the author, but dynamically by the teacher. A module can be simply adapted to different didactical strategies. In contrast to other projects, WWR is distinguished by the consequent use of XML technology and a very large group of developers and users (teachers as well as learners).

**Concept of the educational material**

The content to be implemented within the project has been structured into 150 modules, each for 4 weeks of lessons and exercises or practical training. A module has the following characteristics (Lucke et al. 2002):

- It is scalable in size respectively intensity. That means, basic, advanced and expert versions can be generated from a single description.
- It contains special elements for learners (for example exercises and tests) and for teachers (for instance sample solutions and didactical or pedagogical instructions).
- From an abstract description, several output formats can be generated, e.g. HTML for interactive use, PDF for printable manuscripts or PPT for a presentation with slides.

In this way, three dimensions of a module are achieved, as visualized in figure 1. This leads to 18 potentially different variants of each module. For the generation of a specific output from the internal data representation, the value of each dimension has to be specified.

![Figure 1 Module dimensions](image)

In order to ensure the reuse of the developed modules, a metadata set following the IEEE Learning Objects Metadata standard, LOM (IEEE 2000) is generated for each module. There are 35 attributes defined as obligatory, because otherwise users are not willing to fill out optional fields (Monthienvichienchai et al. 2001). 18 attributes are fixed due to the project context, 13 can be automatically extracted from the module description, and 4 have to be specified by the author. Furthermore, 4 attributes can be completed by own values. The generation of metadata is done during the upload of a module to the system.

Teachers are able to compose individual courses from this modules. To define a course, a combination of modules with their intensity (basic, advanced or expert) has to be specified. From this description, documents in different output formats and for both target groups (teachers as well as learners) can be generated (see figure 2).

![Figure 2 Generation of course material](image)
Additional information resources are generated from the module and course descriptions, e.g. table of contents, index, glossary, list of abbreviations, list of cited persons. This is done by examining appropriately marked text elements in all modules and sorting them into the corresponding index.

Module implementation

To apply this high amount of flexibility to the implementation of modules, we have chosen document processing based on the Extensible Markup Language, XML (Harold et al. 2001). In contrast to other projects, XML is not only used for modelling of metadata or protocols, but for the whole encoding of a module. The description of documents is split into their syntactical structure (Document Type Description, DTD), the contents (described in XML), and its semantical interpretation (described with the Extensible Stylesheet Language, XSL). Because of the separation of content and its presentation, several kinds of output may be generated from a single XML file. For example, all elements can be marked with attributes to specify the dimensions mentioned above. Furthermore, XML files are completely independent from any hardware or software environment and may be handled easily in web-based applications.

The creation of the XML description language did not start from scratch. Existing languages have been evaluated, their concepts have been partially integrated and combined with the project’s innovative concepts, e.g. flexible definition of module dimensions and different didactical contexts (Dettlaff-Günther et al. 2002). This allows a conversion between the formats by application of appropriate stylesheets.

The XML encoding of educational contents is done by the author of a module, using available XML editors or special tools. Since a lot of educational resources are already existing in other formats, import mechanisms (e.g. from word processing software) are an important topic. Many of the common tools are able to create XML files, which need to be converted into files following the project’s DTDs. Currently, converters from MS Powerpoint, LaTeX, Adobe FrameMaker, and MS Word to the WWR document format are available.

In order to evaluate and to improve the XML concept, it has been validated by several test implementations. Firstly, an example module on workstation cluster architectures has been developed. It realizes all characteristics of the DTDs, for instance elements with different intensities, multimedia components with alternative definitions for distinct output formats, several types of exercises, didactical markings, and so on. Furthermore, the project’s XML working group has provided a specific XML tutorial as well as the documentation of the project’s DTD set following the DTD itself, and gained a lot of useful hints from this. A step-by-step transformation of the local educational material into this format is currently going on at all partner universities. In figure 3, parts of the source files and different output types of a developed sample module are shown.

Figure 3 Input and output files of a sample educational module (in German language)

a) XML, b) XSL, c) online manuscript, d) printable PDF, e) presentation slides
Interesting aspects of XML and stylesheet implementation are, for instance, the definition and interpretation of a multimedia component's attributes. It is necessary to offer a conversion mechanism between dynamic and static media types (as used in interactive and printable manuscripts), e.g. sound, video or animations. Another topic is the description of didactical intensities for the elements of a module, which have a strong influence on the extent of the generated material. Finally, the integration of external programs like simulators is subject of current work, too (Kalfa et al. 2002).

An important point that is often neglected is how to enable authors to produce quality content. Within our project, a special training of involved authors, e.g. for transformation of existing manuscripts into multimedia scripts, took place. Additionally, the DTD requires the specification of important didactical information, like the educational objectives or the explanation of used terms. All universities regularly give reports on and discuss their results in the project meetings. Finally, all modules are evaluated regarding to content, design and didactics by other partners (from universities as well as external partners) before publication. This assures maximum quality of each module.

A more XML-oriented description of this project has been given in some further publications (Lucke et al. 2002).

**System architecture**

Three aspects need to be considered to define the system architecture:

- typical user groups of the system
- the data which needs to be stored
- the processing of this data

Existing educational systems are distinguishing between the following types of users: administrator, author, teacher, tutor, student, and guest. Thereby, guests and tutors are subsets of other roles with restricted permissions, and therefore they do not need to be considered for the identification of architectural components.

Regarding to the storage components, there are two main groups of data: Unstructured, large objects like modules, multimedia elements or DTDs are better stored in a conventional file system; whereas smaller or fine-grained information like user data, module metadata or course descriptions should be managed in a data base system, in order to guarantee fast access and comfortable search.

Moreover, the following steps of data processing can be identified within such a system:

1. content production:
   An author is downloading the DTD set and additional instructions. Based on this information, he encodes his educational content in a module using a converter and/or editor.

2. content upload:
   The author is uploading the module with referenced multimedia elements on the server. It is verified against the DTDs, and the metadata is generated. Further evaluation, e.g. from didactical or content point of view, can take place here.

3. course definition:
   Teachers identify, parameterise and combine the modules needed for their courses, based on the metadata information. The course description is stored on the server.

4. course delivery:
   Teachers and learners are now able to request target group and media specific course material, which is generated from the module and course descriptions.

5. feedback management:
   Answers to exercises, questions for teachers, or remarks for authors need to be collected and redirected to their destination.

This leads to an architecture, which is simplified depicted in figure 4.
Unfortunately, we did not find a platform that fits our requirements (Wiesner et al. 2002). For this reason, several existing tools are currently combined and integrated into an overall solution for our project. Feedback manager, publisher, composer and verifier can be integrated in a web-based interface, which is mainly realized using tools like teaching and learning platforms or content management systems. They need to be adapted to the project specifics, e.g. DTD descriptions, XSL transformations or specifics of workflow management. Finally, any existing XML editor can be used to produce the modules. Project specific support for authors will be given, too.

This architecture not only implements the principles of content on demand. It could also be called format on demand, because it allows the online generation of course material, which is adapted to a specific educational intensity, target group and output medium. Furthermore, the distributed architecture is able to handle large amounts of data as well as users, which is a strong requirement in this field.

Conclusion and further work

Within the joint project „Wissenswerkstatt Rechensysteme“, about 150 multimedia teaching and learning modules for the field of computer engineering will be developed. All modules can be combined together to generate specific courses, according to given educational objectives. Through the use of the Extendable Markup Language (XML), each module is scalable in three dimensions:

- intensity: for basic, advanced or expert users
- target group: for teachers or learners
- output format: e.g. HTML, PDF or PPT

A platform has been presented, which will be used for deployment of the educational modules. The results will be used by all project partners. Furthermore, the partners from the industry and special interest groups will evaluate the modules relating to their content, design, and didactical aspects. The concept to define multimedia educational material completely in XML in order to achieve more flexibility in the dimensions named above is adaptable to any fields of education.

Current work is done on module development, on filter implementation, and on the integration of interactive elements like simulators. Further research will be done on the implementation of a real-time extension for the teaching and learning environment. The objectives of such a system are to allow the users to access applications from one or more central servers via the web, and to manage data and applications shared between many users. In this way, cooperative education using the material developed within the project can take place (Lucke et al. 2001a).

All mechanisms mentioned above are valuable instruments to further improve the quality of education, not only in the field of computer science.

CaSA: A Technology-Based Solution to Improve Learning

Jerome Eric Luczaj and Chia Y. Han
University of Cincinnati, United States
luczajj@email.uc.edu chia.han@uc.edu

Abstract: Immediate feedback and assessment, active and interactive learning, and timely changes to adaptively deliver the curricular objectives within an integrated environment promote effective learning. This paper presents a flexible framework to develop technology-based solutions to augment learning experiences by coordinating and synchronizing instructional multimedia streams, matching lesson plans to student class experience and to program requirements.

Introduction

There are many different factors that influence whether a student has successfully attained core program knowledge. Though the causes for poor student performance are hard to pinpoint, providing timely, factual information to the stakeholders (students, instructors and program administrators) creates a foundation for more productive learning. A comprehensive assessment strategy facilitating two-way communication between each stakeholder, focused on immediate feedback, needs to be defined and implemented. This strategy should skew student performance above the desired threshold, generating “A Significant Difference” (Russell 1999).

It is the instructor’s responsibility to ensure that the course provides the appropriate content for the student, supporting program requirements. Course learning outcomes are accomplished through course delivery and verified through test evaluation. Co-relationships exist between the program-defined content and the lecture-delivered content; and the lecture-delivered content and the student-received content. Unfortunately, a gap between defined, delivered and received content frequently exists.

Educational assessment has multiple, distinct uses in instructional improvement including: school and student accountability for academic achievement, feedback for teachers, data for administrators to allocate resources, and stimulation for students to receive a deeper understanding (Baker 1999). Typically, student performance is evaluated at irregular intervals. Students who were confused during lectures would not find out how far behind they were until it was too late to catch up. Without timely feedback connecting student learning to instructor evaluation, none of the stakeholders have the power to affect change or to correct problems.

A typical classroom experience involves multiple, simultaneous communications or streams of information. These may include verbal and visual presentations, board notes, electronic exercises, overhead presentations, hyper-linked multimedia references, as well as student questions, discussion, and notes. Unfortunately, these different material formats may overwhelm students, in terms of absorption or proper note-taking. Student disengagement in the classroom is an issue that may hinder student’s learning in an information overload situation. Research focusing on getting more out of the classroom experience shows that user-interaction in selecting data keeps the students interested in material (Hannafin 1996). According to Brien and Eastmond the ideal situation is one where the learner knows the final goal as well as the sub-goals that support the final goal. Therefore, it is important that learning outcomes be explicit and feedback frequent (Brien 1994). These studies indicate that students’ needs and viewpoints have to be taken into consideration when course material is given in technology-based classrooms.

Many classrooms at the University of Cincinnati, like other campuses across the nation, are being equipped with the latest e-media technology. As students bring laptops into classrooms, they will have capability not only for note-taking, but also for interacting with the instructional system. These machines present an excellent opportunity for enhanced interaction via immediate student feedback and assessment.

Approach

To facilitate a connected learning environment for students, teachers and educational organizations, there is a need for a flexible instructional infrastructure that can: Augment both classroom and post-classroom learning; Provide a
channel for student feedback; Connect program requirements, course objectives and student learning explicitly so that effective, adaptive instruction can be realized.

The approach is to electronically record instructional content, synchronized with student feedback and assessment data, providing real-time monitoring. Content will be parsed, grouped into content units (CU), labeled, and indexed. These CUs can be connected to lesson plan topics and program requirements, connecting delivered content to defined content and received content. Each stakeholder will be given the opportunity to mark or index into the content. As such, it should become immediately apparent if a requirement is not supported or a topic not received. This will foster two-way communication, facilitate review, and promote incremental, constructive change. The intent is to make connections between stakeholders explicit, immediate and effective.

A new framework, CaSA (Classroom and Student Achievement assessment), designed to develop new systems and instructional software is proposed. CaSA is a flexible framework to augment classroom experience by coordinating and synchronizing instructional streams, matching class plans to student class experience, and presenting instruction in a variety of media forms to promote self-directed learning. As such, it will provide a foundation to facilitate timely feedback and collect assessment data.

CaSA will synchronize information streams, providing context and valuable insight during assessment, instructor feedback, and student review. The strategy will take four forms: student topic marking, periodic electronic concept questions both during and after class sessions, real-time feedback monitoring, and instructional stream review and evaluation. By providing tools that assist students in retrieving, evaluating, comprehending and memorizing information while performing learning tasks the system will provide clear benefits (Aroyo, et al., 2001).

Conclusion

E-classrooms, and CaSA, provide a unique opportunity to augment current classroom experience, aligning the expectations of students, instructors and institutions. Given a system where both instructional and presentational aspects of a lecture can be evaluated promptly, instructors, students and program administrators can react quickly when there is a gap between program requirements, course objectives and learning outcomes, between the intent of one stakeholder and the understanding of another. As such, more effective communication can occur. Information can be gathered to measure student, faculty and organizational achievement and to assist in improvement. An e-classroom framework will improve instructor effectiveness with prompt and iterative feedback, giving them information and guidance regarding the kinds of educational materials and practices that most effectively enhance student achievement. It will increase student engagement, providing an environment that produces demonstrable gain in student achievement.

Creation and implementation of projects such as this will demonstrate the usefulness of technology in education, especially in higher education where significant technological resources are already invested. Using technology to open clearly defined communication from students, instructors, and program administrators will close the gap from defined, delivered and received content and make "A Significant Difference".

Online Professional Development for Teachers: Findings from a Formative and Collaborative Inquiry

Lara Luetkehans  
Northern Illinois University  
USA  
luetke@niu.edu

Rhonda Robinson  
Northern Illinois University  
USA  
rrobinson@niu.edu

Abstract: This presentation will describe and report the findings from two offerings of a new online course on “engaged learning with technology” delivered to K12 inservice teachers. The course emerged as a university-business partnership activity. An overview of the partnership, the framework for course content and design, and research results will be presented. Recommendations for best practices for assisting inservice teachers in developing and implementing technology-rich and engaging learning activities will be offered.

Background

School reformers hold that teaching and learning in schools needs to be reconceptualized from a new paradigm incorporating meaningful and challenging content, higher order thinking, and project-centered, collaborative activities. Technology may be a means for arriving at such a vision (Means, Olson, & Singh, 1995). As a result government, local school boards, and administrators infuse more technology into our schools. By now it is finally being recognized that technology is not a “silver bullet” and that it can create challenges for teachers expected to use it in their classrooms (Earner & Hruskocy, 1999; Means, Olson, & Singh, 1995). Schools will need a “next generation” professional development system that uses the technology to cost effectively engage teachers in ongoing, everyday professional development tightly linked to student learning (NCREL, 2001).

Partnership models have evolved and been recommended as one method of approaching solutions to school innovation, technology integration, and teacher training (Osguthorpe, Harris, Harris, and Black, 1995). In 1998, a “Partnership for Technology Integration” was formed between the College of Education (COE) at Northern Illinois University and the Dukane Corporation. The mission of the partnership was “To act as agents of change toward the adoption and educated use of integrated instructional technologies in K12 settings and higher education”. One of the principle activities charted to carry out this mission was to develop an online course to assist inservice teachers in developing engaging and technology enhanced lessons. The research described here focused on the lessons learned during the development and first two offerings of “Engaging with Technology (EWT): An Online Course.”

The Course

The goal of EWT is to help teachers develop effective technology-supported instructional activities that promote engaged and worthwhile learning as well as enhance student achievement. "Engaged learning" is the concept based on the North Central Regional Education Lab's (1998) promotion for "Learning with Technology." Using the NCREL materials as a starting point, online activities were designed to include individual, small and large group—based instructional strategies. These strategies included Student HomePages, Private Discussion Areas for Peer Feedback, WebQuests, Synchronous Role Play and
Discussion Activities, Streaming Video and Print Case Studies, Existing Web-based Tutorials, and Threaded Discussion Brainstorming and Debriefing Activities.

Methodology

The nature of this inquiry was collaborative and formative. Data sources included Engaged Learning Plans, online discussion (synchronous and asynchronous) transcripts, participant autobiographies, interviews, field notes, researcher debriefings. Each of these was examined using both interpretational and reflective analysis.

Research questions that guided the study included: 1) How do the instructional and communication strategies employed in the online course and course tools assist learners in developing engaged learning lessons integrating technology? 2) How do participants react to learning to integrate technology through a technology-driven course? and 3) What tools and techniques help promote participant interaction?

Findings Highlights

Self-report on pre-survey data for all participants indicated that students beginning the course ranged in their experience with technology skills from novice to expert, but all had access to and had used email and word-processing before enrolling the course. The majority of the students also described themselves as having some knowledge of engaged learning and technology integration, however only one had used a systematic framework for planning such lessons. Some had tried various technologies in lessons. Results on the post-survey showed an increase in familiarity and interest in the systematic planning of engaged learning lessons that integrate technology. Students also reported a wider range of technologies that they were familiar with and comfortable considering for future lessons. The Internet was cited most often as the technology most useful for their lesson planning.

A review and report from the course facilitators on the lesson plans indicated that teachers developed effective lesson plans incorporating engaged learning strategies and technology. Interviews with the students supported consistently a high level of satisfaction with the course, with integration, and with learning to use technologies.

Facilitator and design team reflections from debriefing transcripts and journal entries yielded the following reflections and recommendations:

- Participants need regular and repeated feedback in asynchronous discussions.
- Synchronous discussions have better participation and depth when guided by questions and when participation is limited to small groups.
- Assessment is more time intensive and more essential in the online environment.
- Instructors comfortable with face-to-face instruction have to learn and employ many "personal" techniques to gain the same or similar relationships with students (own web page with personal comments and picture, chat type communication with individuals and small groups).
- Regular communication between the design team and facilitators was necessary even when content was clear and understood.

Applying qualitative research in e-learning. 
Discussion and findings from three case studies. 
Investigating the quality of e-learning towards a knowledge management oriented metadata schema.

Miltiadis D. Lytras, Athanassia Pouloudi, Angeliki Poulymenakou
Athens University of Economics and Business
Greece
{mdl; pouloudi; akp}@aueb.gr

Abstract: The case of learning in digital economy’s era is a fascinating phenomenon. The complexity of learning integrated with the diversification of new technologies set a dynamic landscape where the performance seems to be the overall objective of combined efforts. Our approach tries to investigate the phenomenon from a “myopic” point of view. The starting point of our research effort is the acceptance for the existence of a direct relation that brings together learning, new technologies, pedagogy and knowledge management. In this paper we present the initial findings from the application of qualitative research methodology. More specifically we discuss three case studies (multiple case strategy) concerning e-learning systems implementations and we discuss the way that knowledge management theory can support in practical ways the performance of e-learning systems.

Introduction

A common practice in academic institutions or business units is the employment of new learning technologies in order to support the human resources management. In most of cases the adoption of several Learning Management Systems, provides a context for exploitation but unfortunately the achieved learning performance is rather inadequate (Lytras and Pouloudi 2001a). Several conflicting opinions about the convergence of knowledge management and e-learning realized a dialectic context of reasoning and justification. The fact that knowledge management concentrates on knowledge processes and knowledge artifacts (Mentzas et al. 2001) promoted the initial step in our approach. If in an e-learning environment we can justify several knowledge processes that construct a kind of knowledge artifact that is finally diffused to learners then the information technology can analyze the technical standards and the required applications for the support of our conceptualization.

Research Methodology

In the general literature of research methodologies in information systems, (Orlikowski and Baroudi 1991), we can found many approaches which in general can be placed among the qualitative or in the quantitative research methodology. More over the analysis of our research problem and the justification of our research methodology can be supported by the concepts, which Klein & Myers (Klein and Myers 1999) proposed. The hermeneutic cycle and its basic emphasis on the complementarities of a phenomenon and its component promote the basic idea that a phenomenon such as e-learning has to be analyzed through the qualitative research methodology. The case studies in our research are:

- The Global E-management Master e-learning system and especially the development of the T1 course entitled E-technology, which was delivered to the student of the GEM consortium,
- The XEXO project (Educational space without limits), which objective was to establish an e-learning system and to deliver a master degree course to the students of three universities in Greece
- The Teleducation Center of Athens University of Economics and Business that utilizes the WebCT platform
in order to provide learning content to students.

Conclusions

The limited space of the article, does not allow to present the findings in detail even though that we believe that qualitative research reveals many hidden aspects of the phenomenon of e-learning which no quantitative research can do. Figure 1 summarizes the e-learning content development life cycles.

Semantics for E-learning:
An advanced Knowledge Management oriented metadata schema for
learning purposes

Miltiadis D. Lytras, Athanassia Pouloudi
Athens University of Economics and Business
Greece
{mdl; pouloudi}@aueb.gr

Abstract: In recent years many researchers try to investigate the direct or indirect impact of knowledge management approaches to the achievement of strategic corporate objectives. Several approaches have been promoted, with main emphasis to be paid at the justification of knowledge exploitation processes. Our research effort is concentrated on the demand for high quality interchangeable knowledge objects capable to support dynamic learning initiatives. The general metadata models (Dublin Core, IMS, LOM, SCORM) for knowledge objects enrichment are been reviewed and a well justified critique is provided in order to claim the importance for the justification of an “interchangeable knowledge objects standard” for learning purposes. The overall objective is the justification of a dynamic learning environment capable of supporting the value diffusion.

Introduction

The development of dynamic learning environments requires a systematic justification of methods and processes that vary learning (unique value proposition) for every learner. This challenging situation sets a context that promotes the research in reusability of knowledge resources. A realization of reusability can be based on semantics that enrich general knowledge resources (e.g. an article, a journal paper, a PowerPoint presentation, e.t.c.). The ultimate objective is to expand the customization capabilities of learning environments and knowledge management seem to be a well justified mean for the achievement of such a goal (Lytras and Pouloudi 2001c), (Lytras et al. 2002a), (Lytras et al. 2002b). Our research intents to justify a metadata schema that supports a dynamic e-learning environment. The current situation on metadata is described by a narrow vision on learning.

A synopsis of conceptual abstractions

The organization of knowledge in distinct objects, small structural components, is the basis of reuse. In the case of customized learning the same learning content can be used in many ways due to its integration with other knowledge objects. Our approach is based on two clear assumptions that initiate the whole research: A learning object is a synthesis of knowledge and metadata that expand further the learning effect of knowledge. From this perspective an e-learning environment has to utilize a learning objects base. A critical question is which metadata can we use in order to increase the learning effectiveness. A learning process is an abstraction of a logical sequence of learning activities or tasks. The conceptualization of learning processes determines an interface in which the components of a learning object can be realized. This layout is a value container, which is utilized by the embodiment of learning object. The critical question is which learning processes can we use? And is there any hierarchy of learning processes that determine different value layers?

The underlying issue behind the packaging of knowledge is the reveal of a key idea that will support the accomplishment of a metadata scheme. Our proposition that has been developed after many implementations of e-learning projects in our research unit, ELTRUN. (www.eltrun.aueb.gr) is that the convergence of knowledge management and e-learning is realized through an integrated life cycle model (Lytras et al. 2002a). Each step in this model represents a value adding process. Each step sets a context for questioning about the required metadata that have to be attached to a generic knowledge source in order to formulate learning object. The key proposition in our approach is that a number of metadata can supports each step in the whole model and also the learning processes as learning objects containers. For the specification of the elements of this metadata
schema a review of well-known metadata schema has been undertaken.

**Figure 1: The basic conceptual abstraction**

**Multidimensional Dynamic Learning Proposed Metadata Schema**

Metadata are data about data. In the context of learning, metadata are data about learning objects. This definition provides the major characteristic of metadata: They are descriptive indexing labels. Unfortunately for the case of learning this is not enough. The indexing of learning object it seems to be a management facility with limited impact on the realization of engagement of learners. A lot of approaches concerning metadata have been proposed for general or learning purposes. Some of the most well known organizations that work in metadata specifications are the Aviation Industry Computer-Based-Training Committee (AICC), the IEEE Learning Technology Standards Committee, the ARIADNE, the Educause Instructional Management Systems (IMS) Project, the W3C, and the ADL. The critical review of several metadata schemas including IEEE Learning Objects Metadata, IMS, Dublin Core, SCORM, GEM realizes a gap in learning. This gap in the propositions of the famous metadata schemas sets a context for significant contribution.

**Conclusions**

The overall approach described in the limited space of this paper provides a context for exploitation focusing on learning. The incremental refinement of conceptualization drives to a set of metadata that can assist the transformation of knowledge resources to reusable learning objects. This step-by-step justification finally drives an extensive XML specification of the metadata schema. The selection of learning processes as the carrier of value expands the dynamic nature of an e-learning system. The whole approach seems to integrate the two well-defined and distinct approaches to knowledge management, the knowledge artifact and the knowledge activities approaches. Future research is concentrated on the analysis and the development of a dynamic e-learning environment based on the key ideas of Knowledge Interchange Concept. For this scope an IST proposal is going to be prepare. We welcome any collaboration that will support the refinement of this proposal.

The Learning Support, Training and Environment for Effective Online Teaching and Learning: Sevenoaks Senior College, Western Australia

Jean Macnish jean.macnish@elearn.wa.edu.au
& Dr Sue Trinidad s.trinidad@curtin.edu.au
Curtin University of Technology, Western Australia

The study examines the support, training and environment likely to make possible effective online teaching and learning. It focuses on an innovative new senior college in Perth, Western Australia that is committed to creating an outcomes-focused curriculum by integrating unique Information and Communication Technology infrastructure into the delivery of educational programs, online curricula and management systems for both teachers and students. Sevenoaks Senior College has provided the means to manage education through an infrastructure that supports a learning community via strategic partnerships and online collaboration. This is an important direction for schools as it addresses the educational needs of students with lifelong learning strategies for future work and university life. The study being carried out over 2001-2003 combines quantitative and qualitative research methods to examine the ways in which ICT is used and the learning environment.

Background/Theoretical Framework

In Backing Australia's Ability: Innovation Action Plan, $68.2 million over five years (2001-2006) was committed to the Schools Online Curriculum. The commitment was made on the premise that:

"While investment by all schooling systems in equipment and connectivity has paved the way for change, it is the availability of quality online content that will begin to improve learning”

(Learning Federation Schools Online Curriculum Content Initiative, 2001)

At the local state level, the Western Australian government has invested approximately $100 million on information technology in schools, including approximately $8.3 million to build the Sevenoaks Senior College.

However, increased spending on ICT in schools and educational institutions does not necessarily guarantee improved teaching and learning environments and improved student outcomes (Centre for Research on Information Technology and Organisations, 1999; EdNA, 1999a; White, 1999). Education has a poor history of meeting the challenges of major shifts in Information and Communications Technology (Trinidad, 1998).

Findings To Date – Multi Layered And Multi-Faceted Case Study Of Sevenoaks Senior College

The Online Courses

To date, the teachers at Sevenoaks Senior College have developed 90 courses in WebCT; for the first year of operation, this can be considered a significant success for the teachers and support facilities found at Sevenoaks.

Some of the courses developed online at Sevenoaks Senior College include an English unit dealing with TV drama, a Digital Media unit based on an anti-smoking campaign, a Physics Nuclear Technology unit and a Political and Legal Studies; all used a constructivist framework. Discussions with teachers indicate that time constraints, the need to recognise workloads and set limits within a given time frame is critical.

The Teachers

Interviews have reflected a positive attitude to the vision of Sevenoaks Senior College. However, one of the biggest hurdles that the teachers have experienced is getting students to use their time wisely and effectively. "I found that some students did all the reading that was required but had to be pushed to produce anything substantial, and that the computer nerds talked the language but tended not to do much else” [IDT1:2001]. Observations and interviews with teachers and students indicated that the supportive learning environment created by the teachers was vital to the success of the unit (Aldridge et al, 2002).
A key factor in the development of online learning at Sevenoaks has been the integral role of the Teacher Librarian. The Teacher Librarian has become responsible for facilitating staff development by acting as a staff trainer, a mentor and an initiator in the development/creation of modules of online curriculum.

The Students

According to students studying at Sevenoaks whom were interviewed, computers are used mainly for researching information on the Internet, typing up assignments and accessing course information from the WebCT platform during class time (Trinidad, Macnish, Aldridge, Fraser & Wood, 2001). These results reflect previous research, which has reported that Australian school students spend more time using word-processing software than any other software, and that they use the Internet primarily for email, research and entertainment (EdNA, 1999a; White, 1999).

A significant feature of the Nuclear Physics course was the opportunity available to students to engage in discussion, debate and present and argue about ideas. One student interviewed commented: “I liked the online course because sometimes you can learn more from other students.” Some students indicated their displeasure at the amount of time that was required to research and look for information. On the other hand, one student commented on the advantage of the unit in terms of inquiry rather than being given information by the teacher: “I usually find that, when you actually find out something on your own, you learn more from it” (IDS98:2001).

All of the students whom were interviewed held very positive attitudes towards the use of ICT in the classroom. Student comments on the benefits of online learning included: “You know exactly what to do and there are no excuses for not doing assignments” (IDS12:2001) and “[We are able to] look up more information, which is better than books and gives a wider range to look at” (IDS2:2001).

Discussion and Conclusion

As Sevenoaks Senior College moves into its second year, it is timely to consider ways in which teachers can be helped to use the ICT environment in more innovative ways in their classroom and to move towards a higher level of course development. There is a need for appropriate professional development to move towards developing/adapting courses with innovative models; achieving quality measures and standards; and planning the integration of ICT into classes.

In summary, the learning environment at Sevenoaks is one where teachers and students feel supported. It is an environment that enables students to assume more responsibility for their individual learning and where teachers are provided with the means to manage the transition from a traditional classroom to one that effectively integrates ICT in teaching and learning for the benefit of the student.

Informatics and Media Education -
Designing a Curriculum for Media Education in Teacher Training with Regard to
Basic Areas of Informatics

Johannes Magenheim, Carsten Schulte, Olaf Scheel
Didactics of Informatics Research Group
University Paderborn, Germany
jsm, carsten, olasch@uni-paderborn.de

Abstract: The Didactics of Informatics research group at the University of Paderborn is involved in efforts to design, implement and evaluate a curriculum for Media education for prospective teachers at the secondary school level. One major issue is the question of whether it is necessary for future teachers to learn the basic concepts of informatics, and if so, which topics within informatics are relevant, and which main objectives should be achieved. After two years of seminars on basic informatics for students of education at the University of Paderborn, it is now possible to submit the preliminary results. The presented paper discusses the rationale behind introducing informatics into media education for teachers, and describes elements of the curriculum, as well as the main teaching objectives for a better understanding of computer-based media.

The Role of Computer-Based Media in School

From the Perspective of the Student

Students today should have many different abilities in using computers and computer-based media. First of all, they must have the ability to use hardware and software (i.e. to turn on a computer, use a word processor, work cooperatively over a network, etc.) Because of the ongoing revolution of products and ideas, training for specific software products will not sufficiently prepare students for future demands. Today's students should be able to analyse and evaluate the social impact of using computer systems and computer-based media (CBM). Therefore, it is not sufficient to teach only the basics of computer operation. Students should learn about concepts of computer-based media, digital coding of data, and computer networks (especially the Internet), as well as the relationship between traditional and computer-based media. They should acquire basic skills and understand the functionality of new media such that they can evaluate its future impact on society. These are the elements of competency in media that should be taught to students.

From the Perspective of the Instructor

Educators have tasks which range from planning and instructing courses to administration of schools or counselling of students, and they can incorporate CBM into these areas. But if students should learn more than simple computer operations, then teachers must as well. They should not only have media competency so that they can work with computers, but also didactical media competency in order to integrate computers into the learning and teaching processes. Finally, teachers need media educational competency to teach computer-based media. It is essential that teachers learn to use CBM in different classroom settings (scenarios), in order to enhance the learning process. These scenarios are helpful in designing a curriculum for media education in teacher training (Magenheim & Schubert, 2000).
Organisational Aspects

Administration can also benefit from the use of computer-based media. Although its needs differ from those of the classroom, administration is concerned with the improvement of the school system, and this can be done with CBM. It can be used to create a more customized learning environment, design curricula for media education or create new ways of teaching and learning, make the school more responsive to community needs and vice versa, administrate school equipment and networks, and make the school dynamic and open to change.

The role of computer-based media in school involves learning by the students, instruction by the teachers, and organisation and improvement by the administration. Teachers need not only a specific tool, but knowledge about how it works in order to adapt the tool to their specific needs. This means that the curriculum must be generic, and must include the basics of informatics. If future instructors do not obtain grounding in informatics in their media classes, they will not be able to use the full potential of computer-based media.

To gain an understanding of the possibilities of computer-based media that cover the above perspectives and allow prospective teachers to keep their understanding up to date, a curriculum for media education must supply the learners with a solid foundation. This foundation is built by incorporating the specific qualities of CBM into the curriculum.

One of these qualities is digitalization. CBM uses digitally-represented data, regardless of form (text, video, sound, etc). This quality allows certain features such as transforming, copying, etc. To understand this aspect, one must consider the technical and informatics background of digitalization.

Another important aspect is to understand how the processing of digitally-coded data and its representation is interwoven with the human processing of information in media use. CBM are tools for constructing, transforming, and copying digital data, and simultaneously, they convey information. One must comprehend this duality of CBM in order to fully grasp the effect on our daily lives.

To understand and use CBM effectively, its construction process must be considered; software development is not only a technical process, but must take into account cognitive processes and needs of the users (Magenheim, 2001). This is especially important in an educational context where prospective teachers should learn to apply pedagogical software tools, to evaluate and (hopefully) to improve them in cooperation with software developers.

It is clear that these goals are only reachable by a curriculum that includes basic elements of informatics. These will be discussed later, but first, we consider other elements necessary for the development of a curriculum.
Elements of a Curriculum for Media Education in Teacher Training

Many factors influence a curriculum for media education. Arts and sciences (not a topic of this paper) contribute to its concepts, content, and teaching methods. However, these cannot entirely dictate the curriculum, as they are filtered through normative settings (society, educational conventions and politics). They do assist in forming the requirements, which are necessary in the use of computer-based media. From these requirements, tasks and scenarios can be generated and worked into the construction of the curriculum. Specific contents can be taken from the general curriculum to cover different tasks.

The curriculum for media education in teacher training developed by the research group at the University of Paderborn does not claim to be complete; rather, it is focused on those aspects of a curriculum which require fundamentals of informatics.

Basic Areas of Informatics in Media Education for Teachers

As we have seen, instructors must have different skills and knowledge areas to be successful. There must be a way to distinguish the use of specific software tools from the use of computer-based media. Useful here is Basic Areas of Informatics (BAI), which describes the fundamentals of informatics for general media education (Schulte & Scheel, 2001). BAI serves as a theoretical foundation for forming basic skills and knowledge. BAI was developed in the context of didactics of informatics to specify the role of informatics in secondary education for a general media education. Thus, didactical concepts, common media education concepts, and corresponding work in informatics were analyzed, with a resulting abstract consisting of four tasks for building the informatical foundations of a general media education. These areas are:

1. **Concepts of formalism and problem solving strategies in informatics**
   In informatics, modelling languages and tools are developed for the representation of information. We call them representation techniques. Modelling tools such as UML are usable outside of the software development process. The aim here is to supply students with the background knowledge necessary to competently use these tools. On the one hand, students should be able to express representations of things
structures and processes in different subject areas) formally with the aid of representation techniques. On the other hand, they should learn skills for using software products (i.e. word processors, spreadsheets) to represent things. The aim is not to teach a specific user interface, but rather to teach understanding for the typical media functions of these computer-based tools – for example, the proper use of style sheets. These functions are 1) to represent things, 2) to (re)arrange representations, 3) to save representations in data files, and 4) to provide others with information about these products (see Hubwieser, 1997). This Area does not cover questions concerning the content or aesthetics of representations.

2. Technical basics
This Area describes the technical and informatics skills necessary for using computer-based media. It covers skills such as choosing the appropriate data format and software-tool, building suitable directory trees to manage data, and querying databases and search engines. Students should gain an overview of the technical infrastructure in which they use computer-based media: For instance, the global networks, protocols and software tools that build the World Wide Web.

3. Semiotics
In computer-based media, symbols have a dual purpose: They form programs to control machines, but they also serve as media in a broader sense; for example, source code for a program is executed by a machine but understood by a human. The learning goal of this Area is to reflect on these specific semiotic implications of computer-based media. The user communicates with other users, but interacts with the machine (human-computer interaction). There lies an area between which is a combination between human-computer interaction and communication between humans. This can be seen in automated email systems, in which a message is generated by computer as a result of statistical information, but it is possible for a human to add a personal note (i.e. a user might receive a note thanking him or her for contributions) (Maurer, 1999).

Students should also be able to understand the possibilities and the role of technology in automated and partially-automated communication processes. Therefore they should learn to differentiate between the ways in which humans and computers process data. Media functions can be addressed to further this understanding.

4. Social impacts of computer-based media
The goal here is to become aware that software-tools and description techniques – in short, the technical infrastructure – a) is purposely created to meet specific aims, b) is changeable, and c) embodies implicit values and regulates individual behaviour (Lessig, 1999).

It is important here to contextualise the current computer, software, or internet generation within its development history. In many cases, the functionality of a current version is only clear with knowledge of its evolution.

All in all, the BAI describes essential basic skills for prospective teachers, but does not cover an important aspect which was previously mentioned: The specific function of computer-based media in school and typical scenarios of its use in teaching and learning.

Scaffolding a curriculum of basic informatics within media education
The professional future of an educator is determined by activities within the scope of the classroom, administration, or other didactic area, as well as communications with students, parents, and community administrators. These are termed action scenarios. Often, it is useful or even necessary to integrate computer-based media into teachers’ professional lives.

These situations can be incorporated into seminars for future teachers, on the topic of media education and fundamentals of informatics. First, we analyse professional scenarios of teachers and identify typical situations of computer-based media use. Then, we cover the fundamentals of informatics which teachers should know, in order to foster:
- a fundamental understanding of CBM
- elementary skills in handling a sample of computer-based software tools
- an effective use of computer-based media in school-related action scenarios
- the ability to organise learning and teaching processes with CBM in different subjects
- the ability to organise media education in the classroom, with CBM itself an educational topic
Finally we must structure these situations based on fundamentals of informatics with regard to the tasks previously described. This will generate a generic curriculum enabling us to create a selection of contents and objectives for university courses on the BAI of CBM. The table below describes how to assign each action scenario to a Basic Area of Informatics, as well as describing outlines for problem-centred seminars. The contents listed in the table below should not all be covered in a single seminar, but represent possible options describing how to teach the basics of informatics in a problem-centred seminar. In some cases, it will be possible to re-assign contents to different Areas. For example, xml is assigned to Area 1 (as a formalism) but can also demonstrate how documents are divided into content, structure, and layout, thereby allowing specific semiotic functions and automated processing (see Area 3). Nevertheless, the curriculum will be helpful in organising student seminars. These seminars should focus on practical problems and issues regarding the use of CBM in teachers' professional lives. University seminars and related materials with the topic of BAI should be organised around a certain action scenario. The project should contain an assignment to produce specific computer-based media to be used later in a real pedagogic action scenario. While finding solutions for this relatively complex problem, students shall not only learn about different functions of CBM and how to use them in a pedagogic context but also gain a fundamental understanding of basic areas of informatics. The university seminars should not be organised simply as lectures, but should offer students different action scenarios in which they can exercise the use of CBM and develop media products of their own as a contribution to the complex problem-solving process. The concept also includes aspects of constructivist learning, because students should have access to a hypertext learning environment, with relevant materials such as supplement texts, pictures, animations, videos, interactive forms and so on. By navigating this web-based learning environment, they will be able to organise learning processes of their own and gain the knowledge they need to solve the problem presented in a seminar. This will give them the ability to use their newly acquired knowledge and skills on CBM in a variety of similar scenarios. At minimum, after attending another one or two such courses, they will finally have the media competency described in the objectives above, and be able to independently manage complex assignments using Information and Communication Technologies (ICT).

Abstract: The need for accurate and current scientific information in the fast paced Internet-aware world has prompted the scientific community to develop tools that reduce the scientist’s time and effort to make digital information available to all interested parties. The availability of such tools has made the Internet a vast digital repository of information. But the ad hoc nature in which information is gathered and organized on the web, makes access to such information a time consuming and sometimes frustrating affair. Digital library systems have the potential for solving problems in maintaining high quality scientific content delivered via the web by providing tools for scientists to collect, verify, organize, manage, and update their collections. This paper describes an environment that reduces the effort and time required by scientists to share their data with other collaborators in an automated and asynchronous manner, thereby allowing them to focus mostly on their own scientific practice. The data is maintained as a collaborative collection in a digital library that can also be used as an educational resource.

1. Introduction

Digital library systems have the potential for solving problems in maintaining high quality scientific content delivered via the web by providing tools for scientists to collect, verify, organize, manage, and update their collections. The ability of the Internet to bring geographically distant scientists and researchers together as a community provides the opportunity to build collaborative digital libraries that can provide a larger quantity and higher quality of data. The notions of ownership and attribution of intellectual and scientific property must be retained and the contributors must control sharing of their data.

This paper describes an environment that reduces the effort and time required by scientists to share their data with other collaborators in an automated and asynchronous manner, thereby allowing them to focus mostly on their own scientific practice. The data is maintained as a collaborative collection in a digital library that can also be used as an educational resource [1]. The collection can be continually updated by the contributors and used or reused to build course content via tools provided by the digital library [2].

2. Research Context

2.1 Digital Flora of Texas

The Digital Flora of Texas (DFT) [3] project was established as an open, web-based digital resource. Participants currently include scientists from 43 contributing herbaria as well as many researchers at public
and private organizations [4]. Each participating herbarium (or collection) has its own curator or group of curators who verify and validate the data they contribute. The DFT project has a wide array of web tools, collections and prototype systems that can be used for research or education. The DFT contains information visualization tools for displaying statistical and distributional maps of taxa of the flora of Texas. In addition, upload and data conversion tools provide an automated way for researchers to easily build collections and share them with the scientific community. The DFT collections are accessible through the web, making it easier for researchers, scientists, instructors and students to access accurate and up to date information. Instructors can use the collections to construct web-based content for their courses. These educational and scientific resources can be used and reused in many different contexts [5,6,7].

2.2 Collections

DFT collections are built either by a group of collaborating researchers or by individual researchers. In either case, the collections are publicly available and all scientists/researchers can participate in verifying and validating the result. Researchers, who are geographically distributed, collaborate using the various tools provided by the DFT project to build and maintain the following collections:

- **The Herbarium Specimen Browser** is the Internet’s only multi-herbarium specimen data portal. It offers unique filtering, mapping and listing displays for a growing mass (more than 240,000 currently) of specimens taken from the participating Texas herbaria [8].
- **The Image Gallery** provides access to 8000 images of plants representing families found in Texas [9].
- **The Contributor collection** contains contact information for all contributors who generate digital content for this community-based collaborative digital library [10,11].

The following collections are a result of individual research:

- **The Bibliography** (Wilson) provides over 3000 bibliographic references for the Texas Flora [12].
- **The Checklist of the Vascular Plants of Texas** (Hatch, et al) refers to 180 families, ~1300 genera, and ~5000 species [13].
- **The Centex Flora** (Reed) is a manual of the dicot flora of Brazos and surrounding counties that provides keys and descriptions for 104 families, 489 genera and 1104 species [14,15].
- **The Texas Grasses** (Hatch and Dawson) has keys, descriptions and images for 142 genera and ~550 species in the grass family [16].

3. Design of a Collaborative Digital Library

3.1 Model of Collaboration/Interaction with System Components

In the design of a scientific collaborative digital library, it is of utmost importance for the contributor to maintain ownership of his/her scientific and intellectual property. The notion of ownership and control is maintained in the DFT because the contributors decide when to share their data and what part of their data to share. Automation is used only under control of the contributor and is a two step process: 1) uploading data to share and 2) incorporating data into the public collection. The sharing occurs at different times and from different geographic locations.

3.2 Rationale for Choice of Tools

The DFT is using the previously defined Flora of Texas Consortium (FTC) data model [17] as the common data format for its collections. eXtensible Markup Language (XML) [18] is ideal for the FTC data model since it renders a strong sense of structure to data and can be validated and maintained with little or no programming. A wide variety of Application Programming Interfaces (APIs) are also available that can convert a wide range of data formats to XML.

Greenstone is an open source digital library system that automatically provides multiple, user-defined browsing and searching indexes on the collections it maintains. It provides plugins for converting many standard format files (e.g. Word, PDF) to XML and allows rebuilding of collections while they are in use.
(no down time). It also provides a standard, yet customizable user interface and compresses its documents, thereby saving space and, more importantly, mitigating the effect of long XML tags.

3.3 System Architecture

Contributors can upload their data and build or rebuild a collection in the DFT at any time. The contributors may use any program they wish to maintain their personal collections (e.g. Word, Excel, Access, Filemaker Pro). When they are ready to upload their data, they dump it in a flat ASCII file (an operation that is standard with all data management tools). The upload system converts the data into XML and validates it against the FTC data model. Errors, if any, are reported to the contributors. Records without errors are uploaded and are ready to be added to the collection. The uploaded data is not shared with the other collaborators until the contributor explicitly builds or rebuilds a collection of this validated data, making it available for public use. Other collaborators as well as non-specialists with an interest in the domain can access the collection using the common web-based user interface provided by Greenstone or by customizing their own user interface. This process relieves the scientists of the tasks of converting data into various acceptable formats enabling them to channel more time and effort toward practicing their science (Figure 1).

The Herbarium Specimen Browser, Image Gallery and Contributor collections mentioned in section 2 are collections that are built and maintained by geographically distributed contributors and follow the same methodology as described above. To upload his/her data, the contributor uses the web-based upload system [19] to specify the number and order of fields, field separators and field enclosures. Figures 2 and 3 show the upload form and an example search results page for the Image Gallery collection.

4. Lessons Learned

4.1 Scientific Practice

"The products of Systematic Botany, previously generated locally as static, hardcopy documents, can now be presented as collaborative enterprises from distributed centers as high-content, dynamic data resources that are constantly updated and refined." [1] The system architecture of the DFT enhances the sharing and browsing aspects of collaboration by providing a web-based input system that converts the uploaded data to standard XML format. This data is then added to the shared collection under control of the contributor. Thus, scientists can follow this process without disrupting their normal working style. This automated process shortens the time to share scientific information and the notion of ownership of intellectual and scientific property is maintained, as the scientists control their own collections and share whenever they are ready. The upload system also filters the data and performs various error checks (e.g. typographical error checks) in order to verify the data. Scientists appreciate the fact that their data is verified by the input system and by the information visualization tools (e.g. the mapping system) provided to browse through the digital library.

