Computing and Information Systems, Athabasca University
1 University Drive, Athabasca, AB, Canada, T9S 3A3
E-mails: xiaokunz@athabascau.ca / holt@athabascau.ca

Abstract In this paper, an instruction sequence constrained learning objects composition approach is described and its RDF (Resource Description Framework) implementation model is introduced. Semantically sequential composition of learning objects in the recursive mode is featured at metadata level to allow agent access learning objects automatically in the assigned instruction sequence. The model supplies RDF based dynamic linker to combine learning objects within personalized deployment. Our current implementation is based on Jena API.

Introduction

Term “learning objects” is used by the Learning Technology Standards Committee to define small instructional components, i.e. learning object, as any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning (LOM, 2000). LOM also tries to enable computer agents to automatically and dynamically compose personalized lessons for an individual learner. How to combine instruction sequence design with learning object composition is still an important issue especially when e-learning services are going to be dynamically composed or accessed for agents.

Gagné etc. (1985) refer to the learning conditions as building blocks for instruction since they influence the learning outcomes. In his theory, objects of learning consist of five categories of learning outcomes. With these various types of learning outcome and conditions of learning, there are nine general instructional events to facilitate maximum learning and to support the internal process of learning. Based on Gagné’s theory and point view of software architecture, we proposed a semantically sequential composition model for learning objects to support the capability for dynamically composing learning services. To present multiple granularities of learning objects and instruction processes, the model is recursive as shown in Figure 1 and 2 in which nine steps processes are presented as problem description (PD), objective description (OD), stimulate recall (SR), learning object presentation (LOP), learning guide (LG), doing practice (DP), sending feedback (SF), testing & assessing (TA), and enhance retention and transfer (SRT). There is iterative interaction between LOP and LG to get assigned learning object in the LOP. LOP can be further presented as learning processes (LP) flow in which each LP has similar multiple steps process but at finer granularity level. We believe this kind of recursive pattern presents a generic principle existing in the must of learning process of engineering technology area.
Implementation model in RDF

RDF provides a standard data model for representing machine-readable semantics of information. We use RDF to model instruction sequence logic for the suggested learning process (LP), as shown in Figure 3. In the model, URIs (uniform resources identifiers) of sequential instruction steps such as PD, OD, ERT, and LOP etc are kept in `<rdf:Seq>` container. The iteration between LOP and LG is further modeled in `<rdf:Bag>` container with certain retrieve method to present LG constrained LOP, and this `<rdf:Bag>` container is presented as a resource SOP/LG in the ordered list of resources in `<rdf:Seq>` container. The URIs of learning object such as text, presentation, questions, exam, etc. are kept in `<rdf:Bag>` and `<rdf:Seq>` containers respectively. The learner feature is also attached within `<rdf:Bag>` container to present learner model.

Figure 3 RDF model for the learning processes

The described RDF model of learning process can be used in the several different ways to support adaptive e-learning systems. Our current project intends to use this RDF model for:

- Dynamic virtual linker between learner and learning objects, as shown in Figure 4, or linker between distributed learning objects. The language-oriented RDF query/inferences engine provide basis for semantically driven hyperlink services, and support run-time computation of links and anchors in addition to statically defined links and anchors that defined at authoring time of learning objects. Upon learner profile, dynamic linker may be able to maintain personalized linking configuration to fit individual learner.

- Learning process annotation. Annotation is ability to annotate learning objects and learning process without the need to modify the resource itself. The designed learning process RDF model can be used to allow embedded or external annotation of linker.

- Tracking learning process for learner own using. Track is a way to help learner especially part-time learner's study to keep thinking stream, memory, and reminder, etc. during discrete learning process. Add track sub-model and associated triples based on learning process RDF model can maintain dynamic track record.

- Making learning plan. By retrieve RDF based instruction sequence logic, agent can help to make learning plan or schedule upon available time constraints, workload standard, and assigned due time parameters.

Abstract: Collaborative learning approach is one of the most considerable methods which can be used in computer-mediated learning environment, and an important element in this approach is peer modeling, which aims to resolve how to simulate collaborative learning process and to get high performance for students. Some factors should be utilized to build peer model, e.g., knowledge structure, cognitive and behavioral styles, and physiological elements, etc. Among these factors, according to our experiences, knowledge structure is a significant factor due to it represents the learning and instructional objective. In this paper, an effective method about how to build peer model based on the knowledge structure of Chinese Reading in web-based intelligent collaborative learning environment was mainly introduced.

Introduction

Peer model is a core element of the small learning group to construct the web-based collaborative learning environment, which can be considered as a virtual real learner. The different purpose of peer model can be found in intelligent tutoring system (ITS) environment is to facilitate individual learning performance and in web-based collaborative learning environment is to promote individual and collectivity development and to enhance peers’ interaction. The term peer model comes from student model, and they are the similar concept. When students are organized into different learning teams to work together and to pursue a common goal, the individual can be called peer.

Some examples about various practical and efficient methods and approaches to build peer model in web-based environment can easily be found, e.g. Kumar and et al. (1995) observes artificial intelligent technology in CALL and discusses some techniques about diagnosis. Eliot (1997) constructs a web-based intelligent tutor which requires information about what student has and has not learnt. M. K. Stern (1997) states that the difficulties in web-based tutoring and some possible solutions. According to his opinion, a tutoring system must have function about recording student actions and make decisions based on these actions. There are some elements should be involved in peer model, e.g. knowledge structure, cognitive styles, behavioral factors, and physiological elements. One of the most important elements is expert's knowledge structure, which can be considered as knowledge point. Our past works focus on how to build and realize knowledge-based student model, which already get a significant achievement and can be considered as a general approach to build peer model (Zhao, J. H., 1997).

When artificial intelligent technology was integrated into collaborative learning electronic system, its efficiency and flexibility must be enhanced. Some emerging issues in this area already have been explored, e.g. intelligent pedagogical agent, student models, tutor models, diagnosis strategies, and knowledge intelligent representation. CITS (Collaborative Intelligent Tutoring System) provides an environment in which the student can interact with one or more, simulated collaborative partners and/or fellow students, to progress towards a common goal of learning (Kumar, V. S., 1992). GSS (Group Support Systems) is a set of techniques, software and technology designed to focus and enhance the communication, deliberations, and decision making of groups. In GSS, software intelligent agent which can facilitate and streamline group problem solving in organizations is applied (Jay F. Nunamaker Jr, 1997; Sen, S. and et al., 1997). Brna, P. & Burton, M. (1997) describes modeling students collaborating while learning about energy, which has the
potential for providing better computer-based support in the future – both in respect of providing improved quality dialogues and in terms of comprehending the student’s activities. K. Miyahara and T. Okamoto (1998) studies how to develop information filtering system, which gathers, classifies, stores various kinds of information found on the Internet. According to our experiences, intelligent technology can be used to enhance the quality of web-based collaborative learning, e.g. flexible, efficient, and suitable and to facilitate students learning. Peer model is a core component for this purpose to utilize intelligent technology into instructional and learning system. In web-based intelligent collaborative learning system (WebICL), peer model can be used to decision-making, search, find, and utilize the precise instructional strategies in terms of different learner’s learning status and to evaluate peer’s performance.

Knowledge-Based Peer Modeling

Knowledge-based peer model means how to integrate learning knowledge into intelligent tutoring system to build peer model. In intelligent tutoring system, peer’s behavior includes a lot of knowledge processing variables, which can be used to express student’s learning status. The process of building knowledge-based peer model includes four stages.

Stage One: Core Factors of Web-Based Collaborative Learning

Some methods can be utilized to find the factor variables which related to simulate peer model, e.g. literature research, documentaries research, questionnaire, and case study. According to our experience, all of them can be used to collect research data very well. According to our questionnaire research result, core factors of web-based collaborative learning system can be clarified into four levels, which the first level is learning approach level and involves group composition, task features, communication media, conflict identification, conflict resolution, role playing, and collaborative communication skills (Foote, E., 1996); the second level is personal information level, which involves gender, age, region, grade, ethnic, and year-in-school; the third level is peer’s cognitive structure level, which involves cognitive styles, behavior styles, previous academic performance, and IQ; the fourth level is curriculum knowledge level, which involves knowledge structure, knowledge points, hierarchy of knowledge points, and knowledge categories. All of these factors in different levels can be used to build peer model. As states above, learning knowledge is an important element to build peer, so it can be considered as the umbrella (Zhao, J. H., 1997).

Stage Two: Discipline Knowledge Elements for Language Learning

A peer modeling approach was developed to simulate knowledge-based peer model, which the core factors of course content can be got from questionnaire and factor-analysis. The different weights should be assigned to each factor in terms of the result of data analysis. This modeling method can be considered as a common approach to build peer model based on different learning materials (J. H. Zhao, 1997). Dr. Mo lei describes his research result about Chinese reading for grade six in table 1 (Mo lei, 1989).

| Table 1: Chinese Reading Ability for Primary Students in Grade Six |
|----------------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
|                      | Language Ability | Organizing Ability | Pattern Recognition Ability | Filtration and Store Ability | Language Sensation Ability | Transferred Ability |
| Weights              | .375            | .249            | .128            | .119            | .069            | .060            |

Students in different grade will learn different knowledge, our research addressed in grade three, so we should amend the data described in table 1 to match grade three. The questionnaire is also used to do this work and the amended result can be described in table 2. Comparing the weights in table 1 and table 2, the different weights and the significance for each factor can be clearly clarified.