4.2 Education

We have observed that collaborators use and reuse either their own information content or that of the other collaborators in the digital library to build new course structures and educational packages. Tools provided with the digital library expedite the process of reuse and construction of new packages. Students are also presented with a larger and more diverse collection and are not restricted by the limitations of a localized collection. In most cases, we observed that collaborators found it useful to have cross collection querying/browsing, wherein the results of a search on one collection are used to search an entirely different collection. This exploratory learning methodology helps students find information they are looking for while following trails that interest them the most. Greenstone supports this cross collection querying/browsing model, enabling the user to seamlessly move from one collection to another.
4.3 Digital Libraries

The immediate benefit of having a collaborative digital library is the continuous updating and refinement of the information content and accuracy of information provided by the collaborative interactions of the scientists. Since it is fairly easy to maintain and browse the digital library, we find more and more collections being built using the system we have described. For example, the Image Gallery collection was developed because the scientists involved find the model of collaboration easy to use. Collections do indeed have their own unique identities and are a scientifically valid resource, but they also tend to become integrated in the notion of a digital library that allows cross collection querying/browsing.

Figure 1. Architecture for DFT Collaborative Digital Library Collections.

Figure 2. Example upload form for the Image Gallery Collection.

Figure 3. Example search results page for the Image Gallery Collection.
5. Future Work

Currently, the system does not have collaborative tools to support a peer review process by a group of curators [20]. With this set of tools, any person with botanical interests and a computer connected to the Internet could contribute to the digital library. The curators would be responsible for accepting or rejecting contributions and for maintaining high quality content. Considering the ease of creating and maintaining collections, we would like to put more content in the digital library in the form of a monthly journal, a collection of thesis and dissertations, and a collection of videos of lectures and field trips; thus adding various media formats to the digital collection and enhancing the value of the collections. Currently, collaborating scientists and university students are the main beneficiaries of the DFT. It would also be interesting to see how well the system scales to the needs of primary and secondary students.

Abstract: Chydenius Institute (Research and Training Centre of Jyväskylä University) implements the Finnish Virtual University. In Kaustinen and Kokkola regions, which are rural areas, is created a network of learning centres in municipalities. In this way every citizen has the possibility to develop him/herself occupationally or because of interest. The learning centres have computers with ATM-network and videoconferencing facilities. Every citizen is able to come to study in web-courses, to surf in internet or to take part in conversations in newsgroups or posting lists. There are organized open lessons in real-time via two-way videoconferencing where people can follow experts in different areas of life. Speeches of Studia Generalia offer interesting themes and discussions of current topics. In this way people have the possibility to study and distance makes no difference: we are all equal.

Chydenius Institute is a Network University for adults. It’s located in Kokkola, in the western coast of Finland. Administrative it’s an autonomous Research and Training Centre of Jyväskylä University. Functionally Chydenius Institute belongs also to the University of Oulu because of the agreement of cooperation. Under discussion is the agreement with the University of Vaasa.

Practically Chydenius Institute cooperates with universities in these areas:
- University of Jyväskylä: e.g. educational and social sciences, information technology
- University of Oulu: e.g. medicine, electronic engineering
- University of Vaasa: economics

In addition to this, Chydenius Institute implements the Finnish Virtual University. This consortium of all the universities in Finland has a purpose to develop web-based learning and implement the strategy of the National Information Society announced by the Ministry of Education.

Finland is one of the largest countries in Europe. There are plenty of rural areas and long distances. That’s why it has been natural to develop distance learning methods. Videoconferencing has become very common way of delivering teaching in educational institutes and schools, but also companies are used to have it as a communication tool between them.

Chydenius Institute, an Adult Network University, offers most of the lessons for Master of Electronic Engineering via videoconferencing, using IP- and ISDN-based technology. The students are working daytime and participate in lessons during evenings and weekends. Videoconferencing makes possible for them to work and stay with their families without travelling to the University of Oulu (at 250 km from Kokkola). The same model is implemented with the Master studies of Information Technology organized by University of Jyväskylä. Because the Ostrobothnia region has an ATM-network, there has been delivered earlier mentioned lessons also for homes of some students.
During the academic year 2001-2002 the Open University of Oulu University has offered 15 credits of Educational Technology. This training has delivered for Chydenius Institute in Kokkola and Kaustinen using ISDN-bridge. There has been given lectures also from other universities using videoconferencing.

In Kaustinen and Kokkola regions, which are rural areas in Central Ostrobothnia, has been created a network of learning centres in municipalities. In this way every citizen has the possibility to develop him/herself occupationally or because of interest. The learning centres have computers with ATM-network and videoconferencing facilities. Every citizen is able to come to study in web-courses, to surf in internet or to take part in conversations in newsgroups or posting lists. There are organized open lessons via two-way videoconferencing where people can follow experts in different areas of life. Speeches of Studia Generalia offer interesting thems and discussions of latest happenings. In this way people have the possibility to be aware of recent research and information.

There has been offered training for enterprizes and companies in Kokkola and Kaustinen region using this learning centre network that Chydenius Institute has organised. Municipality of Lestijärvi has own IP and ISDN bridge/gateway, which has been utilised in this training. Also associations and communities use the network of learning centres.

Learning centres are located in municipalities depending on their own possibilities. They might be in school, library, folk institute or municipal office. Every municipality has invested for the infrastructure: in a learning centre there should be a number of computers with ATM-network and videoconferencing facilities. These learning centres are open either office-hours or in the evenings. Every municipality decides according to the needs and practicalness.

Citizens who don’t have computers at home or they don’t have low modems are very welcome to use the facilities of the learning centre. In this way everybody has the possibility to study interesting subjects in open universities, in web-courses and also in learning environments that the Finnish Virtual University offers. People are able to develop their knowledge of ICT and utilize the use of ICT. University studies and networks come close to everybody and distance makes no difference: We are all equal!

Abstract: In this paper we present the way a multi-criteria decision making methodology is applied in the case of agent-based selection of offered learning objects. The problem of selection is modeled as a decision making one, with the decision variables being the learner model and the learning objects’ educational description. In this way, selection of educational content is based on dynamic data input collected at the time of the decision. This methodology is studied in the context of an agent-based e-market for educational content brokering, and is engaged by the broker agents recommending learning objects to learners, according to their cognitive style.

Introduction

In agent-mediated educational content brokering, artificial agents are responsible of locating offered learning objects, negotiating with the content providers on the terms of the service provision, and for presenting the learner with those offers that best match his/her needs and preferences. Successful completion of this task is based on two parameters: the capability of the mediating agent to understand and model the user needs, and its capability to evaluate all available learning objects and recommend the most suitable. The most common ways to introduce intelligent brokering for educational content are based on techniques from Artificial Intelligence (AI): knowledge representation, reasoning, and expert systems, often offer tools and techniques in the developers of such systems since they allow the agent to behave intelligently in two ways; first, with the ability to store the knowledge of the experts (for example using a knowledge base); second, using the previous knowledge to infer rational decisions.

In the last years though, most agent-based e-commerce systems engage methodologies and tools which originally come from sciences other than AI; these include methods and techniques from Game Theory, Optimization and Decision Making (Guttman et al, 1998). In this paper, we are going to approach the problem of content selection (know as the recommendation problem in e-commerce systems) from a decision-making point of view. We are going to introduce how a multi-criteria decision making (MCDM) methodology is applied in the case of agent-based educational content brokering, and we are going to discuss the benefits and drawbacks of this approach.

There is an interesting feature in this approach: it replaces searching knowledge inside a knowledge base, using constraints posed by logical expressions and logic rules, with an evaluation of knowledge using mathematical formulations. It can therefore provide measures of “how much better one decision is compared to another”, even if both decisions are rational and solve the constraints problem. This usually sounds rather awkward though – how can we represent the expert knowledge in terms of mathematical expressions? Logic variables (CategoryOfUser="This") and logic rules (IF CategoryOfUser="This" THEN TypeOfContent="That") are simple, and easily comprehended; how is the learner going to be modeled using mathematical variables, and how is the expert going to express the experience in a mathematical form?

We will try to give answers to these questions by introducing the example of modeling the learners with the classic Honey and Mumford cognitive styles model (1992). We will introduce the basic principles of a multi-criteria decision making methodology, and study which parameters of the Honey & Mumford model serve as criteria for the selection of the available content (learning objects); we will also study a method that can be used to carry out this selection. Finally, we will present how this decision-making procedure is incorporated into an agent-based system, and how the broker agents operate it.
The Honey & Mumford Model

Tennant (1988) defined cognitive style as "an individual's characteristic and consistent approach to organizing and processing information". There are several learning and cognitive styles theories and models, which categorize learners in terms of instructional preferences, information processing and personality styles, and are usually employed for the realization of individualized instruction (for a survey, see Sampson et al., 2002). In order to demonstrate how a cognitive style model can be used in order to create the multi-criteria selection model, we will engage the classic Honey and Mumford model. The Honey and Mumford model (1992) is a cognitive style model, developed for use in commerce, management and training situations. It categorizes learners according to the following dimensions of a person's learning style: Theorist, Activist, Reflector and Pragmatist. In order to rate learners on each one of the categories, the model uses the answers in a specially designed Learning Styles Questionnaire (LSQ) of 80 questions, with binary answers of "Correct" and "False", and after an internal processing of the results, it provides a percentage weight for each category. Therefore, the learner's style is defined depending on the weight at each learning style category.

![Figure 1: An example learner's model after a LSQ is processed. It provides a measure of how the learner 'scored' in every category (source: PSI-Press, http://www.psi-press.co.uk/)](image)

From a practical point of view, it is important that a learner's model describes not only how learners are categorised, but also how the instruction method should be adapted for each learner category (Spector, 2001). The real complexity for the designers of e-learning systems arises when they try to match subject matter with learner characteristics and appropriate instructional methods. Such a process includes both learner modeling (using the Honey & Mumford model results - see Figure 1) and description of the educational properties of the learning content (that is e.g. a description of how suitable a course is for the learners having a specific cognitive style). The matching procedure involves all these parameters as input - and still a proper matching mechanism has to be found. We address this problem as a decision making one.

Multi-Criteria Decision Making Methodology

According to Roy (1996) the general methodology of decision making problems includes four steps: (i) defining the object of the decision, that is the set of potential actions, and the problematic of the decision; (ii) studying the parameters influencing decision and defining so a set of criteria; (iii) choosing an appropriate multi-criteria aggregation method; (iv) proceeding at the activity of decision aid.

Step One: The Object of Decision

The first step includes definition of the decision variables in a form of a consideration set $A$. In the case of educational content brokering, this set includes all the available learning objects, which will be evaluated by the decision maker (in our case, the brokering agent). What is called 'the problematic of the decision' is the definition of what kind of evaluation or choice does the decision maker want to make upon the different objects available in set $A$;
in the case of broker agents recommending a learning object, the decision problematic is “selection of one”. That is
the selection of one action from the consideration set of the form \( \tau = \{ a_1, a_2, ..., a_n \} \).

**Step Two: The Criteria**

The next step is deciding what will be the criteria upon which the learning object will be evaluated. This means defining a consistent family of criteria, assuming that these criteria are non-decreasing value functions, exhaustive and non-redundant. Each criterion is defined on \( A \) as it follows:

\[ g_i : A \rightarrow [g_{i\text{min}}, g_{i\text{max}}] \subseteq \mathbb{R} / \exists a \rightarrow g(a) \in \mathbb{R} \text{, where } [g_{i\text{min}}, g_{i\text{max}}] \text{ is the criterion evaluation scale, with } g_{i\text{min}} \text{ the worst level of the } i \text{th criterion, } g_{i\text{max}} \text{ the best level of the } i \text{th criterion, } g_i(a) \text{ the evaluation or performance of action } a \text{ on the } i \text{th criterion and } g(a) \text{ the vector of performances of action } a \text{ on the } n \text{ criteria (Jacquet-Lagreze & Siskos, 2001).} \]

In the case of educational content brokering, there are two ways to deal with the selection of the criteria. Recommendation is usually based on criteria as price, time of delivery, form of delivery, etc. - a common practice in e-commerce systems. We would like to introduce another aspect of recommendation in agent-based learning environments: based on the pedagogical profile of the learner. That is using the categories of the learner model as criteria; each learning object will be evaluated on how suitable it is for each category of learners. This is exactly the same as making an expression as “TypeOfContent= "That" ”. To be more specific, in a similar case an expert system would need a definition as: TypeOfContent= "SuitableForActivists". In the case multiple criteria are used for the description of the content, this definition is transformed (remaining fully equivalent) to something similar to this:

- SuitabilityOfContentForTheorists = "NotSuitableAtAll"
- SuitabilityOfContentForActivists = "Perfectly suitable"
- SuitabilityOfContentForReflectors = "NotSuitableAtAll"
- SuitabilityOfContentForPragmatists = "NotSuitableAtAll"

Therefore, as criteria we will use the four categories of the Honey & Mumford, which can take their values from a 5-scaled climax of qualitative descriptions ["Not suitable at all", "Not very suitable", "Moderately suitable", "Very suitable", "Perfectly suitable"] showing the evaluation of each learning object upon each categories. It is obvious that a learning object (e.g. an on-line course) is never "Perfectly Suitable" for a learner category and "Not Suitable At All" for the rest -it rather addresses some of the needs of other categories of learners too. Therefore, such an evaluation provides the expert with a way to precisely describe the pedagogical ‘profile’ of a learning object. This meta-data description is a criteria definition that fully complies with the definition of the criteria according to Roy (1996).

**Step Three: The Utility Model**

First of all, we have to define the preference model that will be used from the broker agent to make the decision; as we have already stated, in our case we are using the Honey & Mumford learner model as a preference model. The expression of the model is then \( p_x=[p_1, p_2, p_3, p_4] \), where \( p_1, p_2, p_3, p_4 \) are the weights inferred after the learner has completed the Honey & Mumford LSQ and the results have been processed.

This is the point where the analyst has to define which evaluation method will be used; that is, which multi-criteria decision making method will be engaged in order for the decision to be best modeled and simulated. In this paper we will use one of the most traditional approaches, that leads to a functional representation \( g \) that can be formed directly from the criteria \( g_1, ..., g_n \) that constitute \( A \). The goal of using this approach is to present how the methodology works – depending on the application, other more complex methods can be used. Thus, the comprehensive preference model is characterized by a unique synthesizing criterion \( g: g(a)=V[g_1(a), ..., g_n(a)] \), where \( V \) is an aggregation function. The function will be in the form:

\[
V(a) = \sum p_i g_i(a)
\]

where \( g_i(a) \) are the evaluations of each learning object \( a \) regarding the suitability for each category of learners. The weights \( p_i \) consist the preference model, which are the parameters calculated by the Honey and Mumford LSQ. The final value of \( V \) is the total utility of each learning object for the learner under study.
Step Four: The Activity of Decision Aid

Let us now introduce the way the activity of decision making will be carried out, in the context of an agent-based system. We define a generic architecture, with agents capable of handling and communicating descriptions of learning objects, as defined in the previous paragraph. The three basic roles are:

**The Assistant.** The assistant agents are responsible for user needs and requirements elicitation, and formulation of requests into messages understandable by the broker repository system. The LAssistant is the agent that interacts with the user and can identify the request for a learning object. The CPAssistant is the agent that gets the learning object descriptions from the Content Providers, and publishes them as offers in the e-market. The TAssistant serves as the pedagogical counselor of the learner: it creates the learner model of the user and provides this model to the LBroker. The TAssistant can also be the expert that describes a learning object using the cognitive styles; this is a task that can be directly carried out by the Content Author too, so we will not focus more on this point.

**The Broker.** The broker agents represent each human user in the e-market and facilitate educational content seeking or advertising. The Broker agents interact among each other in the Brokerage Pool and either advertise published learning objects, or make requests when looking for them. The LBroker evaluates the available offers from the CPBrokers in the way described in the previous paragraphs. The LBroker then recommends the content selection to the LAssistant. The Brokers are also responsible for negotiation among the participating parties upon the terms of the service provisioning (beyond the scope of this paper).

**The Matchmaker.** This facilitator agent provides mediating services, by informing agents about other agents of the broker repository and their availability. The Matchmaker provides all necessary administrative support information to the human administrator of the agent pool.

We can see that the Broker agent engaging the multi-criteria methodology previously described is the LBroker. In order to pedagogically evaluate the available learning objects and recommend one to the learner, the LBroker needs the learner model (provided by the user) and the meta-description of the available learning objects (provided by the CPBroker or the Tutor). Other kinds of evaluation of the offers (e.g. based on the price, time, and other terms of delivery) are beyond the scope of this paper.

Usage Scenario

Let us demonstrate how the recommendation procedure works in this agent-based system. A content author creates different elearning courses concerning the same subject. The author wishes those courses to address different learner needs, depending on the cognitive style of the learner. When a learning object (course) is created, the content author also provides an evaluation of its suitability for each different category of the Honey & Mumford model. The author creates thus five different learning objects, with different pedagogical descriptions (as depicted in Table 1).

<table>
<thead>
<tr>
<th></th>
<th>LO1</th>
<th>LO2</th>
<th>LO3</th>
<th>LO4</th>
<th>LO5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activist</td>
<td>3</td>
<td>2</td>
<td>5</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>Reflector</td>
<td>1</td>
<td>3</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>Theorist</td>
<td>4</td>
<td>5</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Pragmatist</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>5</td>
<td>2</td>
</tr>
</tbody>
</table>

Table 1: The content author provides an description of each learning object (LO) on a scale from ‘1- Not Suitable At All’ to ‘5-Perfectly Suitable’, regarding each one of the cognitive categories.
Introducing the multi-criteria methodology presented in the previous section the Broker will select a learning object according to these steps:

1. The Tutor provides a multi-attribute cognitive model of the user, according to the results of the Honey and Mumford model (Table 2).
2. When the Learner’s Broker receives the five offers for learning objects, it calculates the total utility (that is suitability) of each one, using the methodology described in the previous section.
3. The Learner’s Broker selects the most appropriate learning object to be presented to the user (Table 3).

It is interesting to note in this example the difference between the application of a simple rule-based selection of the learning object (in this case the agent would classify the learner as ‘Activist’ and would propose the learning object LO3) and the proposed methodology. Using the multi-attribute cognitive model and the multi-criteria evaluation model, we observe that the most appropriate learning object seems to be LO4, being the only one suitable for the combination of categories that characterize the specific learner’s cognitive style.

### Conclusions and Future Work

In this paper we presented an agent-based recommendation system for educational content brokering that implements a multi-criteria decision making methodology. Due to the differences of learners’ cognitive models, recommendation can be either carried out by classifying learners into broader categories that then are directly linked to learning objects e.g. with rules like IF ‘this type of learner’ THEN ‘this type of material’ or by enhancing the mediating agent with the appropriate intelligence to propose the most suitable learning object available at the market. By engaging a multi-attribute utility (MAUT) model, the brokering agents do not need to possess intelligence in the form of a knowledge base or hard-coded rules but only to include the multi-attribute evaluation logic in their decision making module. In this way learners are modeled in a multi-attribute way, instead of being simply classified into a general learning category, learning objects are described according to their educational scopes, brokering agents dynamically evaluate all available proposals of content, and select the learning objects most suitable for the specific learner’s profile, and finally the knowledge the broker agents have to contain in permanent storage is minimized since only the MAUT evaluation formula is needed; all other input is provided at run-time.

In this paper, the decision problem was modeled using the Honey and Mumford LSQ parameters as the preference model, but we believe that the proposed methodology can be similarly applied in the case of other cognitive style models too. Future research will be focused on applying of several other LS models, either separately or combined. An issue to be also studied is the application of more complex multi-criteria decision making methodologies for modeling the user preferences; such methodologies provide easier and more realistic means of expressing preferences, but require more complicated MCDM methods to conclude to the best proposal for each learner, as one of the famous family of the ELECTRE methods (Roy, 1996).

Current international standardization efforts regarding syntax and semantics of a learner model that characterize a learner and his or her knowledge/abilities; i.e. IMS LIP (IMS, 2001), IEEE LTSC PAPI (IEEE, 2000) do not explicitly define information about the cognitive style of the learner. However, both the IMS LIP and IEEE PAPI Learner preference/performance data types provide data elements that allow cognitive style related information to be
stored in an appropriate form. These data types could be used in order to represent a multi-attribute representation of
the cognitive style model of the learner, by an appropriate extension of the corresponding XML schema.

The IST Project KOD “Knowledge-On-Demand” (KOD, 2001) engages a multi-agent brokering system for
selection of learning objects and dynamic synthesis of on-line courses. In the case of KOD, intelligence is included
into the learning objects in the form of rules that express the suitability of the object for each type of learners, so that
courses can be constructed based on how the learning objects are characterized. This is a case very close to the
problem we introduced, and we are currently studying ways to introduce the multi-criteria descriptions in the learning
objects of KOD, in order for the KOD agents to be able to dynamically assess and synthesize courses based on the
introduced decision making methodology and not on prescribed rules.

“Supporting Interns’ Work in Inclusive Classrooms”

Cindy Marble, John Davis
National Center for Online Learning and Research
University of Idaho
United States
cindym@uidaho.edu
jcdavis@uidaho.edu

Abstract: The University of Idaho has been redesigning its teacher preparation program for four years. The redesign has included the development of a set of core courses that are required for all teacher certifications. These four courses include a “strand” of content about students with disabilities and methods for working with them in inclusive settings. The special education content in the final course is focused on mediating the interns’ experiences in their yearlong internship placements, which are all over the state. We are currently developing an online support structure for the students to complete the special education component of the final core course. This paper describes that online structure that also includes a method for collecting data about the interns’ use of the system and the content they submit.

Introduction

Research on models of training teacher candidates for their work in inclusive environments has shown that special education content integrated into existing coursework with an accompanying field experience is more effective than other models studied. Further, recent research has shown that the integration of online delivery modes with traditional instructional practice is effective. Therefore, the integrated model we are implementing to provide continued support during the internship holds a great deal of promise for helping our teacher candidates to become effective inclusive educators.

Issues in the Preparation of Inclusive Educators

Teacher candidates enter their programs with clusters of beliefs based on their experiences as students, values, and other background determinants. These determinants influence how they approach their programs and their developing perceptions of what it means to be a teacher (Richardson 1996).

Teacher candidates’ entering beliefs about students and learning will be challenged when they encounter student with disabilities in the general education classroom. The belief that teaching is a matter of telling or showing and learning is committing information to memory will come into question since many students with disabilities have difficulties with this kind of teaching practice (McDiarmid 1989).

These beliefs about teaching and learning make it difficult for teacher educators to help teacher candidates understand instruction about accommodating students with disabilities. Anderson and Bird (1995) point out that, based on their lack of exposure to inclusive practices, teacher candidates may have difficulties assimilating instruction about accommodating students with disabilities into their current understandings of teaching and learning. Mediating these beliefs is especially critical for facilitating the progress of inclusive efforts in schools.

Teacher educators have attempted numerous designs to train general education teacher candidates specifically for effective inclusive practices. These designs have ranged from one-time training events, to separate courses, to the infusion of special education content into the general education curriculum (Bradley, King-Sears, & Tessier-Switlick 1997).

Rademacher, Wilhelm, Hildreth, Bridges, and Cowart (1998) studied changes in the attitudes of general education teacher candidates toward students with disabilities who participated in one of three possible course configurations. The researchers concluded that the teacher candidates who had direct contact over time...
with students with disabilities in regular and special education placements, along with reflective discussions and assignments, appeared to have a significant, positive impact on their attitudes toward students with special needs, inclusion, collaborative teaching, and their self confidence.

Description of Online Support Structure

The online support structure will offer resources to help the teacher candidates as they make the transition from student to intern and work within the inclusive environments found in today's schools. First and foremost, an online support system will provide a synchronistic communication system to allow for immediate discussion of issues and concerns with field placement personnel. As has been demonstrated, (Seabrooks, Kenney, & LaMontagne 2000) interns benefit from online mentoring. The interns will benefit from online conversations among themselves. They will learn from each others' experiences and gain information about various inclusive settings. The web site will provide the interns with links to information that will help them to problem solve and make instructional decisions. The interns will also use the site to post completed assignments for the special education portion of the final core course.

All of the online data will be archived for purposes of qualitative and quantitative research analysis. By examining the frequency of use, nature of the discussions, and coursework, these data will provide a continuation of the data collection that started in earlier core courses around inclusive attitudes and practices. We will be contributing to the present research about how teacher candidates learn from their programs and utilize that information in field experiences. We will also be able to learn more about the challenges currently faced by teachers practicing in inclusive environments through the content of the discussions. All of the data will help the teacher preparation faculty at the University of Idaho to improve the content and structure of the core courses.

Future Directions

Along with continuing to improve the online support structure based on the data collected, we plan to expand the content to serve a broader audience, i.e., the supervising teachers. We would like to offer an option of the final core course that would invite the participation of supervising teachers. They could take “Inclusive Strategies” for one credit and complete projects with their interns based on models of action research. This practice would help the supervising teacher to improve the work being done in the classroom and provide the intern with a model of data collection and analysis that could be utilized in the future.

Mind the Gap: An Overview of Perceptual Barriers to K-12 Information Literacy

Marcia A. Mardis
Merit Network, Inc. at the University of Michigan
United States
mmardis@merit.edu

Abstract: Because the explosion of electronic and print information requires that productive citizens be able to locate, evaluate, synthesize, and communicate ever-increasing amounts of text, hypertext, visual stimuli, and data, the need for information literacy among students is paramount. However, perceptual barriers to implementation by both teachers and librarians keep information literacy a much talked about, much written about, yet infrequently attained goal in K-12 education. This paper discusses obstacles to K-12 information literacy and presents possible solutions.

Introduction

Despite the attention given to the topic of information literacy, it has yet to be realized among K-12 students in a widespread manner. So, what is in the gap between the definition information literacy and the realization of information literacy? Although students are the ultimate beneficiaries of information skills, gap analysis indicates that teachers and librarians in the settings of classroom and libraries are key factors in the transfer of information literacy skills. An examination of the literature about teacher Internet use, perceived barriers to implementation, and potential vehicles for transformation identifies some ways that teachers and librarians can diagnose the distance from information literacy and begin to close the gap.

How Do Teachers Feel Well-Prepared To Use Computers And The Internet In Teaching?

A recent survey conducted by the National Center for Education Statistics (NCES) found that 99 percent of full-time regular public school teachers reported they had access to computers or the Internet somewhere in their schools. Sixty-six percent of public school teachers reported using computers or the Internet for instruction during class time; thirty percent reported assigning research using the Internet to a moderate or large extent. The ways teachers direct students to use computers or the Internet varied by instructional level, school poverty level, and hours of professional development. Elementary school teachers are more much likely than secondary school teachers to assign students practice drills using computers and to have their students use computers or the Internet to solve problems. Secondary school teachers, however, are more likely to assign research using the Internet (NCES, 2000).

This sense of technology confidence affects the ways teachers control knowledge in the classroom. Because information literacy is an outcome that is linked to technology related skills, it requires a shift to self-directed and recursive instruction. Teaching strategies, therefore, need to be revamped. This need for alteration in teacher practice can cause mental and practical confusion and discomfort (Farmer, 1992). Most often, this discomfort manifests in perceptions about information literacy skills including insufficient class time, teacher fear of failure, and perception that information literacy skills are the role of another class.

Librarians: Untapped Colleagues and Collaborators

Librarians recognize the critical importance of their participation in curriculum development; however, their actual involvement in collaboration with classroom teachers does not match the theoretical role and the role they were trained to perform (O'Sullivan, 2000). Collaborative planning requires a knowledgeable and
flexible librarian, with good interpersonal skills and a commitment to integrated information literacy instruction, and the active support of the principal.

Because students are familiar with computers, assumptions are made about their knowledge of information sources. Researchers have demonstrated that students teach themselves to search for information by looking on the Web for entertainment related information (Dresang, 1999). Certainly, this information is not closely scrutinized for quality and veracity. Rarely do students need to synthesize information about entertainment related issues and communicate in a sensible and holistic way.

Coordinating information gathering activities with a librarian can often a crucial step in the lesson's success. Librarians know whether print or electronic resources would be appropriate for the lesson as well as if the lesson can even be completed with the school's resources. By bringing the librarian and other colleagues into the planning process, teachers can help the information skills be distributed across classes as well as relevant to material being taught in all classes.

For information literacy, the library is a crucial venue and the librarian is a crucial agent of change (Kulthau, 1990). Information literacy is essentially about getting a sense for the range of resources available and how to organize the information these resources provide. Librarians are able to work with teachers and students to obtain knowledge, share knowledge, and keep track of knowledge systematically.

Collaborative Action Research Can “Fix It In The Mix”

Action research can help teachers and media specialists/librarians understand important variables related to student Internet use, how students perceive it as a source of learning, and the challenges educators face in effectively introducing the Internet into the school curriculum. Action research linked directly to the learning needs of students and validated through empirical research has the potential to be the foundation for introducing information literacy on a school-wide basis (Bruce & Easley, 2000).

The immensity and complexity of information literacy forces teachers into collaborative mode. No one teacher or librarian knows how to locate, evaluate, synthesize, and communicate text, hypertext, visual stimuli, and data. The integration of research and teaching methods must be a shared endeavor aimed at helping students learn. (Kiernan & Shaw-Reeves, 2001). The empirical findings of action research can act as a measure of how far students are from being information literate. The final component of collaborative action research is to present the methods and findings of the research to the larger educational community (O'Sullivan, 2000).

By recognizing the power of individuals, collaborative planning, using the library as a setting, and applying action research to test results, perceptual barriers to adopting information literacy activities such as lack of readiness, insufficient time, and improper context can be rethought. When educators begin to acknowledge and address these barriers, students will benefit. Information literacy will provide students with the critical-thinking skills they need to transform information into the valuable knowledge required to make informed decisions in the 21st century.

Educational Digital Libraries: Building Community, Building Libraries

Mary Martino, University Corporation for Atmospheric Research
Tamara Sumner, The University of Colorado
David Fulker, University Corporation for Atmospheric Research

This panel will present various perspectives on designing and implementing community-based educational digital libraries. The educational, social, and technical challenges of digital library development will be explored, in addition to the promises that digital libraries and other types of distributed learning environments hold for improving accessibility, developing community, and advancing the educational reform agenda of particular disciplines. An emerging digital library program, the Digital Library for Earth System Education (www.dlese.org) will serve as an instance of digital library development issues for the panel discussion. The presentation will also include a demonstration of this library effort to date.

Position Statement
Community libraries are evolving with the information age. The past decade has witnessed the increasing ubiquity of the World Wide Web in homes and schools, the emergence of new kinds of “electronic communities,” and the widespread creation and distribution of digital educational materials. Digital libraries are becoming a means for disciplinary communities to share, organize, and assess their intellectual holdings. To date, there are many digital library efforts underway aimed at improving K-12 and undergraduate science education.

Over the past three years, The Digital Library for Earth System Education (DLESE) has emerged to support the specific educational needs of the geoscience community within this larger national library network. In the tradition of community libraries, DLESE can fundamentally change the way students learn, instructors teach, and researchers interact, by providing new ways of sharing information, tools, and services. As such, DLESE provides unprecedented opportunities for scientific learning and discovery, for increased access to and diversity within the Geosciences, and for revolutionizing teaching and learning about the Earth.

The value of DLESE lies in its potential to scale success on a national level. At the technical level, we are building on the ubiquity of Internet and web technologies, and the maturation of digital library technologies. At the educational level, DLESE scales successful innovations by providing a venue and a forum for creators of educational resources to share, on a national scale, both their educational products and their creativity and expertise. At the social level, DLESE provides a community platform for social creativity and the creation of intellectual capital.

What is DLESE?
DLESE is conceived as a community-based resource that will serve the unique needs of Earth system educators and learners at all academic levels, in both formal and informal settings, by providing:

*Interfaces and tools to allow student exploration of geospatial materials and Earth datasets.* Though a wealth of Earth data exists on the Web; much of it is difficult for educators to use. DLESE will provide student-friendly access to a wide variety of archived and real-time datasets.

*Rapid, sophisticated access to collections of peer-reviewed teaching and learning resources.* Earth science educators have been frustrated in attempts to find high quality teaching resources appropriate for their teaching style and educational level on the Web in a timely manner. This resource discovery
challenge is being met with the creation of metadata schemas, controlled vocabularies, and cataloging
best practice recommendations, all informed by community participation.

Services to help users effectively create and use materials. A full array of digital and human-mediated
services for both users and contributors to the library is critical to the vision of DLESE as an active
organization that both builds and serves its community.

A community center to facilitate sharing and collaboration. DLESE will serve as an intellectual commons
for the global Earth system community by being the primary contact for educators, learners, and citizens
who seek reliable information about the Earth.

A federated collection of holdings. DLESE is being designed from the beginning to support resource
discovery across a diverse, federated network of holdings and collections (e.g. NASA, Alexandria Digital
Library). These distributed resources will be complemented by a small, centrally managed core collection.

The DLESE Community Framework
DLESE is a significant undertaking, and our library building effort is as much a social experiment as it is
a technical challenge. DLESE’s community participation framework and participatory design process
emphasize inclusiveness and promote a process of cultural change, and is essentially the intersection of
three primary functions: policy, operations, and community.

Policy. Critical to the construction and management of DLESE is a governance structure that supports
wide involvement in policy decisions. Library policy is set by the DLESE Steering Committee, broadly
representative of Earth science education in K-16 and informal education, informed by Standing
Committees (Collections, Technology, Users, and Services) reflecting the diverse needs of the community
DLESE seeks to serve.

Operations. The DLESE Program Center (DPC) performs key operational functions for the library, and is
headquartered at the University Corporation for Atmospheric Research (UCAR) in Boulder, CO. Critical
activities underway include the development of the DLESE system architecture, user interface, and
standards and protocols for metadata and interoperability.

Community. A third, and crucial, leg of the DLESE framework is an informed and engaged community.
By shaping the conditions of library use, community members are subsequently better positioned to
influence policy decisions. Community members have contributed user scenarios, resources, developed
review criteria, reviewed metadata standards, and articulated policies for academic recognition and
intellectual property.

Accomplishments over the past year include: developing and evaluating a library testbed, significantly
engaging the community in the process; establishing a community-led governance mechanism; initiating
collections development activities; and designing and developing a metadata schema and cataloging tools.

Conclusion
A distinguishing mark of DLESE is its grass-roots foundation and its emphasis on participatory design.
As the library grows and matures, DLESE will face the special demands of scalability and sustainability
that accompany such ambitious efforts. Although there are aspects of our experience that are unique to the
discipline of Earth system education, we believe that most of the challenges that we have encountered are
applicable to the development of distributed learning environments across a wide variety of disciples.
The work described in this panel proposal is funded under Cooperative Agreement #ATM 9732665 between the National Science Foundation and the University Corporation for Atmospheric Research (UCAR), Grant Awards #9978338, # 0085600, and #0086100, and by supplemental funding received from the National Aeronautics and Space Administration (NASA).

Panelists:
Mary Marlino (University Corporation for Atmospheric Research) is the Principal Investigator for the NSF sponsored Digital Library for Earth System Education (DLESE). For the past three years, she has been the Director of the DLESE Program Center, and is responsible for the overall direction for the library-building effort. Marlino has extensive experience in large project management, and the design and evaluation of instructional technology. Prior to coming to UCAR, she was Director of Educational Technology at the US Air Force Academy for nine years.

Tamara Sumner (The University of Colorado) is an Associate Professor of Computer Science at the University of Colorado, and is a Co-PI on the DLESE project. Her areas of expertise include both computer and cognitive sciences, with emphases on user-centered design methodology, usability evaluation, distance education, and system design to support electronic publishing in scholarly communities. Prior to joining the University of Colorado, she led numerous software development projects at both The Open University and at Hewlett Packard.

David Fulker (University Corporation for Atmospheric Research) has 15 years of experience in leading community-based technology programs, including the Unidata Program Center and the newly established National Science, Technology, Engineering, and Mathematics Digital Library Program Center. In this capacity he is responsible for overall management and technical direction of this emerging national effort.
Infrastructures for Web Based Support of Campus Learning: 
Applicability in Engineering Colleges

Constantino Martins (const@dei.isep.ipp.pt), Isabel Azevedo (iazevedo@dei.isep.ipp.pt) - Instituto Superior de Engenharia do Porto (ISEP) – DEI, Portugal 
Carlos Vaz de Carvalho (cvc@ipp.pt) - ISEP – DEI, Portugal 
Lígia Ribeiro (lrmr@fe.up.pt) - Faculdade de Engenharia da Universidade do Porto (FEUP) – CICA, Portugal

Abstract: The purpose of this paper is to present an ongoing research project that evaluates and identifies the requirements and needs for Web Based Support to learning environments in an on-campus context. These environments supplement, with different methodologies, the traditional teaching and learning in engineering institutions of higher education. A set of undergraduate and postgraduate courses of the Porto Polytechnic School of Engineering (ISEP) and the Faculty of Engineering of Porto University (FEUP) will be used as test beds.

Introduction and motivation

Academic institutions and companies operating in the education “market” are increasingly exploring the use of Information and Communication Technologies (ICT) to develop teaching and learning environments accessible through a Web interface (Flanagan, 2000, Collis, 1998). Diverse models and patterns for these environments have been developed and implemented in undergraduate and postgraduate courses (Nachmias, 2000, Seufert, 2000, Cardoso, 2001). 

like most higher education institutions, ISEP and FEUP have launched a few elearning initiatives on an experimental basis, whose results are being evaluated. However these initiatives have not been conducted in a systematic way and have not been integrated with the information systems of the institutions, taking profit of the management and communication facilities offered by them. This is a serious limitation, as “Information systems also constitute an important tool to support the evolution of the pedagogical process and it is expected to contribute to the continuous education effort” (David, 2000).

Project Development

The project is being conducted during the present academic year, with a special focus on the Computer Science Departments of both Institutions.

The first phase goal was to identify the requirements for a Web Based Environment, which advantageously complements the traditional learning process. For this purpose, a set of tools was designed to provide this information, taking in account the nature of the stakeholders (higher education institutions, teachers and managers). The first tool was a questionnaire created to study the perception of the teaching staff in relation to the introduction of elearning in each institution and to identify possible areas where elearning can be used. The questionnaire also allows determining the statistical, technological and e-learning profile of the teaching staff and the institutional profile of each institution. The questionnaire was initially delivered to a dozen teachers to assess its reliability (internal consistency and stability). For the pilot test; using Cronbach's Alpha formula; reliability for the total of the items was + .80. There is general agreement that + .75 or above indicates appropriate instrument internal consistency (Woodward, 1983 ).

Later, the questionnaire was delivered in paper to each teacher of the two academic institutions. We have gotten above of 100 responses in each institution, which represents about 21% of the total target. 

Based on the questionnaire results a directed interview was conducted to a small numbers of teaching staff and managers in crucial leading roles (department directors, scientific and pedagogic council, etc.).
Simultaneously, an analysis was made on existing Web Based Environments. We synthesized existing studies on these tools as well as case studies in other academic institutions.

The triangulation of the results from the previous tools, allowed to organize the requirements, in a preliminary way, in terms of features concerning trainer's support (authoring facilities and course management), learner's support (learning; collaborative and interaction facilities) and technical administrators support.

The second phase of the project (currently ongoing) will look into the adequacy and advantages of integrating Web Based Learning Environments with the information system of the two academics institution. The evaluation will be based on the requirements and in terms of its value of use and analysis of cost/benefit.

The first step was to select, acquire and install a Web Based Learning Environment (WBLE) for each Institution, based on the respective requirements.

The next step in this phase is to integrate the WBLE with each information system, test and evaluate the final environment. This is currently being done but has proved to be a more difficult process.

We have selected pilot courses (and a corresponding teaching/learning methodology) in each Institution to evaluate the efficiency of the WBLE and its integration with the Information System. Before the courses start, an assessment of student's technological profile was conducted through a questionnaire.

As it is difficult to demonstrate that a change in practice or in knowledge over time can be attributable to a single isolated resource (the WBLE, in our case), the Integrative approach therefore looks at how the resource is used in conjunction with all the other resources that are available to its users. It will focus on users' opinions and level of use of the resource, and on how it is embedded into the course as a whole. Also the opinions of the administrative staff and technician involved in this study will be heard.

Conclusions and Expected Results:

The expected results are twofold: identification of the requirements and evaluation of the effectiveness of an integrated e-learning/information system environment in engineering education.

We expect that the results of this project may be useful for other engineering institutions of higher education that wish to create, manage, access and share Web Based Infrastructures for "campus-learning". We also think that the experience of this work represents an alternative view about the role of learning Web-based environments/systems in educational processes.

Toolbook Instructor Authoring Software for Interactive Mathematics Courseware

Samuel Masih
Department of Mathematics and Computer Science
Albany State University, Albany, GA
smasih@asurams.edu

Abstract: ToolBook Instructor is a comprehensive desktop authoring software [7] designed for use by a broad spectrum of course developers and instructional designers to create standards-based content. The purpose of this paper is to describe the development of an interactive multimedia courseware for college algebra and precalculus. The course work developed using the Toolbook Instructor provides lectures, examples, simulations and exercises on topics usually covered in a precalculus course.

1. Introduction

The multimedia Interactive courseware is in the form an electronic book. The presentation of a topic is done via hypermedia. Text, sound, graphics and animation are used to present a topic. This is followed by examples. The user is then provided with a chance to do interactive exercises. The multimedia authoring software used in writing the precalculus book is Toolbook Instructor II ([7]). Most of the computer algebra used in arriving at the solutions of the mathematics problems in the book is written in the scripting language of the authoring software. Many of the decision in the presentation of the mathematical expressions are dictated by the limitation of the authoring software. The book has been used as tutorials for trigonometry, algebra and precalculus courses. Several chapters were integrated into interactive classroom lectures. However, reliable evaluation of the courseware is still pending. Students have given high marks for the software in the student evaluation of the courseware. The development of the courseware got its start from the Minority Science Improvement Program (MSIP) funded by the U. S. Department of Education in 1994-96. One of the objectives of the project was to develop interactive multimedia computer assisted instructional (CAI) modules for topics in trigonometry.

3. Courseware Design And Educational Issues

In developing the electronic book the author looked at several design issues that one must consider in developing interactive instructional material. Many of the earlier problems in designing and developing interactive educational software are well stated by Jones, Farquhar and Surrey [4]. The uses of design elements such as pull down menus, multiple windows, navigational buttons, help buttons, and the uses of program metaphors are discussed by Jones [4]. Jones & Okey [5] give helpful suggestion to the designers of interactive software. Burbulas and Callister ([1]) discuss the roll of Hypermedia for the presentation of educational material. Integrated text, sound, graphics and animation in the presentation of information should not only enhance means of providing rapid information but should also motivate and keep the student interested in the material presented (Hooper [2] and Romiszowski [6]).

4. General Technical Issues

Toolbook provides object oriented programming with integrated multimedia tools. Toolbook has its drawbacks, especially, when one is writing a book for doing mathematics. The main drawback has to do with mathematical typography. There is also a serious problem with the fonts substitution in a text field. There also exists the problem of displaying mathematical expressions and formulae on the screen. Mathematical equations and formulae have to be imported as graphics and pasted in the text field. One can cleverly get around this difficulty but it requires great programming effort. Beside the presentation problem, there are obvious problems of creating interactive mathematics tutorials. There is a problem on how to evaluate student’s responses to a problem generated by the computer. There may be several correct responses to a question. The program has to parse the student's answer and
compare it with the possible correct answers generated by the program. Directing the student to answer a question using a certain pre-arranged format can reduce some of these difficulties. There are some basic requirements that are common to the field of electronic book publishing in the category of educational software Romiszowski ([6]).

**Computer Algebra and Computation**

After all, the pre calculus electronic book teaches mathematics. So, how are the calculations and algebraic manipulations performed? Toolbook provides basic functions that are available in any programming language. All the calculations and operations are programmed using the Toolbook script. For example, the programming for interactive algebra section took about three months. There are programs that factor polynomials of degree six or less. The program can find real and complex zeroes of polynomials of degree six or less. If no rational zero exists, the program attempts to find approximate zero using the standard numerical analysis methods such as Newton Law or the Intermediate Value Theorem. If rational zero exists, it attempts to provide rational zeros and factors. Since the purpose of the software is to provide instruction only, the software is not a sophisticated computer algebra system like Maple or Mathematica. However, it is able to do the algebra problems that are found in an elementary algebra book. It will do algebra of rational functions. It will solve polynomial equations of degree six or less. It will graph polynomial, rational, trigonometric, logarithmic, and exponential functions. And it will do so interactively. It demands the students to know these functions and challenges them to interactively graph them using various important properties of the functions. The whole theme of the book is about student involvement. It demands understanding of topics discussed. There are no multiple-choice questions. All question require that student perform calculation to arrive at the answers. The book is capable of giving objective type tests and could provide instantaneous results.

**Web Connection and External Help**

One can provide connection to Web by creating buttons with hyperlinks. In the Precalculus book each chapter contains a button for launching a web page specially designed for the courseware. The page provides links to existing precalculus material on the web. Moreover, the page can be used to provide an instructor means of providing external help through links to other web pages and other material developed by the instructor. The content of the page can be changed to fit each instructor individual needs. This gives a instructor the chance to customize the page as desired. In fact, the purpose of this web page is to provide links to interactive tutorials, homework assignments, and other support material for the course.

From Gutenberg's Galaxy to Cyberspace: A New Model for a New Writing Space

Jean S. Mason, PhD.
University of Toronto at Mississauga
3359 Mississauga Road North – KC207
Mississauga, Ontario L5L 1C6
jsmason@sympatico.ca

Abstract: This paper synopsizes the central findings of a two-year empirical study into how the new rhetorical situations presented by hypertext affect the writing process and thus impact upon literacy and education. It theorizes a conceptual model based on these findings.

New technologies are transforming literacy in general and writing in particular. Hypertext is perhaps the most radical transformation to date. In hypertext, writers struggle to master a new process that includes electronic links, visual images, sound, animation, and other forms of data within a single digitized writing space. This transformation challenges educators to reframe our roles and points of reference as we increasingly use hypertext in the form of websites to enhance curriculum. Hypertext offers new opportunities for optimizing learning if we use it well. We need new process models to help us rethink our conceptions of writing in order to adapt this new form of writing to best pedagogical practices. This paper presents such a model.

This paper synopsizes the key findings of a completed two-year conceptual and empirical study of the hyperwriting process. My research was guided by the overarching question: How are writers’ perceptions of the new rhetorical situations presented by hypertext affecting their attitudes towards writing and the consequent decisions they make in response to these perceptions? The study was the basis of my recently completed doctorate. My position within the study was that of an “indwelling researcher” who inhabits the world s/he is studying. That is, my dissertation was composed and submitted as a hypertextual website. It was the first dissertation of its kind at my university—both content and form—and one of the first in the world. It challenged academic norms in both content and form and successfully redefined academic notions of literacy to some degree.