Stage Three: Basic Static Knowledge Peer Modeling

Based on the factors’ weight in table 2, the basic static knowledge peer model can be formulated as

\[
G = \begin{pmatrix} 0.421 & 0.256 & 0.064 & 0.13 & 0.061 & 0.066 \\ \end{pmatrix}
\]

Where \( G \) is the objective weight matrix.
When peer register to the WebICL system, he/she will be provided a pretest opportunity. The points of each learning objective will be calculated and the pretest evaluation matrix will be expressed as

\[ P = (s_1 \ s_2 \ s_3 \ s_4 \ s_5 \ s_6) \]

Where \( P \) is the score matrix for peer and \( s \) is score that he/she got from each question; \( s_i \) is the score for each learning objective; \( i = 1,2,3,... 6 \).

\( P \)'s Regression result can be expressed as

\[ P = (s_1/t_1 \ s_2/t_2 \ s_3/t_3 \ s_4/t_4 \ s_5/t_5 \ s_6/t_6) \]

Where \( t \) is the mark of each question; \( t = 1,2,3,... 6 \).

Table 2: Chinese Reading Ability Structure for Primary Students in Grade three

<table>
<thead>
<tr>
<th>Ability Structure</th>
<th>Language Decoding Ability</th>
<th>Organizing Coherence Ability</th>
<th>Pattern Recognition Ability</th>
<th>Filtration and Store Ability</th>
<th>Language Sensation Ability</th>
<th>Transferred Ability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>.421</td>
<td>.256</td>
<td>.064</td>
<td>.130</td>
<td>.061</td>
<td>.066</td>
</tr>
</tbody>
</table>

The evaluation result for each peer can be got from fuzzy evaluation method and can be expressed as

\[ \tilde{A} = G \cdot P \]

Where \( A \) represents that each student's synthetical fuzzy evaluation result.

**Stage Four: Dynamic Knowledge Peer Modeling**

Dynamic knowledge peer model can be simulated based on the basic static knowledge peer model in WebICL system. Tutor and system will monitor peer's behaviors when peer mates start to discuss or negotiate each other in learning group. The system can record and save the group and peer's learning history record. When they finish one topic, tutor will assign the average score to each peer in the same learning group based on the result of intergroup evaluation or other similar approaches. In order to getting the peer's score and the peer performance points, peer should attend the individual formative examination. When the peers are taking a formative examination, two elements will be concerned, which are peer's performance score and the time of peer resolving question which will influence peer's performance score. To get this score about student resolving question, the following strategies will be used (Zhao J. Hua, 1997).

\[
\text{Score}_{-i} = \begin{cases} 
\text{score/times} & \text{times } \leq n \\
0 & \text{times } > n
\end{cases}
\]

Where \( \text{times} \) is peer to try times to resolve the question; \( \text{score} \) is each question's marks; \( \text{Score}_{-i} \) is the student's factual score of each question.

The time which peer resolving each question spends also influences the peer-performance's score. The following strategies can be adopted (Zhao J. Hua, 1997).

\[
\text{Score}_{-i} = \begin{cases} 
[1 + (\text{spend} - \text{spent})/\text{spend}] \cdot \text{score/times} & \text{times } \leq n \\
0 & \text{times } > n \text{ or } \text{spend } > 2\text{spend}
\end{cases}
\]

Where \( \text{spend} \) is the average response time (time limitation for problem-solving); \( \text{spent} \) is the factual time which peer spends to resolve question; \( \text{times}=1,2,3... n \).

The data of static knowledge peer model will be modified when peer finishes the formative examination, and then the dynamic knowledge peer model can be formulated based on the result of fuzzy evaluation. Each item in different test will be organized based on the learning objective by tutor. Peer can get the different evaluation score when he/she answers the different questions and one score matrix will be built. The matrix B can be described as follows.

\[
B = \begin{bmatrix}
\ s_{11} & s_{12} & s_{13} & s_{14} & s_{15} & s_{16} \\
\ s_{21} & s_{22} & s_{23} & s_{24} & s_{25} & s_{26} \\
\ s_{31} & s_{32} & s_{33} & s_{34} & s_{35} & s_{36} \\
\ s_{41} & s_{42} & s_{43} & s_{44} & s_{45} & s_{46} \\
\ s_{51} & s_{52} & s_{53} & s_{54} & s_{55} & s_{56} \\
\ s_{61} & s_{62} & s_{63} & s_{64} & s_{65} & s_{66}
\end{bmatrix}
\]
Where $B$ is score matrix of peer, $s_{ij}$ is each score for different objective; $i = 0, 2, 3, \ldots 6$; $j = 1, 2, 3, \ldots 6$.

Peer knowledge dynamic model can be formulated as follows, which it indicates the status of peer's knowledge which already learnt based on different learning objective.

\[
A = G \cdot B
\]

\[
= \begin{bmatrix}
s_{11} & s_{12} & s_{13} & s_{14} & s_{15} & s_{16} \\
s_{21} & s_{22} & s_{23} & s_{24} & s_{25} & s_{26} \\
s_{31} & s_{32} & s_{33} & s_{34} & s_{35} & s_{36} \\
s_{41} & s_{42} & s_{43} & s_{44} & s_{45} & s_{46} \\
s_{51} & s_{52} & s_{53} & s_{54} & s_{55} & s_{56} \\
s_{61} & s_{62} & s_{63} & s_{64} & s_{65} & s_{66}
\end{bmatrix}
\]

Where $A$ is the result of fuzzy evaluation which represents the dynamic knowledge peer model.

The main feature of dynamic knowledge peer model is that its data will be modified and updated in terms of the learning objective. The score which assigned to dynamic peer model can be considered as one of the components of peer’s learning performance which is the average score of group’s learning performance.

**Peer Modeling in WebICL**

Peer model in WebICL involves two kinds which is general peer model and virtual peer model which can be considered as peer agent.

**General Peer Model**

General peer model in WebICL represents the status of student who registered (logged) in the system. Five basic elements are involved in the general peer model, which they are gender, former learning performance, IQ, and cognitive style. The general peer model can be simulated in terms of these five elements, which it can be described as one-dimension matrix.

\[
GPM = (iG \ A \ iQ \ iCS)
\]

Where $GPM$ means general peer model, $iG$ means gender, $A$ means student learning performance which was introduced above formula (1) and (2), $iQ$ means student’s IQ, and $iCS$ means cognitive style. The value of IQ and cognitive style can be got before collaborative learning in web-based environment through psychological survey. $A$ is the result of fuzzy evaluation to student. Three elements are the permanent variables, which they are $iG$, $iQ$, and $iCS$. The result of $iG$ can be got in term of peer’s personal registered form; $iQ$ and $iCS$ can be got through psychological survey. The result of $iCS$ mainly used field-dependent and field-independent style field survey and it can be got before peers start collaborative learning process.

**Virtual Peer Model (Peer Agent)**

Virtual peer model (VPM) can be organized into the same group with general peer model if the number of peer cannot reach the group size. VPM includes three components, which they are knowledge database, strategies database, and deducing mechanism. The virtual peer model can be described as figure 1.
Knowledge Database

Knowledge database provides knowledge support for virtual peer agent, which is similar with knowledge database in WebICL. Especially, it is more related to learning task. The structure of knowledge database for peer agent includes five elements, which they are knowledge number, knowledge types, knowledge content, question and answer, and grade level, which knowledge number means knowledge record number in knowledge database, knowledge types means the types of discipline and task, knowledge content is used to record learning content, question and answer represents learning question and its normal answer, and grade level represents which grade level of learning task.

\[ KD = (Kn \ Kt \ Kc \ Qa \ Gl) \]

Which \( Kn \) represents knowledge number, \( Kt \) means knowledge types, \( Kc \) is knowledge content, \( Qa \) means question and answer, and \( Gl \) is grade level.

\[ Kt = (a \ b \ c) \]

Where \( a = 1, 2, \ldots, n \) means discipline, \( b = 1, 2, \ldots, n \) means task, and \( c = 1, 2, \ldots, n \) means difficult level.

\[ Kc = (d \ e \ f) \]

Where \( d = 1, 2, \ldots, n \) means content number, \( e = 1, 2, \ldots, n \) means content index number, and \( f = 1, 2, \ldots, n \) means learning content showed times.

\[ Qa = (g \ h \ i \ j \ k) \]

Where \( g = 1, 2, \ldots, n \) means the number of question, \( h = 1, 2, \ldots, n \) means the number of answer, \( i = 1, 2, \ldots, n \) means the difficult level of question, \( j = 1, 2, \ldots, n \) means the question showed times, and \( k = 1, 2, \ldots, n \) means the index number of question.

\[ Gl = (m \ q) \]

Where \( m = 1, 2, \ldots, n \) means educational level (primary school, junior school, senior school, etc), and \( q = 1, 2, \ldots, n \) means grade level.