The findings of this study are contextualized within a significant body of pre-hypertextual writing theory and a small but growing body of hypertext theory. Unlike writing theory, hypertext theory consists principally of speculative theorizing. Little attention has been paid to the particulars of the writing or reading processes, and empirical studies are virtually non-existent. This study begins to address that imbalance.

The design of my study is based on phenomenological concepts and methods common to qualitative research using an emergent, field-based, ethnographic approach. This framework is well-adapted to the complex nature of the writing process—a process that is rooted in individual human cognition contextualized within a social experience. Because our “social universe” is constructed, it does not exhibit the same kind of cause and effect consistency as the physical universe. A qualitative methodology allows for the unpredictability and variability inherent in this socio-cognitive process (Denzin, Donmoyer, North, Villanueva). The emergent interdisciplinary paradigm of the ethnographic approach (Clifford and Marcus, Geertz) further supports the goal of discovery and deeper understanding, important in a discipline such as hypertext theory that is itself interdisciplinary and emergent. Purposive sampling allows for a range of experience with maximum variation, and data collection in natural settings respects the importance of context in an intrinsically social activity. Inductive analysis helps to ensure that what is seen as important is determined not only by the researcher, but by the informants and the data they generate (Eisner, Glesne and Peshkin, Maykut and Morehouse, Strauss and Corbin). Data collection methods include interviews, observations, correspondence, journals, and artifacts. A significant amount of data was collected over the Internet using asynchronous and synchronous communication (Markham, Mason, “Ethnography in Cyberspace”).

The informants in this study include writers whose orientations range from academic, to business, to creative. At the time of data collection, they all composed regularly in a hypertextual writing space and published on the World Wide Web. Although it is possible to compose in hypertext that is not destined for the Web—thus integrating only internal hyperlinks—I did not encounter writers who used hypertext this way. To my informants, hypertext and the
Web were virtually synonymous. I collected data from seven “major” writers who used hyperwriting in their professions, and approximately ninety “minor” writers in the group setting of three classroom-based writing courses. Further, having authored extensively in hypertext myself—and having assumed the posture of the “indwelling inquirer”—I also drew on my own experiences. In my dissertation, I reported my complete findings in the manner of an “emic” or “thick” description extended to include interpretations, speculations, and pedagogical applications (Mason, From Gutenberg’s Galaxy). In theorizing a conceptual model based on my findings, I believe I have achieved the ultimate goal of qualitative research to develop “the highest level of interpretation and abstraction from the data in order to arrive at the organizing concepts and tenets of a [grounded] theory to explain the phenomenon of interest” (Maykut and Morehouse 122).

As stated above, the principal conceptual framework for my interpretations is a significant body of pre-hypertextual writing theory, and a small but growing body of hypertext theory. I will elaborate on this framework by giving a brief overview of writing and hypertext theories as follows:

The 1960’s witnessed a major shift away from a behaviorist understanding that viewed writing principally in terms of models and rules derived from finished texts. This shift is embodied in what we now call writing theory or composition theory. Writing theory is grounded in a philosophy of rhetoric that rejects a traditional product-oriented understanding of writing in favor of a process-oriented approach. Early writing theory draws heavily on the philosophies of Kenneth Burke who regards language first and foremost as symbolic action and only second as representation. The work of Richard Rorty, Thomas Kuhn, and Clifford Geertz further shaped writing theorists’ growing understanding of the role of social and cultural contexts in the writing process. Moreover, the influences of Michael Polanyi, John Dewey, Suzanne Langer, Lev Vygotsky and Jerome Bruner inspired the notion of writing as both a tacit and a transactional process with both cognitive and social implications. Early explorations of the writing process focused on an individual writer’s cognitive process. Tensions soon broke out between theorists who focused on individual cognition and those who viewed writing as a socially contextualized process. Bizzell and Faigley synopsize this complicated intellectual exchange in theoretical models that help us to understand the evolution of writing theory. Exchanges among process theorists set in place a framework for “reinventing” the rhetorical tradition (Freedman and Pringle) in such a way as to emphasize ultimately both the cognitive and social dimensions of writing in order to reveal the full complexity of writing as “a manifestation of complex and interpenetrating cognitive, social, and cultural processes” (Kennedy 243). It is upon this dynamic that the sub-division of writing theory known as genre theory is built. Genre theory is the most fully elaborated theory of writing to date because it joins the micro level of writing to the macro level of discourse, unites process with product, and connects the individual (cognitivist) and the social (constructivist) approaches. It is the link between writing theory and hypertext theory.

Genre theory bridges the theoretical gap between traditional writing and hypertext because, like the broader conceptual framework of discourse theory, genre theory recognizes writing as a form of social practice. Genre is understood differently than in its more traditional literary sense of textual features (Freedman and Medway). Genre here includes the interests, goals, and shared assumptions implicit in different discourse communities. Genre theorists explore the ways in which these factors function as heuristics of process that culminate in textual practices and features (Berkenkotter and Huckin). Noted discourse theorist Norman Fairclough details the ways in which discourse is social practice. In his 1995 study, Critical Discourse Analysis: The Critical Study of Language, Fairclough defines discourse not only as language in sociocultural practice; he further observes that “texts in contemporary society are increasingly multi-semiotic. . . not only because they incorporate photographs and diagrams, but also because the graphic design of the page is becoming an ever more salient factor” (4). Writing in 1995, Fairclough’s definition of discourse anticipates the impact of hypertext on text. Genre theory provides a much-needed link to discourse theory and, by extension, to hypertext theory since writing theory, with few exceptions, (Hawisher and Selfe, Selfe and Hilligoss) treats hypertext as a displacement of print-based literacy (Johnson-Eilola). Like Lemke, I find it more logical to view hypertext in the larger ecocultural context of a communication continuum that begins with grunts and cave drawings.

Hypertext theory is an interdisciplinary framework that that draws on postmodern theory in general, and literary, communication, and social theories in particular. Best known among hypertext theorists are George Landow, Jay David Bolter, Paul Gilster, Richard Lanham, Michael Joyce, Paul Levinson, Steven Johnson, Janet Murray, Stuart Moulthrop, James O’Donnell and Sherry Turkle. What all these theorists share in common is a view of hypertext as a paradigm shift, and as a physical embodiment of the ideal text envisioned by the postmodern theorists such as Foucault, Barthes, Derrida, and Bakhtin; that is, text whose structure consists of multi-sequential nodes, links, and
networks, whose content can include the aural and the pictorial, and whose interactive nature re-negotiates the relationship between reader and writer. Hypertext is thus understood by hypertext theorists as a phenomenon that reconfigures the writing space and the thinking processes behind it. As Gilster observes, “hypertext is a mental process as well as a digital tool” (138).

It is within the theoretical framework described above that I interpret my data. In the original full length study (Mason, From Gutenberg’s Galaxy) I identified, reported, and interpreted a number of immediate contextual concerns. These included the Internet as a public writing space, multimedia, collaboration, and “techno-angst.” I further extended my interpretations to suggest pedagogical implications. Finally, I used my interpretations as a scaffold upon which to build my own theoretical speculations about the impact of hypertext on ways of thinking and knowing. In the limited space of this paper, I offer a much-reduced synopsis of the central focus of my research: the particulars of the hyperwriting process. From my interpretation of these particulars I theorize a new process model. While avoiding the positivist pitfall common to generalization, I do believe it is both the prerogative and responsibility of the qualitative interpreter to identify commonalities as a basis for theoretical speculation. It is these common practices among my informants that I will now describe.

The Importance of the Visual

The need to visualize both the “look” on the screen and/or the overall design of their “docuverse” was uppermost in the minds of most informants when they faced a new hyperwriting task. (“Docuverse” is a term coined by Theodor Nelson to describe a hypertextual document.) Different informants had different ways of addressing this challenge, but each relied on some form of visual schematization. Terms such as story-boarding, mind-mapping, sketching, and drawing were commonly used by the writers under study to describe their process. The words of my informant, Mac, best represent this experience. Mac said, “Well, I think the first thing—and everything plays off this—is that you start essentially with a storyboard, much more the way you would approach putting together a cartoon or a movie than a simple piece of writing.” Concern over how to visualize their writing space ranged from envisioning the macro level of the site as a whole—colors, shapes, and structural relationships—to envisioning the micro level of individual page layouts. Further, the potential to include images—both still and animated—seemed to invite writers to imagine the pictorial as an intrinsic part of whatever text they were composing. The need to visualize occurred early in most writers’ processes and persisted throughout.

Considerations of Structure

According to hypertext theorist Jay David Bolter, “In this shifting electronic space, writers will need a new concept of structure. In place of a closed and unitary structure, they must learn to conceive of their text as a structure of possible structures” (144). A concern with structure in terms of navigational paths was common to all my major informants. They acknowledged this to be a new writing concern. My informant Jay put it this way: “I had to determine how people might look through the material and what people looking through the material might be searching for, and what kinds of questions they might have, to first and foremost anticipate the kinds of twists and turns that my readership might take. I had to go there before they did. This is different, this trying to anticipate the thought processes of other people.” I believe Jay identifies a fundamental difference between printed text and hypertext. Writing in hypertext forces a higher degree of audience anticipation on the part of the writer. It is easier to predict reading patterns in print; options are fewer and more obvious. How to divide text, what to include in menus, and where to place hyperlinks in order to build trails and “leave breadcrumbs” thus become crucial decisions in hypertextual structuration. In building these trails, however, writers must envision the stability of their text much the way Schryer describes genre in the context of social practice as “stabilized-for-now” (Freedman and Medway 105-124). Janet Murray comments on this complex socio-cognitive process in Hamlet on the Holodeck when she observes, “authorship in electronic media is procedural. Procedural authorship means writing the rules by which the texts appear as well as writing the texts themselves” (152). It is questionable, however, to what extent those writer-based rules will be followed. Readers in hypertext are free to follow whatever paths they choose and create their own structures. Hypertext theorists comment widely on the role of the reader in creating coherence. It may well be that, as Myka Vielstimmig suggests, when it comes to hypertext “the coherence is performative” (31). Nonetheless, writers appear to be challenged to envision a range of paths in order to create a navigable structure. Furthermore, the writer’s acute awareness of the reader’s role in negotiating meaning emphasizes the redefinition of the constructivist
transaction between writer and reader that is emerging in this medium (Bolter, Landow, Johnson-Eilola, Sosnoski). Fairclough's definition of discourse as "language seen as a form of social practice" is clearly evident (6).

Content and the Place of Words

Composing in a multi-medial "writing" space, my informants began to question the role of words. The majority tried to eliminate words when possible, sensing that in this medium, "a picture is worth a thousand words." Among my informants, Mary, an English teacher, noted that when she hyper-writes words are the last element she considers whereas in traditional text they are the first. Mary also observed her tendency as a hyper-writer to avoid complex sentences in favor of subject-verb-object, and—much to her amazement—a sudden acceptance of incomplete sentences. Informant Don described how he went to extraordinary lengths to minimize words. He even claimed his primary concern was "how the page looks rather than the content it contains." To get the "look" he wanted, Don admitted he'd do anything to "make the words fit into a specific size cell in the table." Rose, a writer of hypertext fiction, still valued words but said that in hypertext, "I think I tend to be shorter—both my stories and the sentences and words in them." Several informants remarked that the ability to hyperlink to external resources often eliminated the need to "write" text at all in some circumstances. In sum, my data suggests that hyperwriting requires more than word-based language skills, and that content is defined as more than words. Writing in this medium thus appears to draw on more than "linguistic intelligence" (Gardner), and re-configures the role of words within the semiotic configuration of the writing space. This multi-medial reconfiguration of the writing space may be welcome news to intelligences and learning styles that have been previously undervalued in the traditional curriculum.

Conventions

As with any new medium, conventions develop. In printing, for example, we take for granted pagination, margins, standardized spelling, indexes, and so forth. Hypertext in the form of a website is no exception. My informants concerned themselves with the increasingly expected conventions of this medium. They knew, for example, that readers would expect a navigation bar on each page, and they deliberated about where to place it. Informants concerned themselves with page titles, menus, banners, headers, footers, back-to-top icons, home icons, authorial information, and dates. They also pondered what to do about conventions connected to the "Gutenbergian artifact" (Negroponte) of copyright. They worried about if and how sources for material they included in their websites should be cited, and whether and how to copyright their own original material. Informants also had to unlearn and relearn common habits based on print-based conventions. Underlining, for example, creates confusion if used to highlight text since hyperlinks themselves are underlined. Finally, within a medium as new as Web-based hypertext, conventions metamorphose continually as technology creates new options. Thus, my informants were confronted with the stress of a medium whose points of reference were constantly shifting.

The particularities of the hyperwriting process that I have highlighted above constitute a brief overview of the key findings in my study. A more extended analysis, and a range of less commonly cited habits are detailed in the full study (Mason, From Gutenberg's Galaxy).

A Conceptual Model for the Hyperwriting Process

Perhaps it was working in such a visual medium that prompted me increasingly to visualize the substance of my interpretations as a concept map. "A Process Model" (Fig. 1) represents the interpretations of my empirically grounded theory in a single conceptual image. This model is not meant to be definitive or prescriptive in any way. Writing is a highly individual yet complex activity that cannot be reduced to a single model. Furthermore, as research evolves new ways of understanding the hyperwriting process will emerge. The value of any model, however, is that it allows researchers a concrete point of reference from which to question and conceptualize further. As a result of my findings, I have also come to believe that graphic representations engage a part of the brain that words do not and thus, when combined with words, can transform scholarly theorizing into a more whole brain activity.
Here is how I would verbally describe the hyperwriting process as it is represented in the "new model" presented (Fig. 1). The "typical" hyper-writer appears to hold in mind and make key decisions about many elements of a given writing task at the same time. Some of these elements are common to a Gutenbergian writing space and are a given in any writing medium (e.g., audience, purpose, words); however, many elements are new rhetorical considerations (e.g., multimedia, hyperlinks, technical functions). It is these new elements that this model embodies. Because of the number of diverse elements the hyper-writer appears to consider both simultaneously and sequentially, it seems logical that different levels of consciousness may be involved. Moreover, the hyper-writer must consider both the macro-level (e.g., navigational system, style templates) and the micro-level (e.g., page layouts, content) simultaneously as they impact on each other in an electronic environment that is always in a kind of inter-dependent controlled motion rather than frozen on a printed page. To accomplish this multi-faceted procedure, the hyper-writer likely processes these elements internally at different levels of consciousness both simultaneously and sequentially, while at the same time representing these elements and their evolution externally on either paper or—more likely—by using web authoring software or even hard-coding in HTML. These external representations appear to be highly graphical in nature as compared to the traditional writing process that is constituted largely by words. Holistically, this model represents what may be the most crucial distinction between traditional writing and hyperwriting, between Gutenberg's Galaxy and Cyberspace—as most of my informants noted in various ways—there is just so much more to deal with all at the same time!

Desktop Streaming\textsuperscript{TM}

Khawer "Kavi" Masood
Information System and Services
The George Washington University

April 30, 2002

1 Abstract

In the Information Age, Help Desks play an increasingly important and highly visible role in providing effective customer service and satisfaction. Effective communication is a key component in delivering customer satisfaction. Therefore, we at the ISS Help Desk, at The George Washington University, purchased Desktop Streaming\textsuperscript{TM} - software that allows remote screen sharing, without client side installation, over a standard internet connection.

2 Introduction to Environment and Users

Any large organization, like The George Washington University (GW), has an eclectic mix of computer users and an equally varying computer skill set.

And it is when computers do not function properly, that clients call the Help Desk.

3 What Does the Help Desk Do?

Ideally,

- Resolve the issue over the phone
• If issue cannot be resolved, assign the call to another division

Computer problems are not easy to describe and sometimes, neither are their solutions. Verbally instructing clients, particularly novices, on the steps to troubleshoot computer issues can be time consuming and frustrating to clients and IT Support Staff.

In a small organization, it is feasible to walk over to the cubicle down the hall to solve the problem in person, but that is not always possible with large and/or off campus/site users because

• of distance
• of time to get to off-site locations
• it reduces Help Desk coverage.
• you always forget something at your desk

and you almost wish you could see the user's computer from your desk.

4 Enter Desktop Streaming™ (DTS)

DTS is a great tool for remote screen sharing. HelpAlert™ - "call" routing software - is about 2 MB is size and works on any Windows based machine. The client visits a web site using a Java enabled browser over a standard internet connection, and you can see the client’s screen within a minute.

No Client Side Install The was very important to us. It was not is to install/push software on the client machines (10,000+ computers). All the client needs is an internet connection and a Java enabled browser. Both IE and Netscape worked great, but we’ve heard of (not experienced so far) issues with Netscape.

Screen Sharing This is neat part about DTS. You can share the client’s keyboard and mouse, but the client has ultimate control over their computer. We try to emphasize this before we access the client’s screen. The screen sharing session starts in draw mode, and the Help Desk Analyst has to manually switch over to share the client’s keyboard and mouse.

---

1Distance Learning students as far as California, Remote Campuses, Faculty at Conferences
2A 4 hour flight to California
3You can screen share with any Windows and Solaris based machine
4This prevents computer accidents
Web Push Type in a URL and click Push, and the web page loads on the client's screen. Great tool for getting to sites quickly.

File Transfer Exchange files using regular FTP - you don’t have to forget CDs/floppies at your desk.

ChatLink\textsuperscript{TM} Allows the Help Desk Analyst to instant message with client if need be. We hardly use this as we usually have clients on the phone when we are screen sharing.

Whiteboard You can draw on the client’s machine. Lets say the client cannot find something on the computer, you can circle it. The software always starts out in whiteboard mode, which is very useful.

Management Console Gives access to logs for screen sharing, and chat sessions. Handy for metrics, if you are into that kinda stuff.

5 Conclusion

DTS offers several features that make technical support efficient and reliable.
Hypermedia Educational Technology And Teaching Strategies

Milan Matijevic
University of Zagreb
Teacher Education Academy, Croatia
milan.matijevic@zg.tel.hr

Abstract: This paper presents the basic knowledge about the influence of hypermedia educational technology on the selection and design of the teaching process for new generations of adolescent and adult students. The global teaching model which is predominant in the present-day school could be called "the class-subject-lesson system". This didactic system cannot meet the needs and expectations of young people and adults at the start of this millennium.

Introduction

In the mid 17th century J. A. Komensky (1592-1670) established the teaching model which is termed "the class-subject-lesson model". This model, according to which a group of students meets every day in a school building for common teaching activities, is still predominant today in most schools around the world. This group of students is taught by one teacher in one classroom. Activities alternate every 45 minutes. Such a teaching model has provided cheap education for a large number of students in compulsory education. It is regarded that mass education of young people was made possible by the most revolutionary invention of that time, i.e. the book.

Although the model established by Komensky has been criticised during the last three and a half centuries, it still represents the basis of the teaching process even today. This system received a most severe blow at the beginning of the 20th century from the well-known movement of reformist pedagogy (J. Dewey, M. Montessori, R. Steiner, C. Freinet, P. Petersen, etc.).

Today, young people and adults live in an essentially different media environment compared to the one J. A. Komensky did. How would Komensky have designed the teaching process in school if he had been surrounded by the present-day communication media?

Some empirical results

In Croatia, children spend at school about a thousand teaching periods a year (one teaching period lasts 45 minutes). One year has 8760 hours, which means that the students spend at school about one ninth of the total time of one year. Moreover, the teaching activities for students are organized during 180 days within a year. This means that students do not attend school more than half of the year.

On a sample of primary school students attending lower grades of primary school (N=3245) it has been tested how many students have a personal computer at home and how many of them have had the chance to use the Internet. The sample comprised children from 6 to 10 years of age. The results showed that 31% of the students have a PC at home and 25% have experienced the benefits of the Internet. More than 50% of the teachers teaching these students are computer literate and use a PC in their everyday work.

A sample of grammar school students (N=308) showed that 61% of them have a PC at home and 70% have had a chance to use the Internet. The sample comprised students between 15 and 19 years of age. In Croatian schools teacher-oriented teaching is still predominant. Students are dissatisfied with such situations and react by not attending classes and by passively boycotting their teachers' occasional appeals to become involved in the common activities. A number of secondary school students decide to withdraw from full-time education and enrol in some kind of distance education. These forms of education ensure a more flexible planning of their school- and free time (Matijevic, 1996).

Teaching aims and strategies

Nineteenth-century school is considered by experts to have been intellectualistic. This means that teaching activities were mainly oriented towards cognitive development. The educational ideal was to learn
as many new facts as possible. The emotional and psychomotor development was in a position of secondary importance. In the school of the 20th century some things changed.

Apart from the teaching and learning of facts the school is required to take into consideration the emotional and psychomotor development of students. However, this is more of a declaratively stated wish than the real state of affairs in schools. Because of an essentially different media environment and the revolution in technology and information science which has been going on in the last 20 years of the 20th century, some new aims of teaching and learning have been gaining ground. Experts have observed the existence of much better media for storing and processing information than students' heads. Instead of learning facts the students should learn how to learn independently and how to find and use information. Besides, school has started to prepare young people for changes which will become part of their lives. The educational value of learning social and communication skills has also been observed. These aims could not be realized by means of traditional didactic solutions based on teacher-oriented teaching, where, generally, the role of the teacher was to speak and show, and that of the students to sit, listen and watch.

The students, who live in a new learning environment and media environment could not be satisfied with a passive role in the teaching process. There are many things going on after the time spent at school, which are much more interesting than the contents explained and shown by the teachers. School faces many changes. Komensky, in his time, had only the book at his disposal as a teaching medium and the voice of the teacher. If he were alive today he would probably offer a more diverse didactic repertoire for school activities than the class-subject-lesson system.

The class, as a relatively constant group in terms of experience and previous knowledge on similar topics, does not exist any more. There are noticeable differences among individuals of the same age. These differences are determined by greater mobility (travelling) and by the rich media environment. The differences in the interests and in the mental condition are evident. It is very difficult to organize a teaching activity aimed at cognitive learning, which can, at the same time, satisfy the needs and expectations of a group of students.

This media environment essentially determines the new roles of the teacher. Traditionally, teachers were trained to implement a certain curriculum with groups of students. Today the school needs teachers who can help with and successfully solve the educational problems of individual students. The school needs teachers-mentors and not teachers-lecturers.

Hypermedia educational technology surpasses the didactic framework of the class-subject-lesson system. Experts in European schools frequently make the mistake of trying to find ways of using the advantages of the Internet and multimedia exclusively within the class-subject-lesson system. In this way, the possibilities of hypermedia are substantially reduced.

Conclusions

Hypermedia educational technology not only provides opportunity for the solution of many problems of traditional teaching but it also raises numerous new questions. Some of the most important ones are the following: To what extent and how to use this technology to accomplish the aims of education in modern school? Which teaching aims should be ceded to this technology and to what extent, and what should be left for direct human communication between students and teacher? What kind of relationship should exist between learning by means of hypermedia educational technology and learning in authentic reality? Which teaching aim cannot be achieved through the use of hypermedia? What are the new roles of the teacher with regard to hypermedia educational technology? The question posed by J. Kemp (1973) acquires a new meaning in relation to hypermedia educational technology. Experts for teaching and learning issues must search for answers to the above-mentioned questions. A lot of multimedia software exists on the market which cannot be accepted as satisfactory by educational experts and which is harmful for the development of young people in the same way as the worst solutions in traditional teaching are. One must not lose one's way in technology, or, in other words, technology must not be more important than man.

Fostering Inquiry-Based Learning Online: A Case Study

Inquiry Online: The Challenge
Using examples from TERC/Lesley University Master's in Science Education online courses, this presentation will explore strategies for fostering inquiry within a distance learning environment. The topic will be investigated from two perspectives: that of a course developer and that of a program participant.

This presentation is a case study in two respects: a case study of the online program and a case study of a program participant's response to the experience. Each course component discussed will be paired with an example of that participant's work.

To place our program within the larger context of online learning, we will address a range of questions relevant to the development and implementation of online environments:

- What online course features support or detract from a learner's inquiry experience? What assumptions about inquiry are encoded into an online course's structure and presentation?
- Are some aspects of the online environment actually more conducive to inquiry than face-to-face classrooms? How can educators take best advantage of the Internet-mediated learning context?
- How can online course developers tell if the understanding goals are achieved? How does one assess the extent to which learners genuinely become engaged in inquiry?

We have grappled extensively with these questions in the process of developing and implementing our own courses. This presentation is an opportunity to share what we have learned, grounding our theories and insights about online learning with actual examples from our program.

About the Program
The Science in Education Master's program is a two-year program for K-8 teachers who are currently teaching in classroom settings. The program, a partnership between TERC and Lesley University whose development is funded by NSF and FIPSE, launched its first course in the summer of 2000. The first cohort of degree recipients will graduate in the winter of 2003.

Course Implementation: Our program is delivered entirely online using a combination of Blackboard online courseware and a multimedia-rich web site interface. All of our courses are team taught by a scientist and a science educator.

In each course, program participants: 1) engage in sustained science investigation; 2) learn strategies for supporting inquiry in the classroom; and 3) put new pedagogical ideas into practice in their own classrooms. They further their understanding of science content by carrying out a series of investigations at home, then go online for in-depth discussions to share results, look for patterns in their findings, and generate explanations based on evidence.
Their coursework carries over to the classroom where they try out ideas for supporting learning through inquiry and for assessing inquiry-based experiences.

Course Development: A development team that includes a scientist, educator, and instructional designer/multimedia specialist produces each course. In the formative phase of course development, the team works with an advisory group of teachers. The course is then piloted twice, with weekly formative assessment informing course revisions.

Our multi-year project also includes an extensive research study of our model for online learning. Wynne Harlen's Model of Inquiry, used as a key organizer in our online Master's program, has informed the development of instruments to evaluate the impact of the program on participant understanding. Indicators of inquiry learning are obtained from the following sources:

- data collected via weekly online formative evaluation questionnaires;
- participants' comments to colleagues and faculty in course discussion forums and in email correspondence with faculty;
- videotaped interviews with program participants;
- observation of teachers working with students in their classrooms; and
- comparison of pre- and post- course thought experiments performed by participants.

This extensive research, coupled with our thoughtful development model, has given us valuable time for group dialogue about the nature of inquiry and the unique characteristics of online learning.

Implications for Others
The ultimate goal of this project has been to rethink what teaching and learning can look like in the best of all worlds, then translate their new vision into high-quality online courses for teachers.

Preliminary research results indicate that our model for online learning is successful. Our finding indicate that program participants:

- devote more time to their coursework online than when the same course is taught face-to-face;
- demonstrate a greater increase in science content knowledge than their face-to-face counterparts;
- develop a deep sense of responsibility and community with their fellow learners;
- develop the perspective of scientists - behaving more like graduate level science majors;
- become deeply invested in the program (our 96% retention is unusual for distance learning); and
- change how they teach as a result of their online learning experiences.

Our work should be of interest to anyone contemplating teaching online, but it also has larger implications for furthering our understanding about teaching and learning in general.
Collaborative learning in an online masters program

Ellen Goddard
Department of Rural Economy
University of Alberta
ellen.goddard@ualberta.ca

Abstract
The Master of Agribusiness program developed by The University of Melbourne is offered to off-campus students using an online mode of study. The approach to study is based on collaborative learning, to develop graduate skills in communication, negotiation and teamwork in addition to the program's focus on Agribusiness. This study outlines the theoretical basis and the development of the program and online learning materials. Evaluation data from post-course questionnaires and a focus group highlight the features and difficulties of the program from the student perspective.

Introduction
A major concern for teachers using online delivery is how to ensure that their students attain a high level of understanding and ability from the course. Performance outcomes need to meet the expectations of the professional area in which the students will work. The development of a Master of Agribusiness program at The University of Melbourne's Institute of Land and Food Resources was based on two key considerations: it needed to reach a geographically widespread rurally-based target group of students nationally and internationally; and it needed to use the methods of teaching and learning that had been found to be most effective in learning business management skills. To achieve these aims the course was modeled on a similar course offered by the University of Guelph in Canada (Sparling, 1998; McAlpine, 2000). Online delivery is used as the means of reaching the students. Collaborative learning is a fundamental aspect of the approach to teaching and learning. An important reason for this choice is that the collaborative learning approach was developed in business schools as an effective means of developing the communication and teamwork skills that are needed in the business environment, in addition to the course subject matter (Milter & Stinson, 1995a). Online delivery enables this approach to be applied in a distance-learning environment, by providing both the means of access to course materials and the communication channels necessary to implement a collaborative learning approach. This article considers some of the teaching and learning issues relating to the implementation of collaborative learning in an online environment, using the Master of Agribusiness as a case study.

Improved learning using technology
One of the principal reasons for using online technology is to achieve higher quality learning outcomes than are being achieved through current means (Bates, 2000). The use of instructional technology is increasing as an aid to learning by the design and development of courseware to facilitate student-centered outcomes-based learning (Oliver & Omari, 1999). Online delivery has been identified as having the potential to increase access to education, promote improved learning, and to achieve this while containing, rather than increasing, the cost of education (Owston, 1997). The desired outcome of instructional design and courseware development is materials that promote effective learning.
Research on the application of technology in education has focused on how the technology can be used to enable students to learn more effectively. This is not based on a view that the use of technology automatically improves learning outcomes. Rather, the research examines ways that the technology can be applied to provide the resources that facilitate ‘learner-centered’ activities. These resources may be information sources or tools, such as databases, that promote enquiry and information seeking (Hannafin & Land, 1997). Technological resources such as computer conferencing, databases, spreadsheets, and simulators, may be used as ‘cognitive tools’ if their purpose is to support thinking and learning processes that will enhance the quality of learning (Jonassen & Reeves, 1996).

The theoretical basis for this research is the cognitive-constructivist view that students learn most effectively by actively creating meaning from their own learning experiences (Jonassen, Mayes, & McAleese, 1993). To ensure that the meaning created is effective learning, the students’ learning needs to be centered on activities that develop critical thinking, problem-solving and reasoning skills (Hannafin & Land, 1997). Investigations have found that the most effective learners make learning an active, engaging process that develops a rich pattern of meaningful associations. An important aim for teachers and educational developers is to design learning activities that require learners to engage in the active learning processes that the most effective learners do naturally (Biggs, 1999).

From this theoretical position, technological resources can be developed to enhance and guide the process of student learning. The active process of constructing a meaningful interpretation from complex learning tasks is supported by rapid access to resources and tools, by creating communication channels that enable speedy resolution of problems and the development of new ideas through interaction with teachers, other learners, and experts who may be external to the teaching/learning situation. They enable the learners to work with information and data quickly in order to develop solutions. By being designed and developed to support these activities, technology can enable effective learning outcomes.

**Collaborative Learning**

Students need to experience the cultural context and the environment in which knowledge will be applied. An important aspect of collaborative learning is that the students can apply their own experience to the learning process, and benefit from the experience of other students. In this way, students can use their own interests and experience as ‘springboards’ to the achievement of a deeper level of knowledge generation. This has been described as a move from dependence to interdependence, using dialogue as a fundamental mode of enquiry (Palloff & Pratt, 1999). An important aim is to develop critical thinking, reasoning and problem solving skills. Glaser (1990, cited in Jonassen et al., 1993) argues that cognitive development occurs through processing concepts that are originally experienced in social contexts, and that while meaning may be an individual construct, shared understandings result from social negotiations of meaning.

The vital part of using online discussion in any format is to keep the students actively engaged. Palloff and Pratt (1999) suggest a range of activities that foster active engagement, including:

- Posting instructions and learning expectations;
- Forming teams and posting guidelines for their performance;
- Encouraging a search for real life examples;
- Using dialogue as enquiry by encouraging thought provoking expansive questioning;
- Sharing responsibility for facilitation among group members;
- Promoting constructive feedback.

Open-ended questions such as “What do you consider to be the ethics of a computing professional?” (McLoughlin & O’Sullivan, 2000, p. 47) are useful to facilitate dialogue as enquiry. A statement that is designed to promote discussion should be very effective in promoting dialogue (Palloff & Pratt, 1999).

The role of the online tutor is critical to attaining effective learning outcomes. Tutors need to set appropriate activities and provide the right kind of guidance. Feedback from experienced tutors indicates that online tutoring can be more demanding than tutoring in a face-to-face situation. Some students show a
high level of appreciation for online conferences, but students are likely to be dissatisfied if there is a lack of participation by others (Mason & Weller, 2000). For online conferencing to be successful, participation needs to be directly assessed or closely associated with assessment tasks.

**Building a learning community**

One of the important outcomes of collaborative learning online is a sense of community among the learners. In some studies both learners and tutors report the feeling of getting to know their fellow participants even better than they would in face to face tutorials, and how this process enabled students to build confidence and to extend themselves further (Mason & Weller, 2000). Bruffee (1999) argues that the development of a learning community is a critical part of the education process. He sees the role of the teacher as helping students to negotiate their way into membership of communities they aspire to join, that is the practitioners of the knowledge they are learning. Klemm and Snell (1996) propose that students need to adopt roles, and to change roles, to help to build collaborative communities.

**Case study of the Masters of Agribusiness**

**Design**

The online study courseware is based on a similar course that is offered by the University of Guelph in Canada (Sparling, 1998). Materials are structured to facilitate collaborative learning. To achieve this, the courseware is organized to provide access to course content materials, study guides for each course, and guidance about study in this mode, contacts for support if this is needed, a means of assignment submission online, access to library materials, and access to a range of online discussions. Several separate discussions are each focused on a specific purpose. In this way, discussion about a specific assignment, information about administrative or technical issues, and specific questions to the course tutor do not all appear together, as this may be confusing for many students and be distracting from the main issues to be addressed. Each course has a homepage that links to the content materials and study guides, to the various online discussions, to information on assessment and assignment submission, and to library resources.

Course content is organized around weekly topics. Each topic has reading material from a text book or other sources. The online content materials provide guidance as to what should be done each week and, sometimes, additional readings if the information in the text book is insufficient. A discussion, called the Online Workshop, is used for ongoing discussions of the weekly topics. Students are required to make a contribution to these discussions. Typically there is one new topic each week. There may however be additional topics also. Students are encouraged to interact with each other in the discussions, rather than making postings that are written as a comprehensive individual presentation. The course tutor’s role is to keep the discussion on track, to raise important matters that the students may miss, and to assist the students to develop their ideas.

Students are given individual and collaborative group assignments to submit. Specific online discussions are established for small group collaborative tasks, with access restricted to the students in the group and the course tutor. These enable the students to discuss how they will do the group assignment, to allocate roles, and to send drafts to each other. Students can access library materials online, in the form of access to full text articles from some journals. Assessment for each course is based on individual and group assignments, and on the student’s contribution to the online discussion of weekly topics.

**Evaluation**

**Questionnaires**

A questionnaire that could be completed online was developed for this evaluation. The questionnaire used a combination of specific statements to which the students were asked to indicate agreement/disagreement on a 5 point Likert scale, and questions that asked for open-ended comment. Statements were arranged in groups addressing the following issues:
• technical issues of access and clarity of use;
• effectiveness of content information, how to learn and assessment;
• computer conferencing and collaboration;
• involvement of the course lecturer and perceived effectiveness of learning.

Each group of statements was followed by an open-ended question. Responses to the statements most relevant to this paper have been reproduced and are discussed below.

<table>

Table 1 Responses to questions on technical issues and clarity of use for three courses.

Data from the questionnaires for the first three courses offered online have been included in this study. One course is notable as it provided the students with more online content, and had more input from the lecturer into the online workshop discussions than the other courses. This course was rated more positively by the students than the others. The positive rating was consistent across nearly all of the questions, indicating the pervasive nature of the perceived benefit from this input.

The responses in Table 1 show a diminishing level of issues and problems relating to the use of the technology. The students had many difficulties with access, as they needed to install software (lotus Notes Client) as well as establish an Internet connection to the server. This caused some delays in fully getting to grips with the first course. One student commented: 'It was extremely difficult to try to come to grip with the course material whilst using the browser and trying to get Notes running. More consideration should be given to supporting student with the set-up. We did feel like guinea pigs'. These initial problems were sorted during the first course, and there were few problems relating to access after that. A student's comment in the second course was: 'Technical problems did improve with time'.

Questions 9 and 10 in Table 2 focused directly on collaborative aspects of the course. Students were consistently positive in their responses to the question about working closely with others. They were more divided on the issue of learning from each other, with a minority either neutral or in disagreement with this statement. One student commented on the value of other students' responses as follows: 'The answers to the compulsory questions from the other students were very informative and gave me a broader understanding of the course.' Comments in two courses pointed to difficulties with the computer conference medium, which did not allow a free flowing discussion. After the first course, a student's comment was: 'It is almost impossible to 'discuss' on this basis and the freedom of expression one has verbally cannot be replicated literally.' Some students felt that meaningful discussion needed to be by phone. This does not appear to have been a problem in the third course. One of the students wrote of this course:

We are at last getting a real methodology of handling an ideas session online. Each contributing many points for elaboration by others and by ourselves in turn. Then editing and re-editing. A real online brainstorming session!
Table 2 Responses to questions on computer conferencing and collaboration for three courses.

It is likely that the students were becoming more accustomed to using the medium. More important, however, was the way that the course tutor managed the online discussions. This is elaborated further in the discussion content analysis. The overall success of the course, and importance of guidance for group work is evidenced by the following:

I really enjoyed the … course. The workload was appropriate and the fact that it was well related to my area of work was very beneficial for me. Although it is up to groups to work out how to work together, suggestions from past experiences could be made. It took us three goes to get a really good group way to approach the assignments. I guess you could say that this is continual improvement as we went. Some suggestions may be useful to others.

Focus group

A focus group discussion was held with the students after the courses included in this evaluation had been completed. Topics included in the discussion included technical issues related to connection with the system and working collaboratively in an online environment. The students expressed a high level of interest in the way that the program was run and how this affected the way that they learned. The discussion focused on the overall program, rather than differences between one course and another.

The students all had vivid memories of the initial phase of the program, in which they had to install the client software and make a connection to the server through an ISP. As this happened during the initial weeks of the first course, students had to deal with installation while to keep up with the course activities. Two student comments illustrate some of this frustration:

I actually spent several days of actual assignment time in economics trying to get to a computer to run with Lotus notes. It's not as if I am a recent convert to computers — I've been using them for a long time.

It's a huge issue; it affects our ability to study.

The students proposed earlier installation with more support as a solution:

We need a lot more IT advice on how we are actually going to get connected and make sure that everyone is connected right from the start.
After the connection issues were overcome, the students needed to learn to work with the technology as a learning support tool. One student summed this up by saying:

I had a few initial teething problems which were really I mean they just came down to IP addresses and that type of thing with Lotus Notes, but on the whole once we got over that initial hurdle everything ran – it just took a week or two to get everything sorted but after that it did work quite well I thought.

Another commented on the use of the discussion groups specifically:

I think the Lotus Notes worked quite well as a group discussion basis as well, I mean most of the discussion groups we had there were some hiccups at the beginning, but really as a tool to use as a group discussion basis and to get your work done, once all those teething problems were finished I think it’s quite a good use of that technology and it went well, I think, for most of us.

Collaborative tasks were the most challenging aspect of the course to the students, as they had issues of negotiation and organization to deal with as well as the information and interpretation associated with the content of the task. As they progressed through several courses they improved their ability to work together. Two comments illustrate this process:

... when [we] ... did our first one we actually divided up the task... and then each one had a task – well that was alright except I think it worked better with actually building it up and moving the assignment around and each person contributing ...

Other comments also reflect that the process was difficult at first, but became easier with practice as the students got to know each other and improved their organization. The students generally saw the collaborative tasks as a good way to learn despite the added stress:

Yes it was good – nothing will ever replace sitting in a room with people and talking to them but to do the group work that way – you certainly got to know the group members much better and you interacted with their thoughts and ideas and that’s the way you learned.

Conclusion

In general the students were strongly supportive of the Masters program. They set a high value on the collaborative aspects. They got to know each other well and appreciated working together on learning tasks. Apart from the initial problem of access, the students found that they learned to work with the online technology, and that it was an effective way of facilitating their learning. The course focus is to develop knowledge and skill in the management of Agribusiness. The online technologies enabled those students based in rural areas to participate in the program. Learning to work collaboratively overcame any feelings of isolation the students may have experienced, and led to skill development that built on the knowledge and experience of the students as well as the staff.

Abstract
Developing a course for online study by off-campus students requires a major change of approach to teaching and learning. This study outlines the constructivist theoretical basis and the approach to teaching applied in the development of a humanities course. The study includes analysis of the turning points in the students' learning as identified in asynchronous discussion postings and evaluation feedback from a post-course questionnaire. Analysis of discussions and student feedback are used to demonstrate student learning and attitudes to the new mode of study.

Introduction
Transforming a traditional course to an online offering to off-campus students requires a reconsideration of the approach to learning and teaching. Using online discussions may be a new experience for both teachers and students. Consequently, learning new ways of interacting via an unfamiliar medium may be a major part of doing the course, and the student has a few hurdles to jump over before learning the course topic can begin.

This paper considers theoretical aspects of online learning in relation to the design, development, and implementation of an online course. The project began with a need to offer the course to off-campus students. The course requires the students to analyze art and literature to identify the influences of culture and ideology on perception. An important aspect of the teaching and learning is the development of the student's ability to analyze issues, compare and contrast different art works and art forms, and to synthesize a level of understanding and a new perspective. The major requirement of the course is the development of a specific set of higher-order cognitive abilities. The online courseware and the learning and teaching strategy were developed to support this particular type of student learning.

Online teaching and learning
Research on issues relating to online teaching and learning reveals a number of issues that are critical to the tasks of design, development and teaching of an online course. Major issues that must be critically examined in relation to current research include:

- Using online technologies to enhance student-centered approaches to teaching and learning to ensure high quality learning outcomes;
- The use of online discussion to support teaching and learning;
- Providing effective support mechanisms for off-campus students.

The following sections will examine these issues to identify the key points from current research that are important for online course design.
Online technologies for learning enhancement

In a situation in which a course is offered entirely online the application of the online technologies has two critical roles: to enable an effective teaching and learning approach by supporting and enhancing the essential teaching and learning processes; and to make the course accessible for the off-campus student. From an instructional design perspective it is critical for the design of the course materials to be based on sound educational theory. The constructivist approach to teaching and learning has been developed to empower students to attain higher-order levels of understanding and the ability to work with complex issues (Hannafin & Land, 1997). An online course in which students are engaged in exploring to find new meanings and to engage in knowledge construction can be considered to be a constructivist learning environment (Jonassen, 1999).

To enable the most effective knowledge construction the student must engage in learning activities that foster the desired learning outcomes. Learning activities should be structured to actively engage the learner in higher-order thinking and learning by analyzing topic material, comparing alternative opinions and perspectives, and synthesizing a new level of understanding and awareness. Biggs (1999) describes as ‘alignment’ a process of: formulating learning outcomes that reflect the appropriate level of knowledge and skill; designing learning tasks that will foster knowledge construction and skill development; and setting assessment tasks that require the student to apply the appropriate level of knowledge and skill. To achieve this, learning tasks and assessment tasks are either the same task, or closely related. Collaborative work with other students and the teacher, possibly in the form of collaborative assessment tasks, should be a part of the learning process as this fosters deeper learning outcomes (Biggs, 1999).

The design of the online learning environment needs to be structured to support the most effective learning activities. In an online course, critical considerations are the way that the course materials support the student to know how to use the courseware, how to find the learning resources, how to access guidance about understanding the course topics, and how to use the communication systems. The structures to achieve this can be conceptualized as tools, such as cognitive knowledge construction tools, or communication tools (Jonassen, 1999). Student guidelines can be considered as scaffolding, or supports that can be provided where necessary and removed when the students have attained a level of ability and no longer need them. Important types of scaffolding are:

- Conceptual  – guiding the learner in what to consider
- Metacognitive  – how to think during learning
- Procedural  – how to use the features
- Strategic  – how to analyze and approach learning tasks

(Hannafin, Land, & Oliver, 1999, p. 131).

In the instructional design process it is important to ensure that these supports are in place and accessible.

Online discussions

A key element in a constructivist approach is active learning through discussion and sharing of ideas. Laurillard (1993) outlines a process of discussion, adaptation, interaction, and reflection that represents an exchange of ideas that is essential before cognitive change can occur. This process has a strong social element, as it is through interaction and sharing that a sense of a learning community is created and a high level of engagement with the learning task occurs. Learning is seen to revolve around learners’ conversations about what they are learning, not teacher interpretations (Mills & Cotteill, 1998, p. 229). In this context, group activities are considered to develop generic skills that are transferable to other situations, such as communication, negotiation, and interpersonal skills, and to enhance learning leading to deeper learning outcomes (Morris & Hayes, 1997).

In the context of online learning, discussion and interaction occur using online conferencing tools. These tools are considered to be some of the essential ‘cognitive tools’ provided by a computer-supported learning environment to aid knowledge-building through sharing ideas and collaboratively
constructing knowledge (Jonassen, 1999). Online discussions are applied to enable the cognitive processes described above to occur in an online environment. They should not, however, be seen as a direct equivalent of group discussions in a classroom. Asynchronous online conferences are conducted in writing, which changes the nature of the discussion. Comparative research indicates that while online discussions may be less spontaneous than the classroom equivalent, they are more reflective and often demonstrate a higher quality of learning as a result (Newman 1997). Consequently while the use of online conferencing is growing as a method of supporting off-campus students it is also being used in conventional on-campus courses (Romiszowski & Mason, 1996).

As online discussion is new to many teachers it is appropriate for online teachers to consider appropriate methods for facilitating teaching and learning in this way. Studies of courses in which an online discussion is an optional extra without teacher involvement often report some shortcomings in student use of the discussion. To use online discussion as an essential element in the learning process an appropriate level of involvement by the teacher is essential (McAlpine, 2000).

Salmon (2000) presents a five-stage model for the development of student ability to engage with online discussions. She describes the teacher’s role in an online discussion as ‘e-moderating’. In this role the teacher must ensure that the students move through the stages of:

- Access and motivation
- Online socialization
- Information exchange
- Knowledge construction
- Development.

Salmon recommends that at the early stages of an online discussion the e-moderator needs to provide online activities that will facilitate the student’s ability to manipulate the conferencing tools and to develop knowledge by exchanging and expressing ideas through the online discussion process. It is only when the students have reached the fourth and fifth levels of ability that the students are able to engage in the type of knowledge construction through dialogue that is the goal of the learning activity.

**Review of theory**

The use of online technologies to promote knowledge construction and active learning requires a range of critical supports and guidelines for learners. They need to know how to use the online courseware and where to find the necessary tools and resources. A critical tool is the online discussion. Through this means the learners can be guided in how to share ideas and work with other learners, and how to develop their understanding of the topic. A staged process beginning with simple tasks for online discussion building to more complex ones is helpful to learners as they come to terms with a new mode of study.