Strategies Database

Some strategies about how to build the virtual peer model based on the on-line peer's situation in the WebICL system and organize them into different learning group. There are five elements are included in the strategies, which they are strategy index number, performance level, role-playing, peer number, and role gender.

\[ SD = (Si \ PI \ Rp \ Pn \ Rg) \]

Where \( Si \) means strategy index number, \( PI \) represents performance level, \( Rp \) is role-playing, \( Pn \) means peer number, and \( Rg \) means the status of role gender.

\[ Si = 1, 2, \ldots, n \]

\[ PI = (Hi \ Mi \ Lo) \]

Where \( Hi \) means high level, \( Mi \) means middle level, and \( Lo \) means lower level.

\[ Rp = 1, 2, \ldots, 18 \]

The value of \( Rp \) represents different role in learning group, which it can be described as table 3 (Donelson R. Forsyth).

<table>
<thead>
<tr>
<th>Index Number</th>
<th>Role-playing</th>
<th>Index Number</th>
<th>Role-playing</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Initiator/Contributor</td>
<td>10</td>
<td>Energizer</td>
</tr>
<tr>
<td>2</td>
<td>Information Seeker</td>
<td>11</td>
<td>Encourager</td>
</tr>
<tr>
<td>3</td>
<td>Opinion Seeker</td>
<td>12</td>
<td>Compromiser</td>
</tr>
<tr>
<td>4</td>
<td>Information Giver</td>
<td>13</td>
<td>Gatekeeper and Expediter</td>
</tr>
<tr>
<td>5</td>
<td>Opinion Giver</td>
<td>14</td>
<td>Standard Setter</td>
</tr>
<tr>
<td>6</td>
<td>Elaborator</td>
<td>15</td>
<td>Group Observer and Commentator</td>
</tr>
<tr>
<td>7</td>
<td>Coordinator</td>
<td>16</td>
<td>Follower</td>
</tr>
<tr>
<td>8</td>
<td>Orientor</td>
<td>17</td>
<td>Recorder</td>
</tr>
<tr>
<td>9</td>
<td>Evaluator/Critic</td>
<td>18</td>
<td>Procedural Technician</td>
</tr>
</tbody>
</table>
Pn = 1, 2, 3, 4

The value of Pn means the peer number in learning group.

Rg = 1, 2

Where Rg = 1 means peer is male and Rg = 2 means peer is female.

**Reasoning Mechanism**

Reasoning mechanism is the representative of expression and discriminant. The virtual peer model will be formed based on its reasoning result. The condition-decision is the formal approach to realize the reasoning mechanism. The basic decision norm is rules that it defines an applied framework. There are various rules can be used to make reasoning decision. One of the examples is as follows.

If <group_number less than three> Then

Case 1 if group_number=2 then <compare the differentiation of real peer and determine the VPM >
Case 2 if group_number=1 then < determine other two VPM based on the peer’s situation>

**Conclusions**

According to our study, peer model can be used to design and build web-based collaborative learning system and enhance its flexibility and adaptability. Peer modeling should be built in terms of the peer’s personal characteristic and learning content of curriculum knowledge. When the number of peer’s login is less than the necessary number of one group, WebICL system should simulate virtual peer according to the actual on-line peer. Peer model is an important approach to utilize intelligent technology into web-based collaborative learning system.

Understanding the social context for online learning

Melanie Zibit
Boston College
Chestnut Hill, MA 02467
Goldmame@bc.edu

The world of online learning is fascinating and so different from face to face. What are its characteristics? What kind of learning works best in these environments? And how do you take advantage of these characteristics when you are designing your online curriculum?

An online learning environment works most effectively to facilitate the examination of issues from multiple perspectives. People can take time to read, reflect, and respond. This gives a participant a sense of security to say what she really means. The combination of a certain anonymity coupled with a sense of connectedness allows people to open up and take risks to express their thoughts even in areas they are just learning. The environment motivates people to think rather than to take a fixed position - divergence rather than convergence (Zuboff, 1984).

Mathemagica, a five-year mathematics initiative funded by the Department of Education Star Schools initiative, is developing an innovative model for online professional development for K-8 math teachers. Our online professional development philosophy is captured in a statement from the NCTM discourse standards, "When teachers make public conjectures and reason with others about mathematics, ideas and knowledge are developed collaboratively, revealing mathematics as constructed by human beings within an intellectual community." One component of the professional development is rich multimedia math applets that empower both teachers and students to investigate mathematical topics. For example, one series will allow students to experiment with (and even invent) computational algorithms using base ten blocks, arrays, and number lines. Another component is a sequence of mathematical investigations using the applets combined with readings and reflective tasks that teachers work on collaboratively in teams of 8 facilitated by a moderator. The applets and professional development are being piloted with 50 teachers who have a wide range of skill in technology and inquiry math practice.

This paper and presentation will describe the design of an online learning environment used with teachers in a math professional development project. The model builds upon key understandings about the social dynamics of online learning. The session will include key characteristics and strategies as well as several vignettes that demonstrate the model's effectiveness.

MoBy: Modular Multiple Media Course Content for On-Line Courses

Harry R. Matthews and Lisa Wilson, IET Mediaworks, UC Davis

Abstract
The MoBy interactive content delivery system addresses the problem of providing complex, well-integrated, multiple media course materials on-line, in a form that is maintainable by content experts, and with a process that is scalable.

The system is delivering content, testing, and tracking in courses as diverse as Chemistry pre- and post-laboratory materials, Arts of Asia, Anthropology, Winemaking, and others. The Andrew W. Mellon Foundation has funded detailed evaluation of the cost-effectiveness of the system that is also being used for research on student profiling and learning styles.

Introduction
MoBy is a development of a system prototyped with a biochemistry course in 1997 and 1998 (...) and demonstrated at an Internet2 conference and the showcase of an EduCause annual meeting (...). MoBy differs from commercially available learning management systems in the full integration of varied multiple media as the natural presentation and interactive modes of learning on-line thereby enriching the learning process.

Design principles
The fundamental design principle is modularity and flexibility within a common framework. This is achieved by combining both the content and its method of display within a single object, the content module or learning object.

The second design goal is control by the content expert. The modularity of the learning objects allows the content expert to rearrange and re-use modules without any restrictions or code changes.

The third design goal is to integrate MoBy with the campus portal that handles course management chores including student registration and grade calculations and reporting.

Implementation
Implementation is based on the three design principles: learning objects; editing by content experts; and integration with course management.

Learning objects, organization and structure
A content module, also called a learning object, is a record in the database table called Module. The Module Table is part of a hierarchy of relational tables. The tables above the Module Table in the hierarchy contain information that is used to organize the modules into lectures and courses. The tables below the Module Table in the hierarchy contain information about the data and files that comprise the content of the module.

Editing by content experts
The content may be in any form that can be displayed by a Web browser. Two strategies are used to broaden the range of tasks accessible to a technically unsophisticated content provider. The first strategy involves building the Flash animations using templates that draw their content from database tables. The second strategy is intrinsic to the object-based approach. Content modules can be rearranged, added, deleted, and re-used by making changes to the database contents, which again is achieved through the use of HTML forms that a content provider can easily use.

Integration with course management
MoBy needs to be aware of which students are registered in each course, for tracking purposes and for password-protection of course materials that are governed by copyright fair use or intellectual property restrictions. Registration information resides in a central student information system (SCT BANNER) and is accessed by faculty members and students through a custom portal known as MyUCDavis. Access to this information requires authentication and authorization. Authentication is handled by a separate enterprise-level Kerberos system and authorization is controlled by MyUCDavis using information in the student information system.
Examples of Use

MoBy is used in several undergraduate courses at both lower and upper division level and in a professional school course. These courses include Chemistry pre- and post-laboratory materials, Arts of Asia, Anthropology, Winemaking, Introduction to Biology, Food Science & Technology, Molecular & Cell Biology, and additional courses planned for Winter 2002.

The primary driving force for the use of MoBy at UC Davis is the urgent need to accommodate rising student enrollments, together with a determination that the quality of student education should not suffer in spite of enrollments rising faster than physical facilities can accommodate. The costs and educational effectiveness is being studied with the help of a grant from the Andrew W. Mellon Foundation.

Conclusions

The use of learning objects allows seamless integration of multiple media into course delivery. This allows authors to concentrate on using the best media for each concept or example without the need to embed it in an HTML page and with complete transparency to the user. The learning objects can be easily rearranged and re-used because they contain both the data and the method of display. Eventually, it will be possible to exchange learning objects between systems, allowing the construction of courses using the best available objects from disparate authors.
The Virtual Platform SENEKA - A knowledge management network tool

Dr. Phil. Regina Oertel, Georg Schoeler

Abstract

The Virtual Platform SENEKA - information, communication and knowledge management system of the SENEKA project - is in every-day use since July 2000. Here about 30 partners of the research project get the latest news about meetings, project data, conferences or information with relevance to the research community. The business processes hold up on the Virtual Platform SENEKA via email, document sharing or discussions. Thus, in using the Virtual Platform SENEKA the project participants are able to enlarge their knowledge and learn to integrate information and communication technologies in their daily work. By these means the Virtual Platform SENEKA supports the idea of "lifelong learning".

Introduction to SENEKA

SENEKA is a large scale entrepreneurial and research project supported by the German Federal Ministry of Research and Education focussing on knowledge management, learning and networking. The project's aim is to enhance the management of information and knowledge as well as to reinforce its usability in innovation processes within small and medium-sized enterprises. To achieve this aim 26 – small and medium-sized as well as multi-national – enterprises in co-operation with 6 research institutions work together in a vivid network. The project started in 1999 and will last until 2004; the total financial volume adds up to about 20 million Euro.

The Virtual Platform SENEKA

The Virtual Platform SENEKA is the web based information, communication and knowledge management system of the SENEKA project. It was designed during the first half of the year 2000 and is in full operation since July 2000. By now the platform is widely utilized by the project participants. It supports the project internal information and communication with the concept of shared working spaces for the different project units. The project partners are able to upload and categorize documents of general interest, inform co-workers automatically or manually via email, start discussions on the new content, manage project meetings with special appointment folders and, of course, search and download documents of their special concern. This features list shows that the platform works an integration of different IT support systems. There are aspects of content management system and data management systems as well as project management systems. Moreover, as in the internet, communities can be established on certain topic fields.

The necessity of a Virtual Platform

As mentioned above, SENEKA is a large industry and research project with a very heterogeneous national and multinational partner structure. Already at the start of the project in the year 1999 following reasons showed the necessity to develop a web-based IT-system. Because of the organizational conditions in the co-operation of such different partners, which work on different topics and in different parts of the country. The partner structure represents a
cross section of completely different habits in the use of IT tools. This lead to the idea to take the project network as experimentation and evaluation field for such a knowledge management tool. The focus of the project belongs to knowledge management, networking and competency development as central topics in SENEKA. On this background it is necesary to develop best practice solutions which represent an optimal interlink of real and virtual knowledge transfer processes.

Thus the Virtual Platform SENEKA has a double function in the SENEKA project: It is at the same time tool for the project and also product of the project. It directs to support and organize the knowledge-oriented working processes between heterogeneous senders and recipients by accentuated IT application. Virtuality – as the idea to work and learn independently of time and space – here offers the possibility of dealing with the increasing complexity of information and communication.

Authors & contact
Dr. phil R. Oertel is project manager of BMBF-project SENEKA and works at ZLW/IMA of RWTH Aachen. Dipl.-Ing. G. Schoeler works at the same institute and is entrusted with the scientific co-ordination of the project and the development of the Virtual Platform. For general information on SENEKA, please look up http://www.seneka.de. For further information on the Virtual Platform SENEKA, please contact schoeler@zlw-imas.rwth-aachen.de.
Weaving the Web for all: Creating institutional policy to support Web access for those with disabilities

Cyndi Rowland, Ph.D.

Overview

Postsecondary institutions must insure that their Web sites can be accessed by those who have disabilities (i.e., faculty, staff, and students). Creating institutional policy and a climate for coordination and reform can be a difficult task. This presentation will begin where reform efforts must begin, with an understanding of the problem. Several multimedia simulations will be presented to enable participants to understand what happens when designers do not keep web accessibility in mind as they build out a site. Following this, participants will hear about an 8-point model for institutional coordination of Web accessibility. This presentation is important because many participants of Ed. Media have long been the technologic elite on their own campuses. When these participants return from this conference session they will have practical knowledge regarding Web accessibility. They can then share what they know with administrators and colleagues and thus help their institution begin the work of Web accessibility coordination and reform.

An UnderstandingOf The Problem?

The latest census figures indicate that approximately 59 million Americans have disabilities. Clearly all of those individuals do not use the Web nor are they all blocked from the Web because of their disability status. Reports do indicate that at least 4 million individuals with disabilities ages 16 and older report that they use the Web. However, it may be impossible to determine how many do not use the Web because they cannot gain consistent access, or how many use the Web inconsistently because of accessibility problems. No matter the exact number, we know that there are millions of individuals in the U.S. alone that cannot freely use the Internet because of inaccessible designs.

Empirical investigations on the accessibility of the Internet are relatively new, and current studies are complicated by the use of dependent measures that produce both false positives and false negatives. With this said, there exists a surprising constancy of summary data. As a general statement, less than 25% of Internet pages sampled in the literature are accessible to those with disabilities.

This is a horrendous statement considering the fact that few individuals go to a specific page. If you were to search the Web and could not fully access 3 of every 4 pages, how successful would you be?

Who are these individuals that are affected by inaccessible designs? The range of disability types is wide and represent persons with challenges in vision and/or hearing, motor skills, cognitive skills, and seizure disorders, as well as age-related processes. It is important to remember all of these distinct groups. Often Web developers address the accessibility needs of only one or two groups. The group most typically discussed is the blind. It helps to understand the experiences of all groups of individuals with disabilities. The following provides a peek into their use of assistive technologies, the problems they can experience using the Web, and thoughts for designers who wish to consider the needs of these individuals.

- Vision impairments—Web design can affect three categories of individuals with visual problems. Those include individuals who are blind, have low vision, or experience color blindness.

- Those who are totally blind typically surf the Web through the use of a screen reader (packages include JAWS, Window Eyes, and HomePage Reader). The reader provides voice output that essentially "reads" what is on the screen, although it is really reading the code behind what is seen. When images or elements appear that do not have alternative text placed in the code, the reader defaults to reading anything it can find, such terms as image or graphic or a file name or even a number or coordinate grabbed remotely from the server. Sometimes the reader skips elements of a page entirely, since it cannot detect that anything is there. The presence of alternative text (ALT tags in HTML code) is particularly important if the images happen to be navigation buttons. Imagine the frustration of an individual who's encountered a page for the University of the Anarctic that the screen reader reads as Welcome, choose what information is important to you today, image1.gif, image2.gif, image3.gif, image4.gif, image5.gif. Look at the code and see what the screen reader must try to interpret:

```html
<title> University of the Anarctic</title>
<map name="Welcome, choose what information is important to you today">
<area shape="rect" coords="509,43,565,62" href="image1.gif">
<area shape="rect" coords="428,45,505,62" href="image2.gif">
```
There are many individuals who are cognitively impaired. Cognitive impairments and learning disabilities may lead to difficulties in understanding and remembering information. For example, individuals with attention deficit hyperactivity disorder (ADHD) may have trouble staying focused on tasks, while those with dyslexia may have difficulty with reading and spelling.

Motor skill impairments are another common issue. Individuals with cerebral palsy may have limited movement and coordination, making it difficult to use a mouse or keyboard. Those with spina bifida may also have trouble using these devices. Some individuals may need to use assistive technologies such as speech recognition software or special keyboards to access the Web.

Hearing impairments can also pose challenges. Many people who are deaf or hard of hearing use sign language or other forms of communication. This can make it difficult to understand audio content on the Web. Some individuals may also have trouble understanding captions or transcripts.

Vision impairments are also a common problem. Those who are blind or have low vision may need to rely on screen readers or Braille displays to access the Web. Some individuals may also have difficulty reading text due to poor lighting or other factors.

Motor Skill Impairments
The range of individuals considered to have motor impairments is great. Those with quadriplegia will require an alternative way to get commands into the computer (including devices such as voice recognition and/or switch access) since they are unable to use the keyboard. Those with cerebral palsy may have problems with accuracy of mouse or keyboard access. Some individuals with neurologic conditions can experience extreme fatigue or tremors, affecting mouse or keyboard use. For any of these conditions the designer must understand issues of accuracy (for instance, how small to make the hit box around a navigation link), and fatigue (if an individual can only move from one link to the next by pressing the Tab key, how many times must it be hit to get through the site). Understanding how these individuals experience the Web will go a long way toward fixing potential problems that can keep individuals with motor impairments out of your site.

Experience it yourself: Go to Experience it yourself: Go to

Cognitive Impairments and Learning Disabilities—There are many individuals who are cognitively impaired.
(developmentally delayed or have a traumatic brain injury) who would like to use the Web. Moreover, there are millions of individuals with learning disabilities (which are not cognitive impairments) who experience difficulties with Web sites. The most salient problems experienced by both groups of users are their inability to synthesize complex information quickly and their inability to adapt to inconsistent interfaces. It is very likely that a designer who works hard to attend to usability in design will also accommodate this group of users.

Experience it yourself: Although this is not really a simulation of having a cognitive impairment, go to . This simulates having multiple task demands simultaneously. The “hard” version simulates what it is like to have an inconsistent interface. Often, those with cognitive disabilities express that the Web is too much to process at one time. See how you do in a task overload situation.