**The Course**

The course on which this study is based was designed as part of a UNSW initiative to encourage online teaching in General Education. General Education is a requirement by UNSW that all students take some courses in disciplines outside their faculty, to broaden their education and introduce them to forms of knowledge and styles of thinking outside their normal study.

The course is called ‘Seeing Australia’, an examination of the ways in which Australia has been represented through its history in different modes of cultural production. The content addresses various forms of written and visual representation, including fiction, poetry, non-fiction, painting, photography, and prospectively, film and television. The learning outcomes of the course involve high level cognitive and interpretative abilities. At its completion the students should not only be able to identify various ways of representing Australian place and society, and to distinguish between two predominant traditions of ‘seeing’ Australia, but also be able to recognize that ‘seeing’ itself is not a simple ‘natural’ activity, but based upon cultural assumptions and traditions that largely go unnoticed.

The course was run for the first time on a trial basis in the second semester 2001. For this trial a small, totally external, student cohort was selected. Nine students were Singaporean Chinese enrolled in an
external Safety Science degree at UNSW, one was an accounting student from rural NSW. None had taken a humanities subject before. These students were relatively familiar with WebCT, but had not previously engaged in external study that used online technologies as the main focus for learning activities.

**Course Content versus Learning Outcomes**

The course was divided into Six Modules containing topics that approximated a weekly schedule. Once the students (eventually) came online the introductory module, involving their ‘seeing’ of their own neighbourhood and of Australia worked well. However, it quickly became clear that the students were not able to maintain a weekly schedule of topics as might be demanded in a face to face course. This immediately suggested that the online format provided a ready diagnosis of student progress, otherwise unavailable if they had sat quietly and uncomprehending in an on-campus class.

The most interesting outcome was the discovery that course content could be sacrificed in favor of the learning outcomes. Although the course was not structured according to a progressive format, in which the student could only move ahead once a topic had been mastered, it was clear that there was no point moving forward unless they had fully grasped the conceptual skills involved in a module. By privileging the learning outcomes over content, four topics in a module could be reduced to three, or even two, in practice, although the content was available in the Reader for the better students. This meant that difficult theoretical topics were engaged by students with no background, by ensuring that they could work at the issues through discussion. In the workshops a certain momentum built up so that even slower students became engaged with the more difficult topics by entering into the discussion. Conversely, it was clear that once a new topic began it took some time to build up momentum. In effect, it became necessary for the content to be reduced so that the learning outcomes could be achieved by all. One positive corollary of this apparently slow rate of progress was that the online delivery of content, particularly of paintings and images, allowed the students considerable time for study and reflection at their leisure.

In addition to the slower rate of progress, it was clear that some issues of cultural analysis were simply too difficult for students of non-English speaking background with no experience in the Humanities. Nevertheless, by maintaining a clear focus on the learning outcomes, these problems could all be circumvented. Whereas a concentration on the content might have suggested that the course was falling short of its aims, it was clear that not all conceptual issues or forms of content were necessary for the skill-based learning outcomes to be reached.

**Diagnosis of Learning**

The discussion provided a ready indication of the degree to which students had grasped the conceptual point or the extent to which they needed to be encouraged to progress. The following comment is from a slower student who is entering a discussion about Oliver Sacks’ story “The Man Who Thought His Wife was a Hat” which touches on the neurological bases of seeing as an introduction to the ways in which ways of seeing can vary.

Hi Bill I am a down to earth person and believe in seeing with my own eyes. In my opinion, Dr P can be describe as followed: Like most musician and painter, he is a man with creative mind as shown in his previous painting work and his love on music. Most people see with their eyes, but after reading his story, I found that one can also see with their ear and nose. In the story 'journey to the west', I remember the monk preach his followers to see with their heart. At that time, I thought it was only a story, but now I found that in real life, they are actually people seeing things in another angle. In Dr P case, Music is the whole world to him. His love for music is so great that he can teach music to his student till the last day of his life. That make me wonder how powerful is our mind.

Here we find a student at an interesting juncture between his understanding of himself as ‘a down to earth person’ and therefore not amenable to exotic ideas about seeing, and his beginning to comprehend the complex cultural bases of vision. Critically, this turning point comes when he incorporates previous knowledge to construct his understanding. At this stage he is not quite aware of the implications of someone ‘seeing’ with ears and nose, but the phrase ‘how powerful is our mind’ is a
significant entry to the understanding of the cultural bases underlying ways of seeing Australia. This was a beginning that could be built on by the instructor. But it was a beginning constructed by the student’s incorporation of previous knowledge.

**Turning Points**

It became possible to tell when the learning outcomes were being reached by observing the emergence of active learning in the online discussion. This was particularly so when the Singaporean students constructed the requisite knowledge from their own experience. Throughout the discussions constructivist ‘turning points’ could be distinguished, at which the students reached learning outcomes by actively constructing the learning central to the course.

This learning construction could sometimes occur in a frivolous way, as we see here from a student who proved to be the mentor and driving force of the Singapore students.

> We often go through life "doing", "seeing", "hearing" and "feeling" things out of habits, which we actually don’t intend to do or be conscious about! My personal experience it that I have a wife that is so tidy that very often annoys me. Everyday she simply goes about doing her routine out of habit more than necessity. No item is allowed to be misplaced in the house and that include children toys, so you can imagine the amount of shouting going on around the house every day! Well, this is just her way of seeing life! I certainly do not intend to see Australia through her way!

A much more significant example occurred during discussion of what proved to be an difficult, but ultimately extremely productive topic. This topic was based on a complex essay on the Eurocentric bases of the Mercator projection map. While the content proved to be very difficult for this class, other content was sacrificed so that the link between the map and ways of seeing the world could be confirmed. The discussion threads provide a concrete record of the gradual movement from the idea of a map as a simple description of the real world, to the concept of the map as based on the cultural phenomenon of Eurocentrism.

One turning point was significant for the whole class. The following comment is from the student most ready to go beyond the confines of the material. It represents the kind of moment that teachers look for, and which are all too hard to isolate or analyze in oral discussion.

> I am still looking for the Japanese map of the world which put Japan at the centre mentioned in Message:142. However, I managed to view a 12th Century map of the world which is called a "T and O" map. The world it portrays is a circle, divided by a T-shaped cross, the center of which is in Jerusalem. The circle represents perfection; the world as the object of God's affection. The world is divided into three continents, named after the sons of Noah. This map represented the Church's truth. It conveyed everything important to know for those who lived in a world where nature was unfolding according to God's plan. I will try to look for the Japanese map as mentioned.

The student has actively constructed knowledge of the cultural bases of maps by means of a cultural comparison that is germane to his own experience but also critical in the progression of the whole class towards the learning outcomes.

It is moments like these that the instructor can justifiably say “Bingo!” Fascinatingly, it wasn’t until I was reviewing the postings on the second reading that I realized just how significant the turning point had been. The review of written responses was crucial in both diagnosis and a perception of the gradual achievement of the learning outcomes.

**Evaluation**

An evaluation questionnaire was completed at the end of the course. Questions relating to content and online discussion are included below.
The online discussion and group learning tasks elicited a strong favorable response (see Table 1). While the content itself was regarded as difficult by this cohort, the online discussion meant that students felt that their learning had been facilitated. Typical responses were:

I am very satisfied with the online Group Project method of learning. It was something very new to me and my group members. I would not have acquired such a method of learning if not for this online Group Project. Thank you.

I am happy with the group learning tasks. I enjoyed working with the other group members.

Consequently, although content was often regarded as difficult, the response to the content was very positive.

Table 1 Student feedback on online collaboration

Although the content was reduced the responses to the questionnaire confirmed the fact that the learning outcomes were met by allowing longer time to discuss difficult concepts (see Table 2).

When I enrolled for this subject, I thought Seeing Australia was a 'holiday subject' not requiring any effort to learn new concepts. It was in the thick of the subject that I learned that Seeing is not necessarily what I used to think but a whole new concept which I never knew existed.

Table 2 Student feedback on learning from the course

**Conclusion**

Courses taught in the Humanities are extremely amenable to the active construction of knowledge because they do not come with ready-made answers. Skills of analysis and discernment are crucial to the nature of the knowledge these courses present. Nevertheless active learning is habitually discouraged by an obsession with content which is usually held to be synonymous with learning. The presentation of courses online enhances the processes of active learning because the need to write postings and the length of time allowed to consider content, increases reflection and engagement, and provides a ready-made diagnostic tool for the instructor's evaluation of the learning process. But the course, "Seeing Australia," also demonstrates that high level cognitive skills can be achieved by
students of all abilities if content is subordinated to learning outcomes. The written record provides examples of turning points in the students' learning at which major advances were made as they found the skills required by the course by moving outside the content to engage the material in a more culturally familiar context. These turning points no doubt occur in all teaching, but the written record of online discussion provides confirmation that turning points occur when the learning is constructed as authentic for, and by the student.

Interactive Web Page Development for Undergraduate Science Courses: A Discussion of Process and Problems

In 2000 and 2001, three institutions of higher education attended workshops at the Marshall Space Flight Center (MSFC) and Johnson Space Center (JSC) to develop interactive web-based inquiry activities for science courses that serve preservice teachers. These web-based lab activities were developed to provide active learning modules that linked course content to research conducted by scientists at the National Aeronautics and Space Administration (NASA) centers. The participating colleges and universities are members of consortium of universities that form the NOVA network. NOVA is a NASA initiative to improve the quality of undergraduate science and mathematics content courses that serve preservice teachers. NOVA was created to develop and disseminate a national framework for enhancing science, mathematics, and technology literacy for preservice teachers in the 21st century.

In order to foster the goal of increasing the use of technology to enhance learning in science and mathematics, NOVA offered a NOVA Phase III grant opportunity to network members. These grants provided funds to develop interactive web-based activities that linked faculty at NOVA institutions with NASA scientists whose research informed concepts in science courses supported by NOVA. Workshops were held at NASA centers. Science faculty spent five days at a NASA center. The morning was spent with scientists whose research related to topics covered in the courses taught by the faculty. Afternoons were devoted to interactive web page development. NOVA provided technology experts to assist faculty with software and technology training. NASA staff provided resources in the form of images, data, and information on the location of web-based resources.

NOVA team leaders were available to provide expertise in instructional design for active learning environments. The NOVA model promotes instructional strategies that are inquiry based and student centered with extensive use of technology to facilitate learning. A learning cycle approach is the approach used by all three institutions in the development of the interactive web sites. A common version of the learning cycle has three phases, engagement, concept and term introduction, and elaboration. Students are introduced to new material by engaging in an activity, investigation or discussion of a question posed to the class. The explanation phase allows the students to verbalize their conceptual understanding. After students have had the opportunity to explain their understandings, the instructor may introduce scientific terms and explanations. Group and whole class discussion during the explanation phase replace the lecture component of the course. Students apply what they have learned during the elaboration phase of the learning cycle.

Two web modules have been completed and are currently being used by the faculty teams at two schools. One team has completed work on a second module which will be available in the spring of 2002 for classroom use. The third university is in the process of completing their interactive web site. Each web-based activity was developed by a team consisting of a science faculty member, a science educator and technical support personnel. NOVA staff were available for technical assistance with the projects. Faculty were given stipends to support the development of the web activities. These web activities are presently used as a web-based component in face-to-face courses.
One of the web modules links students to research on the phenomenon of urban heat islands. Students explore this topic by making observations of thermal images of cities that were gathered by satellites. Web-based resources provide students with information on the concept of heat islands, the causes of heat islands and the means of reducing heat in urban areas. Students collect data on temperature variation in an urban area using graphing calculators with temperature probes and GPS units. Data is recorded, results are analyzed and conclusions are reported on the web site. This web activity was developed at the MSFC and is based on research by Dr. Dale Quattrochi of the Global Hydrology and Climate Center (GHCC).

A second module was developed at the JSC and is based on the work of Dr. David McKay. This module relates to the requirements and characteristics of life, classification of cells by cell infrastructures, and evidence of life in extreme environments. Students engage in the concept by formulating ways to gather evidence of life on Mars. Web based resources provide students with information about life in extreme environments and about research that may indicate the possibility of life on Mars. Students examine and compare size of cells and cells structures from different groups of organisms. Web-based research of new discoveries of nanobacteria and debates among scientists provide additional resources for students to draw their own conclusion about the evidence for life on Mars. Student design an experiment to find microbes in harsh environments in the immediate area. These experiments are performed in the laboratory.

The members of the panel will present the web-based modules and describe the process and problems of interactive web page development. The presentation will include discussion of the problems encountered in finishing the projects after the NOVA Phase III workshops. Technical support issues will be included in the discussion. Implementation of the project in the classroom and student problems with the modules will be discussed. Issues of faculty time and evaluation are important issues in integrating these web modules into the curriculum. Each panel member will have 10 minutes to present the interactive web module.

The presentation of the module development will be followed by a thirty minute discussion that focuses on the problems of development and implementation of interactive web modules for undergraduate science courses. Science is an active process and developing inquiry based web activities is necessary when e-learning is used in science teaching. Development of these sites is time and resource intensive. Participants will be encouraged to share their experiences in using and developing interactive science web sites. The discussion will focus on barriers to web-based instruction in science and how to overcome those barriers.

The panelist are scientists and science educators that are members of the NOVA Network. All are faculty members at colleges and universities and have participated in NOVA workshops at NASA Centers. Each panelist has developed an interactive web page that is used in an undergraduate science course.
Transforming Student Technology Use through Faculty Development Grants

Science classrooms at a small religious, liberal arts university located in an urban area of South Texas have been transformed technology use in the classroom through faculty development programs. Participation in a National Aeronautics and Space Administrations (NASA) program for college faculty, campus faculty development programs and Department of Education Title V (Title V) faculty development funds paved the way for integration of technology into biology classrooms and increased opportunities for students to apply technological tools to solving problems, to understanding fundamental concepts and to research in current issues in biology.

The university enrolls 3,500 undergraduate students. Seventy-one percent of the student population can be designated as minorities with the majority (54%) coming from Hispanic households. Most of the students are first-generation college attendees who use financial aid to pay for their education (77%). The university qualifies as a Hispanic Serving Institution (HSI).

In 1996 two biology faculty members received a grant from Project NOVA. NOVA is a NASA initiative to create a national model for change in the way that introductory science classes for pre-service teachers are taught. NOVA supports college faculty and administrative teams in activities that apply the principles of constructivism and national reform to content courses in mathematics and science. The National Science Foundation (NSF) has called for more opportunities for students to use graphing calculators and computers in the classroom and outside the classroom as a necessary element of reform in science learning (NSF, 1996a). The National Science Education Standards (NRC, 1996) call for making “the available tools, materials, media, and technological resources available to students” (NRC, 1996 p. 43) and for providing a learning environment that engages the student in actively constructing knowledge by engaging in the process of science.

At the time the NOVA funding was granted, the biology faculty members involved in the project did not have the technological skills needed to implement the use of technology in the classroom. This was a university-wide problem that was recognized by the Office of Instructional Technology (OIT, www.uiwtx.edu/~cheryla). In the summer of 1998, OIT obtained university faculty development funds to develop a program to train faculty in use of instructional technology in the classroom. A key element of the training was to introduce faculty to the instructional design process. Although most participants in the workshops had taught for years, many had little formal training in instructional design. The STI is currently funded by a Title V grant for HIS.

One result of the training for the biology faculty members was that they received a supplementary grant from NOVA. This NOVA Phase III grant provided the faculty members with the opportunity to spend a week at the Johnson Space Center (JSC) to develop an interactive web site for their revised course. This faculty development opportunity was a valuable experience and facilitated development of interactive technology materials for student learning.

As a result of attending OIT training workshops and receiving technology fellowships, the biology faculty gained the technological and instructional design skills to develop instructional products to increase student technology use in the classroom. One important use of technology is the ability to link students to real-world problems and to
create an interactive environment for students to solve problems (Bransford, et al, 1999). The biology faculty used NOVA funds to develop a course web site with activities linked to NASA research (www.uiwtx.edu/~mccormic/nova). These activities require web-based research, data analysis, and electronic submission of research results.

The course has evolved from a classroom that had almost no technology use to one that is multimedia enriched and requires students and faculty to become proficient in technology use. The success of the inclusion of technology in the NOVA supported course has been extended to other classrooms in the department. As the biology faculty became more proficient in incorporating technology in instructional design they began to incorporate technology use in other courses.

An additional problem for the students at the university was the fact that many students come to us families who statistically had a low use of home access to computers and Internet service. In August of 2000, the U.S. Department of Commerce (2000) reported that only 37% of Hispanic households owned computers and only 16.1% of Hispanics accessed the Internet from home. To address this problem the University became the largest IBM ThinkPad University in the South. All full-time students, sophomores through seniors, have laptops with software and wireless cards. The laptop program provided the means to fully integrate technology use in the classroom. Faculty development led to increased demand for student access to technology and contributed to the need to change the method of providing computer access to students.

The National Science Foundation (NSF 1996b), calls for all students to “have access to supportive, excellent undergraduate education in science, mathematics, engineering, and technology, and all students learn these subjects by direct experience with the methods and processes of inquiry.” Faculty development programs model requirements for teaching using technology consistent with national reform movements. As students collaborate with faculty to apply technology to solve problems, students and faculty become part of a technologically literate community. Providing laptops and Internet access bridges the digital divide and reduces competition for scarce resources. Everyone has the technological tools available in the classroom.

Cognitive Tools in Web-based Learning Environments: Implications for Design and Practice

Patricia McGee
The University of Texas at San Antonio, USA
pmcgee@utsa.edu

Abstract
Cognitive tools are well documented in multimedia learning environments but there has been limited transfer to online learning environments, particularly to Web-based Learning Management Systems (LMS). This paper describes specific tools appropriate for LMS and advocates purposeful integration of cognitive tools in support of adaptive learning for diverse populations.

Industry, government, and higher education have been pressed to offer training that meets the needs of the 21st century worker and student offering flexible scheduling and self-paced courses (Woods & Cortada, 2002; Fjortoft, 1995) at reasonable costs (Aldrich, 2001). Some experts believe that conventional education and training are obsolete in view of increasingly sophisticated and readily available learning management systems (LMS) (Delphi Group, 2000). Because the Web-based learner is physically isolated from peers and typically learns autonomously he or she may or may not be prepared to construct effective learning supports. Therefore the integration of tools that support learning are most critical, even more so when the instructor is not present to determine learner’s progress or understanding. This paper briefly discusses cognitive supports as they relate to the nature of Web-based Learning Environments (WBLEs).

Conceptualizing Cognitive Tools
Web-based Learning Environments (WBLEs) typically require that the learner work autonomously and independently. Feedback mechanisms are mostly user-generated rather than technology-generated and yet there are many instances in which WBLEs have provided mechanisms that support the learner in a variety of ways: with study strategies (Morgan, Dingsdag, & Saenger, 1998), prior knowledge evaluation (Portier & Wagemans, 1995), resources for information retrieval and problem solving (Oliver, 1999), tutorials, and advising services (Wright, 1991). These supports are primarily cognitive, supporting the mental functions required of the online learner.

The term cognitive tool has been defined in several ways. Jonassen (1994) states that computers and the software that provides interactivity are cognitive tools that allow the learner to use them “as tools for knowledge construction rather than media of conveyance and knowledge acquisition” (p.2) as learners are actively involved in constructing their own knowledge and learning with technology (Jonassen, 1991). Others define cognitive tools by the function served within an electronic learning environment (Lajoie, 1993). This approach is not in conflict with Jonassen's general notion but more specifically identifies cognitive devices which support learning strategies that vary by learning context. Such tools may support cognitive processes, reduce cognitive load of the learner, extend the cognitive capabilities of the learner or allow the learner to test ideas within problem solving contexts (Lajoie, 1993). Katz (1997) suggests that cognitive tools should support processes of learning that are associated with study strategies such as review, rehearsal, attention, practice, and application. Regardless of how cognitive tools is conceptualized, learning at a distance is essentially learner centered and as such requires supports that are responsive to the learner’s immediate needs (Thompson, 1998).

Sugrue (2000) identifies four aspects of learning environments that require cognitive strategies that could be supported by tools, only one of which can be reasonably applied to learner-only interaction, Information Organization and Access. Helping the learner navigate and interact with the electronic environment supports Lajoie's (1993) idea that cognitive tools can reduce cognitive load and assist with lower level thinking processes so that the learner may engage in higher order thinking. Many cognitive tools identified and used in interactive multimedia learning environments resemble devices found in print materials that assist in identifying location within

1 The other strategies require opportunities to interact with others: Authentic Activities, Collaborative Learning, and Student Modeling.
a system or finding one’s place, such as bookmarks (Katz, 2001). Erickson and Lehrer (2000) suggest that hyperlinks serve as cognitive tools if they are used intentionally and for specific purposes such as for navigation functions, offering elaborative information, or for structural organization. Index or navigational interface windows (Jonassen, 1998) provide the user with information about their location and/or progress, possibly through a program or site map.

Other tools assist the learner in locating information such as find, glossary (Katz, 2001; Sinitsa, Mizoguchi, & Serdjuk, 2001), and help functions which may also provide cues, elaboration or explanations (Katz, 2001). Tags, pop-up graphics, or rollovers may also direct the user to useful or clarifying information. It may be that visual cues such wipes and dissolves direct the user’s attention and support the perceived coherency of the material presented (Slatin, 1991). Additionally, explanatory interface windows (Jonassen, 1989) may elucidate, give details, or coach the user. Others have identified cognitive tools that may serve as an organizer of knowledge or illustrate the relationship of parts to the whole illustrating how knowledge is represented in memory (Sugrue, 2000). Concept and knowledge maps can help learners see the big picture of the relationship of concepts within a specific structure more clear (Rewey, Dansereau, Skaggs, Hall, & Pitre, 1989), making connections between prior and future learning. Metaphorical interface windows provide a representation of material designed to link prior knowledge to materials being learned and organization interface windows support the user’s process of making sense out of information (Jonassen, 1998). Devices that allow the user to record and organize information are also described as cognitive tools. Harper, Hedberg, Coderoy, and Wright (2000) suggest that authoring tools are a means for students to present ideas for examination by others. Not all learners work well with 2-dimensional electronic representations so notepad (Katz, 2001) or downloadable documents may also function as a cognitive tool if they are used to store ideas and thoughts that are referenced in the process of learning.

Implications and Further Studies

It may be that the nature of Learning Management Systems (LMS) is grounded in the notion of knowledge management as opposed to knowledge construction. Activating the learner’s schema is less likely in a prescribed and pre-determined WBLE, however, adaptive cognitive tools may allow the learner to construct understanding by facilitating the learner’s organization of information (Woolf, 1992) which can then be substantiated through interaction with other learners and the course instructor (Derry, 1992; Jones, Greer, Mandinach, du Boulay, & Goodyear, 1992). If a learner enters a WBLE and is offered a path that appropriately supports his or her entry level skills, technology or content knowledge, or learning orientation, the cognitive load will be diminished and embedded supports will facilitate understanding and more authentically respond to the unique and individual needs of the learner (Laurillard, 1992). This is the intent of cognitive tools, particularly in systems which presuppose or require the learner to work to some degree without interacting with others.

Abstract: This paper details the work performed toward building a reliable, automatic, content analysis suite of tools that analyzes online educational discussion list messages. This project is nearing completion and is conducted under contract by Georgia Tech’s Center for Education Integrating Science, Mathematics, and Computing (CEISMC) with the Institute of Higher Education at the University of Georgia under a service agreement with the University System of Georgia Board of Regents’ Advanced Learning Technologies Unit.

Introduction

In the state of Georgia, the number of credit hours offered online jumped from 59,593 in fiscal year 2000 to 94,531 in FY 2001, an increase of 59% (Yahoo!Finance, 12/11/01). Meanwhile, IDC estimates that the e-learning market will grow from $2.2 billion in 2000 to $18.5 billion in 2005 (Moore, 2001). This growth in electronic learning means that the discourse from many of these learning environments is very easily captured providing an opportunity for researchers to study the process of learning in a way that has never before been available. This study outlines the initial phase of the construction and use of an artificial neural network (ANN) to perform a content analysis of a large body of student messages for cognitive presence. This research seeks to answer two questions. First, can neural networks be used to analyze and describe the cognitive landscape of online educational discussions? Second, at this phase, how is cognitive presence revealed in an online course? This work is based upon the cognitive presence element of Garrison, Anderson, and Archer’s (2000, 2001) community of inquiry model. Unlike Garrison, Anderson and Archer, this work uses a neural network combined with the General Inquirer (see Danielson & Lasorsa, 1997; http://www.wjh.harvard.edu/~inquirer) to analyze messages. Additionally, this analysis extends the General Inquirer by adding self-defined categories designed to improve the classification into cognitive presence categories. The suite of tools developed for analyzing these courses may ultimately be used to gauge, guide, direct, and manipulate any learning environment employing online discussions.

The Study
To answer the two questions, can neural networks be used to analyze and describe the cognitive landscape of online educational discussions and how is cognitive presence displayed in an online course, a content analysis of six eCore™ freshman and sophomore history and political science courses was performed during phase one of this study. Phase two of the study will include modeling the decision-making process of the content analysis coders using artificial neural network software. Six coders were trained in the use of a rubric based Garrison, Anderson, and Archer’s (2000) cognitive presence hierarchy, which consists of: triggering event, exploration, integration, and resolution. After completion of the training, each coder used the rubric to categorize a set of randomly selected 100 reliability messages and another set of 200 randomly selected course messages. Since the coders represent a subset of a larger population of teachers, Shrout and Fleiss’ two-way random effects model was used (ICC(2,6) = 0.8231). Barrett (2001) considers an intraclass r statistic above .74 to be excellent. Pairwise, the Cohen’s kappa (k) rater reliability scores ranged from .504 to .747 with a mean of .608. This compares well with Garrison, Anderson and Archer’s reliability data for two coders, which yielded k = .35, .49 and .74 for three successive trials. Scores below .8 are acceptable for cutting edge research, that which is breaking new ground, a category under which this research clearly fits (Riffe, Lacy, and Fico, 1998).

Conclusion

The study yielded insight into potential improvements for the rubric and coder training. Coders had difficulty in correctly coding Triggering Events that were intentionally initiated by the instructor. In some instances, these messages were coded as Unrelated/Course Management. This was due to the fact that the Subcategories under Triggering Event, Sense of Puzzlement and Recognizes Problem, were inconsistent with an intentional, instructor initiated Triggering Event. Clearly, the instructor was not puzzled, nor was he/she recognizing a problem. In future studies, we intend to modify the rubric by adding a new subcategory under Triggering Event for instructor initiated Triggering Events. Further, increased reliability may be achieved in future studies by providing additional training to coders on distinguishing between exploration vs. integration, exploration vs. not cognitive, and triggering event vs. exploration.

Bridge over troubled water: Creating effective online support for the metacognitive aspects of problem solving

Catherine McLoughlin
School of Education, Australian Catholic University, Australia
c.mcloughlin@signadou.acu.edu.au

Rowan Hollingworth
Chemistry, University of New England, Australia
rholling@metz.une.edu.au

Abstract: In the context of higher education, the development of students' problem solving skills continues to be an area of much ongoing research. Effective teaching of problem solving requires the adoption of process-based approaches that reveal to students the ways that experts solve problems, and the coaching of students in higher order and metacognitive skills that lead them away from a preoccupation with finding solutions and towards building up a repertoire of problem solving strategies. It is suggested that online environments and computer resources can scaffold the acquisition of domain knowledge and systematic problem solving skills. This article acknowledges that there are multiple ways to support complex problem solving, and that online environments hold great promise in creating effective instructional interactions. This study focuses on the metacognitive aspects of problem solving and more particularly on those aspects of technology-based scaffolding that support reflection, process support, and the anchoring of skills to domain knowledge.

Problem solving skills as central to learning

In tertiary education, there is an urgent need for professionals who can solve real problems, anticipate and predict problems and find realistic solutions. To meet this need effectively tertiary educators must now reexamine methods of teaching problem solving. In discussing pedagogical approaches, Hobden (1998; 223) states that:

"It (problem solving) is a routine activity occupying a large proportion of curriculum time and plays a central role in student's experience of classroom life. From the first days of science instruction, sets of routine problem tasks assigned by the teacher have been part of classroom life. As a teaching strategy, they have largely been used uncritically. It would appear that nearly all physical science education, and especially the physics component, seems to be based on the optimistic assumption that success with numerical problems breeds an implicit conceptual understanding of science."

These comments apply to the way problem solving has been taught in the past, and to approaches that rely on traditional 'show and tell' where students do not engage actively with the problem or context. The traditional method of showing examples of solutions to problems followed by student practice represents a rather primitive approach in contrast to the teaching of acting, music or a sport, where the skills required for competent performance are taught in context, often in real world scenarios, and integrated so that expert performance results. Taconis et al (2001) have recently analyzed articles appearing in international journals between 1985 and 1995 on the effectiveness of teaching strategies for science problem solving. Very briefly, this analysis showed that in student performance and achievement, knowledge of strategy and practice of problem solving turned out to have little effect, whereas accounts of effective teaching of problem solving all give attention to contextualised strategies related to mastery of domain knowledge. The learning conditions recognised by Taconis et al (2001) as significant for building problem solving skills were those which provide learners with guidelines and criteria they can use in judging their own problem solving processes and products. The provision of immediate feedback to learners is also essential. These conclusions are congruent with earlier research carried out by Alexander & Judy (1988), Clarke (1992) and Lajoie (1993).
The learning paradox

A number of contemporary designs for learning environments require student self-direction and high-level metacognitive control. Exploratory and open-ended learning environments enable students to generate knowledge and engage in critical thinking. Similarly, project based approaches assume that students are able to generate questions and produce a final product that represent knowledge integration. Many students however lack essential metacognitive skills and a repertoire of learning strategies to enable them to maximise their learning in innovative learning environments. Table 1 shows how a range of contemporary learning designs assume metacognitive knowledge.

Table 1: Metacognitive requirements of contemporary student-centered learning environments

These learning environments though highly successful, assume that students are goal driven and self-directed. Yet, these expectations bring with them a range of assumptions, primarily that students have metacognitive skills to enable them to cope with self-direction learning. Other research has shown that the processing demands of these environments are problematic and need to be investigated. One of the issues of most concern is that of the learning paradox noted by Schank & Cleave (1995) "How can students learn by doing what they do, when they do not know how do what they have to do to learn?". Stated quite simply, project and problem based learning assumes that students can access and apply knowledge and metacognitive strategies and engage in self-regulated learning. It is well established that in order to learn effectively, a repertoire of learning strategies and the capacity to manage one's own learning are fundamental (Boekaerts, 2000; De Corte et al, 2000). It is this range of skills that we refer to as metacognition.

The role of metacognition in learning and problem solving

Metacognition is a learner's knowledge about his or her processes of cognition and the ability to control and monitor those processes as a function of the feedback the learner receives via outcomes of learning (cf. Metcalfe & Shimamura, 1994; Schraw 1998b). Metacognitive knowledge refers to what the learner understands and believes about a subject matter or a task, and the judgments s/he makes in allocating cognitive resources as a result of that knowledge. Metacognitive control refers to the strategies the learner uses to achieve specific learning goals - strategies like planning and organizing, allocating attention to relevant and irrelevant factors, looking for relationships and patterns, monitoring comprehension, identifying and testing procedures, evaluating outcomes, and reflecting on learning (cf. Jacobs & Paris, 1987). Schraw (1998a) explains that attentional resources, existing cognitive strategies, and awareness of breakdowns in comprehension, are all enhanced by training in metacognitive knowledge and skills. While there are examples of successful metacognitive instruction in the literature, the most effective ones involve
providing the learner with both knowledge of cognitive processes and strategies, and experience or practice in using them. Simply providing knowledge without experience or vice versa does not seem to be sufficient for the development of metacognitive control (Volet, 1991). It is also essential that learners have an opportunity to evaluate the outcome of their efforts, to reflect and self-assess their own approaches to learning.

Four categories of metacognitive knowledge are recognised as important and affect task performance and achievement of distance learners (White, 1999). These are as follows:

- **Self-knowledge**: Self-knowledge entails individual capacity to recognise their strengths and weaknesses and to evaluate themselves.
- **Task-knowledge**: This involves understanding the demands of tasks and what they require.
- **Strategic knowledge**: This refers to the knowledge of usefulness of strategies available for achieving learning goals.
- **Knowledge of plans and goals**: This refers to learner’s capacity to set and maintain goals and to record what they intend to do through their learning.

### Design of learning environments for metacognitive support

In response to a perceived need to support problem solving, an on-line tutorial designed in WebCT, called metAHEAD, has been created for first year science students in Biology, Biophysics and Chemistry. The aim of the tutorial is to help students explicitly develop their metacognitive skills in science problem solving. The tutorial comprises four modules - an introduction to thinking and learning, knowledge maps, explanations and descriptions, problem solving. In developing the resource, instructional design was guided by current research on constructive learning, and metacognitive skills development. Lin et al (1999) in considering the technological design of learning environments have noted that four features are important for effective scaffolding of reflective thinking by students. These are **process displays**, **process prompts**, **process models** and **reflective social discourse**. The first module of metAHEAD introduces students to key aspects of learning and problem solving and allows them to rate their own problem solving skills on a standard metacognitive inventory test. The second module helps them to build concept maps for topics in their subject areas. The last two modules concentrate on the sorts of skills needed for explanations and descriptions (as most often needed in Biology) and quantitative problems (more often needed in Biophysics and Chemistry).

As students tackle problems in the modules they are asked to engage in a number of the following activities: predict their own expected success on problems; discuss their success with other students during and after attempting the problem; explicitly consider strategies for use with particular problems; examine other students' answers and comments on them; listen to audio clips, view video clips or read transcripts of other students as they worked on problems and comment on these; rate other students' answers; post their answers to a bulletin board for discussion with other students; view lecturer's model answers and comment on them.

Students maintain an on-line logbook to record their responses to the various prompts throughout the tutorial and to record their answers to problems. In metAHEAD particular attention has been paid to supporting the four categories of knowledge identified as essential for development of metacognitive skills (White, 1999). Process prompts and process models are in evidence in the learning activities, which precede the solution of example problems, and in the many worked answers of students and lecturers and comments thereon. Bulletin board discussion of strategies and problem solving skills together with the creation of collaborative teams provide opportunities for reflective social discourse.

**Evaluation of metAHEAD**

It was intended to carry out a formative, integrative evaluation of metAHEAD in order to improve the design and to refine various aspects of the resource. Oliver (2000) has remarked that while a range of methodologies exists, each may be restricted in its use and in the range of situations it can be applied to.
From our pragmatic perspective, we found the Open University model as described by Jones et al (1996) a useful framework. This approach focuses on three main themes: context, interaction and outcomes. This is outlined in table 2, and shows that range of data that was collected and analyzed. As practitioners, we sought an evaluation approach that was broad and flexible enough to suit our situation, which was the introduction of an innovative resource within a university context. From the outset, data has been gathered on the design and use of metAHEAD from pilot studies, practitioners' opinions, instructional designers who have used and developed the program and academic staff who have used sections in their teaching. It was important to include this data in our evaluation, as we needed a holistic picture of its benefits.

<table>
<thead>
<tr>
<th>Rationale</th>
<th>Interactions</th>
<th>Outcomes</th>

<td>Focus groups, tests and questionnaires</td>
</tr>
</tbody>
</table>

Table 2: Features of the evaluation approach adopted

As metAHEAD is embedded in Web CT, it allows for the gathering of the following types of data for the evaluation of metacognition, data collection was relatively standard self-rating quiz data taken at beginning and end of semester; students' self predictions of level of success with particular problems and reflection upon these on completion of the problem; on-line log book entries including students' notes on strategy use and actual problem solutions; bulletin board discussions. These data are complemented by further data gathered from small face-to-face focus group discussions. As a further elaboration of our evaluation approach, we collected a range of data relating to the interactive and scaffolding features of metAHEAD. These are summarised in table 3.

Table 3: Evaluating metacognition in online environments

Evaluation and data analysis

Data has been gathered from focus groups giving feedback on technical issues and development of problem solving skills. There are two main areas of feedback gained from this evaluation. Students have greatly appreciated the availability of other students' answers and particularly the comments on them. This has allowed them to put their own answers into a better perspective and to give a clearer idea of what the lecturer expects. (The fact that assessment and lecturers' expectations drive the majority of students cannot be escaped.) These do provide process models and support reflection by the students on many aspects of problem solving. Coincidentally, other student answers help some students to feel more of a part of a
group and that they are "not so stupid after all", which can affect student motivation to succeed along with others. Students have identified that their motivation often parallels their success in the subject. Becoming part of a community of students working on a unit is particularly important for distance education students, who may be otherwise rather isolated. The ability to discuss issues on the bulletin board has been helpful for these students.

Students have also mentioned that planning and analysis of problems, whereby parts can be tackled step by step has been helpful to them. Becoming more aware of and practicing such skills has been beneficial for students who in the past may have been daunted by a problems and given up too soon when it seemed too difficult. While we have provided some models and coaching online, students appear to need a more staged approach, with step-by-step examples and support. This 'cognitive apprenticeship' approach is in tune with the constructivist principles underpinning the design of metAHEAD. Table 4 shows a summary of student comments gained from the evaluation.

<table>
<thead>
<tr>
<th>Comments on what students gained from metAHEAD</th>
</tr>

</tbody>
</table>

Table 4: Summary of comments from evaluation data

Implications for instructional design

The aim of metAHEAD was to design a learning resource to offer students support in metacognition and problem solving and a learning experience that was different from traditional teaching in first year (freshman) study. The focus was on building student self-awareness of metacognition and strategy development infused into disciplinary content (chemistry, physics and biology). Our initial evaluation has shown both positive and negative aspects of the resource, and insights gained will be used to design the resources and improve its capacity to support problem solving. Our choice of evaluation approach has been effective and worthwhile, providing valuable data on context, interactions and outcomes of the resource. Continuing evaluation will assist in refining the resource, tailoring to student needs and improving its relatedness the context in which it is being used i.e. the support of metacognition at tertiary level.

Joe Luca
Edith Cowan University, School of Communications & Multimedia, Western Australia
j.luca@cowan.edu.au

Abstract
The needs of learners are changing rapidly and continually in response to an environment that is characterised by change at economic, political and technological levels. There is greater pressure on universities to work more closely with employers in contributing to the process of economic development through the creation of a skilled workforce. Universities are becoming increasingly flexible in their responses to meeting the lifelong learning agenda. Online experiential learning is an essential element in the move towards more situated and professional orientations and with the drive to providing students with real world working knowledge. Asynchronous communication tools and tasks are ideal conduits for the refinement of professional skills. This case study profiles an on-line approach to developing professional project management skills for multimedia developers and presents snapshot views of an online learning environment in which students developing real projects for industry clients.

Theoretical Framework: Experiential Learning

Through the design of an asynchronous online learning space, learners to were introduced to situations and ways of working with others that were experientially based. The processes of learning were emphasised from the outset and students were encouraged to have ownership of the learning, assessment and reflection processes. For Kolb (1984), the actual experiences people go through become the starting points for learning, and this underlying educational approach was reflected in the design of the online environment. Emotion and reflection are also an integral part of the cycle of learning, and reflective processes are intrinsic to learning from experience.

In an experiential learning cycle, the learner passes through each of four stages: concrete experience, reflective observation, abstract conceptualisation, and active experimentation. Our design ensured that we linked the experiential learning cycle to the online environment and the collaborative tools afforded by the technology as follows:

- **Active experimentation**: Students engaged in the discussion and resolution of problems through online discussion using multimedia tools to support the display of responses (e.g., Cox, 1994).
- **Task engagement**: Peers analysed the output of the task, and compared problem-solving approaches through discussion, email and conferencing activity (Bonk & Cummings, 1998).
- **Reflection**: Individuals analysed and reflected on the learning tasks, group processes and self-development as they tested new ideas and perspectives in virtual learning groups (English & Yazdani, 1999).
- **Formation of abstract concepts**: Utilising peer and tutor feedback, students developed understandings of key course concepts through engagement with new ideas supported via communications networks (Collis, 1998).

Experiential learning was reinforced in various ways through the course pedagogy, which focussed on both process and content aspects of learning. Students participated in decision-making processes by choosing and defining a topic for their project, creating and managing their own development team and negotiating peer assessment. The design was based on pedagogical and curriculum philosophies that acknowledge group work, peer feedback and support as essential to the development of independent learners and practitioners (Candy, 1994; Schrum, 2000). Reciprocity in giving and receiving peer feedback provides learners with opportunities to deepen their interpersonal skills. Through these processes they also developed reflective skills, and learnt to monitor their own learning and appreciate the contribution of others to their learning (Biggs, 1999).
Thus, by focussing on learning process and peer supported activities, the learning activities took on a broader perspective, to include the totality of the learning experience while consolidating those aspects of professional learning that would enable the learners to develop transferable skills. This process is illustrated in Figure 1, which shows a focus on using learner-centered strategies that encourage learner independence and peer support, which in turn promotes the development of professional skills and process knowledge. These then directly contribute to deep and meaningful learning experiences, and as part of the authentic learning experience, students were able to share their knowledge and experiences with their peers through the Listserv.

Figure 1: Student Learning Process

Context of the study: Course description

At Edith Cowan University, final year multimedia students are required to complete IMM3330/4330 “Industry Project Development”. The aim of the unit is to consolidate core multimedia skills learnt in other units, while at the same making industry contacts and developing a portfolio item to assist with job applications. Students are provided with industry projects made available through the Faculty, or they can negotiate a project of their own, as long as it fulfils the course requirements, team-based, commercial in nature and not trivial. As part of the unit requirements, students are required to perform a needs analysis, provide a design specification, develop the web site, evaluate it, implement it and produce the required documentation (legal, procedures, metrics, templates and standards). The course objectives were closely linked to the professional competencies required for multimedia development in the industry and integrated authentic assessment tasks where learners could develop multimedia products in a team environment, thus replicating the skills required of them in the workplace.

The unit runs over a fifteen-week semester, with three hours allocated per week for tutorials and lectures. There are no formal face-to-face classes, the unit is largely run online from a Listserv, which provides a rich arena for advice, comments and feedback as there is about one hundred participants subscribed on the List, including industry representatives and ex-students. The constructivist approach used in structuring the project work and the Listserv activities was that students should benefit from the experiences of other students, industry representatives and academic tutors in an environment that promotes the exchange of ideas.
A salient feature of the assessment tasks was the focus on learning processes, rather than mastery of content as this matched the orientation of the course towards skills development. The assessment tasks and associated learning processes are presented in Table 1.

To initially motivate students in using the Listserv, assessment was included which acknowledged individual contributions (for “quality” feedback and advice) as well as submitting team progress reports, which included students posting design ideas and prototypes and requesting feedback from others. Students were given templates to use in preparing these reports as well as rules or “netiquette” they were required to use when posting information to the Listserv. Encouraging students to initially use the Listserv by allocating marks was necessary, as proven by previous experience. However, in all cases, as the semester progressed, students became more comfortable with using the Listserv, and were posting on a variety of topics.

The tutors’ involvement on the Listserv was structured to be non-interventionist so that they acted more as facilitators by focusing discussion, rather than as the “founts of all wisdom”. Figure 1 outlines the model used for promoting discussion on the Listserv. Issues were generated from team progress reports or from individual queries about technical, content, procedural, client, communication, team/peer through to how to get employment in the industry! However, as time progressed, students more freely contributed to the Listserv with many other issues, some of which were more philosophical in nature and posted without the objective of obtaining marks.

An example of how the Listserv was used to promote real world learning is as follows. The unit had 72 students, and the number of posts made to the Listserv over the semester was 1035 in total. In the example given below, a student is seeking help on a difficult issue i.e. how do you develop web sites.
which are compatible across all browsers? This problem has no real solution and is also a problem for professional developers in the industry. So this is a rich, authentic topic for discussion, in which students can assist their peers by giving their opinions or help on the issue. Another 12 replies follow in this thread, where the students kept debating the issue:

- Initial Post "BROWSERS GRRRR " - Hi all Scamers, I have come to a stage in the project where I just wish that there were a universal Web browser that combines Internet Explorer and Netscape!! It is Frustrating to design and program a website that will look exactly the same on both browsers, well it doesn't!! Not even with CSS style sheets that is the biggest nightmare I have been going through... Furthermore how the browsers for the different platforms ex Mac and Pc reads the content but does not display it the same... I believe that it is a common problem that web developers have to deal with and I wonder if one have to be a fascist and say...Ok The site is gonna look best on IE assuming that 70 % of the market is using it! And forget about the rest!!! It is a nightmare and I just cant get my head around it , Just want to continue the development of the clients site. Oh and our client is aware of the problem and has given us an Ok to ignore the small errors between the browser but still this is something that we have to deal with in future projects/ I will be glad if somebody has a good solution for my problem..

- Reply 1 - It is just a problem that exists, and seemingly always will, the CSS sheets will look different because Microsoft have one set of codes, and there is another for Netscape preferences. If you think the differences between Mac & PC are bad, I wouldn't recommend looking at what Unix would do to your code, furthermore the world does not end at MAC & PC if you get lucky and enough money see what a Sun system does they're maybe around $20k - apparently lots of fun with graphics and 3d. The only thing I could perhaps suggest is survey a portion of the target market early in the project to see what the majority of users have as browsers.

- Reply 2- Don't forget Amigas. I actually know one guy who has browsed the net with a Commodore 64 :) And soon Dreamcasts and Playstation 2. X-Box? But you have to draw the line somewhere, don't you?

- Reply 3- I don't know that you can, when it comes to your customers. It seems fairly certain that web developers, and web development technologies themselves, will have to grow to accommodate the fact that the web is now being viewed on everything from 35" monitors to mobile phones.

- Reply 4- As designers we need to design *for* the medium, not expect the medium to conform to our design. The nature of the web is just so variable that its stupid/lazy io just design for one browser or platform. As mentioned by Oliver, its just going to get worse when people start wanting to get web content on phones and PDA's. Remember that content is what people Care. It is mostly textual and text will go anywhere. Its not impossible to design an engaging site that will view correctly in all browsers from v3 upwards on all platforms (including *nix / webtv / dreamcast / palm) its just requires a bit of creativity. Something every designer should have an abundance of. I really want to see that c64 browser.

- Reply 5- I don't think there is a solution - other than creating very standard html sites that can be viewed from lynx to ie 5.5. But that's a bit boring... Create for the majority, that's my solution. I'm concerned with the ie4.75 on Mac that does not seem to support dhtml. Other than that I've been able to create a site that works the same on ie and NN 4.x and above. That's good enough for the client so I'm happy.