Seizure Disorders—Some individuals have a particular type of epilepsy called photoepilepsy. Seizures can be induced if these persons encounter information that is blinking at a rate from greater than 2 cycles per second to 55 cycles per second. Blinking content is discouraged for this reason. If the designer insists on using it, setting the blink or flash rate to under 2 cycles or greater than 55 cycles can avoid triggering seizures. It also helps to reduce the size of any necessary blinking material.

Experience it yourself: Go to any irritating blinking ad to see this (e.g., http://webaim.org/training2002/week1/seizuregraphic) Please do not view these if you have photoepilepsy

Age Related Processes—The largest growing segment of our population is the elderly. As we age, we will likely continue to enjoy the use of the Web. The aging process includes many of the disability types described above. For many of us, we will progressively lose vision, hearing, or motor skills. To the extent that we work to fix the problem of Web inaccessibility, we will work to continue our own Internet enjoyment for years to come.

An 8-Point Process for Coordination and Reform

The Use of the Web in Postsecondary Education

The winds of change have blown over postsecondary education. As Internet technologies transform our educational experiences, so these technologies create a wide chasm. There is a very real divide between students who do and do not have access to the Internet in education today. As our nation grapples with issues of physical access to hardware, software, the Web, and a National Information Infrastructure, decision-makers must be mindful of those with different issues of access. These individuals are those with disabilities and their issues of access are related to the environment of the Internet today.

Postsecondary entities, like the rest of our society, use the Internet more and more for the things that they do everyday. The rapid rise in the use of the Internet as well as the functions of pages within sites grow each day. Today if you were to go to almost any institutional site, you would find that students could at least do the following:

- get information about required courses,
- register for courses,
- look up transcripts,
- order books,
- pay for educational expenses with a credit card,
- take online courses,
- gain access to Web-enhanced courses,
- complete Web-based assignments,
- meet others in virtual student lounges,
- conduct research from library holdings or the Internet,
- take tests online (e.g., MAT), and
- get information from Web-based kiosks about social and community events and issues.

Each day students can find new ways to interact with their education provider as new functions are added to sites. It is clear that the Web is seen as a central element in postsecondary education. So much so that many institutions are dedicating enormous resources to keep up with the advantages that technology holds for students. This access is viewed as desirable, if not necessary, for students to succeed in their educational endeavors and participate in the digital community that has emerged. However, population of students with disabilities are being increasingly shut out of these opportunities.

When institutional sites are not accessible we harm students with disabilities in at least 2 ways. First, they may not have an educational experience that is equivalent to their non-disabled peers. Second, they loose out on
opportunities to learn how to efficiently gather Web-based information. It becomes a tail-chasing phenomenon where lack of access reduces skill acumen and fledgling skills further reduce access. In our grandmother's words; "practice makes perfect". Students without opportunities to practice cannot be as prepared to meet their future, one that will include the Internet. The potential failure of postsecondary education would be that systems are not created or sustained to help students with disabilities participate in the Web-based society that is growing with each day.

So what can be done about this important issue? The only way to really get the job done is for institutions of higher education to engage in a system-change effort where they are dedicated to coordination and reform of their Web site.

Institutional Reform Efforts and the Future of Accessibility

On the topic of producing a campus-wide plan of institutional reform, Cynthia Waddell stated, "Just as a removal of architectural barriers requires a plan for implementation, the removal of technological or digital barriers in programs and services requires a comprehensive institutional plan impacting every campus office." (The Growing Digital Divide in Access for People with Disabilities, 2000)

There are many elements to the future success of postsecondary access. The most salient would be (a) commitment, (b) action, and (c) an eye toward new technology solutions. Postsecondary entities must begin to grapple with current inequities and federal mandates. Institutional commitment and coordination will go a long way toward reforming the present crisis. The institutional "actions" that are taken will show the commitment that is present. These actions must include all stakeholder groups: students, faculty, Web designers, departmental units, administrators. Action plans should be created with input from all and should articulate change in small, measurable steps that are place along a reasonable timeline. Systems that include multiple points for input in the process will be more likely to succeed over time.

Principles of Institutional Reform

Institutional reform is not a simple process, but a very complex one whose scope and importance are increasing with the growth of the Internet's use. Before moving on to explaining the specific steps of the process of institutional reform, it is valuable to keep in mind a few key principles.

Principle 1. Understanding the Problem

Always in take into account the size of the problem by taking into account the size of your institution. It is certainly easier to coordinate the actions of 10 individuals than 1,000. Moreover, it is easier to insure coordination across 15 units than 150. Size does matter in coordination and reform efforts in postsecondary education. This is not unlike any corporate environment that struggles to support, monitor, and ultimately comply with internal policies or federal regulations. As you progress through each step of the process, remember that the size of your university may affect decision-making and action.

Principle 2. Understanding the Process

Due to the complexity of the issue of Web accessibility, it requires a solid commitment to the process in terms of people, time, money and facilities. Resources committed by a postsecondary entity also factor into the complexity of the problem. Entities that can appoint someone to chair an accessibility committee as part of their role assignment (e.g., half time for the first year) will do better with Web accessibility than those that cannot.

Also, postsecondary entities that use their resources to create a stable environment for Web development staff will have a better chance delivering accessible sites across the institution. Training and support in accessible design for Web developers are two important elements of this. Salary and career incentives for technical development personnel to stay in postsecondary education are others. Over 1,400 Web masters in postsecondary education were electronically surveyed by WebAIM staff in 2000. Of the 536 response (representing a 38% response rate), most had been in their current position for only 2 years. Just over half of the sample (54%) indicated Web design as their full-time responsibility. Sixty-two percent (n=334) reported that they had learned about at least some aspect of accessibility; most (n=300) reported that they did so on their own and not during any pre-service or inservice training. It is likely that frequent changes in Web personnel would have a negative affect on the accessibility of sites within a postsecondary institution. Postsecondary entities that commit more resources to this issue will also be able to better monitor the accessible design of their Web development staff.

Besides personnel, another resource that must be considered is money. This allows for the allocation of
personnel time (as part of role assignments) and for training efforts that will ensue. It is possible to secure outside sources of support. However, you should not count on obtaining these types of support (e.g., grants, donations). Moreover, you should not wait to secure outside sources of support prior to initiating policy efforts. The most reasonable source of funding will come from line items within the institutional budget. It is much like the physical facility changes that were required when the Americans with Disabilities Act was implemented on campus. It is not wise to wait for money from outside sources to begin the process of institutional reform. Your institution could put itself in a vulnerable legal position.

The 8-Step Model of Institutional Reform

There is a model of institutional reform that may be helpful in planning change at your institution. This model is comprised of an 8-step process. Each step is like the spoke of a wheel, and each is essential to the overall function of the wheel. If you miss even one spoke, or if a spoke is weak, you compromise the integrity of the wheel. So, as you begin your journey of institutional reform, we'd like to give you some information to plan for a safe journey.

Step 1. Gaining Administrative Support

Setting out on your journey of accessibility must begin with gaining administrative support at your institution. This backing is important for three primary reasons. The first is that it helps to validate the cause of Web accessibility at your university. This gives it more visibility and verifies a commitment that other members of the institution can then look to in their own dedication. Even in institutions where change can occur from a grass-roots level, it will be important to secure support from those who are charged to make institutional decisions and those who control budgetary items.

Another reason the sponsorship of your administration is beneficial is the value this status sheds on accessibility. Those both outside and inside the institution may see this as more important if the administration is committed to making positive changes. Over time it will help you set policy, create training and support mechanisms, as well as monitor the success of your institution's work.

Step 2. Organizing an Institutional Web Accessibility Committee

Once the administration at your institution supports the importance of Web accessibility, a group should be formed to draft accessibility policies and to see the process through its implementation. It is vital that this group be comprised of other key individuals at your institution. Those chosen should be respected in their individual fields and have the ability to influence change with their colleagues. They must also be able to commit the time necessary to see the process through. In some instances this could be a substantial 2-year commitment.

So, who should be part of this process? It is important to remember that every institution will need to approach this process in a slightly different way, thus membership of this committee should reflect these differences. There are typically at least 5 groups of stakeholders who should take part in this process. These groups include: the administration, the faculty, the Section 504 and ADA coordinators, Web designers, and students with disabilities. At least one member from each of these groups should participate in a Web accessibility committee, although it may make sense to have more than one representative for certain groups.

It is important that this committee be constructed in such a way that all members will work constructively toward the goal of helping to create a fully accessible Web for their institution. Please remember that these individuals will report back to the larger groups from which they came. As such, it would be helpful to the process if they were respected within their own groups. Representation and support by all parties is essential if implementation is to be widely accepted. The implementation of Web accessibility at your institution will be much easier and when all of these pieces fit together.

Step 3. Web Policy: Defining a Standard

Defining Web Accessibility

After you gain administrative support and organize an effective Accessibility Committee, the next step is to develop the institution's Web policy. There are 2 important components to the overall Web accessibility policy. The first is the standard, or institutional definition, of Web accessibility. Second is the implementation plan. Taken together, they form the complete policy. What follows is a description of the accessibility standard. Descriptions of the implementation plan will be discussed in Step 4.

One of the first responsibilities of the Web Accessibility Committee will be to draft a document that will be
used to define what is meant by the phrase "Web accessibility". Different individuals might define this in different ways. The importance of a clearly defined Web accessibility policy cannot be overstated. This standard will enable everyone to understand the level of accessibility your institution will employ. It will also act as a planning guide for developers; they will know precisely what practices they must include in their design to fit the institutional standard. Furthermore, this standard will serve as the template in any future monitoring effort. This process is not unlike the process of designing the specifications for the production of a car. What laws are in place describing weight and size of specific features or the minimum requirements of certain functionalities? Beyond the basic elements required by law, what special components do you want to add to your product? Will you have air bags or anti-lock brakes? Determine then that the first task of this group is to develop the "specifications" of a Web accessibility definition for the institution.

Composing a Detailed Accessibility Standard
To define a Web accessibility policy for your institution, it is critical to remember 3 things. First, it is important to make sure you compose a detailed accessibility standard. It does little good to announce that your institution will be "ADA compliant" or that "We will insure all our pages are accessible to students with disabilities". Ask yourself, what does this mean? Would others in the institution interpret this statement in the same way? If you were a Web developer would you know if you had created a document that followed institutional policy? If you were monitoring the accessibility progress of this institution, would you know how they are doing? In order to help those that will work with the policy you must first define the standard by which all will comply. Provided below are resources you can consult in forming your own standard. These are 3 sources that will provide you with detailed descriptions of Web accessibility standards and guidelines. Remember that these guidelines are provided as models and references for you. There are no hard and fast rules to setting a standard and there is no right answer. But you must make sure that standard that you choose or create suits your institution.

1. The Web Accessibility Initiative (W.A.I.) of the World Web Consortium (W3C) has studied this topic in depth and has published a set of guidelines which define accessibility. These guidelines have been organized into three priority levels. Priority 1 guidelines are those which must be met for a page to be accessible. Priority 2 guidelines should be met. Priority 3 guidelines may be met (it would be nice if they were, but perhaps not necessary). Because of the credibility and international scope of the W.A.I.- and because of their affiliation with the W3C - the W.A.I. guidelines have served as a basis for organizations setting standards for Web accessibility. Nevertheless, the W.A.I. guidelines as they are currently written may not necessarily fulfill the policy-setting needs of all organizations. It may be beneficial for some organizations to include in their standard other principles of Web accessibility which the W.A.I. has not enumerated. For example, the W.A.I. does not mention the timeliness of accessible content as one of their guidelines. In the case of online courses, it is important the online syllabi be made accessible to students with disabilities at the same time that they are made available to other students, to avoid putting the disabled students behind. Organizations may find other considerations which the W.A.I. guidelines do not address, which are important to the organization. To more specifically study the WAI Guidelines, visit to http://www.section508.gov/index.cfm?FuseAction=Content&ID=12.

3. Many institutions have created hybrid standards that blend elements of both the WAI and Section 508. Some have even created some of their own standards. These are found in the Online Institutional Examples section below.

Review and Revision of Your Accessibility Standard
Once you have a draft of an institutional standard for Web accessibility, it is important that the initial draft of the accessibility standard be sent out for review by others at your institution. Including others in open dialogue will improve the likelihood of adoption and successful implementation of the standard. Institutional ownership that results from this feedback step is often a key to standard success. We would recommend the draft be seen by the groups who have representation on the committee as well as those who will responsible for implementing it (i.e. designers and faculty). Finally, it would be good for the Committee to assume that the draft will be reworked after it has gone out for review, rather than assume that it will receive widespread approval. Most importantly, the members of the Accessibility Committee should insure that all feedback is strongly considered in any reworking of the draft for production of a final policy.

Step 4. Web Policy: Creating an Implementation Plan
In postsecondary education, a priori systems must be created to optimize the participation of all students and staff. It is imperative that we create goals aimed at establishing coordinated systems that enable full access for all. The
sooner we create and implement sustainable solutions, the sooner ALL students can participate in their right to experience the power of the Internet for lifelong learning. The community of postsecondary education is a resourceful group of individuals, so the composition of an implementation plan can be accomplished in these environments.

An essential part of creating an implementation plan is to thoroughly document the actions taken by the committee and institution at every step. The Web policy you construct is not only a great way to lay the foundation for your accessibility travel and destination, but it also documents your good faith efforts for others to see. At every step, the policy should leave a detailed and well-documented proceeding for others who may use it as a reference. When you are constructing your institutional Web implementation plan, there are four areas to consider. They are establishing timelines, setting priorities in terms of what standards to achieve and on what timeline, delegating responsibilities and monitoring the progress. These tasks often do not occur in order, but should be addressed when needed.

Establishing Timelines

The first task in formation of your plan is establishing a time frame for implementation. Depending on the size and scope of need for change at your institution this time frame may extend from weeks to years. It is important to recognize that this is a complex process. Establishing a timeline allows you to sequentially follow the tasks and duties you lay out for all of those participating in Web accessibility at your institution. It also stimulates action and accountability in all involved by creating deadlines by which work must be completed. However, keep in mind that, although initial timelines are an aid in your travel, Web accessibility compliance is an ongoing process and must be established permanently as well as in the short-term beginning phases. Plans should be made for both initial changes and long-term establishment of Web accessibility as a priority at your institution.

Setting Priorities in Terms of Standard Achievement

Due to the complexity of the institutional reform process, setting priorities at the onset along with deadlines for observance is essential. These priorities outline which pages will be required to be compliant in what order as well as the minimum requirements for established deadlines. This process may also take part in phases. For example, one university required that the pages with the top 20% of hits on the institutional Web site were the first priority. These pages, as well as training fell into the first phase, while matters such as gathering further funding fell into a third phase.

Delegating Responsibilities

Once standards and a timeline have been determined, the next step is to delegate responsibility for each of the tasks. This portion of the policy should include a breakdown of each work group's purpose and tasks. As tasks are delegated to specific members of the main accessibility committee, subgroups will form. Who will be included in these groups? When will they meet? A list of campus entities and what their responsibilities are to enforce the university policy should be delineated clearly.

Monitoring Progress

The best implementation plan does no good if there is no accountability. Laying a foundation for monitoring progress and following through is the best assurance that institutional reform will be successful and complete. It is very important that you develop a system by which to identify and maintain contact with individuals who have been assigned specific responsibilities within your plan. The administration can provide this leadership in monitoring and compliance, as well as delegating specific tasks and follow-up to others.

For example, the administration in some higher education entities require that Web masters attend training on institutional policies, sign agreements to follow them and are monitored over time for compliance. Of course such an endeavor would assume that the administration has a way to identify and track ALL individuals who place web content on an institutional sever and monitor accessibility as one feature of broader institutional policies. The framework for these abilities must be laid early on.

There are many different methods emerging throughout the nation on how progress is being monitored. Let us present a few for your consideration. The first is random checks. This is fairly self-explanatory, involving persons being hired to randomly test Web pages for compliance to institutional standards. Another method is a yearly purge, in which all pages not declared compliant by campus designers are swept off the system. This may help to clean rogue content off the system, however, it still does not have a system for verifying whether the sites are actually compliant or not.

Another method is the honor system, where it is assumed that those responsible for development will keep
their sites fully accessible. However, this brings up the dilemma of ‘Why have a policy if we don’t even know whether or not anyone is following it?’ A final method is the peer system. In this system, a network of designers is set up to provide mutual feedback, support and idea-sharing opportunities. This association has established policies and meetings. In addition, sites are sent to one another in this peer group for review. This is typically done on a regular basis (e.g., 2 pages, twice a month). The sites are checked against the established policies of the group and feedback is returned to the university Web master as well as the designer of the given page. In this system it is imperative that feedback be supportive, as well as constructive.

Step 5. Gathering Baseline Information

Conducting a baseline is an essential part of institutional reform. Once you have created your institutional policy (the standard and implementation plan), it is time to discover where you lie according to the standards you have set for yourself. This will help you know where to concentrate your efforts and where you need to continue to work.

When conducting a baseline, it is valuable to test approximately 8-10% of all pages on your institutional Web site. It also makes sense that as you randomly sample these pages you insure that you have included pages across all levels and departments. In order to gather this information, you could create a checklist of your institutional standard for Web accessibility. If your institution chose Priority I and II of the WAI or Section 508, you may be able to use some of the features of accessibility validators that are available today. An example of a checklist that was developed based on the Section 508 standard (http://www.webaim.org/standards/508/checklist) might provide some insight into how you could blend automatic features of validators with manual checks to gather baseline data.

Techniques for Establishing a Baseline Measure of Accessibility

Technique 1: Evaluate the Site Using an Automated Accessibility Validator

Products such as Bobby WorldWide (commercial version), AccessEnable, AccVerify Server, PageScreamer Spider, and InFocus can scan through entire Web sites and generate reports based on the errors which they find. Most of these programs allow you to choose which criteria to designate as "errors" for the purpose of the report. It is a good idea to decide ahead of time which of the criteria will cause a page to fail. This will eliminate the extraneous information that these programs can produce that, while sometimes useful to developers, can sometimes confuse the issue by labeling too many things as errors, some of which do not apply to the site at hand. These programs can flag such errors as missing alt text and missing frame titles, but they will not be able to determine whether or not the alt text or frame title is the most appropriate for the context. That is why Step 2 is so important.