This example shows how students supported each other through the virtual community and in doing so helped to develop their skills in communication, problem solving, and giving/accepting positive criticism from others. This community provided a "conduit" for the students in which they could share their experiences and knowledge, and provided a platform to constructively help each other.

**Evaluation**

As part of the project requirements, students were responsible for making contact with the client and discussing the scope and legal aspects of the development (educational software, IP, etc). These had to be negotiated so that the client had their needs satisfied, while at the same time the students were involved in producing a web-site that conformed to the requirements of an academic unit. This often
involved firstly understanding the client's needs and "educating" the client about web production, maintenance and costs.

From the evaluation questionnaire conducted at the end of the unit it appeared that the students were very positive about the structure of the unit and the use of the Listserv. Almost all the students wanted to remain subscribed on the List as a form of graduate Listserv (as well as offering advice to other students who will be enrolled in the future). Grounding the industry project in a commercial environment with the use of a Listserv for inter-team and inter-student communication was clearly successful, and added value to the students' experience in this unit. Contributing factors that led to its success include:

- The Listserv was treated as a mainstream activity which replaced face-to-face classes, and was integrated into the assessment system
- The industry partnership involved students dealing with authentic commercial, client and technical problems in the workplace and using the Listserv to ask for advice and share experiences

The tutors acted as facilitators and not experts by not fostering discussion rather than questions; dealing with inappropriate responses offline; and identifying underlying issues and redirecting these as questions back to the Listserv for students to reflect on and discuss where appropriate.

Critical success factors

In this online unit, project based learning combined with asynchronous learning tools enabled students to develop a relationship with a client, create solutions to a design problem and develop a project brief. In the approach adopted here, the practice has added to it the learning aims, specific learning processes, assessment processes and the learning outcomes. Each of these involved partnerships with industry clients with learners taking advantage of the real world context to gain professional knowledge.

The success of the unit can be attributed to the following factors:

- A virtual community was formed through the use of a Listserv, which encouraged collective and collaborative learning rather than individualistic. The online social environments provided scope for group interaction, sharing and discussion and in depth exploration of issues.
- The content of the course was opened ended, and students had access to a website where they could add resources or choose the most relevant ones (see Figure 3). Access to relevant knowledge resources was one of the "just in time" approach to planning, i.e. the choice of selecting resources is left to students who have to identify a learning need;
- The development of networked collaborative learning requires a focus on the processes of collaboration, and the well-being and development of the collaborative group (McGrath, 1990). In summary, this involves:
  - openness in the educational process
  - self-determination in learning
  - a real purpose in the cooperative learning process
  - a supportive learning environment
  - collaborative assessment of learning
  - assessment and evaluation of the ongoing learning process.

The notion of professional development and growth was recognised by learners to be more important than learning facts, figures and project management procedures. Students had to work closely with an industry client, develop a project brief and then communicate and negotiate the final product to a group of peers. Peer learning enabled students to reflect on the experience and learn from it.
Conclusion

The study illustrates an effective learning design involving experiential real world learning, which was integrated into the final year of tertiary multimedia course. The unit aimed to consolidate core multimedia skills learnt in other units, while at the same time having students making industry contacts and developing portfolios item to assist with their job applications.

Through authentic settings, students were engaged with industry projects, clients and assessment tasks. This was complemented with a virtual environment and asynchronous conferencing in which students exchanged ideas and helped each other cope with these authentic tasks. This, in combination with client negotiations, promoted the development of professional skills and process knowledge, which supported both process and product skills.

Mara Koplin
University of Wollongong, Australia

Abstract: In the past decade, the use of technology for foreign language instruction has expanded rapidly and with it has come the expectation that online methods of teaching will supersede other more traditional methods of language learning. This article reports on a longitudinal study of Australian students studying French in three different modes. The results indicate that performance and achievement in 'open learning mode where students self-direct their own learning, has the most successful approach, and that multimedia enhanced teaching of foreign languages is highly successful.

Literature review

A number of benefits for students related to the general use of technology for foreign language learning. These include improved motivation, self-concept and mastery of basic skills, increased student centered learning and engagement in the learning process (Stepp-Greany, 2002). Use of multimedia technologies for low achieving students have been shown to have facilitate learning when used to illustrate concepts and factual information (Nowaczyk, 1998). For networked classrooms, Beauvois (1998) found that more student-student interaction promoted communicative awareness, as self-disclosure through conversation was common. While technology enhanced learning has been applauded in the research literature as enhancing and supporting language learning, it is the theory of constructivism that underpins instructional design of technology that drives new approaches to language learning (McLoughlin & Oliver, 1998). The present study provides evidence that technology enhanced learning promotes successful outcomes when compared with more traditional methods of language teaching.

A longitudinal study of different language teaching modes

Longitudinal research, which has monitored three discrete types of students learning French ab initio, has been carried out at the University of New England, Australia, since 1992. The three modes investigated were for a (i) on-campus (on campus) students, who received face-to-face teaching (ii) off-campus (distance education) students, studied at a distance except for a four-day intensive on-campus workshop each year; and (iii) Open Learning students, who learnt entirely by correspondence and had no face-to-face contact with academic staff. See table 1.

</tbody>
</table>

Table 1: Student groups and modes of study
The study provides evidence that technology enhanced learning promotes successful outcomes when compared with more traditional methods of language teaching (Hutchinson & Koplin, 1998).

**Confirmatory evidence of the success of the open learning mode**

In 1993, the results showed that Open Learning students performed significantly better than the students in the other two groups but, again, a controlled statistical study was not possible, as there were still data limitations (See Table 2). The question was raised, of course, as to whether this was merely a chance occurrence and, if it were not, then why the Open Learning students outperformed the others so convincingly when they appeared to be the most pedagogically disadvantaged?

<table>

Table 3: Relative performance of modes of study

Further investigation involving a comparison of the performance over three years of all French in Action (multimedia) students (from 1996-2001) with that of all students studying a more traditional method, showed that students learning with the multimedia course had outperformed those learning in a more traditional manner (Hutchinson & Koplin, 1997). The results of the study support the findings of Dywer (1996) and Weiss, 1994). In summary, the results indicated that students studying without any direct teacher contact outperformed students in the other two groups because of the use of a multimedia learning package which allowed self-paced, self directed learning to occur.

**Conclusions**

The purpose of the longitudinal study was to investigate the comparative academic achievement of these modes of language learning, and to apply lessons learnt to the creation of improved models of language teaching. The solid performance of students using a self-directed multimedia package, when compared with other students of French following a more traditional course, even with online enhancement, shows the pedagogical benefits of the multimedia learning environment.

Multiple perspectives on the evaluation of online discussion

Catherine McLoughlin
Australian Catholic University, Australia
c.mcloughlin@signadou.acu.edu.au

Mary Panko
UNITEC, New Zealand
mapanko@unitec.ac.nz

Abstract: This paper attempts to examine different methods of content analysis for student inline discussion that takes place on bulletin boards. The purpose of that analysis is to determine whether higher order thinking can be distinguished within transcripts of dialogue. The context of the analysis was a higher education undergraduate course. A group of students were presented with a discussion topic and were given a series of criteria against which their work would be assessed. At the end of the discussion their dialogue was analysed using three different techniques which were then compared to identify whether any one method could be recommended to other practitioners. Suggestions for evaluation of bulletin board transcripts are made on the basis of this investigation.

The development of discussion boards as learning tools

Discussion boards or bulletin boards are part of a general category of CMC. Discussion boards allow students to interact with one another and with a facilitator and can be used for a variety of teaching techniques designed to stimulate cognitive and metacognitive skills.

An extensive literature base (Harasim, 1990; Mason, 1994) has developed which supports the educational value of CMC as a teaching and learning strategy. However, most investigations into the benefits of this form of interaction have tended to be quantitative in nature (McKenzie & Murphy, 2000; Nastasi & Clements, 1992) concentrating on either the number of exchanges that take place, or on diagrammatic representations of the pattern of interaction between participants. During the last decade however, methods of analysis have been applied to this communication technique to identify more precisely the varied educational dimensions that may be found within the online text (Henri, 1992; Gunawardena et al, 1997). Different forms of ‘content analysis’ have been developed and refined to aid the categorisation of dialogue produced in any debate or online seminar. MacKinnon and Aylward, (2000) for example, have used a system of coding online dialogue using ‘cognotes’, where the e-moderator attaches icons to ongoing text in order to indicate the nature of the interactions which are occurring. This is intended to encourage higher student achievement and more positive relationships between the participants.

Aim of study

Currently, content analysis has been seen as a time-consuming activity which, while it can produce valuable insights for educational researchers, does not lend itself to practical application by teachers who might want to evaluate the online discussion element of their programmes. This pilot study seeks to compare the relative strengths and limitations of established content analysis techniques and then propose a simpler method that is useful and practical. This would then allow course providers to decide whether their course participants are displaying cognitive and metacognitive aspects of learning at the level they expect.

Depth of learning

McLoughlin and Oliver (1998) have indicated that Higher Order Thinking (HOT) is not easy to define but can be recognised when encountered. These authors have summarised recent debate on the definition of
HOT as referring to thinking which is complex, multi-faceted, self-directed and one in which the learner plays an active role (1998, p. 242). This is in line with Sternberg's (1985) theory of intelligence that considers the basis for higher order cognitive processing to be executive processes used in planning, monitoring and decision making. For the purpose of this paper cognitive skills are generally regarded as applying to student understanding, reasoning, and the development of critical thinking and problem solving skills, while metacognition relates to knowledge of one's own cognition and the further regulation of that cognition (Hara, Bonk and Angeli, 2000). Henri and Parer (1992), in addition to their model of content analysis, also identified the level of information processing as 'surface' or 'in-depth'. They recognised surface processing to include: making judgements without justification; stating that one shares opinions already stated; repetition; and irrelevant questions. In-depth processing, Henri stated, was demonstrated when participants linked facts and ideas; offered new elements of information; discussed advantages and disadvantages; and made justified judgements.

The study

A group of 10 adult learners on a higher education programme took part in an online discussion which was an obligatory part of their course assessment. None of these participants had previously experienced online discussion. The asynchronous computer conferencing software used was the discussion board contained within BlackBoard CourseInfo, a web course management system. The discussion was entitled: "Integrating technology into education - a constructivist approach". The students were required to take part on at least four occasions in a discussion on the topic within a four-week time frame. The criteria upon which their contributions were assessed in the course were obtained from Campbell's experiences (1999) and were: regularity of contribution, links to the comments of others, sharing of ideas and experiences, and reference to readings or Websites.

Evaluation by content analysis

Content analysis involves comparing, contrasting and categorising elements of written dialogue for meaning, as opposed to discourse analysis which examines the process of communication including specific speech acts. A range of examples of models have been selected for this study including those developed by Henri (1992) and Gunawardena, Lowe and Anderson (1997) and an earlier method of determining the complexity of student responses, the Biggs' SOLO taxonomy (1982). Modifications to these schemes are also incorporated in the analysis, 'since every computer conference will have its own unique attributes, researchers may have to design electronic discussion group evaluation criteria on a case by case basis,' (Hara, Bonk and Angeli, 2000, p.143). In particular the models were chosen to enable higher orders of thinking to be identified in the dialogue, as this is frequently identified as a required outcome in tertiary level education programmes.

<table>

</tbody>
</table>

Model 1: Gunawardena, Lowe and Anderson's (1997) criteria for content analysis

This model was originally designed to examine the construction of knowledge within online debates in a similar manner to the design of Nastasi and Clements (1992) who considered that the resolution of cognitive conflict could be used as a measure of cognitive learning. See table 1.
Model 2: Henri and Parer's qualitative criteria for content analysis (1992)

This model identifies five dimensions within the framework of the content analysis: participative, (examined by quantitative analysis), social, interactive, cognitive and, metacognitive. Each of these have operational definitions and related indicators, however only the latter two have been examined in this study as the focus of the study was to analyse participants’ learning outcomes rather than the collaborative process of achieving that result. Nevertheless, it is recognised that in a constructivist learning environment, where collaborative learning is occurring in a social setting, interactions between the participants must play a significant role in the achievement of understanding.

<table>

</tr>
<tr>
<td>2. Metacognitive skills</td>
<td>Planning, regulation, evaluation and self-awareness</td>
</tr>
</tbody>
</table>

Table 2: The Henri and Parer content analysis model

Hara, Bonk and Angeli (2000) have added the categories 'reflection' and 'self-questioning' to Henri’s list of metacognitive skills and these have been applied in this study. Even with these modifications, metacognition is not often clear, possibly because it occurs infrequently in the discussion being studied.

Model 3 – Biggs’s SOLO taxonomy (Biggs and Collis, 1982)

This form of textural analysis, designed primarily for the print-based word, was an earlier attempt to examine the complexity of students’ responses. Although it was not designed to function as a model of content analysis, it was trialed in this study to see if Biggs’s categories of HOT would provide a useful alternative technique. The outcomes have the advantage of being generic, and provide a fairly clear cut-off between students’ surface and deep learning approaches, at a point separating level three from level four.

<table>
<thead>

</tr>
</tbody>
</table>

Table 3: Levels of Biggs’s SOLO taxonomy

Method applied in this study

The fifty messages contributed by students, primarily in chronological order, were first listed by dialogue number. Remarks made by the e-moderator were deleted from this list. Initial entries placed on the board during the first face-to-face session were also removed as these did not pertain to the assignment but were designed to familiarise students with the process of contributing.

Following this preparatory stage the three main techniques described above were applied to the whole sequence at an entire dialogue message level. In addition, surface processing compared to in-depth processing following the Henri model was also evaluated. Within each message the category was selected on the basis of the highest order of thinking demonstrated within the dialogue. In other words, messages were not sub-divided into smaller units of meaning. There were three reasons for this; firstly, subdivision
would have simply produced additional data indicating an increased amount of lower value learning levels without affecting the extent to which higher order thinking might be discerned. Secondly, this whole message analysis overcame the problem of deciding where to slice the dialogue to achieve appropriate subsections. Thirdly, it saved a large amount of analytical time. It did however obscure the precise identification of student performance, as described in Gunawardena’s model where each of the five phases is categorised in more detail. To increase the rigor of this subjective process a second researcher examined every fifth entry and applied the same series of content analyses to this 20% sample.

Results

All models showed a distribution of rating scores from 1 – 5, with relatively few responses at the higher level of cognition. Table 4, indicating the relative ratings allocated by each model, shows that the Gunawardena model produced a greater proportion of low-level ratings than the other two. In the Henri model metacognitive references were also listed (M) which occurred mainly in the cognition category 5 ratings but also one occasion in the category 4. This table indicates overall comparative frequencies but does not indicate similarities or differences between the models per individual dialogue.

<table>
<thead>

<td>-</td>
</tr>
<tr>
<td>Biggs</td>
<td>.6624</td>
<td>.7025</td>
</tr>
</tbody>
</table>

Table 5: Correlation Coefficient between content analysis models

Table 5 shows that there is a strong correlation between the Henri and Gunawardena models and a lower one between the Gunawardena and the Biggs analyses. The reason for this difference is that results from the Gunawardena rating allocate 50% extra scores at the lower end of the learning level scale in comparison to Biggs (see Table 4). Nevertheless, all three models do show statistically strong degrees of correlation.

Conclusions

Two main conclusions can be drawn from this study. Firstly, practitioners wanting to apply one of these models will be able to do so quite readily if they select their categories at the level of the whole message, rather than sub-categorising the text. The consistent application of any appropriate technique will then indicate levels of HOT in their own online discussions which can then be used for modifying teaching techniques.

Secondly, the nature of the discussion and the expectations of the course providers should determine the choice of the primary model selected. If the aim is to encourage a collaborative learning environment, then the Gunawardena model provides more insight into whether or not that has been achieved. This model also incorporates metacognition into the main framework, which is essential if any evaluation of HOT is
required. The Henri model, with its metacognitive aspect applied as a separate framework dimension tends to highlight individuals' success in displaying internal cognition in a more Piagetian sense, although within some of her categories there are opportunities to acknowledge the interactive nature of the discussions. A major criticism of Henri’s model (McLoughlin and Luca, 1999, p.223) is that ‘it was designed for contexts where there was a strong teacher presence, and is not readily applicable to a learner-centred conferencing environment’. These authors consider that the Gunawardena model a more suitable tool for reflecting collaborative and social factors, on the basis that it proposes a social constructivist approach to knowledge building in an online environment.

In the Biggs model the categories are clearly hierarchical which leads to an overall value judgement about the content of each message. This rules out completely the possibility that socially interactive functions are acknowledged as part of cognitive development. Although all three are structured to indicate levels of learning and deeper understanding demonstrated by the text, it is only the Gunawardena cognition model that relates this achievement to the degree of collaboration demonstrated.

In considering what model to apply and what modifications might be required, the nature of the student body should also be taken into account. The learning style of participants is one issue that should be considered and ‘it is suggested that current research literature in the area of learning styles and strategies can provide instructional designers with insights into differences in learning and performance that can be factored into the design process’ (McLoughlin, 1999, p. 223). Research has shown (Klemm and Snell, 1996) that unless discussions are summatively assessed, dialogue will be minimal. It might be asked if instructional designers are merely providing increasingly elegant hoops for learners to jump through.

**Summary**

The significance of this paper is that it should encourage online teachers to develop more effective teaching techniques by enabling them to evaluate the effects that their own online practices play in students’ cognition and metacognition. A summary of the analysis approach for online transcripts can be summarised in these steps, and requires the selection of a content analysis approach that is congruent with the intended learning outcomes and pedagogy of the course of study.

The three stages for analysis are as follows:

1. First, analyse dialogue content at whole message level.
2. Second, allocate a rating according to highest level of thinking evidenced in message (See for example the scheme proposed by McLoughlin & Oliver, 1998).
3. Third, select or modify a content analysis technique that reflects the philosophy of the course in respect of student learning outcomes and pedagogy.

Data analysis and coding of transcripts can then be carried out to determine the forms of thinking and cognitive skills that are embedded in the dialogue.

New Directions in Science Teaching Online: Value adding with ICT

Catherine McLoughlin
School of Education, Australian Catholic University, Australia
c.mcloughlin@signadou.acu.edu.au

Rowan Hollingworth
Chemistry, University of New England, Australia
rholling@metz.une.edu.au

Abstract: Conducting scientific investigations and thinking scientifically are among the most complex intellectual activities that learners can pursue, yet the teaching of science in general has not fully adopted innovative and constructivist approaches to develop these skills. In addition, progress towards the practical, widespread implementation of technology to support constructivist teaching approaches has been limited. Where there is a smaller number of leaders who do embrace newer educational theories and attempt to incorporate research findings in their teaching, there continues to be a substantial gap between educational research and development projects and actual practice in science teaching overall. This paper discusses present barriers to adoption of ICT in science teaching, current thought on how ICT can transform science teaching and how technologies can support the development of scientific understanding.

Overview
A preliminary survey was taken of tertiary teaching staff to seek comments on their use of ICT and its impact on their teaching and their students’ learning. Data obtained from first year science teachers in the few Australian universities offering science by distance education, together with the Open University in the United Kingdom and Athabasca University, the open university in Canada, reveals widespread use of ICT but fewer instances of innovative learning designs supported by principled application of technology. This evidence suggests that there may be a dearth of innovative teaching in the sciences using ICT, and that while technology has the potential to play a role in supporting authentic scientific activity in the classroom, there are nevertheless barriers to the adoption and integration of ICT to teach science subjects at a distance. Specifically, while technology can place a greater range of tools and resources at the disposal of teachers and students, and increase the opportunity for social interchange at the heart of authentic science practice, there remain a range of problems to be addressed.

Barriers to ICT adoption in science
The focus of the remainder of this paper is on the teaching of first year university science by distance. Teaching tertiary level science subjects with practical components in the distance education (DE) mode present some particular difficulties and this may be one reason why teaching some science subjects at a distance is still relatively new in Australia. For example, simply making resources available in flexible mode or online and expecting students to learn in neither realistic nor effective. Attention to new pedagogies and curriculum structures is essential to ensuring that technology is integrated with learning. There has been some reporting of teaching science at a distance in the literature, (Rowntree, 1992), (Bennett, 1994), (Druskovich, Klease, Teague, Lyall, & Mayes, 1996), (Hollingworth, 1998), (Kennepohl & Last, 2000).

Difficulties and problems which must be addressed in the teaching of science, include:

- There is a tendency for teachers to opt for "content coverage" rather than teaching of higher order thinking skills.
- The need to foster understanding of concepts related to thinking processes in science. Hypothesis formation and generation, problem solving, critical thinking are higher order cognitive skills require advanced level teaching skills and use of ICT in innovative ways (Hollingworth & McLoughlin, 2000).
Teachers need to focus on development of metacognitive awareness of students' own learning and their skills of reflection. At first year level many science students are at Perry's basic dualism stage of development (Perry, 1970).

Some further difficulties which must be addressed in online and distance delivery of science are:

- The need to provide adequate practical experience in the distance mode. This includes the physical difficulties of providing convenient laboratory facilities and timing difficulties, if it is desired to give a parallel presentation of theory and practical.

- The need to provide students with opportunities for social discourse with peers and lecturers in which knowledge of science concepts is constructed and more generic communication skills are developed.

These problems and others restrict the usefulness of educational technology in distance learning contexts. Other issues may be lack of teacher expertise with computers, issues of access and uptake and funding pressures that restrict innovative applications.

**Current & future practice in science teaching at a distance**

The average ratings on statements in the survey about the impact of ICT on lecturers' approach to teaching and their students' approach to learning are given in Table 1. Ratings were based on a 5 point Likert scale ranging from 1 = Strongly disagree to 5 = Strongly agree. Not all respondents were involved in both on campus and off-campus teaching, so some statements were not applicable to them.

<table>

</tbody>
</table>

**Table 1: Rating of impact of ICT on science teaching and learning**

The most significant points to note from Table 1 are that strongest agreements are on the impact of ICT on campus teaching and on the convergence of the on campus and off-campus modes of teaching. The lack of impact of ICT on distance teaching may be due to the fact that off-campus students do not have as ready access to computer facilities as on campus students, and that print materials tend to dominate. One respondent commented: "We have continuous competition between exploring new technologies to improve delivery versus staying with low technology to make the course materials universally accessible." Convergence of on campus and off-campus teaching may be because of the contraction of staff numbers in science departments around Australia, there has been pressure to rationalise the teaching of on campus and off-campus students as much as possible. In addition, the availability of the Internet means that more and more of the learning resources being developed are as readily accessible to off-campus students as on campus, increasing convergence between the two modes of delivery.

Current practices in science teaching in distance learning contexts and the implementation of ICT may be evaluated with respect to a number of relevant criteria. Essentially, constructivist learning with technology should enable students to develop skill in designing and constructing new knowledge (Jonassen & Peck,
Best educational practice would explicitly aim to enhance these skills. We discuss current practice and use of ICT under three main headings in the following.

**Communicating and constructing new knowledge**

Survey quotes: "Communications with off campus students is the major change." "Off campus students are sometimes reluctant to use discussion groups, but it is improving."

The survey showed asynchronous communication tools such as e-mail, bulletin boards, telephone conferencing and voicemail are in common use. The number of DE students having access to Internet facilities has increased markedly in the last five years from about 20% to 80%. Some lecturers have noted a reluctance on the part of students to participate in on-line forums, etc. experience in other areas shows this could be overcome in part by making participation assessable, (Fox, Herrmann, & Taylor, 1999) but there are still equity issues to be faced before making use of these avenues for communication mandatory.

In the authors' experience reluctance to participate in discussion may be greater with first year science students, because they may have had limited previous experience in this. More mature students in DE units are often willing to participate. Few guidelines exist on how skills in communicating in the sciences are best developed online, but it certain that more attention needs to be given to supporting learning online (McLoughlin, Winnips & Oliver, 2000). Online teaching can improve the level of conversation beyond that of content transmission by allowing students to enter into dialogue with their peers and lecturers. This is in contrast to the more traditional transmissive style of pedagogy often encountered by on campus students in lectures.

**Learning complex concepts**

Survey quotes: "Methods used in teaching DE, which require a more careful analysis of the way we teach, are useful when it comes to teaching on campus."

"More supplementary resources are being built up (e.g. web pages in science). When enough of our students have access to technologies to make use of these, the materials will be become required."

The understanding of science requires an ability to operate and move between three levels, the microscopic, the macroscopic and the symbolic (Johnstone, 1991). Chemists have long been at the forefront of developments in computer visualisation, because of their need to visualise molecules and chemical processes, which cannot be seen directly. There are many examples of multimedia materials now being produced to address these problems (Tasker, 1998), (Russell et al., 1997). Example applications readily accessible on the Internet include Chime molecular visualisation plug-in program (MDL, 2001) and a range of science Java applets modelling chemical processes (Gargus, 1999). CD ROMs and CAL packages are also now available from many of the large publishing houses to assist students’ understanding of chemical concepts (Kotz & Vining, 1999).

Numerous attributes of multimedia learning materials involving computer simulations, which are beneficial to learning, have been identified from recent literature (Gaddis & Anderson, 2000). They provide feedback to enhance conceptual understanding; provide dynamic animations to emphasize the molecular level of chemical reactions; permit students to generate and test hypotheses; engage students with high level of interactivity; present a simplified version of reality by distilling abstract concepts into their most important elements, making abstract concepts more concrete; standardize instructional pedagogy, teaching, and content across multiple topic areas. Reports in the literature tend to highlight the technology, but the pedagogical benefits of computer simulations are the ingredients that make them such a valuable learning tool. "It is the pedagogy, not the technology that counts" (Cottman, 1997). Participation in collaborative assignments can increase student motivation, which then leads to increases in both active participation and the quality of learning. According to Hilz et al (Hiltz, Coppola, Rotter, & Turoff, 2000)" when students are actively involved in collaborative (group) learning on-line, the outcomes can be as good or better than those of traditional classes, but when individuals are simply receiving posted material and sending back individual work, the results are poorer than in the traditional classrooms."
Experiential learning

Survey quotes: "We use computer lab simulations (digitized stop-action video) to prepare students for in-lab work. .... the simulation students did slightly better on the in-lab quiz which tests for practical in-lab knowledge."

Providing a convenient laboratory experience of sufficient quality is one of the major difficulties to be faced in teaching practical science subjects by distance education. This is a major reason for the reluctance of science educators to provide DE courses of study. In science some use has been made of microscale or full-scale kits, which allow experiments to be done in the home (Kennepolh, 1996) (Bennett, 1994) (Druskovich et al., 1996). Efforts have been made to produce low cost, low maintenance equipment (Hodges, Pillekers, & Hodges, 1991). In practice, students usually either attend short residential schools for concentrated practical experience or attend designated labs over the semester.

ICT can play a role in laboratory work through programs to collect and analyse data and increasingly through computer control of instruments, but at first year level, this is not yet very important. More significantly, with respect to teaching and learning, a range of simulations of simple experiments and instrument simulator software are now available on CD ROM and on-line and may provide a pedagogically sound DE laboratory component (Cartwright, 2000). The benefits of computer simulations are numerous: they can replace experiments that use hazardous materials; reduce cost; replace experiments that occur too quickly or too slowly to be done in a regular laboratory period; reduce cognitive noise, so that students can concentrate on the concepts involved in the experiments; allow rapid data collection; serve as pre-laboratory preparation to aid understanding of the lab. "In fact, computer simulations may provide a more cognitively meaningful laboratory experience than an on-campus laboratory class" (Gaddis, 2000).

Remote controlled labs are starting to become available on-line, for example CNC machines in engineering (Wong, Ferguson, Florance, Bantwal, & Jones, 1999) and the Scanning Probe Microscope. (IN-VSEE, 2000) The availability, variety and sophistication of such labs is expected to increase rapidly in the next few years and will bring the lab experience of DE students much closer to that of on-campus students. Such on-line labs will in the future provide the opportunity to perform experiments which have never before been possible for first year students at all. The distinct benefits of computer mediated collaborative learning tasks have been well documented (Saltiel, 1998). As an example in science, a virtual organic science lab, where on campus students worked collaboratively, produced significantly increased understanding in students. (Gaddis & Anderson, 2000)

Self-monitoring and metacognitive skills

In science subjects there is a great emphasis on content to the point that often this leads to surface approaches to learning as a coping skill by students. Science teachers may feel little inclination to include more generic skills as a part of their teaching. Studies show that interventions which improve strategy use, develop metacognitive awareness and skills and increase student skills of reflection can be very beneficial to students (Pressley & Wharton-McDonald, 1997). It is time to give more consideration to these factors as on-line learning resources are developed. As an example of an innovative ICT project, an on-line tutorial, metaAHEAD, develop metacognitive awareness and to strengthen the metacognitive skills of first year science students. It provides students with ample opportunity for personal reflection and for reflective social discourse on their metacognitive and problem solving skills (Hollingworth & McLoughlin, 2001).

Summary

Table 2 summarises the current use and possible future directions for ICT in science education. It is evident that multimedia resources offer opportunities far superior to print materials for visualisation of chemical concepts. They can provide opportunities to explore chemical concepts and processes in more depth, to repeat simulations, to change variables in different scenarios, all leading to deeper understanding. Such materials have usually been professionally designed, often at very high cost by teams of professionals with a breadth of skills.

As many have pointed out implementation of ICT in teaching and learning does not usually involve cost savings. In these times of financial stringencies it must also be noted that, to assure quality online courses, selection, support and development of faculty teaching skills are critical (Sener & Stover, 2000).

Self-moderation: Is it a useful strategy to encourage online collaboration?

Catherine McLoughlin
School of Education, Australian Catholic University, Australia

Mitchell Parkes
University of New England, Australia
Mparkes2@metz.une.edu.au

Abstract: A great deal of research has been conducted on the roles of online moderators and on support structures needed for successful online collaboration and productive learning. While some research indicates the need for highly structured environments with facilitation and tutor support, this case study suggests that by utilising well designed inquiry oriented tasks, students learn to self-direct their own activities. In the study presented here, the assessment of the task increased student motivation and task based interactions indicated that supportive feedback and social exchange was a characteristic feature of successful task engagement.

Introduction

On-line forums provide opportunity and potential for collaborative work, dialogue and study that can increase the flexibility of learning while motivating participants. By enabling teacher-learner and learner-learner dialogue computer-based course systems can support the essential elements of a learning conversation by providing scope for discussion, interaction, dialogue and reflection (Laurillard, 1995). Clearly, the opportunities for learner-centered activity, flexible access and asynchronous discussion creates new opportunities for adult learners and scope for self-direction and inquiry based learning.

Instructional designers and teachers alike must confront an envision the need for learner-centered pedagogies and provide opportunities for learners to have control over their own learning (Doherty, 1998). According to Hannafin & Land (1997) open-ended learning environments provide opportunities for self-regulated learning, collaboration learner driven inquiry and exploration. Instead of providing direct instruction, the teacher will foster expectations for increased learner control and knowledge generation. This study takes as its starting point the need for self-directed learning and provides an example of how a task focused environment online provides opportunities for learner self-direction.

Study Context

Computers in Teaching and Learning is a one semester unit that forms part of the Bachelor of Education and Master of Education programmes at the University of New England. It is offered online via the Distance Education mode using WebCT software. In this unit, students explore the use and integration into classrooms of a variety of software tools such as word processors, spreadsheets, databases, drawing and paint programs, multimedia and the Internet. To help achieve the objectives of the unit a number of compulsory learning activities and associated assessment items were designed around the online tools provided by the WebCT environment. These online activities contributed 80% of the final grade for the unit. The remaining 20% was allocated to a paper based assessment task.
Table 1 provides a description of the online assessment tasks and their associated WebCT tools.

Table 1: Summary of Online Assessment Tasks

Assessment tasks were designed to provide students with a range of online experiences from interacting on bulletin boards to working collaboratively online. These tasks also modelled for students the potential of the online environment as learning and teaching tool. As a consequence, the experience of completing the assessment tasks helped achieve the unit’s objectives as much as the completed tasks.

Research Questions

The purpose of this study was to determine that to what degree students would moderate themselves if provided with a task with very little organisational structure. Berge (1995) has identified four roles of e-moderators and classified them as: Pedagogical, Social, Managerial and Technical. These roles as used as the basis of classification for the current study. In particular the following questions were to be investigated:

- If a task is structured to encourage self moderation is there evidence of any of these roles being dominant over the others?
- Would any increased responsibility required for self moderation interfere with the successful completion of the task?
- Is there any educational advantage for structuring a task to encourage self moderation?

Group WebQuest Activity

The assessment task forming the focus of this study was a group WebQuest activity. Dodge (1995) describes a WebQuest as “an inquiry-oriented activity in which some or all of the information that learners interact with comes from resources on the Internet”. The fundamental idea behind WebQuests is that they are designed to prevent students from aimlessly surfing on the Internet. A well designed WebQuest will help give students structure and guidance as they use the Internet as a tool to support their own knowledge construction. For the group WebQuest activity, students were expected to complete a WebQuest about WebQuests Figure 1. shows the introductory page for the WebQuest activity. This task involved students being placed in groups of four (except one group which was reduced to two members shortly before the task started) and each adopting one of four possible and evaluating the WebQuest using the criteria associated with each particular role.

These roles were:

- **Efficiency expert**: Does the WebQuest keep students on task?
- **The Affiliator**: Does the WebQuest encourage collaboration?
- **The Altitudinist**: Does the WebQuest encourage higher order thinking?
- **The Technophile**: Does the WebQuest make the best possible use of the available technology?

The individual component of this assessment task involved evaluations being done by the students within their selected roles. The collaborative activity involved students negotiating with each other via the bulletin board tool to answer the following questions:

1.  Which two of the example WebQuests listed were the best? Why?
2. Which two were the worst? Why?
3. What criteria were used to base the group decisions upon?

The lecturer gave no guidance or direct assistance on how to complete this activity. Students were expected to organise themselves in order to successfully complete the task. This include setting up deadlines for individual submissions, providing advice, feedback and encouragement to each other and developing selection criteria to identify the best and worst WebQuests.

Once completed, students had to submit their tasks via e-mail. This submission included each student's individual evaluations and the collective evaluations from the group. Marking was based upon a combination of the individual and collaborative activities. The educational objective of this task was to provide students with the opportunity to observe how the concept of a WebQuest worked from a participant's point of view while at the same time, gain some exposure as to what constituted an effective WebQuest. Figure 1 shows a screen dump of the activity.

Introduction
Since early in 1995, teachers everywhere have learned how to use the web well by adopting the WebQuest format to created inquiry-oriented lessons. But what exactly is a WebQuest? What does it feel like to do one? How do you know a good one when you see it? With the other members of your group you're going to grapple with these questions and more.

Task
To develop great WebQuests, you need to develop a thorough understanding of the different possibilities open to you as you create web-based lessons. One way for you to get there is to critically analyze a number of webquest examples and discuss them from multiple perspectives. That's your task in this exercise.

By the end of this lesson, you and your group will answer these questions:

1. Which two of the example WebQuests listed below are the best ones? Why?
2. Which two are the worst? Why?
3. What do best and worst mean to you?

Methodology

Description of Coding System
Berge (1995) has identified four broad roles that e-moderators play in an online environment. These are: pedagogical, social, managerial and technical. Bulletin Board posts from students in the Group WebQuest assessment task were analysed and classified according to these categories. Decisions were based on the following criteria:
Pedagogical: Posts were classified as pedagogical if the majority of the post was directly related to the assessment task.
Social: These posts involved interaction primarily at the social level for example: “How is the weather where you are?”
Managerial: Posts that contained organisational information for instance setting up posting times or deadlines.
Technical: Posts that contained advice at the hardware or software level. An example would be instructions on how to upload an attached file.

Once coded, the number of each type and the number of words per post was recorded. From this data the average words per post was calculated.

Results

Table 2 shows the number of messages classified by role and the percentage of each to the total number of messages posted (n = 306). The results indicate that the largest number of posts to the WebQuest forum were managerial in nature. Posts centred on discussion of the actual activity (Pedagogical) were the second highest, followed by social and technical respectively.

Table 3: Total Words and Average Words per Post

Discussion

Due to the activity being largely student directed, it is probably not surprising that the highest number of posts were classified as managerial in nature (n = 95, 31% of total). Students had to spend time as a group organising themselves in order to complete the collaborative activities. However in terms of actual word length, managerial orientated posts did not dominate the discussions with the average length of each post being 38 words. Students were able to set up an organisational structure that did not appear to interfere with the educational objectives of the task. In fact, as a consequence of organising themselves, students may have been more motivated towards the task they had to undertake.
Posts classified as being pedagogical in nature were the second most extensive type of post in numerical terms. However, the average length of these posts far exceeded any other category (96 words per post on average). This suggests students were deeply engaged in the process of collaborating with each other in the construction of new knowledge.

Implications of the study

Despite a large percentage of social posts (n = 86, 28% of total), these were relatively short (19 words on average) and consisted of mainly short social exchanges or pleasantries. Nipper (1989) expressed concern that the process of social interaction online may overshadow its educational focus. However, in this instance, this appears not to be the case. These social exchanges in the group WebQuest activity appeared to form a "social glue" helping support group cohesiveness. Berge (1995:22) believes these types of exchanges are necessary for the creation of an environment that will "promote high quality and individual and social interaction for the student during the construction of knowledge".

There were relatively few posts that were technical in nature (n = 36, 12% of total). The unit had been in progress for several weeks before this activity so it appears that students had been given the opportunity of becoming familiar with using the WebCT software. The exchanges were also relatively short in nature (33 words per post on average) so it is unlikely that technical aspects had any major impact upon the collaborative activities and the shared construction of knowledge amongst students.

Conclusion

According to (Ragoonaden & Bordeleau 2000:368)

the success of collaboration via the internet lies in the design of virtual courses and in the embedded pedagogical model. The collaborative process has to be an integral part of the course framework and activities based upon constructivist approach. In this manner, students are compelled to communicate and to work with distant partners in order to construct new knowledge.

Such was the case for the WebQuest activity. The deliberate lack of lecturer direction forced students into having to take on many of the multi-faceted roles of e-moderators individually. It can be argued, that as a consequence of this expanded role, students were more than simply participants but rather organisers of the activity. This led to deeper levels of engagement in the task at hand. By being given the opportunity of being able to take on the roles generally associated with e-moderators actually enhanced the students' ability to communicate and work with others on the successful completion of the group WebQuest activity.

Scaffolding the Development of Students' Cognitive Self-Regulatory Skills

Mark McMahon & Joe Luca
School of Communications and Multimedia
Edith Cowan University, AUSTRALIA
m.mcmahon@ecu.edu.au, j.luca@ecu.edu.au

Abstract: Increasingly, universities are being asked by industry, government and funding authorities to help prepare students for industry with appropriate professional and lifelong learning skills. How can tertiary educators design and implement learning activities to help promote the development of these skills? In this paper we investigate a method of scaffolding the development of these skills through a conceptual framework based on self-regulated learning. This framework is applied to a third year higher education learning environment, and supported with a variety of on-line tools to scaffold students learning. These include an on-line validated professional skills testing instrument, an on-line self and peer assessment journals which are consolidated into streamlined reports for the tutor, and on-line student contracts, designed to encourage commitment and strategy formation early in the semester. Each of these are discussed, and also pre and post testing results are shown for a validated testing instrument, given to students to identify their strengths and weaknesses.

Introduction

With the rapid growth of Interactive technologies and on-line learning, there is a consistent demand for graduating students to have lifelong learning skills that enable learners to continually upgrade their skills and knowledge through their own self-motivation and learning skills (Bennett, Dunne, & Carre, 1999; Candy, Crebert, & O’Leary, 1994; Dearing, 1997). An important aspect for achieving this goal is to help students take more responsibility for managing their own learning by helping them become more strategic learners. Biggs (1999) argues that there are certain limits to what certain students can achieve, and these are beyond the teacher’s control. However many claim that such skills can be taught, that while they may be developmentally based, the fostering of general skills still requires proactive involvement and strategy forming (Zimmerman, 1989). The challenge for educators then is to find teaching and learning methods that can support the generation of lifelong learning skills that are relevant to a wide variety of professional contexts.

This paper will discuss three specific techniques that are used both to assess and enhance students' abilities to create lifelong professional and learning strategies. These strategies are framed within a theoretical model of self-regulation that identifies the psychological states, processes and outcomes that are inherent in independent learning. The aim of this study was to implement strategies that could be used within each of these levels to support the development of these skills.

A Definition of Self Regulation

Self-regulation is somewhat easier to define than understand. It has been described as ‘the process whereby students activate and sustain cognitions, behaviours, and affects, which are systematically oriented toward attainment of their goals’ (Schunk & Zimmerman, 1994, cited by Boekarts, 1997, p. 171). This definition is reinforced by Brooks (1997), who argues that it is active and goal directed, resulting from self control of behaviour motivation and cognition. This emphasis on multiple constructs places Self-regulated Learning at the juncture of several fields of research (Boekaerts, 1997). It emphasises students' reliance on their own internal resources to govern their learning, but these resources are not easy to delineate. Self regulated behaviour is an end process, dependent upon the affects and cognitions that precede it. These are to a certain extent inaccessible, since they are internally constructed and not always explicitly articulated by individuals.

Also, the notion of self-regulation is prone to multiple interpretations based upon educational philosophy. Zimmerman (1989) identifies it in terms of Phenomenological, Social Cognitive, Volitional, Vygotskian and Cognitive Constructivist Theories. All of these approaches bring a unique framework to the concept. Behaviourist approaches emphasise self-monitoring, self-instruction and self-reinforcement, while a phenomenological approach defines it in dimensions such as self worth, planning, and goal setting. Common to most of these however, is an acknowledgment of the interaction of affective and cognitive processes at a level of abstraction. Self awareness at a cognitive and emotional level appears to be the key process in the development of self-regulatory strategies.
A model of Self Regulation

A number of models have been developed to explain the processes that underpin Self-Regulated Learning. (Boekaerts, 1997) provides a six component model based upon the notions relating to cognition, metacognition, content and motivation.

These elements are co-dependent and interact with each other in the application and development of goals, strategies and domain-specific knowledge. Garcia & Pintrich (1994) articulate self-regulation in terms of knowledge and beliefs, strategies used, and outcomes. Each of these is moderated by motivational and cognitive components such as personal beliefs and conceptual knowledge, motivational and cognitive strategies, and quantity and quality of effort. Common to both models is an integration of both affective and cognitive issues:

"Neither motivational nor cognitive models alone can fully describe the various aspects of student academic learning, yet the two types of models are complementary due to the respective strengths and weaknesses of motivational and cognitive models." (Garcia & Pintrich, 1994, p. 127)

Figure 1 represents a synthesis of the above frameworks. It accommodates the role of both affective and cognitive aspects of self regulation, but also acknowledges the effects of external environmental factors upon an individual's ability to regulate their learning. Self regulation is viewed here as the intersection of self awareness at both a rational and emotional level. Metacognition and self concept are seen as the primary enabling process in this model, with self monitoring and motivation as subordinate processes which are involved in the development of cognitive and motivational strategies.

Enhancing Cognitive Self-Regulation Through Scaffolding

There is a large body of work which examines ways in which the affective components of self-regulation can be targeted to increase students' motivation and persistence in their learning. Emotional factors are generally seen to be more accessible and amenable to change than the cognitive aspects. In fact, the two are not unrelated. Corno (1986), for example, argues for metacognition as the dominant controlling process; that "affect is the subjective perception of emotional states; thus associated attempts to control negative affect fall within the domain of metacognitive control" (p. 334). However, the focus of this paper is on the specific knowledge that students have about their abilities and the cognitive strategies they use rather than the subjective values which they attribute to themselves and their abilities.

The primary enabling state for cognitive self-regulation, Metacognition is a concept that this fraught with contention. Some have argued that it is an inherent psychological state that cannot be changed, although this view has come under increasing criticism. There is a growing consensus for example, that Metacognition is only mildly correlated with unalterable measures of ability such as IQ (Schraw, 1986). Recent theorists are starting to examine the construct of Metacognition from social and environmental perspectives. Rather than being developmentally fixed, the acquisition of Metacognition may be subject to instructional intervention (Boekaerts, 1997).

This, however, doesn't solve a major problem, which is how to design instruction that will actually enhance students' ability to regulate their learning. Does it come through modelling regulatory strategies, having students monitor their performance, or by attempting to raise general metacognitive awareness? This paper argues a process of scaffolding that may be implemented at each of the three cognitive levels of Metacognition, Self-Monitoring, and Strategy formation (Figure 1). At the broadest level, students need to be placed in the mode of reflecting on their own cognitive abilities. This may be general in nature, but can be enhanced through the use of self-monitoring. Also, cognitive strategies for regulation need to be enacted in a purposeful and structured way. This is not going to happen automatically; the role of scaffolding is to support the learner's transition from dependent learner to self-regulating learner.
Scaffolds are forms of learning support provided to bridge the gap between existing skills and potential skills. Central to the notion of scaffolding is Vygotsky’s Zone of Proximal Development (Vygotsky, 1978), which can be seen as space between the level of actual achievement and the level of achievement possible with assistance. Just as physical scaffolding provides an framework during early phases of building, instructional scaffolds act as initial support which is gradually removed as the learner becomes more independent. Scaffolding can take many forms. Winnips & McLoughlan (2001), for example, propose video commentary, providing Web links, and linking to good examples of student work among others; but such scaffolds can exist within the following broader macro strategies proposed by Hogan & Pressley (1997):

- Pre-engagement
- Establishing a shared goal
- Actively diagnosing the understandings and needs of learners
- Providing tailored assistance
- Maintaining pursuit of a goal
- Giving feedback
- Controlling frustration of risk
- Assisting internalisation, independence, and generalization to other contexts

While many of these strategies are targeting the affective rather than rational components of self-regulation (for example 'controlling frustration and risk'), they still provide a useful heuristic in developing scaffolds to support the constructs of Metacognition, Self-Monitoring, and Strategy Development shown in Figure 1.

Scaffolds for Metacognition

Metacognition is self awareness at a global level, and exists independently from a specific context. Scaffolding for Metacognition, then, must be done at a level that can exist outside a particular knowledge domain. This may exist as explicit instruction, though the internalisation of such abstract concepts may be somewhat challenging. In this case, Metacognition was stimulated through the use of the WORKING assessment instrument (Miles & Grummon, 1996). The WORKING inventory is a self-assessment package for workplace skills, designed to help students understand what skills employers require, and how they rate against these. These skills are generally quite different to the regular academic and technical competencies students are normally tested for. They include the following nine skills: taking responsibility, working in teams, persisting, a sense of quality, life-long learning, adapting to change, problem solving, information processing and systems thinking.