Technique 2: Evaluate the Site Using a Checklist

Using a checklist, evaluate the subjective elements of all or randomly-selected pages. The WebAIM Section 508 checklist is an example of a pass-fail checklist that could be used for this purpose. Before embarking on this step, though, it is important to ensure high inter-rater reliability. The people using the checklist should be familiar with Web accessibility concepts. They should independently rate a test group of pages, then compare notes and opinions. Step 2 will be effective only if it is clear that these people will rate pages similarly.

Technique 3: Interpret the results

It will probably be helpful to generate a few different types of reports. For example, it can be helpful to compare the pass/fail ratio of pages evaluated with the automated software to the pass/fail ratio of pages evaluated by human evaluators. You could also separate out the errors by type, WAI priority or other criteria.

Step 6. Training and Technical Support

The Importance of Training and Technical Support

Once you have institutional support, policies and plans in place, as well as a baseline of your current situation, the next step is to provide training and technical assistance for those who place content on the Web. Training is a critical element in the implementation and success of your institutional reform. Web accessibility may be a brand new issue for many who will be responsible for its implementation. The training and support you provide will be absolutely necessary to help them fulfill the institutional policies that have been established.

Identify Your Audience

It is important to identify those who place content on your institution’s Web site. As you design your training and support mechanisms, please be aware of the skills of these individuals. Situations can arise where anyone with Web development skills or the desire to learn the skills are given responsibilities to create and post Web content on an institutional Web site. Some of these individuals may be professional Web developers, such as in-house Web design
staff or outside design contractors. Some of these individuals may be faculty or other support staff that wish to explore Web design and, in return, provide a "free" service to their workgroup or department. Some may be students hired for a single term or for one year. Other individuals may be nephews and neighbors, friends and children. Anyone with skills to write in a markup language (e.g., HTML, or hypertext markup language, the language of the Internet), or understand authoring tools, or course management systems (e.g., Blackboard, WebCT, E-college) can be given the task to design and develop elements of a postsecondary education Web site. Few campuses actually know all of the individuals that develop and place Web content onto the institutional server system. If the institution cannot identify all of these individuals it is unlikely that they can provide the necessary direction, support, training, and monitoring for accessibility.

In addition, although accessibility fixes may not be a difficult task for those who are technically skilled, new techniques and content can provide some initial confusion. You will want to create a structure in your institution that is supportive of implementing these changes and not merely request change in the absence of support. The training and resources you provide must be as clear as the standards you wish your developers to follow. Web accessibility can be a complex process but is simplified with good training and ongoing support.

Areas of Training
You could focus training in at least three primary areas; the areas of Web accessibility, your institutions’ accessibility standards, and strategies and techniques for accessible coding (e.g., HTML, CSS, XML) and multimedia (Flash, Video, PDF, Power Point).

Web Accessibility Issues (coding and multimedia)
It would be reasonable to create a workshop that would focus merely on accessible HTML (or other code techniques) and multimedia. These are the techniques needed by designers to create accessible content. However, in order to help designers and faculty understand why they need to design and develop accessibly, it is valuable to help them first understand the broad issues of accessibility itself.

1. Understanding the perspectives of the student with a disability is critical (http://webaim.org/training2002/week1/). Often, if Web designers really understand what student with disabilities face, the designers will embrace this perspective and be able to internalize many of the changes at an intuitive level. Introducing staff to the personal stories of students and faculty at your institution can be a powerful experience for Web developers as well. Simulations and videos, in combination with live interviews or panels can be another powerful aspect of your training. Help those involved answer questions such as; "What population is benefited by an accessible Internet? What problems do they face without it? How can these problems be overcome?" Having an experience with those who struggle with the Internet helps promote a greater desire to change professional practices.

2. Understanding the incentives for implementing Web accessibility, the reasons of ethics, business and law (http://webaim.org/training2002/week2/), can also motivate them to initial acceptance and help them effect change.

Institutional Standards
Secondly, in development of training it is also essential that all parties involved understand, not only the reasons for accessibility in general, but your institution’s choice of standard. When designers and faculty clearly understand the exact regulations of compliance chosen for your university, they are more likely to effectively fulfill their commitments to Web accessibility. Consider training in the following ways:

? Include specific wording of the Web accessibility policy of your own institution
? Provide contact information for people so they can ask questions of those in charge
? Make specific dates and schedules for training available on the current institutional policy or plan

Techniques and Strategies
As far as an overall plan for institutional training and technical support, many factors must be taken into consideration. Will you create the actual training in-house or will you outsource? Will you need separate training for designers than for faculty? In what areas will you specifically need to train? It is important that you consider the unique needs of each group at your institution. Even within groups, there will be different levels of need. Designers are more likely to need training in both multimedia and coding techniques, whereas most faculty will benefit more from knowing how to optimize the tools they use, such as PDF files, PowerPoint, or how to make accessibility workarounds for a
course management system (e.g., WebCT, Blackboard).

One good place to start making plans for training is to conduct a survey of the accessibility knowledge skills among those who will be involved. Questions could address what they know about the issues, as well as specific coding techniques. These skills and knowledge might also be discovered as the baseline study is performed for your institution. Understanding the needs of your designers and faculty is valuable to create or tailor training.

Other decisions to make in regards to training involve resources and method of delivery, timing and accountability. Will the training be conducted face to face or online? Will online resources be provided that link to valuable, informational Web sites? Will all faculty and designers have a point-of-contact for answers that cannot be found in manuals or on the Internet?

Step 7. Monitoring Your Institutional Policy

At this stage of the journey you are well on your way toward accessibility. The key now is persistence. Now is the time to execute the strategies you outlined for monitoring progress in your implementation plan. This is the time to make sure that all goals for implementation are being fulfilled. Find out where the problems lie and offer support and training to alleviate them. Take any steps to insure established accessibility and make sure Web accessibility becomes a permanent process at your university.

Questions to Ask Yourself

At this point it is a good idea to reevaluate the commitments to Web accessibility made by those at your institution. Consider some of the following questions:

? How are your Web designers performing?
? Have they all completed training?
? Are the pages up to standards?
? Are certain designers or faculty members having difficulty in maintaining the standards? How might they be encouraged or helped?
? Are there new designers, faculty or administrators who need accessibility training?
? Are there changes that need to be made to the training?

Planning Guide

This is a good time to pull out your implementation plan and evaluate your progress in terms of the timelines and guidelines established. Go through the plan section by section and be certain everything is moving along according to plan.

Step 8. The Importance of Flexibility in Change

Perhaps the most important concept to remember as you travel the road of institutional reform is that change is a dynamic and flexible process. There will be changes in staff, standards and technologies. Your institution must have in place a system to with these changes and a mechanism to update standards as new technologies emerge. You should also remember that there will be turnover of designers and new hires all the time. In that case, new training will be required, as well as retraining when standards change or work becomes sloppy. Your institution must always be at the ready for revamping and retooling as necessary. In fact, there should be allowances and provisions made for this in all policy plans.
Learning Anew: An Exploratory Study about New Online Learners' Perceptions of People Interaction and Learning to Learn in an Online Course

Patti Shank, Doctoral Student, University of Colorado, Denver
Venita Doughty, Doctoral Student, University of Colorado, Denver
May 24, 2002

Abstract: This study looked at how new online learners in the first course in a graduate level online instructional technology certificate program experienced interacting with others in an asynchronous online discussion and learning to learn online. The study followed twelve new online learners throughout the class using email questionnaires and email follow-up questions. Significant themes included difficulties and fears, time factors, and desire for more feedback and smaller groups. Over time, most participants adapted and found benefits in addition to challenges. One-fourth of the participants did not adapt and left the program at the end of the course. Postings gradually became more social and fewer were directed primarily to the instructor. Correlational and predictive analyses provided insights into the importance of computer skills, initial experiences in the course, and quantity of discussion postings.

The entire paper (with full literature review and additional tables and participant data) is available at: http://www.learningpeaks.com/discussion_study.

Introduction

Student discussion in a college classroom conveys numerous instructional benefits and is considered to be critical to learning (Gunawardena and Zittle, 1997; Nunn, 1996; Ormrod, 2000). If interaction with people is important and discussion is the primary venue for this interaction, we must understand why learners chose to (and not to) participate, in order to optimize decisions about design and facilitation in online learning environments. The goal of this study was to take a close look at the thoughts and feelings of adults who are new to online learning as they take their first online course. The primary research questions at the outset were:

- How do new online learners view online discussions?
- What factors influence participation in online discussion? What makes participation more likely? Less likely?
- Do learners' views and participation change over time, as the course progresses?