The inventory does not just provide a tool to diagnose the understandings and needs of learners, but also acts as a means of giving customised feedback to the learners and is a vital tool to assist with learners’ pre-engagement. In stimulating their perceptions of their own working abilities, the WORKING inventory works both to assess and assist in the development of Metacognition. The instrument was used in semester 1, 2001 with a class of ninety final year multimedia tertiary students studying project management methodology. It was given at the beginning and end of semester and showed an overall increase of 13% across the nine scales.

Table 1: Pre/Post WORKING Results

Feedback was given to each student, based on their overall scores. For example, “Level 1: Beginning ABE Literacy” is explained as: “Has few or no effective workplace habits and skills; likely to lack a well-developed sense of flexibility, persistence, and quality; poor at problem-solving and learning. May have a low sense of responsibility". Students were also given tailored feedback on each scale, which allowed them to target specific weaknesses, by trying to develop strategies to enhance these skills over the semester, supported with tutor help.

Scaffolds for Self-Monitoring

Weinstein & Mayer (1986) argue that all metacognitive activities incorporate to some extent the monitoring of comprehension, and all models of self-regulation, from behaviourist to social-cognitive involve self-monitoring as the core metacognitive process, whether described in terms such as self-monitoring, self-observation, or inner speech (Zimmerman, 1989). Self-monitoring strategies may involve tracking of attention while reading a text or listening to a
lecture, self-testing through the use of questions about text material to check for understanding, monitoring comprehension of a lecture, use of test taking strategies (e.g., timing questions) in an exam situation (Garcia, 1994). Core to all of these however is the evidence of a reflective process on the part of the learner. One method of encouraging self-monitoring is to use the strategy of journaling. Journaling has been identified as a useful tool to increase self-awareness (Brooks, 1997) and is an ideal scaffold in that it assists the internalisation of new understandings as well as the setting of goals and monitoring of their achievement.

![Student 1 Student 2 Student 3 Student 4]

**Figure 2:** On-line journal for weekly peer assessments

In this study, students completed self and peer assessment journals each week through an on-line application. They completed self-assessment journals in which personal views of their progress were recorded. Here, students considered their success in finishing assigned tasks (scale from 1 to 5), the quality achieved (scale from 1 to 5), how successful they had been in managing their time (scale from −2 to +2), and comments justifying these scores. This was available for peers to view and consider before peer assessment took place, which was based on agreed tasks for that week (Figure 2). Students confidentially rated their peers on four criteria: attendance at meetings, collaboration, success in completing required tasks and quality of delivered tasks. Tutors used this confidential information to discuss progress and make decisions about transferring marks at "tutor led peer assessment sessions". These sessions provided a forum in which students could see the results of their self and peer assessments, and how accurate they had been in relation to the teams’ interpretation and the tutor’s summary.

**Scaffolds for Strategy formation**

Cognitive strategies are, in effect, the outcome of Metacognition and the self-monitoring process. These strategies are numerous, and include approaches for rehearsal, elaboration, and organization (Weinstein & Mayer, 1986). Certainly self-regulating students use techniques such as paraphrasing, highlighting and concept mapping, and these are skills that can be taught through direct instruction. Ultimately, however, the implementation of such strategies must be enacted by the learner. Assisting learners to articulate at the outset the strategies that they will be implemented within their projects provides a strong initial scaffold, as it allows the establishment of a goal, and the plan for maintaining the pursuit of that goal. The teacher can use this plan to tailor assistance, and the plan itself acts as a milestone against which learners can continue to assess their performance.

As a pre-engagement tool and to enhance the authenticity of their projects, learners in this unit were required to enter into a student contract (Figure 4). The contract was an agreement between themselves, their team members’, and the tutor. Its purpose is to outline each student’s responsibilities such as team role, responsibilities, topics for their portfolio, amount of time committed to achieve these tasks, and contributions they would make to help the group achieve its goals. This is completed in week 3, with a meeting in which a "Team Contract" is signed, were all team members agree that the roles, tasks and times allocated for all team members’ are acceptable. This helped students commit to specific responsibilities in order to create a collaborative environment in which they would establish shared goals through an agreed plan.
Figure 4: Sample Student Contract

Conclusion

There is currently much debate focused on creating optimal conditions in learning environments for self-regulated learning, to help students develop as independent learners. This paper has provided a conceptual framework to help identify important elements needed for self-regulation, and provided scaffolds to support Metacognition, Self-Monitoring and Strategy Formation. However, providing appropriate learning environments and valid assessment instruments to help students develop these skills is not an easy task. At which level should Self-Regulated learning be targeted? Should Metacognitive strategies be targeted before Strategy Formation, or should Self-Monitoring be practised first? We suggest that all of these cognitive elements need to be considered concurrently. The design of the learning environment must integrate appropriate learning activities as outlined above, to scaffold the development of these skills.

Students must actively engage with authentic learning activities, which are student-centred but scaffolded to give guidance and support. In the above examples, the WORKING inventory helped interrogate students' professional skills, and provided customised feedback on how to improve these, as well as providing tutor and on-line support. At the same time, students were continually monitoring self and peer performance through an on-line application that provided regular and consolidated feedback on their progress and viewpoints. These activities enabled students to regularly gain feedback on how successful their strategies had been as outlined in their contracts, and through reflective practice allowed them make continual improvement.

Implementing Technology in Higher Education: The Management of Multiple Dimensions

Carmel McNaught
Centre for Learning Enhancement And Research
Chinese University of Hong Kong
carmel.mcnaught@cuhk.edu.hk

Abstract:
The paper will explore the environment of intense change that characterises most Australian universities (and indeed universities in much of the world). In this environment, universities have had to reassess their fundamental business and the way they go about it. Information Technology (IT) is viewed as an important factor in streamlining their operations and all universities are investing heavily in systems and services. If this implementation is not managed in a collegial way there is a very real danger that academic teachers will resent the changes being made and undermine the investment. Polarity theory will be described and a model will be developed which shows that the 'zone of effective change' in universities requires that several dimensions need to be managed at the same time. Examples of these dimensions are:

- top down *versus* bottom up decision making
- management *versus* scholarship
- systems *versus* services
- central *versus* devolved
- focus *versus* variety
- mass change *versus* growing individuals
- competition *versus* collaboration

It will be argued (with examples) that changing 'versus' to 'and' allows a new perspective to be added to university implementation of policies and practice.

The Changing Terrain of Higher Education

This paper is based on two sets of experiences; the first is the ongoing experience of working in academic staff development in three large Australian universities over the last ten years, and the second is directing a recent national study about the uptake of technology for teaching and learning across the Australian higher education sector.

Universities are currently in an environment of intense change. They are being required to educate more students, from an increasing variety of backgrounds, with decreasing government funding. Universities are required to compete vigorously for student enrolments and external sources of funding. In this environment, universities have had to reassess their fundamental business and the way they go about it. Information Technology (IT) is viewed as an important factor in streamlining their operations and all universities are investing heavily in systems and services. The implementation of technology covers aspects like IT infrastructure (networks, standards, hardware, etc.); online learning management systems (such as WebCT or Blackboard); academic management systems (e.g. PeopleSoft) which may be fully integrated with the learning management systems and financial systems; digital library investments; and extensive staff development.

Yetton et al. (1997) make it clear that communication and information technologies will be a major part of future university planning. Yetton’s research team examined 20 universities' management of IT. They noted that an organisation’s performance is a function of fit among five factors: strategy, roles and skills, management processes, structure and technology. They noted the need to change terms and conditions of employment in universities and the need for rationalisation. “There will be winners and losers” (p. xiii). In this paper I will discuss a few ideas about how universities might manage internal policy development and their approaches to collaborative ventures in order maximise their chances of being ‘winners’.
Innovation and Change

We should not underestimate the difficulties involved in innovation and change. Marris (1986) parallels the sense of loss during bereavement to the resistance one can feel when letting go of known ways of doing things and embarking on new strategies. For many academics the increasing emphasis on the use of computer technology for administration, research and teaching is highly threatening. We need to recognise these fears and devise plans that build staff confidence and motivation, and provide adequate support and training opportunities. Changing educational practices and styles can produce many negative reactions and this negativity needs to be acknowledged and managed effectively. Change should be introduced and implemented within a supportive environment. The culture of the organisation needs to be able to embrace change while offering staff opportunities to manage their own levels of comfort with the change.

Conventional texts on management often define organizations as groups of people united by a common goal, but our common experience (and our common sense) would tell us that organizations are only rarely so united and so rational. Ford et al. (1996) acknowledge the complexity of modern universities and provide descriptions of various perspectives of people who work in and with higher education. However, some of the passion and trauma of change seems to have been sanitised out of this book and others like it. The authors operate on an evolutionary approach—“the principle that diversity and change are forces to be managed and harnessed rather than resisted” (p. 2). The strength of individual innovation seems stifled, and yet such innovation is one catalyst for change.

It is important to consider how innovation leads change, and how inappropriate management strategies can either stifle the innovation or cause a long time delay between the innovators developing and evaluating their work, and the results moving into other areas of the organisation.

Argyris (1991) discusses how relatively simple models of problem-solving such as action learning do not go far enough because they focus on “identifying and correcting errors in the external environment” (p. 99). He suggests that the way problems are perceived and defined needs attention as well.

Senge (1990) argues that the modern organisation needs not only knowledge at all operational levels, but also the capacity to learn. His model of a ‘learning organisation’ draws on the work of Argyris and Schon (1978) on single and double loop learning; single loop learning is simple problem solving; double loop learning looks at fundamental organisational structure and embeds individuals’ discoveries, inventions and evaluations in organisational memory (Argyris & Schon, 1978, p. 19). For Senge, teams are the learning agents that can achieve double loop learning and translate individual work into new theories of action for the organisation. This, at least, is closer to what my experience of effective change has been. Senge suggests a range of strategies—personal mastery, building mental models and shared visions, and forming learning teams.

Polarity Theory

Instead of thinking of a range of problems, issues or options that needs to be considered during the implementation of an innovation, Johnson (1992) suggests that it is more realistic to consider a series of polarities. He claims that polarities are sets of opposites which can’t function well independently. Because the two sides of a polarity are interdependent, it is not possible to choose one as a solution and neglect the other. The aim of polarity management is to get the best of both opposites while avoiding the limits of each. The solution resides within the tension between polarities. For example, we can view collaboration and competition as being at two poles; they are not mutually exclusive, but rather both need to be accommodated in our strategic planning. Polarity theory does not offer defined solutions to organisational problems. It emphasises that change is a messy and dynamic situation; as the appropriate balance point for one set of polarities shifts, this will influence others.

Fig. 1 shows a series of polarities, intersecting in what I have called the ‘zone of effective change’. I will make a few comments on and/or provide illustrations for each of these polarities in turn; no priority is indicated by the order of discussion.
Figure 1: Effective change as the management of multiple dimensions or polarities

**Top down vs Bottom up**

Large scale 'social re-engineering' from the top can get a process going but it is too difficult to sustain unless genuine commitment develops locally. Over the past few years, RMIT University in Australia has made a substantial investment into the use of online learning technology, aimed at improving the quality of programs by reviewing their educational design and adding greater flexibility to modes of studying them. This initiative, called the IT Alignment Program (ITAP), has involved investment in infrastructure, enterprise computer-based systems which are IMS-compliant (http://www.imsproject.org/), Library resources, staff development, and program and course renewal (http://www.lts.rmit.edu.au/renewal/). RMIT has tried to move on several fronts at once, and many of the policies and processes that have been developed are still being refined (Kenny & McNaught, 2000). While the original vision for how technology might enhance the processes and procedures for the University came from the top (Fallshaw, 2000), the success of the implementation will be determined by the take-up in faculties and departments. Kenny (2001) explores this tension in the area of courseware development at RMIT. Based on several years experience of working with RMIT staff, he proposes a model to combine the benefits of project management for ensuring quality educational outcomes and a return on investment to the institution, with scholarship and ownership within the project teams to ensure individual commitment and satisfaction.

**Management vs Scholarship**

Bowden and Marton (1998) depict the 21st century university as the University of Learning. All aspects of university work—teaching, research and community involvement—are forms of learning for the individual, the collective scholars at a discipline level, and for the local (and increasingly global) society. All these types of learning involve growth and change, often in unpredictable directions. Yet, universities are large organizations and need to have some defined parameters. Willets (1996) has written a humorous article, entitled 'The best ways to survive reengineering. Expert tips on how to reinvent your attitude'. But there is a great deal of irony beneath his light advice. The sense of powerlessness that organizational change can often engender is very real. One strategy for universities is to keep the nature of the business which is scholarship at the forefront of management meetings. ‘Will this process enhance scholarship?’ is the question that must constantly be debated.
Systems vs Services
Quality assurance systems are a good way to illustrate this tension. Evidence must be scholarly, not just an audit trail. If information about the quality of academic work does not feed back into quality improvement, it is hard to justify the resources used to collect the information. Quality assurance systems must also provide service to the organisation. One example is the ISO9000 system (http://www.iso9000.org/). It has 125,000 registered and certified organizations who use, and pay for, its methodology. This may be fine for several types of businesses but universities need to question how applicable it is for higher education. “Despite more than a decade and three evolutions of ISO9000, the model has made little significant impact on higher education. This is not surprising because, despite tinkering with it, ISO9000 was never fundamentally designed for an educational context” (Harvey, 2001, p. 59).

Central vs Devolved
There are many tensions in the central/ devolved debate. One major issue is whether university funding for courseware design and production should be through central or faculty-based processes. Faculty staff want the skills and expertise that exists in central units, but wish to have it provided without reduction in funding to faculties. The requirement to pay for services from central units can set up resistances. Most universities use both approaches (McNaught, Phillips, Rossiter & Winn, 2000). It is finding the appropriate balance point that is the challenge. Tab. 1 summarises the arguments for and issues associated with each approach.

<table>
<thead>
<tr>
<th>Centralised funding</th>
<th>Devolved funding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Points in favour of:</td>
<td></td>
</tr>
<tr>
<td>Can reduce duplication of expensive services by funding a range of projects, the design ideas and products of which can be used in other faculties.</td>
<td>Can fund projects based on local knowledge of curricula and faculty culture.</td>
</tr>
<tr>
<td>Can foster cross-faculty collaboration and communication.</td>
<td>Can develop stable ongoing teams for future developments.</td>
</tr>
<tr>
<td>Can allow university strategic priorities to be enacted.</td>
<td>Can allow local ownership and commitment to grow.</td>
</tr>
<tr>
<td>Can foster the integration of outside funding with university priorities.</td>
<td>Can source funding from discipline and industry-related bodies.</td>
</tr>
<tr>
<td>Issues associated with:</td>
<td></td>
</tr>
<tr>
<td>If the funding committee is not broadly constituted, this can result in a restricted range of models being favoured.</td>
<td>Traditional practices in the discipline can dominate, and it may be difficult for some innovative projects to be funded.</td>
</tr>
<tr>
<td>Can be dominated by a few strong university personalities; this may disadvantage certain faculties.</td>
<td>Can be dominated by a few strong faculty personalities; this may disadvantage certain departments/ schools.</td>
</tr>
</tbody>
</table>

Table 1: Pros and cons for centralised and devolved funding (McNaught et al., 2000, p. 113)

Focus vs Variety
Coordination is the key here. If administrative or academic support units have too many functions, their energy can be dissipated. If they have too narrow a focus, then the result may well be isolated units who do not see ‘the big picture’. Clearly articulated functions and effective coordination between units is the answer.

An example of how diverse the range of services offered by university units is given in this list I made at a national meeting of 20 Directors of Staff Development of Australian universities in May 2001. Each of these items was supported by several of the universities present; minor or unusual services are not noted. This list refers to teaching and learning support. This list is in addition to the courseware production aspect of several units which are part of large flexible learning centres.

- Graduate Certificate in Higher Education programs;
- series of workshops and seminars across the university;
- academic induction programs;
- activities based at local faculty or department/ school level;
- student evaluation service;
• support for sessional staff, both onshore and offshore;
• post-graduate supervisor training;
• support for heads of departments/schools linked to development of local policy;
• support for graduate capabilities, especially for programs leaders/ coordinators; and
• liaison with learning skills and library staff in course renewal teams.

So, academic staff development units are in danger of having too much variety. While some liaison with student support and library staff was noted, the focus of discussion remained on coping with the variety of internal activities, rather than on coordination with other units within each university.

Mass Change vs Growing Individuals

One example to illustrate how individual growth can dovetail with overall strategic directions is a recent academic staff development program run at RMIT University. A Learning Technology Mentor (LTM) program at RMIT ran from mid-1999 to the early part of 2001. The LTM program provided for 120+ academic staff to have one day per week time release over one semester, in order to:

- learn how to use the University’s recently established online education system,
- design and implement online learning in their faculty’s education programs, and
- promote and support similar activities among colleagues in their departments.

The aim of making a significant investment in learning technology mentoring by academic staff—rather than establishing a specialist online design and production unit to service them, for example—was to achieve widespread adoption of online learning as part of effecting a change in the culture of academic work. Extended time release of more than one semester was required to achieve useful outcomes in some cases; these academic staff were called Experienced Learning Technology Mentors (ELTMs). Over this time, in several faculties, a network of individuals developed that remained after the formal end of the program (McNaught, 2001; Gray & McNaught, 2001).

Competition vs Collaboration

There are benefits in both perspectives. Fig. 2 summarises the drivers for both collaboration and competition. If the aim is to produce high quality educational offerings there are drivers for both collaboration and competition relating to quality standards, financial viability and raised prestige.

Figure 2: Summary of drivers for both competition and collaboration
(after McNaught et al., 2000, p. 160)

Summary

One simple summary of polarity theory and its applicability to higher education today is the reframing of the set of dimensions I chose as follows:
top down and bottom up decision making
management and scholarship
systems and services
central and devolved
focus and variety
mass change and growing individuals
competition and collaboration

Remove all oppositional 'versus' thinking and replace it with ways to consider how to gain maximum benefit by embracing both ends of poles. The zone of effective change can only be formed by the inclusion and balancing of both ends of each dimension.

Web-based Computer Simulations for In-Class, Individual, and Small Group Work
Donald E. Mencer, Department of Chemistry, Wilkes University
Wilkes-Barre, PA 18766
http://course.wilkes.edu/mencer
mencer@wilkes.edu

Abstract

Introductory college chemistry can be "taught" by a mode of instruction other than lecture and careful use of the web can alter the way chemistry is learned. The web provides a means to deliver educational resources via a universally accessible platform. The medium is relatively easy to develop materials for and provides a level of interaction that cannot be provided in a textbook. The interactive nature can be used to deliver simulations of chemical and physical processes (animations of phenomena) or interactive simulations of experiments that may (or may not) be done in the laboratory portions of a general chemistry course. This paper discusses a variety of the interactive materials that have been tested in the author's first semester general chemistry course. The simulations presently involve material from approximately three quarters of the course. The interactive web-based activities serve as the starting point for small group classroom discussion and assignments. It is important to make the use of simulations an integral part of the course, provide a motivation for individual students to perform the simulations, and to provide a setting in which the students can exchange ideas and insights. The positive aspects of the learning tools discussed in the paper will be highlighted. However, the web cannot solve all of the challenges of teaching chemistry. Therefore, brief discussion of the difficulties encountered in using web-based simulations for small-group assignments will also be discussed.

Introduction

When deciding upon making changes to any course, there are several questions that instructors typically consider. First, "What works in the present course and are there 'problems' that need to be addressed?" Second, "Who are the students in the course?" and "What is the nature of the institution?". The answer to these questions will suggest what ought to be changed and help the instructor decide what changes best fit the needs of the students and the institution. A final question that is key to the success of any changes in the course is "Who is the instructor and what role are they comfortable with in the classroom?"

The following conditions apply at the author's institution. Wilkes University is a private, co-ed, comprehensive institution founded in 1933. Wilkes serves approximately 2,000 full-time undergraduate students from 20 states and 15 foreign countries and it has a School of Pharmacy. The freshman chemistry courses serve approximately 175 students in the fall semester. The author's course is the four credit "Elements and Compounds" course (offered in the fall semester) that meets for four 50 minute periods per week plus one “three hour” lab. The students enrolled in this course are nearly all traditional age students, over 95% are first semester freshman, and are nearly all required to take the course as part of their major. Most are pursuing a bachelor degree in engineering or science (but few are chemistry majors). The largest majors represented in the class are pre-Pharmacy, Pre-med, biology, and engineering majors. The class size ranges from 45 to nearly 85 at the start of the semester (this year there were three sections offered at different times). The on-line simulations were originally developed and implemented at the author's previous institution, The Pennsylvania State University - Hazleton Campus. There were two problems the author wanted address: (a) students were not spending adequate time engaging the course material and (b) some topics covered in the lecture portion of the course either had too little, or no, coverage in lab.

Aside from the adjustments to the "normal" structure of their lives that traditional age freshman must make when they enter college, there are a number of factors that make the first year college chemistry course challenging:

- the quantity of the material covered
- the variety of material covered
the requirement to perform calculations (especially solving "word problems")
the requirement to relate the abstract to the concrete
the misconceptions, alternate conceptions,(1) from prior courses or life experience

Traditional lecture and recitation sections do not capture the interest of students and suffer from other difficulties: (a) little time for remediation of basic skills, (b) ineffective for some learning styles, (c) students cannot control time, place, or pace, and (d) interaction with the instructor is avoided (especially in medium to large classes). As a result, students do not actively engage the course material nor do they develop the depth of understanding that is desirable. For some students, learning and grades suffer because interest in the course is low. A recent study also indicates that a general chemophobia may contribute to lower achievement in chemistry.(2)

Some of these difficulties can be addressed by using modes of instruction other than traditional lecture. As many instructors know, a major key to improving student learning is getting the students to spend time engaging the course material. It is in this area that the web can be useful as a way to "teach" chemistry. The web provides a universally accessible platform for the delivery of interactive educational resources. The medium is relatively easy to develop materials for and provides a level of interaction that cannot be duplicated by a textbook. Additionally, students can control (to some extent) the place, time, and pace of interaction with the material. The interactive nature can be used to deliver simulations of chemical and physical processes (animations of phenomena) or interactive simulations of experiments that may (or may not) be done in the laboratory portions of a general chemistry course. A variety of interactive materials have been developed and tested in the first semester of the author's general chemistry course. Attempts (both successful and not so successful) to implement web-based course materials, especially small group use of simulations, will be described.

Interactive Web Based Simulations

The author has developed a series of interactive simulations for use in the first semester of a college general chemistry course. Students are exposed to assignments that require active participation and these simulation assignments serve as the starting point for small group discussions. The activities require students to "perform experiments", collect and analyze data, and arrive at conclusions about the behavior of matter. This is more consistent with the practice of science than the traditional lecture mode of teaching. This allows the students to:

- become involved in the process of learning,
- develop a sense for the process of doing science,
- and learn to think more independently relying less on a textbook for answers and more on their own ability to understand and correlate data.

The simulations (found at http://www.hn.psu.edu/faculty/dmencer/chemsims.htm, the author's old web site) address areas of content typically found in the first year college curriculum.

- density of solids and liquids- perform density determinations on liquids and solids
- mass laws - investigate mass changes in reactions to "discover" (a) mass conservation, (b) law of definite proportions, and (c) law of multiple proportions
- compound stoichiometry - determine empirical formulas using a simulation of combustion analysis
- reaction stoichiometry - investigates mass changes in reactions to "discover" (a) limiting reactant and (b) theoretical yield
- ideal gases - investigate relationships between pressure, volume, temperature, and number of moles of an ideal gas
- investigations of bonding - the effect of electronegativity difference on bond strength
- calorimetry - simulations of both a bomb calorimeter and a coffee cup calorimeter
- heat and work - investigate relationships between heat and work in both constant pressure and constant volume systems

Other activities (without simulations) explore periodic properties, the atomic mass scale and the mole, atomic structure, and aspects of intermolecular forces.

**Small Group Work**

Small group work was employed because research has shown that cognitive learning has an important social aspect. (3) Small group use of the interactive web-based activities has been attempted using two methods in the author's course. In the first and second year of use (at PSU-Hazleton), students were clustered into groups of three to five students and assigned a simulated experiment to complete. A worksheet was available to guide them through the exercise. They had to analyze the data and determine the significance of the results. Based upon their interpretation of the data, the group then developed a lesson for the rest of the class. Prior to teaching these lessons, the groups met with the instructor as a quality control check for the lesson plan. Students received an individual and a group grade for their efforts.

The "Ideal Gases" simulation was used by four groups to investigate simple gas laws as shown in Table 1. Students worked as a group to collect and analyze the data. They were not told the name of the gas law they were to investigate prior to the meeting with the instructor. Each group collected several sets of the requested data. Each data set was collected using different values for the constant variables. For example, in the Boyle's Law case, P vs. V data would be collected with one set of n and T values, then again with a new set of n and T values, and finally a third time with one more set of n and T values. The worksheet prompted the students to determine whether the relationship between the two variables was direct or indirect (inverse) and to prepare a linear graph of the relationship. Students were also asked to write the relationship for their data as a proportionality. Students could then solve initial state/final state problems using the simple gas law they have "discovered". Students were also prompted to calculate $PV/RT$ for every data point. The four groups presented their finding in class and the instructor would use this as a starting point for discussion of the combined gas law and the ideal gas law.

This small group method was not as successful the author had hoped. Students in the small groups learned the material well: they completed the assignment, developed a lesson plan, met with the instructor, taught the material, and fielded questions. This process increased the group members' success with the material. However, students who were not assigned to teach the material did not respond well to peer teaching: they did not use the simulations, they "turned off" during in-class peer teaching, and they did not develop good questions for the presenters. This method of using the simulations with small group peer teaching was also time consuming for the instructor. Assignments were developed and coordinated for all of the groups (approximately 20) with each group requiring a minimum of a single half-hour meeting to review their lesson plan. Some groups needed a follow-up meeting. The same method was repeated for a second year with the hope that it could be made to work better. Questions based on the presentations were included on quizzes and exams to try to increase student involvement. However, student reaction to peer teaching was still poor. Other instructors might be able to employ this method of peer teaching successfully, however, the author tried an alternative method.
During the fall 1999 and 2000 (at PSU) and Fall 2001 (at Wilkes University), the author committed to getting all students involved in every activity. To achieve this goal, the class is divided into either three or four large groups. Each group is given a different investigation to perform using a simulation. In the case of the "Ideal Gases" example, four groups are employed and the assignments are the same as those listed in Table 1. Each student is required to complete his or her group's assignment working alone outside of class. Every student now has to access the web pages and use the simulation. On the assigned day, all students are required to bring the results of their investigations (compiled data/completed worksheets) to class. The students then split into small groups comprised of one member from each large group (in the "Ideal Gases" example each small group would have members from groups 1, 2, 3, and 4). The students share what they learned within their small group. Since each of the large groups have a different assignment, every student makes a unique contribution. Also, since each student completes a worksheet and graph for the assignment, they can more readily interpret data presented by others.

In order to provide external motivation to complete the assignments, the instructor can randomly collect completed data/worksheets from students. Students needn't know in advance whose assignment will be collected. Make-up assignments can be given, or not, and the assignment grades can be factored into the overall course grade. This method proved to be successful in increasing student involvement with the assignments. The logistics are somewhat simplified since the meetings with individual groups are eliminated. However, there are written assignments to grade, and some students hand in poorly completed worksheets or none at all.

Assessment of Effectiveness of Web-based Activities

Student surveys, and the author's personal assessment, have been used to assess the use of simulations and other on-line materials. Surveys assessed:

- reaction to the use of simulations (along with questions about the other on-line materials)
- interest in and/or attitude toward learning science/chemistry
- attitude toward science/chemistry as a process (vs. a set of facts and equations)
- self-assessment of their level of ability to carry out scientific data collection and analysis

The results of these surveys indicate a positive assessment of the simulations and other web-based materials (for example, on-line course notes). After completing the course with the simulations student self-evaluation also indicated improvement in the other three areas. However, data from a control group (a section of the course taught without the simulations) are not complete at the time of paper submission. The author has also examined other means of assessing the new course materials. An interesting trend was observed in student course evaluations at Penn State (Student Ratings of Teaching Effectiveness, SRTEs). The students' overall evaluation of both the course and the instructor declined for the first two years that on-line course materials and simulations were employed (fall semesters 1997 and 1998). Several colleagues (in a number of different disciplines) at the same PSU campus have also noticed a decrease in course evaluation upon adoption of "nontraditional components" to their courses. The two most recent semesters for which data is available (fall 1999 and 2000) showed a reversal of this trend with evaluations climbing back to the level from the fall of 1996. Course retention rates have been evaluated from late drop data and have been compared to data from previous years of the author's course (1996 to present). Retention rates in the author's course have been declining steadily when referenced to his first year at PSU, 1996 (the only year with no on-line component). Class grade point average has also declined during the same period. Exams comparable to previous years were given and student averages on each quiz and exam have been compared to the same quiz or exam in the previous years. However, these comparisons do not account for differences from one semester to another in other variables linked to student success rates (average preparation level, motivation level, and other class demographics). The reasons for these trends may be related to the teaching methods used in this course, or they may reflect
trends at the national or institutional level. In order to place the trends observed in the author's course into context, more data is needed (for example, average math and chemistry placement scores could be compared).

Improved performance of the "learning" taking place in the course is much trickier to assess. The author has anecdotal experiences that indicate use of the simulations and small groups can help students overcome misconceptions, better understand concepts and phenomena, and better learn "problem solving" skills (vs. using rote algorithmic methods to solve problems). For example, many students have deeply rooted misconceptions about density, displacement, and buoyancy. The density determination simulations serve as a good starting point to discuss phenomena related to density (for example Archimedes Principle). The simulation of solid density simulation relies on displacement for the volume determination. During the in-class discussions, the instructor carefully reviews the requirements for a solvent that can be used to determine the volume of a water reactive low density solid (like sodium, Na). The discussions invariably turn to other "real world examples" of displacement and buoyancy (for example the class has discussed ice cubes floating in liquid water and hot-air balloons). Students completing the simulated density experiments and the small group work appear to have a better understanding of the phenomena of displacement.

A second example involves mass conservation and the concept of limiting reactants. When performing mass conservation simulations some students are surprised to observe that excess reactant can remain after a reaction goes to 100 percent completion. Class discussion time is spent in careful examination of atomic theory to see how it can explain the Law of Conservation of Mass, the Law of Constant Composition, and the Law of Multiple Proportions. Even after this effort some students are still confused when the concept of limiting reactant is introduced in the following chapter in the context of mole calculations. The simulations are employed again, but this time students are expected to work in moles instead of in mass. Although the average quiz score on this chapter has not improved, the author has noticed a number of students employing mass conservation concepts (although sometimes incorrectly), mass ratios of elements in compounds, and other "interesting options" when solving stoichiometry problems. Although these methods are not always employed properly, it seems that some students are doing more than simple algorithmic problem solving on these questions; that is they seem to be thinking. The use of the simulations along with the small group work allows students to: (a) engage the material actively, (b) develop ideas/relationships, (c) test them, and (c) learn on their own and from other students. In-class examples and instructor led discussion are used to supplement the group work as needed.

One final difficulty with the assignments is the vast range of prior knowledge of the students in the course. The "best" students found some of the assignments trivial, while other students found some assignments (or perhaps just the instructions) confusing. It is clear from this work, and from other studies (ref. 4 and references within), that computer-based assignments can improve student performance and attitude toward chemistry. However, it is important that the level of the student and the assignment be well matched. It is also important to recognize that improved student performance on exams may not reflect increased understanding (1). Also, gains on exam scores may not be attributable to the particular type of assignment or the mode of delivery. A recent study of a web-based system of homework and testing showed a strong positive effect on exams scores. (5) One finding was that scores on practice exams increased with the number of times they were attempted. This may simply be a function of the time spent engaging the material. This needn’t negate the positive aspects of computer-based assignments; but similar gains might be achieved by other assignments that increase "time on task".

Individual and In-Class Use

The simulations can be used to provide practice problems or to provide a starting point for in-class discussion. Students can attempt the problems and then check their answers against the simulation's result. The author also uses them to develop problems during office hours. The author plans to add more "drill and practice" types of exercises to the course site. These exercises are intended for students needing
skill development or remedial work. These types of exercises should also help to address the increasing number of students who use their calculators poorly.

Conclusion

The web is an effective medium for delivering interactive course materials. Interactive tutorials and simulated experiments provide the means alter the way chemistry is taught. Although it is not the final solution to all of the challenges of teaching college chemistry, it does have some striking strengths. It is imperative to make the use of simulations an integral part of the course, to provide motivation for individual students to perform the simulations, and to provide a setting in which the students can exchange ideas and insights. If small groups are used, it is critical to take steps to minimize the difficulties created by group members that do not "do their parts". Also, students must be given time and guidance to successfully adjust to teaching and being taught by themselves and/or their peers.

Acknowledgements

Support for much of this work was provided by the Jack P. Royer Center for Learning and Academic Technologies at The Pennsylvania State University through Project Empower and Visionworks. Allan Gyorke (PSU) for writing the original Perl interactive cgi scripts. Jackie Ritzko (PSU-Hazleton) for help with the production of animated GIFs writing Perl cgi scripts and JavaScript applets. The author also expresses his gratitude to the students in his Chem 12 (Penn State) and Chm 115 (Wilkes University) classes.

In addition to the links found on various pages of my website (http://course.wilkes.edu/mencer), I also recommend the following.

1. A more detailed version of the small group methods discussed in this paper, and some additional on-line materials, can be found on-line at CONFCHEM: Conferences on Chemistry http://www.ched-ccce.org/confchem/2000/b/mencer/mencer.htm
2. More excellent papers on innovative teaching methods in chemistry can also be found at the CONFCHEM: Conferences on Chemistry archive site http://www.ched-ccce.org/confchem/past.html
3. A nice “Resource for Students and Teachers” (http://www.hwscience.com/smarsden/) is maintained Steve Marsden. Follow the link to topics and click on a topic (for example "Gases"). There are many links to tutorials, notes, and simulations (the links are footnoted with bibliographic information).
Choosing an Online Learning Platform focusing on Reusability of Learning Objects and its Implications for Comparison Schemata Design

Oliver Merkel, Cornelia Seeberg and Ralf Steinmetz

Department of Electrical Engineering and Information Technology
Darmstadt, University of Technology
Merckstr. 25 • 64283 Darmstadt • Germany

{merkel, seeberg, steinmetz}@kom.tu-darmstadt.de

Abstract: Project decisions about suitability of existing online learning platforms are often discussed by using project specific proprietary comparison schemata or via a comparison service offered in the world wide web. As educational material in form of learning objects becomes more available focusing on content reusability aspects is becoming more important for online learning platforms due to cost minimization in content production and preparation for content reuse. Exactly these reusability aspects can hardly be found in these comparison schemata. In learning platforms learning objects are stored in database management systems by using document management systems. Modularization of courses and course building elements as objects are essential for reusability. For effective administration, storage, search, and retrieval of these elements as a part of a reusability process metadata descriptions of the processed learning objects are necessary and fundamental. Our approach to enrich comparison schemata by adding reusability specific elements fills the existing gap between metadata and reusability features implemented in available online learning platforms and popular used comparative analysis tools for online learning platforms, respectively.

Keywords: Reuse, Learning Object, LOM, Metadata, Online Learning, Comparative Analysis

1 Introduction

This paper investigates which criterions for comparative analysis of online learning platforms are considered to be relevant for decisions focusing on content reusability aspects of these platforms when using currently available and often reviewed information systems like [Lan01], [Edu01]. The term online learning platform in this scope is defined by webbased applications to deliver or present educational multimedia course materials on a learner's side and to offer administration features on a tutor side through management of course relevant metadata while authoring support is offered by content management and content creation. Due to the lack of reusability specific categories in these information systems a set of already existing criterions is collected. Referring to this investigation this paper describes an approach for handling a criterion enrichment by adding reusability specific categories to comparative analysis tools.

Therefore the term reusability is described as it is understood in the context of the content of a learning platform as an object in section 2. As a result of this description a metadata schemata for learning objects named Learning Object Metadata (LOM) which is proposed by the Learning Technology Standards Committee (LTSC) of the IEEE [LWG01] is introduced which is especially useful for the attribution of learning resources [HFM+01]. After mentioning use cases working on LOM and currently not solved granularity problems in LOM, section 3 handles the reusability aspects of learning objects implemented in currently available learning platforms. Afterwards this paper is going on discussing included reusability specific criterions in the comparison schemata of [Bat99], [Edu01] and [Lan01]. The following section 4 states a proposal of a hierarchically structured set of criterions with specific categories and elements to allow comparative analysis among online learning platforms. Finally this paper ends with a conclusion and an outlook of its discussed subject in section 5.

2. Reusability

Reusability in general is a possible method for saving monetary and non monetary costs. In the context of learning platforms reuse of learning system components - the implementation itself in modularized form as it is used in
different online courses - or its content can be established. While modularized configurable implementation is a
well solved problem in recent online learning platforms like Lotus Learning Space by Mindspan Solutions\(^1\),
Netcoach by Orbis Communications\(^2\) or Hyperwave eLearning Suite by Hyperwave\(^3\) - e.g. by configuration of
hiding or including a chat or a discussion forum to specific courses for online learning platform users - reusing
content as learning objects in form of documents, images, other multimedia components or a collection of such
components is recently a matter of research [LWG01]. In the scope of this paper reusability has to be understood
as reusability of content representing documents or objects as a part of a document in form of educational
multimedia material used for testing of knowledge or transferring knowledge to a learner.

Content oriented reuse of cnnree material can he done by copying
a selectable collection
of course documents in
whole or building templates from formerly used courses - e.g. like it is done in Lotus Learning Space, WebTycho\(^4\)
or Hyperwave eLearning Suite which are based on document management systems (DMS) on top of Lotus Notes 
/Lotus Domino, or Hyperwave, respectively. At least if content oriented reuse on a more detailed layer is focused,
the typical automatically generated metadata of such DMS have to be replaced by more abstract and learning
specific metadata schemata.

2.1 Knowledge Representation through LOM

To describe a coherent context of a complete reusable unit in [LWG01] the term learning object is used. The
metadata of a learning object LOM is the information about this object. When storing learning objects in local or
distributed repository systems, this metadata can be used to provide effective retrieval, management, transfer, and
use of learning objects, e.g. from a repository system into a course context, by working on the corresponding LOM
entries instead analysing the content of a learning object. Beside that additional metadata information which is not
part of the learning object itself can be stored in LOM. Consequently, the result of the use of metadata is a reduction
of costs through reusability of the described learning objects while facilitating the maintanance of learning objects.
LOM offers data elements and a structure for these data elements to describe metadata of a learning object. It
contains nine main categories of metadata elements representing information about the related learning object as
described in [LWG01].

Since other metadata schemata like those from ARIADNE\(^5\) - a consortium of 20 European universities and 5
international corporations - provide mappings to LTSC\(^6\)'s LOM and the IMS\(^7\) (Instructional Management System)
metadata specification model which is compliant with LOM [MBG+01], the relevance of LOM is becoming
increasingly fundamental for online learning platforms.

2.2 Retrieval and Repository Administration

In online learning platforms working on top of a DMS the automatically generated metadata can be used and often
is used on its own to establish the administration of learning documents. A more detailed access to learning
resources on a sub-document layer results in the need of adding an additional metadata schemata, if comfortable
retrieval mechanisms for learning objects should be realized.

So the learning platform repositories should consist of a content repository separated from the metadata repository.
Retrieval is done through explicit usage and search on metadata which references other metadata or its represented
learning object.

2.3 Granularity

As mentioned before it is of enormous importance, if either reuse should be done on a document oriented layer or
on a sub-document layer inside the DMS environment of a learning platform, too, because in a DMS accessibility
of documents is fundamental, but accessibility of element parts of a document is usually not supported by the DMS
without programmatical effort. Furthermore it can easily be seen that metadata descriptions of more detailed
reusable content compared to a document level can also be used on higher non detailed abstraction levels.

2. URL: http://www.orbis-communications.de/index_nc.htm
3. URL: http://www.hyperwave.de/e/products/els.html
4. URL: http://tychousa.umuc.edu
5. URL: http://www.ariadne-eu.org
6. URL: http://ltsc.ieee.org
7. URL: http://www.imsproject.org
For an increased support of this functionality a granularity element is included in the LOM schemata describing the type and abstraction layer of a learning object. One not yet solved problem in LOM is that this granularity describes a two dimensional area while [LWG01] describes the granularity as a single one dimensional field with no further specification or description about the vocabulary which build the entries for this LOM element. The horizontal direction of the granularity represents the type - not format - of the learning object (e.g. explanatory text section of a learning unit or in contrast questionary text of an exam), while the vertical direction of the granularity represents the abstraction layer (e.g. icon, chart, image, explanatory text section, chapter, document, lesson, course; see [HFM+01]).

3. Current Situation

At the moment commercial and non-commercial well-known online learning platforms only attempt to support IMS or IEEE/LOM or rather announce development of this features in near future [Edu01]. So on the producer and researcher side developers of online learning platforms see the need to support detailed metadata specifications and those features are partly implemented. The currently available versions of comparison schemata in general do not contain any category named reuse or reusability and only one well referenced comparison schemata [Edu01] contains information regarding metadata in its general section.

3.1 Learning Platforms

The following learning platforms were investigated for this paper to see whether they already support any type of metadata for learning objects or whether support is planned or if it is possible to add an own support via a framework or an application programmers interface if existent.

WebTycho

At the UMUC home campus in Adelphi, Maryland, a web-based education delivery system named WebTycho has been developed. It is based on Lotus Notes / Lotus Domino and due to the replication features of this platform WebTycho is offered via several servers located in Germany, Japan, and the United States. WebTycho itself is neither freely available nor commercially offered but often counts as a reference system when comparing online learning platforms. Its current authoring support for reusability of course content offers storing of template objects ranging from whole courses to single documents. Subdocument layer elements reuse has to be done manually. Metadata support beside that of Lotus Notes / Lotus Domino is not implemented so far.

Lotus Learning Space

For practical investigation purposes version 3.5 of the Lotus Learning Space was used in this scope. In general the same reusability options like those from WebTycho are supported. Corresponding to [Edu01] Lotus Learning Space version 4.0 allows import of AICC courses while IMS support is announced. Import and export of course content and course state in XML format is already supported. Since Lotus Learning Space is a database template for Lotus Notes / Lotus Domino with partly open course design (partly changeable sources), actors with designer or manager rights in their Notes access control list can apply implementation specific changes to the learning platform via C/C++-API, Java-API, Lotus Script and Lotus Formula Language.

Netcoach

The Netcoach system is implemented in Lisp and uses the server’s local filesystem as the storage system and repository for all user and course specific data. Courses, exams and user data are stored in different but task immanent files in single Lisp structures. Although this results in a well modularized form, reusability of data is only supported per exporting of courses. Exported data is proprietary so that it can only be imported in Netcoach servers again. Netcoach uses its own metadata structure of course content. The current implementation does not offer mappings or imports and exports to other metadata formats.
Hyperwave eLearning Suite

The online learning platform Hyperwave eLearning Suite is running on top of the Hyperwave Information Server which is a document management system which stores its documents in an object relational DBMS (Hyperwave recommends Oracle). The Hyperwave Information Server and its related additional components are developed at the Technical University Graz, Austria.

The underlying document management system offers superficial support of metadata while the Hyperwave eLearning Suite itself does not support metadata description of learning resources. System immanent development of metadata support or access to course content via an application programmer's interface is supported but results in high efforts.

Direct reuse of courses or course documents above subdocument layer is possible through system functions.

Ilias

The open source Ilias online learning platform is developed at the University of Cologne, Germany. It uses a modularized architecture based on LAMP (Linux, Apache, MySQL, PHP). Ilias uses a proprietary format named VR1 (Virtual Resource Index) to refer to the modularized learning objects dynamically. It directly uses this addressing type of learning objects to support reusability.

The Ilias metadata system VR1 is based on the concepts of IMS, ARIADNE and Dublin Core. This allows direct mappings from VR1 to these target formats. It is used on the course layer, the learning unit layer, the documents layer, and subdocument layers like pages or page elements of the learning platform contents.

Since Ilias version 2.0 XML templates can be used for increased reusability of course content and course properties.

3.2 Comparison Schemata

In [Bat99] Bates suggests an online learning platform comparison schemata named ACTIONS. This name is derived from its main comparison categories: Access, Costs, Teaching, Interactivity, Organisational issues, Novelty and Speed. Without classifying a specific online learning platform it can be implied that the reusability criteria costs and speed are influenced in form of pre-programmed multimedia and the amount of needed re-programming of course materials when stored in repositories or not. The terms reuse or reusability of learning materials itself are not mentioned. Further aspects that can be treated as content reuse oriented aspects are not discussed.

The LandOnline service offered in the world wide web [Lan01] compares different commercial and non-commercial online learning platforms. It is updated and reviewed frequently and its comparison schemata consists of 3 main categories with a total of 15 subcategories containing a total of 62 criterions. At the moment 55 different platforms are reviewed. Regarding the classification of mentioned platforms in reusability contexts the criterion IMS_compliance is the only criterion giving information about learning object reuse.

While Edutech is offering a detailed comparison analysis service in general it is superficial regarding reusability. It is updated frequently and compares 108 criterions on 9 learning platforms. Only its general section handles all available authoring support with reusability oriented criterions.

The obtained list of the considered criterions with reusability aspects over all mentioned comparison schemata therefore consists of the following elements: IMS compliance, standards / metadata support (IMS, IEEE, AICC), XML support, programming interfaces, web technology compatibility (compatibility of presented learning objects with common web media types), import / convert existing material, flexible resource pool (for the course developer).

4. Adding Reusability Features in Comparison Schemata

Summarized it can easily be seen and implied that currently offered popular comparative analysis tools do not comply with online learning projects needs when decisions have to be made regarding which online learning platform should be used.

In this section of this paper a proposal is introduced to add reusability features in comparison schemata. The introduced main category of the comparison schemata enrichment is named reusability and consists of subsections named basic, learningObject, and additional.

1. URL: http://www.ilias.uni-koeln.de/ios/index-e.html
The notation follows the rule that a higher section identifier is separated from the included subsection identifier by the separation character '.' (e.g. reusability.learningObject means that learningObject is a subsection of the category reusability).

4.1 Fundamental Reusability Specific Criteria

- **reusability.basic**: Category grouping general information for reusability support.
- **reusability.basic.architecture**: Category describing the general architecture of the online learning platform.
- **reusability.basic.architecture.type**: Data element describing the fundamental type of the online learning platform (e.g. monolithic or modular architecture).
- **reusability.basic.architecture.DMS**: Data element describing the document management system of the online learning platform (e.g. no clean separation in architecture, Lotus Notes / Lotus Domino, Hyperwave Information Server, Zope).
- **reusability.basic.architecture.ServerServerReplication**: Data element describing if the system provides server-server replication to reuse the same course content at a different location through distribution.
- **reusability.basic.development**: Category grouping developmental aspects of the online learning platform code.
- **reusability.basic.development.systemTemplate**: Data element describing if the online learning platform is a template system as an included application for a DMS (Lotus Learning Space, Webtycho, Hyperwave eLearning Suite) or if it is an encapsulated code (Netcoach).
- **reusability.basic.development.sourceCodeAccess**: Data element describing if platform source code is accessible (Ilias, Hyperwave eLearning Suite, partly available in Lotus Learning Space).
- **reusability.basic.development.APIs**: Data element describing which programming languages are supported through APIs.