What I found in these new online learners' responses went beyond the original scope of these questions. I came to understand how they perceived some of the challenges and opportunities of asynchronous online learning, in general, as well. All of the participants struggled with using a new medium for learning. Most overcame the challenges and found the process to be satisfactory or better. The challenges were insurmountable for a few participants and they chose to not remain in the certificate program after the end of the course.

Participant Solicitation

This study involved twelve out of the thirty students in two online sections of a graduate level, asynchronous, large public university instructional technology course called "Developing Educational Websites." This course is the first in a four course online certification program called "Designing and Developing Web-based Learning Environments." I decided to study only new online learners because returning online learners had already self-selected this method of learning as acceptable to them.

Data Collection

Participation consisted of responding privately to me, via email, to three email questionnaires (I used the term "email journals" with participants in order to encourage in-depth answers) at the beginning, middle, and end of the study. The course was 10 weeks long and the
questionnaires were sent to participants by email in weeks 2, 5, and 10. As students responded, I followed-up via email with additional questions. Questions for the middle and final questionnaires were developed in response to the types of answers received in earlier questionnaires.

Data Analysis

As I read through each journal, follow-up, and discussion posting, I looked for themes. It became apparent to me that participants were also describing their experience of learning to learn in this environment in addition to providing insights about online discussion and interaction. I added an additional question to be answered in this study: How do new online learners experience this environment (in general)?

I started with a list of expected general themes (personal issues, other people issues, technology issues, course issues), gained from the literature, and added additional sub-themes as they became apparent. The general codes I began with served as containers for the sub-codes that emerged. In addition, a general code for general asynchronous discussion and online learning issues emerged. The following sub-themes were coded:

<table>
<thead>
<tr>
<th>Themes</th>
<th>Primary Sub-Themes</th>

Table 1: Themes and Sub-Theme Codes

Venita Doughty, another doctoral student, helped me evaluate discussion forum postings for type of posting and audience of the postings. This was done in order to understand how students used the discussion forum, and provided additional insights into the second and third research questions.

Results

Study participants were primarily mid career adults, working in K-12, higher education, or corporate training, with advanced degrees (or working on an advanced degree). The mean age was 43 years of age, with a range between 24 and 59 years of age. The mean level of education was master's degree.

The nature of the certificate tends to attract people with an interest and aptitude for technology, but many students expressed technical frustrations during the course. The range of skills needed to build instructional websites is broad, and even those with relatively higher technical skills coming into the program experienced difficulties with the range of skills taught.
Many expressed a great deal of nervousness about learning online and learning these skills from the outset.

In the following sections, I will describe the themes that emerged and provide some examples of participant comments that illustrate many of the themes and sub-themes. Pseudonym initials and the journal number precede excerpted comments.

General online learning and asynchronous discussion issues

One of the most pervasive themes that emerged in participants' journals, follow-ups, and discussion postings was that communicating through online asynchronous discussion was generally not nearly as compelling as face-to-face discussion. For many, it felt disjointed. Many participants expressed this much more strongly at the beginning and middle of the course than towards the end. Many of the participants, however, came to find communicating this way as acceptable as the course continued.

The three participants who chose not to continue with the certificate program after the course ended, TZ, CY, and AH, expressed strong negative feelings about online discussion, and these feelings continued throughout the course. A related theme was how the lack of visual cues made communication difficult. A number of the study participants expressed difficulty with knowing who was who. On the other hand, one participant felt that it was actually easier to know about the people in the course in this medium.

Many participants described the challenges of communicating in a written medium. Spoken communication, for most, conveyed subtle and not so subtle benefits over written. Some also felt increased anxiety about communicating in this way. JH felt cautious about communicating in writing and it impacted her willingness to provide substantive feedback. She described an incident where she strongly questioned another student's conclusions and began to write out a response but then changed her mind about posting it. The lack of visual cues in written communication also impacted understanding.

Many of the study participants felt that learning this way felt like a lot more work than learning in a traditional face-to-face classroom. The commitment felt more like 24/7 rather than a more typical face-to-face class where the commitment was "Tuesdays from 5-9 PM."

Despite the challenges, many of the study participants began to see positive aspects of communicating publicly over time. Collegiality and the sense of a shared experience developed over time and under the right circumstances. The right circumstances turned out to be a publicly posted final project and the expectation (assigned and graded) to provide substantive peer feedback on others' projects. Many participants emphasized that this type of authentic activity (rather than "forced interaction") was just the thing to make them feel connected to others and that more of these types of assignments were needed.

Personal issues

One of the most consistent and pervasive comments that emerged, especially in the first and second journals and discussion postings at the beginning of the course was self-consciousness and fear of looking stupid to others. Many of the study participants asserted that others knew an awful lot more than they did. These remarks matched and extended the remarks made about the nature of written communications described earlier.

Issues with others

When asked in the second set of journal questions what would make participants more likely to interact in the discussion forum, the most consistent answer was more feedback from other learners.

Technology issues

Some participants felt that following conversation in the discussion form was confusing, disjointed, and time consuming. Some participants adjusted well to the technology over time but others continued to struggle with it. For those that struggled, the technology augmented the disjointed and time-consuming nature of communication.

Course issues

A number of participants expressed a desire for working in smaller groups. Participants wrote that it would be easier and more comfortable to get know people this way and felt that they would feel more connected and less anxious.
A number of participants chastised me for making participation in the discussion forum such a large part of the course evaluation (it comprised 20% of the final grade). Many said they felt forced to participate. Some said discussion and participation were essentially a waste of their time. They preferred to spend the time in more solitary activities.

**Time...**

An emerging meta-theme that tied together all the others was the element of time. Many of the study participants began to see positive aspects of asynchronous discussion and learning as the course progressed. Many saw that challenges were balanced by benefits, and that both challenges and benefits could exist at the same time. A few even described benefits over learning in a face-to-face setting. Some of the challenges (e.g., takes more time) also contained benefits (e.g., more time to digest).

In general, posting numbers increased over time. Social postings and postings to provide information to others in the class went from 16 in Project 1 to 104 Project 7. At the beginning of the course, many of the posting were targeted towards the instructor. By the end of the course, most of the postings were targeted towards the other students in the course. In general, the postings of those that chose not to increased over the course, too, but they did not increase nearly as much as the others. There did not appear to be a dramatic change in type or audience over time.

Correlational and linear regression analysis was performed with all of the Likert-like questions, the course grade, number of discussion postings, and whether participants continued with the certificate program. These analyses showed the following significant correlations and predictive values.

Table 2: Significant Correlations and Predictive Values

Paired dependent t tests for changes in personal satisfaction between journal 1 and 3 were not significant. There were no significant correlations with grade received in the course.

**Discussion**

*How do new online learners view online discussions?*

The study participants viewed online discussions in many different ways, sometimes at the same time. At first, most found the discussions to be more challenging than beneficial. Over time, benefits began to become apparent to many of the participants. Others' postings provided insights and helped keep them on track. Others' problems provided comfort for those also experiencing problems. The final project provided an opportunity for authentic feedback that engaged most of the participants and helped them see the value of interaction. Some participants never connected and these participants did not continue with the certificate program.

*What factors influenced participation? What makes participation more likely? Less likely?*

The factor that participants said would influence them to participate the most is feedback from others. It is interesting that only one of the participant's reflections included insights about
how their actions influenced others. It appears that it may be helpful to assist learners in gaining early "ah-has" about the value of reciprocal interaction.

Many of the participants expressed irritation that participation was required and some said they only participated because it was required. It became clear that authentic activities provided a better impetus for interaction than simply ordering interaction for the sake of interaction. Number of postings correlated moderately highly with participants assessment of whether they obtained the skills they desired in the course.

Do learners' views and participation change over time, as the course progresses?

Participants' views and participation changed a great deal over the ten weeks of the course. Instead of seeing only challenges, they began to see challenges and benefits. Postings, in general, increased. Social and informative postings increased dramatically. This occurred across the board but occurred much more for folks who were adapting to the environment. This provides yet another rationale for helping people adapt early, whenever possible.

How do new online learners experience this environment (in general)?

This is not necessarily an easy environment for all to adapt to. It takes perseverance, motivation, and a willingness to get past feeling inept and/or anxious. Not all adapt. The high correlation between personal satisfaction in journal 1 and in journal 3 confirms how critical it is that people feel successful early on. It also points to the importance of willingness to deal with uncertainty at the outset.

Conclusions And Opportunities For Further Study

The thoughts and feelings of these participants may not be representative of all online learners but should provide food for thought about the scope of thoughts and feelings of new online learners as they attempt to cope with interacting and learning in this new way. It would be beneficial to replicate this study with different audiences and content.

One of my primary conclusions was that instructional strategies are critical in the learning environment. Those that lower fear and promote quick success at the outset may affect participation and persistence. Authentic activities that involve students with each other early on may reduce fear and make the environment more compelling. Additionally, since this environment may not be optimal or acceptable for everyone, it may be necessary to help potential learners ascertain the suitability of the environment at the outset. When learning in this environment is necessary, we may need to provide additional supports in order to make it satisfactory.