4.2 Learning Object Specific Criteria

- **reusability.learningObject**: Category grouping learning object specific information.
- **reusability.learningObject.access**: Category grouping information about accessibility of learning objects.
- **reusability.learningObject.access.type**: Data element describing the type of access to a learning object (programmatic through API functions, manually by author through platform function).
- **reusability.learningObject.access.granularity**: Data element describing on which content layer the access of learning objects is supported (course layer, document layer, subdocument layer, element collections, single elements).
- **reusability.learningObject.metadata**: Category describing metadata support.
- **reusability.learningObject.metadata.type**: Data element describing the type of metadata representation in the platform (proprietary, LTSC LOM, ARIADNE, IMS Global Learning Consortium, Dublin Core).
- **reusability.learningObject.metadata.version**: Data element describing the version of supported metadata.
- **reusability.learningObject.metadata.mappings**: Data element describing which mappings exist to other metadata formats.
- **reusability.learningObject.metadata.supportLevel**: Data element describing the level of metadata support in the used metadata format (fully, partly, percentage value).
- **reusability.learningObject.metadata.cardinalityType**: Data element describing the number of metadata sets associated to the number of learning objects (1:1, 1:m, m:1, m:n associations).
- **reusability.learningObject.metadata.usage**: Data element describing how metadata is used by the platform (used in retrieval process; import-/export functions).

4.3 Additional Criteria

- **reusability.additional**: Category describing additional criteria with content reusability support.
- **reusability.additional.interoperability**: Data element describing the ability to integrate the platform in an existing computer infrastructure (e.g. to use common webservers, protocols, data standards and programming languages).
- **reusability.additional.contentStorage**: Category describing the platform content storage system.
- **reusability.additional.contentStorage.type**: Data element describing the type of database used (filesystem; proprietary platform build-in; external RDBMS, ORDBMS, XML DB, object-oriented DB).
- **reusability.additional.contentStorage.dataFormat**: Data element describing the format of the stored content (XML, relational tables, proprietary, BLOB, CLOB).
5. Conclusion and Outlook

This work proposes a criterion enrichment by adding content reuse specific categories to comparative analysis tools to support architecture decision making in an online learning environment. After analysis of existing learning platforms and their reusability features implemented in currently available versions an abstract description of decision making on learning platforms was investigated and afterwards concrete existing often referred comparative analysis tools were analysed. Referring to this analysis a proposal has been stated following a logical structure and associates online learning platform properties and features, stored learning object and their metadata properties to significant and meaningful identifiers in comparison schemata design for online learning platforms. Investigated online learning platforms fit in the proposed schemata enrichment very well. Future work might result in implementing the proposal into existing comparative analysis tools. Furthermore an introduction of project characteristic coefficients describing a typical specific property rating spectrum of a project will be investigated. This might allow a more specific choice of an available set of target platforms due to the large scale and variety of different types of reusability demands in online learning projects.

WCET e-Learning Projects and Resources (http://www.wcet.info)

Introduction

This brief paper offers an overview of several key e-learning projects at the WCET (Western Cooperative for Educational Telecommunications). These projects include: a web-based resource that is designed to develop specific tools for the higher education community; a project developing web-based student services including models, resources and processes for their implementation; and the “technology costing methodology” project that enables institutions to calculate the cost of technology within and across higher education.

e-Learning Technologies Projects

WCET was awarded a major grant from the William and Flora Hewlett Foundation to support several critical eLearning projects. This grant is providing generous support for several projects:

- The first, e-Learning Technologies: Web Resource for Comparisons, will provide a resource to help educators analyze and compare vendor-produced course management tools, software products, outsourcing vendors, and e-learning policies.
- A second, just underway, is exploring the need for develop and implement a simple-to-use system for evaluating distance learning courses available from third-party vendors.
- The final project involves the Hewlett Foundation and WCET staffs working together to explore policy issues that are likely to have an impact on policy for the successfully integrating technology into higher education. Based on this work, a paper on open source course management systems will be released early this summer.

Of the Hewlett Foundation funded projects, the Web Resource for Comparisons is well underway to being implemented and will be highlighted in this section. For colleges to quickly implement online courses, many course management software products have been developed. These tools make it easier to adapt curriculum to the Web and to give the student a common “look and feel” in each course.

Over the next two years, this project will redesign and expand the existing site. The new website will be called EduTools (www.edutools.info). We will also develop three new companion sites that apply the same decision-making models for comparisons of other tools. The three new sites will analyze: 1) electronic student support services, 2) instructional technologies, and 3) policies relating to the use of educational technologies.

Beyond the Core: Creating Web-based Student Services for Online Learners

Students participating in distance education academic programs must also have access to student support services. However, one of the biggest gaps in online education is institutions' inability to provide time- and location-independent access to a complete array of student support services. Higher education institutions and other providers must take advantage of technology to deliver
student services to online learners in a way that effectively meets their unique needs. This project will focus on Web-based student support services, defined broadly, and will result in:

- Student services models developed at three partner institutions.
- A set of guidelines for institutions interested in building their own "home-grown" Web-based services.
- Detailed case studies of the institutional change processes required to implement Web-based student services.

The project uses the Web to collaborate and disseminate information on online student services. The project leaders also produce a monthly Webcast series called, Providing Student Services to Distance Learners. Guest experts define best practices and demonstrate effective and innovative online services. This project will result in a number of models and resources for institutions to draw upon.

Technology Costing Methodology (TCM) and TCM2: Completing the Toolbox Project

The original Technology Costing Methodology (TCM) project began in September of 1998 with the goal of developing an authoritative costing methodology (and related procedures) for calculating technology costs (1) within an institution to determine if proposed instructional approaches, that make heavy use of technology, actually do serve to contain costs; and (2) across institutions allowing data to be compared legitimately for different instructional or technological approaches, which will benefit legislatures, state-governing boards, state coordinating boards, and federal agencies.

A follow-on project, Technology Costing Methodology: Completing the Toolbox Project (TCM2), focuses on refining the methodology and assisting decision-makers in exploring and understanding the policy implications resulting from additional costing information.

About WCET

The Western Cooperative for Educational Telecommunications (WCET) is a recognized leader in—and advocate for—the effective use of educational telecommunications. Its membership is open to higher education institutions and government agencies, non-profit organizations, schools, and corporations—regardless of location—that are providers and users of educational telecommunications. Six countries and 43 states are represented among the nearly 250 members. WCET, established by the Western Interstate Commission for Higher Education (WICHE) in 1989, serves its members and the broader higher education community in the following ways.

- Central clearinghouse for information and expertise.
- Source of professional development and assistance including the annual conference will be held in Denver, CO Nov. 6-9, 2002, and the Institute for Managing and Developing E-Learning (MDE) will be held in Park City, UT on July 21-25, 2002.
- Leader in facilitating cross-institutional projects in mediated education.
- Advocate for effective policies and practices supporting e-learning.
- Evaluator and researcher on quality uses of educational telecommunications.

Abstract: A completely new engineering curriculum has been introduced in September 2000 by the School of Engineering of the Université catholique de Louvain (UCL). This curriculum is entirely based upon active and collaborative learning by students. Surprisingly enough, very little is readily available to effectively support this type of pedagogy by means of technology. This contribution looks at available general and special-purpose tools from the point of view of their suitability for problem- and project-based learning. It also points to areas in which adequate support is still needed. Finally, it looks into technology as a way to allow participation by remote learners and tutors and makes the case for ubiquitous access to learning tools.

Introduction

Active learning as embodied in either problem- or project-based learning has been around for more than 30 years. Many authors testify to the benefits of active learning both from the point of view of learning outcomes and from that of student and teacher satisfaction [Vernon, Blake 1993], [Gijsebaers 1996].

After a long and extensive study, the School of Engineering of UCL decided in 1999 to embark upon a complete overhaul of its curriculum in order to implement active learning approaches. We took advantage of this opportunity to precisely define the expected learning outcomes - not to be confused with the customary tables of contents. The new curriculum was launched in September 2000 (for the first year of our 5 year program) and will, over 5 years, gradually replace the traditional approach.

Active learning is the central principle of this model: students are continuously exposed to activities which require direct participation and which stimulate learning. Problems are designed and run in much the same fashion as in by now "classical" Problem Based Learning (PBL) [Boud, Feletti 1997]. Projects are different from what one often finds in engineering curricula in that they are means for acquiring new knowledge and competences, not merely for demonstrating an ability to apply previously acquired capabilities. We use projects mostly to develop interdisciplinary and longer-term (11 weeks) approaches, while problems are used mostly within a single discipline and during a shorter time span (1 week). Our hypothesis is that problems allow students to delve in a more controlled way into disciplinary topics than projects, thereby ensuring that essential topics would not be merely glanced over.

A second major principle of our approach is collaborative learning: groups of 7 or 8 students are constituted randomly at the onset of every trimester. Many - but not all - activities are tackled collectively by all students belonging to a group: this concerns mostly the preparation of individual learning, the planning of subtasks, and the sharing of results. Some of the group meetings occur in the presence of a tutor; much necessary work is done either individually or in groups without presence of tutors. Meetings are run (by the students themselves) according to a set of guidelines, but a lot of leeway is given for organizing both collective and individual work (provided it is organized).

A third essential concept in our new curriculum is a focus on (self-)assessment of progress and on systematic reflection about one's learning process. Indeed, we try to make the learning process as explicit as possible, since we believe that awareness about one's learning process is a necessary condition for success.

This instructional model fits nicely with the learning theory we adhere to: socio-constructivism [Jonnaert, Vander Borght 1999] [Seely, e.a 1989]. Problems and projects are situated in realistic professional contexts and incite our students to build upon existing knowledge to acquire new knowledge; communities of learners stimulate individual learning.

In this pedagogical approach, the role of faculty and other staff is totally transformed: from teachers and assistants we morphed into tutors and facilitators, entirely new roles for most of us. From providing answers we switched to asking questions, to guiding progress, to pointing to resources.

The role of technology

We decided to look at ways to use technology firstly to facilitate and enhance learning by students and secondly to lighten the overall load on our staff. It would of course have been preferable to design and implement necessary tools along as we designed and implemented our new curriculum, but scarcity of resources and the fact that curriculum design and implementation is an ongoing iterative process prevented us from following a concurrent approach. It is thus only after one year of experience with the new curriculum that we started looking into ways to use technology to support our pedagogical approach.

Two kinds of tools may be considered when looking into ways to use technology in education: widely available general purpose presentation and communication tools and special purpose teaching/learning tools. We looked into both categories from the point of view of their suitability for supporting our own brand of active learning. The next part of the paper presents a typical problem based learning cycle and reviews possible uses of technology.
From PBL to e-PBL

In our flavor of PBL, a problem is tackled by a group of students during a time span of one week. The work is organized as follows:

- In the first scheduled meeting, the kick-off meeting, the group will analyze a new problem situation; it will take stock of existing knowledge which may help tackle the problem and it will try to produce a set of specific (learning) tasks which it feels should be accomplished in order to increase its available knowledge in the areas related to the problem and in order to produce whatever outcomes are needed according to their understanding of the requirements of the given problem statement. Resources will then be allocated to the various tasks. The group will also update its weekly schedule in order to reflect its own planning of the work related to the problem at hand. A tutor is present to make certain the group reaches the objectives of the meeting (not to answer questions about the material). Since we have quite a large number of groups, a single "floating" tutor handles three groups simultaneously. A series of questions about the problem may be handed over to the group to help focus their analysis.

- After the kick-off meeting, students will do whatever they have themselves decided to do to get closer to the solution of the problem, trying to keep to the schedule they have set for themselves. They may work alone, in subgroups or in the full group, according to their own preferences and availability. This phase involves identifying and reading of course material and other resources, discussion among group members about issues raised by individual learning, resolving exercises, etc.

- Two or three days after the kick-off meeting, there is a second scheduled meeting in the presence of the tutor. In this meeting, progress towards solving the problem is analyzed and discussed, and intermediate results are shared by the members. This is usually an occasion which raises further learning issues and which may impact the weekly schedule since new subtasks may be identified.

- After the intermediate meeting, students will again pursue their own learning activities and execute whatever tasks the group has allocated them.

- At the third and final scheduled meeting, the group finalizes its production; it may be asked by the tutor to present its solution or any other product of the work. Sometimes, the group is asked to answer questions about the course material which is relevant for the problem.

We won't dwell further on projects, which are run in a way similar to the one outlined above for problems, albeit over a longer time span and with weekly scheduled meetings between groups and their tutor.

If one looks at technology and wonders how it could be marshaled in order to support the process outlined above, one will immediately figure out straightforward ways to use, say, the Internet. Problem statements, resources, focus questions and the like can be made readily available through a Web site. E-mail may be used to communicate among members of a group and with the tutor. Chats may help group members pursue discussions even when not all members are physically present and threaded discussions forums may help a group focus on a given issue until it is satisfactorily resolved. Calendar and planning software may be used to handle the scheduling and planning tasks. Finally, students may be encouraged to write their own Web pages in order to record information they wish to share with other members of their group or with other groups.

Of course, one should immediately point out that using the Web to make resources available to students is still traditional transmissive pedagogy: a book with hyperlinks is still a book. Very few course delivery platforms manage to provide a truly personalized learning experience and, to judge by the amount of paper printouts of Web-delivered course materials, students have not yet been convinced to opt for a paperless society!! It is also worth noting that chats, while eminently suitable for synchronous communication between remote people, are very volatile: they leave no or little useful record of the exchanges for later perusal. On the other hand, if threaded discussion forums are not monitored closely, they may perpetuate and disseminate incomplete or erroneous information. Also, their very nature forces them to grow and become unwieldy: here again, intervention by a qualified teacher is needed to summarize and condense information into an exploitable form.

A first conclusion may be drawn from this mundane usage of the Internet: even though setting up everything that's needed may require more than a casual effort, very little of this usage is actually related to learning! We shall therefore discuss some tools which could provide true scaffolding for the learning process in PBL by looking at some of the activities which occur in this process, some of which are managerial, while others are truly cognitive:

<table>
<thead>
<tr>
<th>Activity</th>
<th>Tool</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analyzing a problem situation</td>
<td>Making choices</td>
</tr>
<tr>
<td>Formulating hypotheses, ideas, proposals</td>
<td>Making all ideas, opinions, decisions known to all group members</td>
</tr>
<tr>
<td>Restating the problem</td>
<td>Finding out how work has progressed with respect to the schedule</td>
</tr>
<tr>
<td>Identifying sub-problems</td>
<td>Proposing paths to solutions</td>
</tr>
<tr>
<td>Preparing or modifying a list of learning issues</td>
<td>Evaluating paths to solutions and solutions</td>
</tr>
<tr>
<td>Preparing or modifying a list of tasks and milestones</td>
<td>Assessing the group's progress in the various tasks</td>
</tr>
<tr>
<td>Allocating resources to tasks</td>
<td>Assessing one's own mastery of the course material</td>
</tr>
<tr>
<td>Scheduling tasks and meetings</td>
<td>Preparing the expected production, results, outcomes</td>
</tr>
<tr>
<td>Structuring knowledge</td>
<td>Assessing other groups' production</td>
</tr>
<tr>
<td>Sharing knowledge</td>
<td>Identifying and resolving conflicts</td>
</tr>
</tbody>
</table>

What we are looking for are tools which support and encourage learning through discovery and peer interaction (i.e., interactions which affect learning positively and deepen student understanding) and which promote collaboration and group cohesion.
Shared workspaces

Shared workspaces such as BSCW [Appelt 1999] provide the basic mechanisms for cooperative work between members of various communities, thus also — potentially — between the members of a PBL group (including the tutor). Shared workspaces are used to collect, structure, and present any kind of information needed for the work at hand, usually arranged in a hierarchy based on commonly agreed upon structuring principles. They may also provide event services, which will inform members of a group that something worth their attention has happened. Additional features may include authentication, version management, search capabilities, discussion forums, etc. Integration of various synchronous and asynchronous communication means is usually provided, up to a point. There may be some support for the scheduling of meetings. Several of the group communication and management activities in the list above may be supported in some way by such shared workspaces, provided the learning curve is not too steep (for teachers as well as for students). However, as general-purpose tools, such workspaces fall short of providing support for cognitive activities. Still, our intent is to deploy such a system next year in order to find out which of the features will be adopted by our students to support their collaboration.

A next step up the evolutionary ladder is exemplified by environments such as the CoVis Collaborative Workbook [Edelson e.a. 1996]. In this system, the objects manipulated by the tools are not just any kind of document, but they are typed according to their use in a learning process. For instance, in the Scientific Notebook, one distinguishes the following types of objects (called "pages"): question, conjecture, evidence-for, evidence-against, plan, step-in-plan, information, and commentary. Students add pages and links between pages as they proceed along their inquiry, which helps structure the process and thus leaves more time for working on the content. The resulting web of pages provides a trace of the process and certainly helps tutors provide better feedback than that which may be provided by looking only at the final results of a group's work. The authors of the system report on several successful uses of their tool in project-based learning.

Still higher on the scale of tools providing effective support for cognitive activities are tools exemplified by IHMC's Concept Mapping Tool CMap [Canas, e.a. 1999]. With this tool, students may collectively build a graphical representation of concepts and relationships between concepts as their understanding of a domain evolves over time. Threaded discussions may be associated with concepts and with links, and a system for managing propositions is also available. The way students model their knowledge by means of such tools provides deep insight in their thinking processes and allows even more effective tutor interaction and feedback. We shall soon look into ways to integrate CMap in our problem and project-based approach since we feel that its knowledge representation power will help us make learning more explicit (as sequences of evolving concept maps).

Time management

As they find out quite quickly for themselves, the scarcest resource for students (and for teachers) is time. Very few of our students manage to successfully juggle the various assignments and tasks which run concurrently. Since we wish to develop self-sufficiency, we refrain from providing complete work schedules for every group. Instead, we schedule only pre-planned activities such as lectures and tutored meetings. We wish therefore to incite our students to pay serious attention to issues such as planning, scheduling, milestones, deadlines and accountability. This is an area in which none of the available software packages we looked into fit our requirements, our needs, and our budgets. Most calendar and planning software is designed for professional use and is much too complex and constraining for student use. Besides, such tools may allow one to enter a schedule, check its consistency, and verify its execution, but do they help one learn how to prepare a valid schedule?

Assessment and feedback

A central tenet of problem and project-based learning is that a student should be constantly aware of his/her progress (or lack of it). Self assessment, peer assessment, and assessment by teaching staff are thus an intrinsic part of any PBL approach. Indeed, some form of assessment necessarily precedes reflection upon one's learning. Since it would be too costly to provide on-demand assessment by staff, numerous attempts have been made to provide on-line interactive assessment tools. Here too, the situation is less than encouraging, since most tools fail to allow assessment of higher order cognitive skills: how does one write a tool to check the validity of a proof, the correctness of a design, the adequacy of a line of reasoning? How does one distinguish between shallow and deep learning? How does one reveal incomplete understanding?

Our experience with on-line multiple choice/multiple answers quizzes shows that they tend to give a false sense of knowledge and understanding and thus fail to promote self-questioning and meta-reflection: students tend to stop trying to learn as soon as their marks reach a "satisfactory" level: scoring high becomes the main goal, instead of acquiring knowledge. Besides, we would like our students to set their own learning goals, not only to try and reach those we set for them. Providing effective on-line self-assessment for student-set learning goals is even harder to imagine!

About the human cost of technology

When we decided to switch from traditional pedagogy to active learning, we knew it would require a lot of effort to design and implement the new curriculum. It turns out that using technology to support collaborative learning has significantly added to our work load: deploying and maintaining tools to help our students is far from cheap with respect to staff costs. Several of us have paid dearly to set up devices whose pedagogical efficiency remains in doubt. The lesson we draw is that, when planning for the use of technology in education, one should run a cost/benefit study taking into account the real added value of technology rather than expectations.
From e-PBL to d-PBL to m-PBL?

We now briefly contemplate what happens when one adds new dimensions to the issue of using technology to facilitate problem- or project-based learning.

A first possible extension consists in allowing some of the members of a group to participate in the various activities while not physically on the premises with the rest of the group. In this case, one mostly worries about alleviating the effects of distance on the dynamics of collaborative work [Davis, Schlais 2000].

Some of the tools such as e-mail, chats and threaded discussion forums, which fail to provide significant support for PBL when all participants are present in the same room, now start playing a much more effective role since they help bridge the physical distance between participants and allow more asynchronous operation of the group. The other tools described earlier will certainly be as useful as in the case of "traditional" PBL. Of course, one should not underestimate the negative impact of distance on social issues such as group identity building, group cohesiveness, and individual motivation (every one of which is essential to the success of PBL) and one should probably not overestimate the power of technology to truly compensate for this impact. Still, this case may be one when videoconferencing might prove useful (certainly for Europeans learners) to overcome the distance barrier between participants.

Another issue which must be faced is that of the availability of technology-based tools to learners. We feel that learning tools should be available whenever and wherever a learner feels like using them. This means that, whenever possible, a variety of terminals (PC, PDA, cell phone) should allow access to these tools with a minimum of technical fuss: what's the use of a powerful agenda tool if it is not available day and night? We are now in the process of providing wireless access to a part of the city of Louvain-la-Neuve in order to facilitate ubiquitous connectivity and mobility. We expect that 3rd generation GSM mobile phones will widen the coverage within a few years. Still, not many of the existing tools cater to terminals in the PDA to cell phone range, which rather limits the usefulness of wireless coverage.

Conclusions

A single year has been concluded at the time of the writing of this paper: it is therefore too early to draw conclusions about the actual learning outcomes of our new curriculum. Still, one thing is quite clear: many of us feel a strong need to use technology in order to enhance the quality of students' learning and, if possible, to relieve staff from some of the pressure inherent to active pedagogy. An overview of existing technology-based tools reveals that few of those which are readily available are really effective in their support of the learning process in PBL. A first challenge is thus to identify and deploy tools specifically to enhance and facilitate learning and related activities, rather than merely automate some of the clerical and managerial work.

A second challenge is to provide ubiquitous access to existing and future tools: learning activities should be possible in every occasion when a learner is (1) available and (2) willing to learn. We feel that too many learning opportunities are missed because technology is not yet available in every case when both conditions are met.

A last -- but not the least -- issue concerns the overhead for both staff and students for using technology-based tools: these tools need to be simple and easy to use in order to allow both categories of participants to focus their attention and devote their efforts to the essential aspects of their respective jobs (i.e. instructional design, tutoring, collaborating, and learning), and not on the use of the tools themselves or the mastering of their interfaces.

From Parrots to Puppet Masters
– an Online Role-Playing Tool for Fostering Second Language Acquisition

John Milton
College of Life-Long Learning,
Hong Kong University of Science and Technology
Hong Kong
lcjohn@ust.hk

Abstract Language learners often leave school able to do little more than parrot second language formulae. This paper proposes a Web-based system for the construction, delivery and management of online language courses. The system and courses it supports are aimed at providing more timely and personalized instruction than learners normally have available. They also provide opportunities for practice in collaborative and creative communication. This paper illustrates an online ESL course driven by this system, and highlights a role-playing activity that encourages the appropriate use of language in social and business contexts. It allows students to gain facility with basic grammar, vocabulary and conversational language devices, as well as ‘higher order’ pragmatic linguistic skills.

A problem in language education
The need to educate a large and varied population in English as a lingua franca in SE Asia has given rise to a number of problems, which are in a general sense also faced in the teaching and learning of other types of knowledge and skills. One of the most frequently discussed problems in SE Asia is the unhappy force-fed pedagogy in which many teachers and students find themselves trapped (e.g. Zeng, 1999). This problem is complicated by a dearth of qualified ESL teachers and a lack of time and resources to develop effective lessons. Educational theorists generally believe the teaching and learning practices based on ‘teaching to the exam’, which are the preferred methods in many public and private institutions in SE Asia, dampen students’ desire and ability to learn (e.g. Paris, 1995). However, because of the face validity that norm-referenced standardized assessment promises, these practices often dominate the curriculum. While this problem is most keenly felt at primary (!) and secondary levels, even tertiary education is not free of it.

One of the shortcomings of these practices is that they habitually result in students merely learning how to parrot formulae. In the case of second language learning, stock phrases taught at school are often made to substitute for grammatical and communicative competence in the target language (Milton, 2001). This practice is not always the fault of the teachers, who are often victims of social pressure to teach test-taking strategies for short-term gains.

One proposal for dealing with the problem
The author was commissioned to produce online ‘workplace English’ courses for professionals, and ‘bridging’ courses for secondary school-leavers who have been out of school for a number of years and who wish to upgrade their English or to enroll in tertiary courses taught in English. These students are mainly Cantonese and Putonghua speakers at a wide range of English proficiency levels, requiring a broad array of receptive and productive English skills.

It was not immediately apparent how current multimedia technologies could be deployed quickly and cheaply in order to develop and deliver high-level interactive online language learning content. Despite the Web’s potential to provide courses on demand, most content delivery systems appear to offer an unsatisfactory range of activity types and learning options for dynamic language learning.

It seems reasonable to expect an online content development and management system to assist materials developers and instructors (who often have limited time and resources) to create engaging and meaningful communicative, collaborative and problem solving activities. We should also expect the courses created on such a system to follow generally agreed educational principles and pressing logistic needs by:

- appealing to a wide range of learner proficiencies and interests;
motivating low-proficiency students, who often suffer from low self-esteem, to engage in high-level interaction, while also enabling a transparent system of student and teacher accountability;

- providing quality, individualized instruction to a large number of varied learners;

- ensuring a coherent, planned and progressive curriculum, and the transmission of core information, while also providing opportunities for self-discovery, problem solving, participation and collaboration, creativity and the pursuit of individual learning paths (i.e. aim at the type of quality assurance outlined by Alley and Jansak, 2001);

- enabling and encouraging the teacher to act more often as a mentor, and less often as a pedagogue;

- integrating intrinsic, criterion-referenced and performance-oriented formative assessment into the learning process, thereby minimizing the need for extrinsic, norm-referenced summative assessment;

- providing quicker and more reliable reporting to the instructor, allow for easy, consistent grading, and also more effective and quicker feedback to learners; and

- allowing ongoing assessment of the content and methodologies by the students.

It was crucial that this online content development system allow for the specific pedagogical needs of language courses. This meant making it possible for students who may have little perceived opportunity to use the target language in their daily life to gain accuracy and fluency in all language skills. These skills include authentic listening, speaking, writing and reading activities.

Internet technologies potentially allow for a highly interactive educational model through retrieval of online data, as well as through enhanced communication among students and with the instructor. However, while access to expert support is important, it is both pedagogically and economically counter-productive to base online courses entirely on a teacher-led model. In the absence of reliable, affordable and widely available Artificial Intelligence systems for human language acquisition and production (e.g. natural language parsing), this requires the careful preparation of objectively scored activities – ideally aimed at ‘higher-order’ outcomes (e.g. Haladyna, 1997). These activities, content and technologies must of course be sufficient and appropriate to meet the learners’ needs and learning styles, which in this case are extremely varied.

More importantly, an effective online language-learning framework requires the development of collaborative activities that make communicative use of the language the responsibility of the students themselves. Various studies (e.g. Johnson, 1993) suggest that a well-organized learner-centered curriculum, especially one that puts extensive resources at the disposal of teachers and students, enhances effective mentoring of students and increases the accountability of students for their own learning. Students in an online environment normally produce far more language (in this case, both writing and speech) than those in a traditional class (Selfe & Cooper, 1990), and the instructor has more often to play a mentoring than the conventional classroom pedagogical role.

Several currently available course delivery systems were evaluated, and while all permit basic information delivery and assessment, none applied the range of mechanisms for language learning suggested above. Also, most systems leave much to be desired in the ease with which content can be authored, the degree to which individual learners can be accommodated and social interaction encouraged. Internet technologies continue to make available new expanded forms of communication and participation, but these new technologies often take considerable time to be integrated into commercial course delivery systems, and most of these systems do not allow new technologies to be easily incorporated on an ad hoc basis. A careful look at the technologies involved suggests that – if it is pedagogically justified – database-driven Internet technologies have matured to the extent that it is technically and economically feasible to develop original, a customizable Web system with the features outlined above that can be used to create, deliver and manage interactive, individualized online content.

Among the parameters set for this system were that it must allow courses to be undertaken through a series of sequenced activities and units: learners are generally held accountable for completing a ‘unit’ within a set period. It must nevertheless allow for streaming so that more or less proficient and independent learners, or learners with different academic or job-related needs, can pursue different learning paths and activities within the same course. It must allow the creation of conventional ‘objective’ activities (i.e. activities that can be automatically graded, such as multiple choice, gap fill, drag-and-drop, matching etc.). Less conventionally, it must also allow the creation of open-ended activities beyond standard essay submission forms and threaded text discussions – for example, sequenced access by learners (via ‘Voice over Internet Protocol’ – VOIP technologies) to asynchronous and synchronous voice discussion Web boards. The remainder of this paper illustrates yet another, even less conventional open-ended module implemented in an online English course currently driven by this system: a module that learners can use to create and post animated role-plays on the Web.
Online Role Plays

Oscar Wilde observed, “Education is an admirable thing. But it is well to remember from time to time that nothing that is worth knowing can be taught.” (1913). How to make known the unteachable may in some sense be answered by Muriel Rukeyser’s 1960 remark that “The universe is made of stories, not of atoms.” Allowing the language learner to adopt the role of narrator as a means of acquiring language skills is particularly relevant.

While not negating the role of the instructor, most academics accept that ‘higher’ levels of learning, such as ‘critical thinking’, which are not easily taught or assessed, are the preferred outcomes of the educational process. There is justifiable concern whether universities are currently producing students capable of achieving the higher order learning outcomes listed in Bloom’s taxonomy of educational objectives (i.e. recall → comprehension → application → analysis → synthesis → evaluation). One term often used by linguists to describe the advanced communicative proficiency that make advanced level communication possible is ‘pragmatic competence’, which includes the ability to critically evaluate what is said or written and to respond in a contextually appropriate manner.

One way such outcomes have been encouraged is through role-playing activities, usually face-to-face or at a distance. These are used in many disciplines, with various online projects using ‘virtual worlds’ (e.g. MUDs) in simulations of business or academic projects. The benefits of role-playing for generalized educational settings are detailed in Jones (1985), and specifically for language learning in Ladousse (1987), Crookall & Oxford (1990) and Bambrough (1994).

In the course delivery system developed in response to the requirements sketched above, students use an online ‘scripting tool’ to manipulate animated characters on screen, assign them movements and gestures (including some body language) and to write dialogue that is synthesized and ‘spoken’ by the characters, whose mouths move synchronously with the dialogue. The technology that runs the animated characters (‘Microsoft Agent’) was originally developed to give a social dimension to the computer interface.

Via this technology, students can listen to their dialogues (or any other text on the Web page) rendered with standard American or British synthesized pronunciation. The current stage of development in freely available text-to-speech technology is such that the synthesized suprasegmentals (e.g. stress, rhythm and intonation) are not entirely human, but the students who have taken the course (almost 300 to date) rarely complain about the quality of the synthetic voices. Indeed, they report finding the relatively high accuracy in pronunciation useful (the voice synthesis can be replaced by a recording of a human voice if the student or instructor wishes – e.g. where prosodic modeling is crucial). This activity has the benefit of allowing teachers and students to script and edit conversational dialogue. It also allows the instructor, who has access to the written script, to supply detailed written feedback on the accuracy, fluency and effectiveness of the students’ dialogues. Students have additional opportunities for direct practice in synchronous and asynchronous conversation with the instructor and with other students on the voice discussion boards mentioned above (e.g. http://ihome.ust.hk/~lcjohn/International_Voice.htm).

Several Second Language Acquisition (SLA) theorists recommend the use of dramatization, ‘actualization’ and narrative techniques for effective SLA, regardless of the age of the learners (e.g. Oller, 1993). Scarcella and Crookall (1990) also review research to show how simulation facilitates second language acquisition by giving students the opportunity to try out new language in a safe environment. The learning theories they discuss claim that learners acquire language when:

- they are exposed to large quantities of comprehensible input through being engaged in genuine communication as part of the roles assigned to characters;
- they are actively involved in worthwhile, absorbing interaction, which tends to make students forget they are learning a new language; and
- they experience positive feelings and attitudes.

Such studies argue that the dramatization of ‘real life’ problems helps students develop their critical thinking and language-related problem solving skills. Role-playing would certainly appear to be a useful language acquisition activity to the extent to which we view language as a vehicle for the realization of interpersonal relations and social transactions.

The particular role-playing activity which this system supports allows students to practice and demonstrate ‘higher order’ linguistic skills such as the pragmatic devices necessary for developing a narration, resolving a conflict, conducting a negotiation etc., while also being a useful vehicle for practice in basic grammar, vocabulary and conversational language devices. Students are guided in commonly avoided, misused or overused language devices. The activity gives students the opportunity to express and acquire cultural values and to be creative, while developing practical language strategies for handling business and social communication. Those who are normally shy to speak
spontaneously in a classroom out of concern for their imperfect English appreciate the opportunity to practice using the language in this context. A serendipitous benefit of the activity is that it appears to give students who have limited technology fluency more confidence in the use of computer applications and enhanced Internet skills. Incidentally, it also appears less prone to plagiarism: students seem less inclined or able to copy holophrastically from other sources when they are scripting for the digital puppets – perhaps because the activity is not so closely associated with academic assessment and right/wrong answers, as is the standard essay question.

This role-play activity (normally assigned once in each unit or in alternative units) was designed to encourage students to work collaboratively at a distance. However, while role-playing may be an ideal participatory exercise in active learning, this ideal cannot be fully realized if students find it difficult to schedule online meetings in order to co-design plays. Most students who have taken the course to this point are professionals seeking to improve their English, and most have chosen not to collaborate with other students in writing their role-plays. A number of students do, however, work with family members in designing and scripting the plays. Even when they write the plays alone, they socialize through the public production of the scenarios, by giving and receiving classmates’ feedback, and through the virtual relationships they establish among the animated characters. Several of the higher-order outcomes that are claimed for team-based role-playing activities are also possible in the creation of individually written role-plays, such as increased confidence in language production, heightened discriminatory skills, and the sheer fun that comes from the act of personal expression and creation. Collaborative elements can nevertheless be retained, even when the students choose not to work together. In addition to commenting on and grading each other’s plays (by assigning ‘stars’), students often spontaneously continue narrative lines from their classmate’s plays.

A functional thematic context (e.g. telephone skills, encouraging and criticizing, the language of negotiation) is developed in each unit. Also, relevant grammar and lexis, along with the features of spoken language (e.g. stress, rhythm, intonation and pronunciation), are provided to students through a variety of high-interest interactive activities (including via licensed popular songs and lyrics streamed from our server). The spoken and written input are based on extensive research into the language learning difficulties of the students, and are more authentic and copious than can normally be made available in the classroom.

Instructors and fellow students supply feedback to each play, and students can re-write their scripts. Care is taken to make the purpose and structure of the role-plays clear, since many students are more accustomed to conventional essay assignments than they are to communicative methods of evaluation (see Li, 1999 for a discussion of the mismatch between student expectations for teacher-led instruction and the participatory methods often preferred by western-educated teachers).

The instructor can exemplify a wide range of language features in communicative contexts with this technique, including problematic or unknown grammatical structures and lexis. Scripts written by learners usually illustrate surprisingly authentic (albeit imperfect) dialogue. Learners are enabled to adopt opposing points of view and often make an effort to use problematic grammatical structures that are frequently avoided in conventional settings. Their errors provide teaching opportunities, and are evidence of involvement in genuine communicative acts, rather than the mere completion of academic exercises in error avoidance.

**Conclusion**

The system outlined in this paper allows language teachers and course writers to take advantage of ongoing advances in Internet technology to deliver instruction while encouraging participatory learning for ‘higher order’ outcomes. The online English course developed on this system seeks to address cognitive and affective learning needs and allows students to pursue their own language learning goals free of many of the logistic limitations of the classroom. The specific modality highlighted in this paper combines Internet delivery with database connection, computer animation and speech technology to enable language learners to experiment with manipulating the second language in simulated and supported contexts.

This role-playing exercise is one of the most popular activities in the current online English course: almost all students find this activity ‘very interesting’, and at the completion of the course, most mention it as one of their favourite activities. The approximately 300 students who have taken the course so far showed an average increase of 35% in their listening comprehension and 24% in grammatical accuracy over the length of the course, based on standardized pre- and post-tests.\(^1\)

---

\(^1\) Changes in performance of productive skills (writing and speaking) have not yet been measured.
There are a number of plans to enhance the use of the narrative and dramatization devices discussed here. In addition to being able to write their own scripts, students should be given more control over the narratives provided by the course author. This will mean building in various forms of student-driven controls, including possibly voice recognition, and writing branched scripts so that interactions proceed according to choices made by the student.

Acknowledgements

The author wishes to acknowledge the HKUST College of Lifelong Learning (CL3 – http://www.cl3.ust.hk/), which has provided support in programming the system and administrating the course described in this paper.

cmail: yin@narita.elec.waseda.ac.jp

Abstract: This paper describes a computer-based English exercise system through pictures using TTS (Text to Speech). With the help of TTS technology, this system can provide the phonetic check function of a learner's input answers in order to overcome the shortcoming of language learning courseware that must rely on sound files. This system can also provide check functions of word spelling and grammar for the learner. The TTS technology can fully display the advantage of computer multimedia teaching and realize the real computer-based interactive teaching.

English Exercise System Base on TTS

In an English lesson, a teacher often draws the content of course on a picture in advance and asks the students some questions about the picture in classroom. This kind of teaching method makes a point of the student's participation and enhances the student's initiative to a certain degree. So this method is in favour of training the learner's ability of studying the foreign language. Different learners will have individual perceptions as well as different language foundations, so they will give different interpretations of the pictures and give different answers. Because of the restriction of course time and the teacher's energy, it is impossible for the teacher to check all answers. Some partial outstanding student's reply may usually replace the entire class student's reply, some partial outstanding student's reply may usually replace teacher's explanation, simultaneously the teacher's answer only can take the reference.

Under this condition, the majority of students may be occupied in the passive study and therefore the student's initiative study and the positive thought can not be manifested fully. Therefore it is very important for a language courseware to provide interactive functions.

In every kind of courseware, the process of sound mostly adopts sound files, namely recording sound of teaching contents in advance to become the sound files, and plays them in the class. The learners can't usually check the pronunciation of their own answers and it is also impossible in advance to record the sound files of all the answers. Regarding any language practice system, it is impossible to enumerate all possible answers, but if it only stipulates one standard answer, it will not conform to real life language. So it is impossible that the courseware to provide interaction functions for the learners. The TTS technology solves this problem in computer-based language teaching.

This paper designed a computer-based English exercise system using TTS. This system takes the advantage of computer multimedia, specially the vividness and interaction of computer multimedia for overcoming the shortcoming of the traditional teaching, at the same time this system also can overcome the shortcoming of the usual computer-based language exercise systems that are unable to pronounce the learner's input answer. Therefore this system has the ability for the learner to feel the different pronunciation between the different sentences.

The system is effective because a learner must see the picture using his eyes, and think of the answer using his head, then type the answer using his hand, pronounce the answer using his mouth at last. All of above may bring the learner's enthusiasm, enhance the study effect.

Database design

Designing a database for storing all the picture files path and exercise contents. Furthermore, all the learner's information is stored in the database.
Most of the language exercise systems use database to store the datum. This paper also selects database to store the picture file path, exercise contents and the learner's information including the study degree of progress. At the same time in order to use the sound files provided by the teachers, the function is set for switching TTS and sound files which means that the fields of question sound file path and answer sound file path are established.

**Word spelling and grammar check**

Providing the functions of word spelling and grammar for the learner to check the input answer by himself in exercise. Because the self-practice is provided for the learners, it is very important to provide the functions for checking word spelling and grammar. This paper uses the check function of word spelling and grammar in Microsoft WORD for providing the reference about word spelling and grammar. This function may not only let the learner understand the possible mistakes, and but also can help the learner to understand the related knowledge, similar to providing a privately owned instructor. Of course, one question can proceed iteratively.

**Checking standard answer**

It will be useful for the learner to understand the study contents by the way of comparing reference answers. Comparing the reference answers will let the learners understand the point contents of the exercise.

**Pronunciation Using TTS**

This paper selects the Microsoft’s Speech API (SAPI) which is well established as the leading platform for adding speech recognition and text to speech capabilities to desktop PC applications. TTS is used to convert the learner's answer into speech. Simultaneously when a question and its answer does not have the sound files, TTS will convert them into speech. This enables the teacher to ask ad hoc some questions in class and let the learners practice them at once.

**Conclusion**

In brief, the union of computer multimedia technology and the traditional teaching method will cause the students to become fully involved. Through studying the scene created by computer multimedia, the study enthusiasm of students is stimulated, the thought angle will be opened up and cause the student's thought quality to take a great leap forward. The stimulation of the student's thought process will incur an avalanche effect and result in a very high role of learning retention.

A Design Method for Multi-Language Support Web-Based Chinese Learning System Using ASP

Ming Yin, Shinichi Fujita, Seinosuke Narita
Narita Laboratory, Graduate School of Science and Engineering of Waseda University, Japan
e-mail: yin@narita.eiec.waseda.ac.jp

Abstract: This paper describes a method for supporting multi-language display in a web-based Chinese learning system created by ASP(ActiveX Server Page). The proposed method uses both databases and ASP dictionary objects to display different language prompts for a learner of Chinese with different mother languages. With multi-language support, the developer of web-based Chinese learning system can avoid massive repeated development. The proposed method based on database and ASP technology provides one extremely good method for realizing the expansion of the web-based language learning system from one language to other languages.

Chinese Learning System Supporting Multi-Languages

When a web-based Chinese learning system is designed, Chinese character must be displayed in all the web-pages. Meanwhile it must be considered that the learner may come from different countries. It means the mother language will be different. For a Japanese, Japanese will be also displayed but for an American, English will be displayed in the same web pages. So it is necessary for a web-based Chinese Learning System to support multi-language display. This question may be considered as using some method to realize fast transformation of the page contents by obtaining the suitable data from a database and then display the data using the ASP dynamic demonstration. All the text and image files of different languages in the web site are stored in the database. All the pages carry a variable to identify which language the site is also to be displayed except Chinese. Based on the language of every learner’s browser, the content is pulled out from the respective tables for the language chosen, and displayed.

Choosing Character Encoding

The first thing is decision of character encoding when designing a web site. For a web site of Chinese learning system, it needs to use two languages on a web page. The web page might include scripts with both Japanese and Chinese string litera ls. In these languages, the web pages may also have static HTML segments and dynamic information acquired from a database. For instance, if Chinese is declared, then the Japanese text will be misinterpreted. So this paper declared UTF-8 which supports many languages as character encoding to format all pages.

Design Text and File Path Database

When the browser language changes, it is hoped that there is no need to modify the ASP pages but only add data to database. For example, if the prompt text in English is "yes", then when the browser language changes to Japanese, the word "yes" will be altered to Japanese word "はい" meaning yes in Japanese. Hopefully, no modification of any ASP pages is needed. Based on above requirement, the database is designed as below.

Two tables are created for saving the prompt text. One table is common strings to save the repetitious words and phrases. Moreover one table is specialized strings to save the words and phrases only used in a specific page. It has advantages that the standard maintenance is simple to store the public text and the specific text separately. The tables use both the field string name and the filed language code as the key filed. The field string name and the filed language code are united to create the main index. The field display string is used to preserve the word, the phrase or the sentence. Only one index is created for all records because all the repetitious input of a word, phrase or sentence must be avoided.

Regarding specialized string table, it needs an extra field for the connection with the common string table. It must be considered that not all data can be stored in the dictionary object, in fact most of them are
retrieved from database when needed. So a special string table is needed to save these data. Only the data in common string table is loaded to the dictionary object because these are not necessary to change frequently.

The fields of the tables are showed as below.

Regarding the picture files, the table can be created with the same step described above to save the file path. Only replace the field display string in the common image table and specialized image table using the file of file name.

**Read Data from Database to Dictionary Object**

The Dictionary object in ASP is a data structure that can contain sets of pairs, where each pair consists of an item, which can be any data type, and a key, which is a unique String value that identifies the item. The values can be extracted from a Dictionary object only simply placing the object.key identifier on the right side of the assignment statement. Such an assignment returns the value of the referenced key. The dictionary object can be set as global action for the entire application scope. Bu it is no need to worry the loss performance.

After the connection to a database is created, the data in database will be received and loaded to the dictionary object. The language code and string name are united together as a dictionary key and the value of field displaystring is set as the key’s value. The result is to put the value of the field display string to the corresponding dictionary data area. Therefore good performance can be obtained, because the lasting database connection is avoided that will influence the performance. In fact, database is only connected one time when application start, after that the ASP page will read the necessary data from the dictionary object.

**Quotation of Text and File Path in ASP Page**

After the data including text and file path are stored to the dictionary object, they can be quoted in the ASP pages. But at first it is needed to know the language of the current user’ browser. It can be obtained the variables of the request object. The text or picture file path saved in the dictionary object may be obtained through the corresponding key value, the key value is composed of the name and the language prefix. According to experience, there is no disadvantage caused by quoting data from the dictionary object instead of the input data directly. This is because the text or the picture file path which is stored in the dictionary object is buffered by the server.

**Example/Discussion**

The proposed method is evaluated using a web based Chinese exam system. This system allows the examiners with different mother languages join the test at same time. When an examiner accesses the system, the web server obtains the language information of browser, then retrieves data from the common string table. For the special string table, the language code, common string name and string name are united as key to retrieve data from the special table. For example, if the language code is en and the common string name is sectionl and the current string name is point1 then the content(word) stored in the special table will be displayed in the web page. So there is no need to modify any place in the web page, it can be used for different mother language examiners.

Certainly, the realization of multi-languages support has more other factors to be considered. When an education system is designed, it is very important that good design is useful both for the user and the developer. In this paper, how to set the isolation between the content the change and the development is explained. This plan may not only regard Chinese learning system, but may be useful for other learning systems. The database and the dictionary object as well as the ASP technology provided one extremely good realizations from one language to other languages in web based learning systems.

Decisions, Decisions, Decisions...how to approach the implementation of a distance learning program.

Description:
The rush to develop online, telecommunicated and hybrid degree and certificate programs has left a trail of failed programs, bankrupted corporations and disillusioned individuals both academically and commercially. Still drawn to the promise of distance education institutions, administrators and faculty alike, are taking a second look and attempting to learn from the successes and failures of others. This panel discussion aims to stimulate thinking in the interest of ensuring that institutions interested in distance education are reminded of what to consider and how to plan for program development and implementation. Three experienced distance learning creators will put it all on the table with lessons learned from the implementation of both online and telecommunicated degree programs.

This panel will present and answer questions covering a broad range of topics from planning within campus wide systems, choosing technology, instructional design and faculty support, intellectual property, marketing and student services. A general outline of what will be covered in each topic area is offered below:

<table>

  - Hardware/ Software Products and Considerations
  - Hard and Softcopy Distribution
Online, A-synchronous Programs – Lesson Learned: Melissa Miszkiewicz

- Planning at the Department Level – Why create an online program?
  - Find your niche
  - Set realistic goals and desired outcomes
  - Consider geography
  - Consider faculty issues:
    - Time
    - Teaching load and other responsibilities
    - Compensation
    - Intellectual property
    - Sharing the burden: teaching courses designed by others
    - Faculty support at the planning level: instructional design, training
    - Faculty support at the course level: teaching assistants

- Planning at the Program level
  - Choosing your platform
  - Identifying resources
  - Technical support
  - Technical requirements
  - Logistics
  - Supporting Documentation and redundancy
  - Instructional design
    - Faculty values
    - Classroom techniques vs. online techniques
      - Instructor presence
      - Learning styles and proof of mastery
      - Structure and time on task
    - Organization
    - Choosing appropriate technology, or choosing not to choose
    - Identifying teaching resources
    - Creating for the future: reusable learning objects
    - Team work
    - Formative evaluation plans: responding to constructive criticism
    - Documents for student support
    - Rules for student participation

Marketing & Student Services – Lessons Learned: Christine Chelus

- Marketing & Recruitment
  - How do I reach my intended audience? - If my targeted audience is 500 miles away, why would they pick up a publication with my institutions name on it?
  - Moving beyond parochial views of OUTREACH.
  - What are your boundaries, how do you fill the gap for other student services offices and faculty members in the recruitment process?
  - How do I disseminate important information quickly when my students are located so far away?

- Specialist or Generalist
  Transferring a call is not an option with Distance Learning students, now that you have your distance-learning students, how will they:
    - avoid fees imposed by due to policies and procedures originally established for on-campus students;
How do you set up relationships with specialists in your institution to accommodate these needs for students at a distance?

- Programs, Certificates and Courses
  - What are the pros and cons of offering full degree programs using distance learning technology for the student and the institution?
  - How do you choose the right program, certificate or course to offer via distance learning technology?

Implementation of distributed learning systems and programs offered through interactive video, on-line Internet based, and residential delivery systems. Guide college utilization of multimedia and emerging technologies, including streaming media and wireless delivery, to provide synchronous and asynchronous learning opportunities. Faculty support and training in distance learning and technology integration into the curriculum.

Accepted Presenter- CIT2001 – The 10th Annual SUNY Conference on Instructional Technologies, presentation – DEVELOPING STREAMING MEDIA IN EDUCATIONAL APPLICATIONS
Presenter and Trainer – ED-MEDIA 2000, Montreal, Quebec, Canada – The World Conference on Educational Multimedia, Hypermedia & Telecommunications - creating on-line media content, presentations, audio, video, and live broadcasts.

Presenter and Trainer ICCE 99, Chiba, Japan - 7th International Conference on Computers in Education, “NEW HUMAN ABILITIES FOR THE NETWORKED SOCIETY”. Adding dynamic, multimedia content to educational website development and distance learning applications.

Presenter and Trainer - ICCE 98, Beijing, China - The Sixth International Conference on Computers in Education. The conference focus, “GLOBAL EDUCATION ON THE NET” served to foster the creation and dissemination of knowledge about the use of information technology in education. Presentations and training sessions on basic and advanced educational website development, electronic curriculum content distribution, and distance education.

Christine Chelus holds a B.S. in Sociology, a M.S. in Student Personnel Administration and is currently A.B.D. in the Department of Communication at the University at Buffalo. Christine was recently selected as the sole recipient of the The Magness Institute’s research grant program for 2002 and will receive funding for her dissertation research regarding educational access to the Internet. Christine also earned her distance learning professional certification from Texas A&M University.

Christine has worked for the State University of New York since 1996 holding numerous positions at Buffalo State College and the University at Buffalo. At Buffalo State, Christine assisted with student recruitment for the Office of Graduate Studies. She also served as program coordinator for the Center for Applied Research in Interactive Technologies. In this role, Christine provided training, marketing, student services and facilitation for over 30 distance learning courses annually.

Upon transferring to the University at Buffalo, Christine served as the primary international education contact for the Center for Applied Technologies in Education and held the positions of Manager of Technology Application Development and Director of New Media Projects. In these roles she served as Project Director for:

- **Buffalo CityNet** - a 20 site interactive video network comprised of educational, government and community agencies. Project coordination included consulting with various community agencies to develop educational programming for the video network.
- **Taking Gombe to the World through Technology** – partnership project between UB and the Jane Goodall Institute to connect their global Roots & Shoots teams through videoconferencing (HOPENet) and to extend Dr. Goodall’s impact on people, animals, and the environment through an interactive educational web-based curriculum (Lessons For Hope) based on her research.
- **Project Loop** – partnership project with CRUSA (Costa Rica – USA Foundation) to use technological resources to provide citizens in geographically isolated areas access to qualified instructors regardless of their socioeconomic status. Provide students in Costa Rica and Western New York the opportunity to interact with people and situations of different cultures.
- **New Media Project** – partnership project with the Office of the Provost, the Graduate School of Education and the College of Arts & Sciences to provide educators in the outlying areas of New York State access to University at Buffalo graduate programs.
Christine has presented and worked with groups on educational technology material regionally, nationally and internationally. In addition to working on site in Costa Rica, Panama, England, and Germany, through videoconferencing technology, she has worked with educators around the world including Mexico, Tanzania, South Africa, Columbia, Guatemala, Argentina, France, and Japan.

Currently, Christine serves on the following committees: New York State Evaluating Technology in Education Team, New York State Distance Learning Consortium, Western New York Distance Learning Consortium, Western New York Higher Education Distance Learning Consortium, and the Blackboard Advisory Committee.

Melissa J. Miszkiewicz holds a B.S. in English Literature from the University at Buffalo and an M.S. in Curriculum Development and Instructional Technology from the University at Albany. She is a member of several educational associations including the Association for the Advancement of Computing in Education (AACE), the Association for Educational Communications and Technology (AECT) and the American Dental Educators Association where she participates in special interest groups in Academic Affairs and Informatics.

Melissa has worked for the State University of New York since 1991 in various roles, beginning her career in higher education at Empire State College where she successfully started up operations for the college’s Workforce Development wing in the Western region of New York State. There she facilitated all aspects of new program development and delivery including conceptualization, proposal development, contract negotiation, staffing, and maintenance.

Melissa moved to the University at Buffalo to start up the online MBA program in the University’s School of Management. As director of the online MBA program Melissa collaborated with all areas of the university to uncover and develop faculty resources, rework University systems and policies to accommodate the new program, develop inter-department partnerships, and to develop a policy on intellectual property and course ownership. In this position Melissa successfully selected technologies, developed strategies for instructional design, and a five-stage plan for formative evaluation culminating in the development of six complete online courses. Formative evaluation and testing took place overseas with the school's international programs in Singapore, and on campus with traditional MBA students. Two courses were delivered to students in the fall of 2001 with great success.

Melissa has recently accepted a position with the School of Dental Medicine as Director of Academic Services. In this position she has been asked to develop the school's electronic curriculum by integrating appropriate tools and technologies, applying appropriate methods of evaluation, and working directly with faculty on pedagogical issues. The University at Buffalo School of Dental Medicine is one of five Dental School’s across the nation to have adopted an electronic curriculum and one of two to first implement the curriculum.

In addition to her formal duties in the School of Dental Medicine, Melissa is currently a consultant to the University at Buffalo School of Nursing for the development of an Acute Care Nurse Practitioner program that will be delivered online. She has also presented and worked with groups on educational technology and, while with the School of Management, routinely met and provided guidance to academic and technical officials from China, Russia, Brazil, the World Trade Centers Association and the Singapore Institute of Management.
The impact of “communicative effectiveness” of computers in use of computers for communication

Ananda Mitra, Ph.D.
Wake Forest University
Department of Communication
Winston-Salem, NC 27109
ananda@wfu.edu

Abstract: This paper uses the data from a longitudinal study to demonstrate that the perceptions of the communicative effectiveness of a computer system has a significant impact on the desire to use computer for communication. The results suggest that it is important to attend to the perceptions when introducing the use of computers for pedagogic communication.

Introduction

One of the key questions that have been raised about the increasing use of computers and digital technology in the educational setting is the way in which students tend to use the computer when they are provided with ubiquitous computing opportunities (see, e.g., Mitra and Hullett, 1997). Studies in the past have demonstrated that usage does vary with different demographic categories just as the very definition of usage remains a contested construct. Indeed, over the time that computers have entered the pedagogic arena, the idea of usage has become increasingly complex as the term “computer use” has become multidimensional. Past research has demonstrated that the computer usage can be considered from various perspectives such as those of use for specific pedagogic tasks to those of communication (Oblinger and Rush, 1997).

There is a growing body of literature that would suggest that the computer has taken on a very critical role as a tool for communication as the digital technologies of electronic mail, instant messaging and the Internet in general have opened up opportunities of enhanced communication options between students, teachers and institutions (Mitra and Hazen, 1999). There has also been a body of literature that has suggested that computer use could be determined, in part, by specific attributes of users and user groups who share certain attitudinal and demographic similarities. This relationship is particularly important to explore because, as a corollary, it suggests that knowing certain characteristics of the user, it might be possible to predict the usage patterns of an individual or group (Woodrow, 1994).

Such studies on profiling of users have typically used two different metrics. On one hand, users have been classified on the basis of demographic characteristics, such as those of age and gender. Past studies have sometimes indicated that men and women have different patterns of computer use (Mitra, et al., 2000a). Similarly, studies on age categories within a general population of computer users have demonstrated that usage trends could be determined by the age of the user (Honey, et. al., 2000). A second relational criteria that has been mobilized to understand and predict usage deals with attitudes of the users. Personal opinions towards computers and computing have known to have an influence on the way in computers are used. In many studies it has been demonstrated that those with a positive attitude towards computing can have a more positive use valence as well (Mitra and Stefensmeier, 2000; Mitra et. al., 1999).

As suggested earlier, there are several different ways to measure attitudes towards computers. It has recently been suggested that there are several different ways in which different attributes of attitudes can be measured and one of those attributes could be the perceptions of the communicative effectiveness of computers (Mitra, 2001). Given the relationship between attitudes towards computers and the use of computers, it can be speculated that those with a positive attitude towards the communicative effectiveness of computers would possibly use the computers for communication purposes as well. In this paper the communicative effectiveness factor is used as the independent variable to test whether differences in the attitude level actually reflect statistically significant differences in the communicative use of computers as well.
Methodology and Data

This paper utilizes the data from a longitudinal study to assess the impact of technology introduction in liberal arts education at a non-technical small private university in the United States. The data was collected over four academic years and this post hoc analysis uses the data collected in the spring of 1999 from a sample of students who responded to a questionnaire mailed to them. The questionnaire was developed by conducting a series of focus group meetings that explored the various technology-related issues that the students were facing with the universal and standardized introduction of technology in teaching. The questionnaire included nearly fifty attitude items measured on a five-point Lickert-type scale. Of these fifty, there were several items that were specific to the local conditions of the university. The relevant items from the questionnaire have been selected to measure attitude and usage.

Instrumentation

The items used to measure communicative effectiveness is based upon four questions that have been found to be reliable measurements of this particular attitude. The measurement of use level is based upon self-reported frequency of use of the computer for specific tasks. Using the work of Mitra (2001), the attitude item is measured on a five-point Lickert-type scale while the use level is measured on a four-point interval scale as well. The items used to measure attitude and usage have all been tested previously to demonstrate that they are reliable measures of the constructs.

The specific items used to measure communicative effectiveness included:

- Computers are effective for communicating with other students about class related work
- Computers are effective for communicating with faculty about class related work
- Computers are effective for communicating with other students about non-course related subjects
- Computers are effective for communicating with faculty about non-course related topics

Thus communicative effectiveness includes attributes that focus primarily on the role of the computer in the pragmatic act of communicating. It can be argued that a change in the perception of the effectiveness of the computer in facilitating communication could have an impact on the use of computers for communication and eventual learning outcomes.

The specific items used to measure the use of computers for communication included questions about the frequency of use of:

- Use the Internet to get information
- Electronic mail with teachers
- Electronic mail with friends
- Electronic mail with family
- Electronic mail with classmates
- Electronic mail with students organizations

All of these items test the way in which the computer can become an effective tool for communicating with a variety of groups that a student can be involved with in the academic setting.

Analysis and Results

As a first step the attitude items were summed to create an overall communicative effectiveness measure. The item was then dichotomized into a high and low level creating to nearly similar sized groups. Tests of difference in mean level of use was then conducted between the groups using an independent sample t-test at a level of p<0.05 to identify if there were significant differences in mean usage for the low and high attitude groups. The results are presented in Table 1.
Table 1: Computer use level based on High and Low scores for Communicative Effectiveness Scale

The next part of the analysis explored the way in which the respondents self-reported their perception of the effectiveness of computer-mediated communication (CMC) for task and non-task related contexts. The results for the two groups are presented in Table 2.

Discussion

First, the data suggests that those who feel that computers do play a role in enhancing their communicative effectiveness tend to use the computer more for communication as well. Furthermore, the analysis also suggested that the primary contributor to the higher communicative use was the perception and other possible determinants such as demographic attributes did not produce statistically significant differences. Consequently, it is safe to suggest that it is important to be able to reliably measure the attitudes of the users towards the communicative effectiveness of the computer. Indeed, knowing the range of the perceptions can help to determine the way in which the computer could be used by a group of students and predicting that use can have a significant impact in policy decisions about the way in which computer networks are designed and maintained on college campuses. This becomes particularly true in view of the way in which band width availability has become an issue on college campuses as students are using the computer more for non-task related CMC (see, e.g., Carlson, 2001). As the data suggests here, a positive predisposition towards the communicative effectiveness can result in a statistically significant higher level of use of the computer.

Secondly, the findings from this study also underscore the importance of measuring the perceptions of the communicative effectiveness of the computer. Although there are different perceptions factors that can be measured with respect to the computer, none of the other factor identified by Mitra (2001) were significant in distinguishing between the different levels of computer use. While the data suggests that there are significant differences, it is really the communicative effectiveness factor that emerges as the critical one. Thus, when considering the measurement of attitudes of students towards computers, it is necessary and essential to evaluate the differences in this factor since those differences can have far reaching usage and effectiveness consequences both for task and non-task activities.

Finally, the importance of the communicative effectiveness should come as no surprise as computers are increasingly being introduced in the pedagogic space. It has been the case that the introduction of the computer in the teaching environment has transformed the process of teaching and learning in so far as that the pedagogic process has become a more dialogic process where the different participants in the teaching and learning process are engaging in the acts of communication. In a way the different players in the pedagogic space have now found their own voices and the traditional relations of power and authority, often predicated upon who was able to communicate with whom, are being dismantled. Those students who are quicker to realize that a shift is occurring in the way teaching and learning is being played out with the help of computers are perhaps also the ones who have a positive attitude towards the communicative effectiveness of the computer. Eventually these students with the more
positive attitude would be more likely to use the computer more for communicating with the various groups they have to interact with in the learning process.

To some degree the positive attitude could also be related to the issues of communication apprehension that have been researched with respect to the use of CMC (Sproull and Kiesler, 1992; Walther 1992, 1994, 1996). Work on interpersonal communication, communication apprehension and the opportunities provided by the use of CMC in teaching has demonstrated that, first, more voices can be heard during the teaching and learning process. The increasing number of voices in the pedagogic space, as the positively predisposed students increasingly use the communicative functions of the computer can have implications on the process of teaching and the organization of the teaching institution. For instance, using a tool such as electronic mail to communicate with the instructor is often accompanied by an increasing burden on the teacher to attend to and respond to all the electronic letters that arrive with missives and from the students who are often the quiet ones in the classroom (Mitra, et. al., 2000b). As the findings from this data suggest, there can be an anticipation that there will be increasing use of electronic mail to communicate with teachers and it is in the interest of the teachers and the educational institution to be able to reliably measure the various attitudes of the students with respect to the use of computers in teaching.

In summary, this data and finding from earlier studies all suggest that there is a need to measure attitudes towards computers. Such measurements can offer insights into the way in which computers can eventually be used in teaching. Furthermore, the findings from such measurements can offer ways to predict and anticipate what the usage patterns could be. Finally, the usage patterns can have an impact on the learning outcomes related to the use of computers in teaching. The data here suggests that among all the different attitude factors that can be measured, one of the most important ones is the attitude towards the communicative effectiveness of computers in teaching. To be sure, the value of this measurement is not only empirically evident but can be ontologically supported given the fact that good pedagogy ultimately remains a dialogic and discursive process.

Adaptive Web-based Learning System with Free-Hyperlink Environment

Hiroyuki Mitsuhara
Information Science and Systems Engineering, Graduate School of Engineering, Tokushima University, Japan
E-mail: mituhara@is.tokushima-u.ac.jp

Youji Ochi and Yorico Yano
Dept. of Information Science and Intelligent Systems, Faculty of Engineering, Tokushima University, Japan
E-mail: {ochi, yano}@is.tokushima-u.ac.jp

Abstract: A typical learning method using the Internet is exploratory learning, where learners frequently reach a learning impasse caused by insufficient hyperlinks. In this paper, we propose an environment that supports open-ended web-based exploratory learning. This environment avoids the impasse by enabling learners to create hyperlinks in the open web and share the hyperlinks. Furthermore, the hyperlinks have been adapted with collaborative filtering.

Introduction

Rapid spread of the Internet enables us to learn with informative web pages that exist all over the world. A typical learning method using the Internet is exploratory learning, where learners construct knowledge through exploring the web autonomously. However, the learners frequently reach a learning impasse caused by insufficient hyperlinks. If a page is not complete with sufficient hyperlinks to fulfill their goal or interest, the learners cannot visit the next page smoothly. Thus insufficient hyperlinks lead the learners to the impasse.

Search engines, which can supply suitable hyperlinks (pages), help escape from the impasse but occasionally return meaningless hyperlinks. Adaptive web-based learning systems, which alter the hypertext contents/structure to learners' characteristics, can avoid the impasse. The existent adaptive web-based learning systems do not present sufficient hyperlinks to fulfill learners' expectation. Almost all such systems limit the adaptation to the closed web (i.e. web pages inside one server), since teachers can hardly describe information indexes and adaptation rules to the open web (i.e. arbitrary web pages). Recently, this limitation has become a major focus in the domain of adaptive hypermedia (Brusilovsky, 2001).

In this paper, we propose an environment that supports open-ended web-based exploratory learning. This environment avoids the impasse by enabling learners to create hyperlinks in the open web and share the hyperlinks. Furthermore the hyperlinks are adapted with collaborative filtering. The prototype system with this environment, which is MITS (Multi-hyperlink Tailoring System), is currently under construction.

Free-Hyperlink Environment

The key idea for avoiding the impasse is a free-hyperlink environment, where learners can create hyperlinks (i.e. free-hyperlinks) in the open web and share the hyperlinks. The free-hyperlink environment will organize scattered pages and consequently form large-scale teaching material with many sufficient hyperlinks, which avoids the impasse. In other words, numerous learners substitute for the teachers who have to complete sufficient hyperlinks.

When reaching the impasse, learners usually try to find suitable pages by using search engines. Taking this process into account, a search engine has been integrated into the process of the free-hyperlink creation. Although this integration is time-consuming, the time will be minimized eventually since the free-hyperlinks can be shared. The free-hyperlinks are created in the following process.

1) Search Query Input: Learners pick a word(s) as the query and send the word to an existing search engine.
2) Search Output Receipt: They receive the search output modified by MITS.
3) Visit and Free-Hyperlink Creation: By their selecting a page, the page and a comment window are displayed. If considering the page to be informative, they input comments on the page (e.g. "This page has useful diagrams"). Immediately after inputting the comments, the free-hyperlink between the word and the page is created.
InternetCop is a comprehensive software for managing and monitoring Internet connection of any type (Dialup TCP/IP, ISDN, ADSL, Cable modem, or Ethernet connection) among several computers in a network. It allows organizations to integrate management of various security functions and protection facilities.

Advantages:
- Maximum utilization of the existing hardware.
- Distribution of Internet time to a number of persons over a small or large area.
- Logs individual user data.

Features

Server
- Creation, Modify
- Shared Time

Client
- View
- Login Time

Original Page

Figure 1. Free-hyperlinks

Figure 1 shows a snapshot of the free-hyperlinks. The free-hyperlinks are highlighted with a star-shaped icon in order that learners can distinguish the free-hyperlinks from original hyperlinks. By clicking on a free-hyperlink, a pop-up box containing the information about the free-hyperlink is immediately displayed. The information consists of page title, URL, free-hyperlink creator's e-mail address, creation date, and comments. The learners select the next suitable page, referring to the information.

Collaborative Filtering in MITS

It is apparent that the increase of the free-hyperlinks causes option overflow. To improve this problem, collaborative filtering is used, which is a technique for recommending items estimated to be suitable by similar learners (Resnick et al, 1994). To calculate the similarity between learners, we assume that the learners who made the free-hyperlink of the same word have similar interest. MITS counts the number of free-hyperlink of the same word. It calculates the similarity by means of Pearson's correlation coefficient (r), and shows the free-hyperlinks of five learners with high similarity (r>0). This is the adaptation in MITS, which strikes a proper balance between enriching information and eliminating redundancy.

Conclusion

A free-hyperlink environment avoids the learning impasse caused by insufficient hyperlinks. Specifically, it enables learners to create hyperlinks in the open web and share the hyperlinks, which are adapted on the basis of the learners' interest using collaborative filtering. However there are some problems with the MITS prototype. One is a failure to modify original web pages. For example, JavaScript embedded by MITS contends with JavaScript in the original web page. Currently, this study is trying to improve the problem and prepare an experiment for evaluation.

Abstract: This paper examines the use of the Web to support continuing professional development (CPD). It outlines the factors driving the adoption of CPD and highlights areas where the Web can aid in the development of successful professional communities. A survey examining the use of the Internet to support professionals working in the domains of the Arts and Science is presented. The study reviews twenty-four sites for the presence and degree of adoption of several key features including: - community building, range and value of content, user friendliness and guidance, sophistication of employed Web technology.

1. Introduction

The use of the Internet and the World Wide Web is growing, and the number of applications where it is employed to support, or even to replace, many traditional activities associated with work and recreation continues to expand. Such new technology means that the nature of the jobs we do has changed, as has the professions in which we work and the skills required. Life-long learning has never assumed greater importance than it does today, allowing us to remain competent and achieve personal satisfaction and job fulfilment, throughout our careers. From an employer’s viewpoint, lifelong learning contributes to competitive advantage through excellence of employees. At a national level, it allows us to remain competitive in a world participating in free trade and experiencing rapid changes through technology.

In this setting it is not surprising that many professional communities have turned to the Internet to augment or replace continuing professional development (CPD) support. Traditional approaches to professional development rely on a mixture of activities including conferences, meetings, scholarly reading, newsletters and short courses. However, no matter how excellent any of these activities prove to be, they are of little value if they are not accessible to those who need them most, when they need them. While many will argue that the Web cannot provide all the things that come with more 'traditional' approaches, Web technology can provide flexible support to professional communities, especially under circumstances where the community members are geographically dispersed and are subject to time constraints.

The level of support will vary between communities, depending on the subject requirements, the technical sophistication of providers and audience, as well as resources available for the upkeep of the support mechanism itself. Resources available on websites supporting professional communities can range from links to other informative sites, to provision of original content, to full-blown community facilities including online discussion forums. In the latter case, the professional community can support itself via a 'Web community'.

Significantly, the use of new technology does not guarantee success in encouraging and supporting CPD. Any successful Web community must be built upon solid foundations. "Web communities need 'social scaffolding' to grow and thrive. Social scaffolding refers to those aspects of a site - roles, rituals, features, events, and leadership - that facilitate community development. Much like a trellis enables a plant to grow, social scaffolding enables members to become progressively more involved in the community" (Kim, 1998). Simply launching a website with a bulletin board and chat facilities does not automatically generate a community (Mager and Karlenzig, 2001). There are numerous examples of quickly launched message boards with many topics but no responses. Creating gathering places alone is not enough - they need to be organised and integrated into the community. The central issues surrounding communities are people issues - Web technology merely acts as a facilitator, providing the tools for helping people come together (Cothrel and Williams, 1999).

This paper begins by outlining the factors driving and inhibiting the formation of Web communities to support professional development. It then goes on to survey two disparate professional groups, in the Arts and in Science/Technology, and attempts to gauge their level of adoption of Web technology in their professional development activities. Twenty-four sites are examined, twelve in each group, and a number of measures, ranging from 'level of adoption of community interaction' to 'technical sophistication', are considered.
2. Continuing Professional Development and the Web

Getting people to 'buy into' continuing professional development can often prove difficult. Individuals often need to be reminded that they have a career - not just a job (Arnold and Smith, 1998). In order to be truly effective, individuals need to take ownership of their approach to personal development and life long learning. The Web enhances this process by allowing individuals to extend their professional interaction, seeking out and exchanging new ideas and opinions, beyond the boundaries of the organisation in which they work. Web technology can be used to complement existing forms of learning and development, delivering CPD to a widely diverse and dispersed audience. Individuals may get less benefit from face-to-face conferences as conference size increases. The Web can mitigate these effects by enabling users to take a more 'personal' approach to professional development, so that individuals can tailor a developmental programme to their own requirements. "Every learner can, at his or her own choice of time and place, access a world of multimedia material... immediately the learner is unlocked from the shackles of fixed and rigid schedules, from physical limitations... and is released into an information world which reacts to his or her own pace of learning" (Benjamin, 1994, p49). While the use of Web technology does mean that individuals can work at their own pace, there still needs to be a forum for obtaining feedback on their progress. Further, there are some subjects, requiring more nuance or hands-on involvement, which may prove more difficult to translate to an online environment (Stuart, 1999).

Professional development can be substantially enhanced by opportunities to collaborate with others within Web communities (Hixson and Tinzmann, 1990). The opportunity to take advantage of the expertise of others can provide community members with important reinforcement and incentive for continuing growth and development, along with enhanced personal status and respect that comes from membership in a learning community with their professional colleagues. The asynchronous nature of much of the communication that takes place online lends itself to CPD and supports synthesis of knowledge (Salmon, 2000). Individuals have 24-hour access to the system and can log on whenever they wish and for however long they wish. Users are able to reflect on issues raised online, and their own ideas and thoughts can germinate through composing replies. CPD is an ongoing process and as such, the use of Web technology to aid this process is not a one-shot event. Traditionally, individuals within an organisation would take one or two weeks off from their daily grind to go on a training course. The use of Web technology enables professional development to be a constant continuing process. However, technology is no panacea for professional development. In order to be truly effective, the use of technology must be linked to the objectives and goals of any professional development programme, and must deliver real value to the community.

3. Web Communities

The use of the Internet to develop Web communities has meant that localised communities can now have a more global outlook. "The Net erases boundaries created by time and distance, and makes it dramatically easier for people to maintain connections, deepen relationships, and meet like-minded souls that they would never have met" (Kim, 2000, p.x). In order to be successful and deliver true value to the users, the aims of the community must be clear and the first step to building a loyal community of members is to understand the purpose of the community (Kim, 1998). Web communities grow and thrive when members are able to fulfil their purpose and accomplish those goals that require other members to participate. The concept of collaborative purpose is one of the Web's premier strengths as a means of building community (Real Communities Inc, 2000). There are a number of features that aid the development of an online community (Kim, 2000). These include: -

**Backstory:** The community's backstory provides a powerful tool in shaping members' expectations about the purpose and personality of the site (Kim, 1998). The term backstory comes from filmmaking and refers to the part of the movie's story that has happened before the first frame of the film. Backstories introduce the community founders, communicate their motivation, and impact a sense of the community's core values.

**Site Map:** The site map gives an overall picture of the community space and may include links to each section of the community. Site maps should be updated as sites evolve and sections of the community are added.

**Feedback:** Through implementation and maintenance of feedback loops, communities evolve over time and may react to the requirements of its members. Regular surveys will help gauge the community opinions and re-enforce a sense of shared purpose.

**Database:** A member database system is crucial for creating and maintaining member profiles that evolve over time. This database can be used to control access to Web pages, mailing lists, chat rooms, conference areas and member profiles. Many communities also allow members to develop their own home pages, thus helping each member develop...
their sense of belonging to the community (White, 2001).

**Frequently Asked Questions:** These address the needs and questions of newcomers without alienating established members. FAQs serve a key role in breaking down initial barriers for new users and making them feel more at ease with the technology and the community environment itself.

**Communication Technology:** Communication is at the heart of online communities. The technologies employed can be public (interactions between several people) or private (one-to-one interactions); synchronous (messages are exchanged in real time) or asynchronous (messages are accumulated and users need not be online simultaneously). All communities need a mixture of public and private meeting places and it can often prove difficult to identify a single space where the Web community 'lives'. This is a result of the range of tools adopted by members (Cothrel and Williams, 1999). The most commonly used tools include: - **Electronic Mail:** The use of e-mail is widespread and as such, it is an extremely powerful communication medium that may be used to hold a community together. E-mail distribution lists may be used for making announcements and for encouraging communication between users. A community newsletter can serve a key role in keeping members up to date with key events or issues that may arise within the community. E-mail can also be used to encourage feedback and suggestion from community members. Poling (1994) found that the use of e-mail enhanced the quality of communication within groups and ultimately aided group cohesion: - **Mailing Lists and Bulletin Board:** Community mailing lists can facilitate conference-style interaction between community members. However mailing lists do not create the same sense of gathering in a location with fellow community members that conference-style interaction can provide (Steuer, 1998): - **Chat:** Real-time chat is a frequently misused community technology (Steuer, 1998). Nothing discourages users more than an empty chat room, or an interactive event that has very little or zero interaction between users. However when utilised correctly, real-time chat can be a very effective communication medium.

4. **A Survey of Arts and Science Websites**

Our investigation of Web-based support for professional development focussed on two broad subject areas, viz., Arts/Humanities and Science/Technology. Twenty four websites were chosen at random - twelve from the Arts domain and twelve from the Science domain (see Table A). The aim of this survey was to gauge the degree and nature of support afforded by these subject-oriented sites. To this end, a feature list was formulated (see Table B) to map the characteristics across the sample sites. The features in question span three broad categories: Usability, Resources, and Community Interaction; with each sample site examined for the presence/absence of these features.

required in order to contribute to site

Table B: Features

Scoring of Features: Having surveyed the presence of various features for supporting communities online, a deeper analysis of each feature sought to gauge the range and depth of material on each site, estimate site reliability, and assess site appearance. The appearance and overall feel of the site is considered significant since this is likely to influence the return of users to a site. Each of the feature categories was examined in detail to afford a further dimension of ranking for our twenty four websites.

As a basis for ‘ranking’, each site was awarded up to 4 points for features in each category. Points are awarded on a qualitative basis, dependant upon areas where there are discernable differences between the features present on each individual site. In cases where a site had none of the features examined in a particular category, the site was assigned zero points for that category. For example, a site that does not have any of the Community Interaction features would be awarded zero points in that particular category.

Technological Features: This final measure gauges the sophistication of the technology used on the website. The technological features present on a site do not necessarily yield better results in terms of supporting a professional community. Four simple to detect measures were used to estimate the ‘sophistication’ of each site. Namely, the presence and use of HTML, different Data Types, use of Scripting, and use of Server-Side Scripting. HTML examines the sophistication of the HTML code employed on the site (see Table C).

<table>
<thead>
<tr>
<th>HTML</th>
<th>Raw HTML code, Image maps, Frames, Cascaded Style Sheets, Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Types</td>
<td>Adobe Acrobat files, Windows Media files, Word documents, PowerPoint presentations, Zip files, Flash, Rich Text Format files</td>
</tr>
<tr>
<td>Scripting</td>
<td>Instances of scripting, Number of functions, Size of functions, Number of times function called</td>
</tr>
<tr>
<td>Server-Side Scripting</td>
<td>Use of GET method in forms, Use of POST method in forms, Use of cookies, Site adding information to their database</td>
</tr>
</tbody>
</table>

The source code for pages from each of the twenty four sites was analysed across each of the four categories to gauge the level of complexity and technical sophistication of the code. In a similar manner to the Scoring of Features section, the categories were assessed in order to arrive at a site ranking that was based on those areas where there are discernable differences between the websites, with 3 points being awarded to the most sophisticated site in each category.

Results and Analysis

Almost predictably, study of the twenty four sample sites has highlighted the fact that Science sites score higher than Arts sites in every respect. This may be explained by the quicker uptake of technology in science-based subject areas, and the greater experience of those maintaining these sites.

Presence of Features

When analyzing the Presence of Features on each of the twenty four sample sites, Science sites consistently score higher across each of the three categories examined. However it is interesting to note that Arts and Science subjects can actually be found to be progressing entirely in parallel. Science sites may be a step ahead all of the time, but nonetheless it holds true throughout that where Science sites score highly in categories such as Resources and Usability, so do Arts sites. Similarly, in the Community Interaction category where Science sites gain lower scores, Arts sites also gain lower scores. It could perhaps be argued that Arts sites are following in the footsteps of Science sites (see Figure A).
If there is one thing that the results do not seem to imply, it is that Arts websites are good at providing one particular thing and Science websites at providing another. Essentially, the experiences of both communities are very similar. However, Arts sites do appear to cater more to the novice Internet user, with 50% of the Arts sites sampled offering elementary navigation instructions to users. Conversely, Science sites appear to assume a higher level of technological proficiency from those accessing their sites, with only 16% offering any form of help to users in navigating between pages.

Both Arts and Science communities have potential to improve the level of community interaction. Neither area has fully embraced the use of communication technology to enhance the level of interaction between community members. The reasons behind this could be varied. Maybe current implementation of these technologies is still relatively new and fragile. Perhaps many existing tools do not mirror well ‘real life interactions’. Maybe the communities see no benefit from these forms of interaction.

**Scoring of Features**

Science sites appear to score higher across all of the categories examined. Similar to the results in the previous section, both groups of sites appear to be progressing in parallel, with Science sites scoring higher in each category (see Figure B). Both sets of sites scored highly when considering the Usability of the sites. Equally, both Arts and Science sites show less evidence of Community Interaction. This concurs with the findings of the previous section, where the majority of sites in each category are not fully making use of communication technology as a means of building community and developing a level of community interaction.

The difference between the scores of Arts and Science sites is greater in the Resources category. Across the sites surveyed, it is interesting to note that Science sites tend to have a greater range and depth of material, while Arts sites tend to rely more on providing links to material of interest.

**Technological Sophistication**

Again Science sites scored more strongly across all categories (see Figure C). This perhaps indicates a quicker uptake of technology or greater experience from those maintaining Science sites. Alternatively, Arts sites may have felt that this level of technological sophistication was not necessary.
Once more, there appears to be a degree of parallel progression between the two sets of sites: Arts sites score highly (though not quite as highly) in the same categories where Science sites achieve high scores. This holds true especially in the HTML and Data Types categories, where Science sites show only marginally greater sophistication than Arts sites. The only anomaly is the category of Scripting, which achieved the third highest ranking in Science, but comes fourth in the Arts. Interestingly, this category also shows the highest divergence between Arts and Science sites, with a difference of almost 10 points.

The main difference between Arts and Science sites appears in the Scripting and Server-Side Scripting categories, where Science sites score substantially higher than their Arts counterparts. There is certainly more complex processing around any areas of interaction on Science sites, and this may be the result of the maintainers of Science sites being more comfortable with using complex technological features.

5. Concluding Comments

The use of Web technology for professional development is perceived as being useful and is currently being employed by a wide spectrum of professional communities. The resources and features available on-line can range from lists of useful links, to the provision of original content, to full-blown community facilities including online discussion forums.

Our survey of websites providing support in the Arts and Science domains has found that overall there is more correspondence than divergence. An analysis of site features shows little difference between the two domains. The most interesting point to come out of this analysis is the relative lack of community interaction facilities on sites in both domains. There may be several reasons for this. Possibilities include a lack of perceived need and/or local administrative or technological constraints. This is an appropriate area for further study.

One of the few elements to show marked differences between sites in the two domains was the presence or absence of elementary navigation instructions. Arts sites are more supportive here, perhaps because their user base is assumed to be less proficient in the use of websites in general. Another marked difference emerges within the technological features, where Scripting is clearly employed more with sites supporting the Science community. This may be the result of the maintainers of Science sites being more comfortable with using complex technological features. Ultimately, however, the examination of the sites shows that, barring the exceptions mentioned above, differences between Arts and Science websites are ones of degree rather than kind.

Abstract

The paper describes the experience of the Faculty of Economics at the University of Trento, Italy, in delivering online courses through the Web. The faculty chose to design and build its own system from scratch rather than buy one off the shelf. We discuss the considerations informing this decision, and present the main functionalities of the system, which was built with a server-side approach. There are asynchronous functions provided, such as the ability for the teacher to upload educational materials and for the student to download these materials through the Web. Some interesting synchronous functions built into the system include the teacher-student chat forum and the low-cost videoconferencing tool where a single student can interact with the teacher who is available on-line at the same time. Everything is integrated in a unique, browser-based system accessible from everywhere. We also describe some important administrative functions of the system.

1. Introduction

Web-based instruction has become a convenient education medium [Aggarwal 2000]: course offerings using web-based instruction are very common in universities [Teare et al, 1999], even if the opportunities for and means of student-teacher interaction can vary with the programme. This paper describes the development of an interactive online teaching system at the University of Trento, and reports the results of the first experiment with course development and delivery in the Faculty of Economics. The faculty has about 3000 students and more than one hundred teachers, some of whom come from other faculties. At present, few teachers have their educational material available online. Some teachers in the Faculty of Economics took the initiative to produce their educational material in electronic format, and created their own personal Web sites with the syllabus of the course, the slides of the lectures, and the information related to practical aspects of the course (room, timetable etc.). However, each of these Web sites had its own design and logic, resulting in a confusing array of links, material, format of lessons, and overall structures that students had to sift through in order to find the desired information. The plea arose from the students for a more uniform presentation of online educational materials and for a standard procedure to access them.

On this basis, in September 2000 the faculty decided to fulfill this request for uniformity. Firstly, we determined which functionalities should be provided and then looked into whether such a system could be found on the market or should be built from scratch. We will briefly discuss this latter issue. At the evaluation stage it was important to investigate the cost of building a system using internal resources. This was because, although there are valid reasons for purchasing an off-the-shelf Course Management System such as TopClass, Lotus Learning Space or WebCT, there are many instances where universities have successfully developed a system by themselves. It was evident that homegrown systems are often more tailored to a university's specific needs. For an analysis of this, see [A'herran 2001] [McMahon et al, 2000]. Courseware management systems are being promoted as a means of simplifying the creation and management of instructional Web sites. There are many studies that compare specific courseware management tools (e.g.[InfoWorld, 1998],[PC Week, 1997]), but it seems that the efficiency and effectiveness of these tools with respect to customized Web-based systems is less easy to measure.

In summary, we decided to build rather than to buy for the following reasons:

- the cost: the systems that manage, distribute and maintain the online learning materials are high-cost systems that also imply secondary costs for adequate hardware and assistance.
- the skills: the faculty has no personnel specifically qualified to work in these environments. Complex systems such as Lotus Learningspace™ or Blackboard™ require personnel specifically dedicated to their management, thus requiring more resources than the faculty can provide.
- the highly specific needs of end-users, in particular the integration with administrative and bureaucratic functions: many of the functionalities that normally relate with the didactic activity of the teacher are closely related with administrative tasks that should be carried out in a specific way and at a specific time, thus constituting a big constraint for packaged systems that have no personalization features or that require a vast amount of adjustments in order to be personalized.
- the time: a prototype was to be ready for the second part of the 2000 academic year (March 2000) with a pilot group of teachers and students, and a beta version of the system was to be available for use by all the teachers and the related students in the first semester of 2001. This schedule was not compatible with our time of implementation of already-built learning environment like the ones cited above.
For all these reasons, we decided to build the system on our own, creating only what we needed. The main objectives of the project were the following:

- to allow the teacher to keep a constant relationship with students, in the different ways that we will explain in the following sections;
- to allow the teacher to distribute educational material to students;
- to keep data for administrative and reporting tasks that must be performed by the teacher and by the secretary of the Faculty.

Some general considerations must be kept in mind to understand the complexity of the relationships among the different entities of the data schema. We have the following constraints:

- A teacher can have multiple courses.
- More than one teacher could teach a course.
- A student can follow multiple courses, and therefore must have access to the different faculty areas of the teachers.
- The educational material must be kept online over a period of some years, in order to let students download the correct material for the year they followed the course, and also to give another possibility to students who have failed to complete their courses within the prescribed time.

A difficult choice, currently under debate in many institutions, regards whether the system should be open to everyone or limited to only registered students, i.e., only regular, fee-paying students. Some teachers believe that the educational material should be freely distributed to everyone in the world, while others prefer that only their students (freely) download the educational material. For the time being the more restrictive vision has been adopted: the students must register with the system by providing their personal data and their faculty registration number. A login and password is released for newly registered students. The same registration procedure is used for the teacher, thus assuring that only the course instructor can load material into the system.

The system is built with several functions, most of which are available to the teacher, a subset is available to the student, and a specific set of functions are devoted to administrative purposes. There are also common functions, though with different privileges: teachers can modify the data while students can only read them. We will now present these functions, distinguishing them by type of user. The main function that the system guarantees is to transfer a file from the teacher's computer to the system, and from the system to the students' computer. By inserting the correct login and password, the teacher can upload the files, categorize them and assign them to the different lessons. The students can work from their home workstations to connect to the system as long as they have a login and password. They can then check for updated information or materials for their courses, and download the relevant materials if desired. The didactic material or administrative information is thus transferred to the student, who can then read, print, or store it as desired. At the moment, the graphic layout of the Web site has not been decided. When all the functionalities of the system have been completed, the designers will look more closely at the "cosmetic" aspects of the site.

2. The Teacher tools

The teacher is the user having access to almost all the functions of the system. After having inserted her own login and password, the teacher chooses the course on which she wants to operate. Courses are also identified by year, so the course entitled "Information Systems" taught in 1999 is found in a different section with respect to the same course taught in 2000, even if it uses the same educational material.

After having chosen the course, the teacher has all the tools at her disposal. All the tools provide the principle functions for managing the material or information, i.e., inserting, updating, deleting and listing. These tools are principally:

- Materials (lecture slides, tests, solutions of tests, notes, graphics, charts, tables etc.) are categorized; the list of types of materials is dynamic.
- A dynamic syllabus, where the educational material can be viewed. The teacher can upload and download material at this location.
- The course programme, timetable and bibliography of related material.
- "Live" links related to the course, dynamically updated by the teacher and directly usable by students.
- Frequently Asked Questions related to the topics covered in the course.
- The diary of the lessons (fig. 1), which differs from the syllabus in that it has a more administrative organization, while the syllabus can also be used to upload/download the materials.
- The newsgroup, up to three for each course: the details are discussed in the next section.
- The list of the students that are registered for the course, with their email address. The teacher can use it as a mailing list to send cumulative or multiple messages to the students on the list; such messages can refer to lesson cancellation, announcement for seminars etc.
- A videoconferencing system (fig. 2), made using a personalized version of the Netmeeting software, integrated inside the browser. When the teacher is online with the videoconferencing system
opened, the students that connect to the videoconferencing page will automatically see a green light indicating that the teacher is available for a live session. The system automatically stores the IP address of the teacher, thereby helping the student and teacher to overcome the technical difficulties of managing a conferencing system via Internet.

Figure 1: The teacher's diary

In the "syllabus" and in the "materials" sections the teacher can upload the material by means of a simple form, just choosing the relevant file from her own hard disk. The system will transfer the file to the server and record the information in the underlying database. In this way, the material is securely transferred to a central station, available for the students to be downloaded. The file is also associated to a specific lesson, thus helping to compile the syllabus. An interesting feature of the uploading process is the possibility of excluding the students from seeing that the file is present on the system. This is very useful in cases where there are multiple teachers on the same course. In fact, the system could be used to create a closed group composed only of teachers and tutors, where some documents are shared only among them and are not visible to the students that enrol for the course. This has been done commonly in courses where tutors and teachers exchanged the test answers before the lesson or test was given.

3. The Student tools
The tools available to the students are the same as those seen by the teacher, although mostly in read-only format. In practice this means that the syllabus can be used only to download material from the server, while the course programme can be viewed but not modified. A specific functionality provided to the student is course enrolment (Fig. 3, item 3). As with any enrolment procedure, the student must choose the courses desired. In this area the student, previously registered with the institution, is presented with the list of the courses offered by the faculty that have online materials, and the student simply chooses the courses she wants. However, the most important feature available that is specifically for students is the “news” section (Fig. 3, item 2).

![Figure 3: The main window of the student](image)

This function is presented to the student when she connects to the system. On the left is the list of courses in which the student is enrolled, while the right part of the window shows a frame with all the documents uploaded since the last time the student logged in. This feature allows the student to go directly to a document presented in the “news” list without having first to choose a course and search for the most recent material. This is particularly useful to the student who cannot be present in the classroom for one or several lessons but who nevertheless wants to keep up with the course.

Another important feature of the system is the newsgroup. The validity of this tool for didactic purposes has been widely analysed and proved. [Collis et al, 1997] [Eastmond 1995] [Hanna 2000] [Horton 2000] [Palloff et al, 1999]. The newsgroup inside the system is related to the course, thus allowing the teacher to have different discussion forums for every course taught. The teacher moderates the newsgroup by acting on the messages in varying ways: recommending a message, deleting messages, voting on messages etc. The messages from the teacher are of a different colour (Fig. 4), this to confirm the different role of the teacher in managing the newsgroup. Each message, both in the summary and in the detailed view, reports the number of times it has been read by other users (Fig. 5, item 1). Students can participate in the forum not only by writing and responding to messages, but also by voting on the messages (Fig. 5, item 2).

![Figure 4: The newsgroup with the different types of messages](image)
This vote is visible to everyone and serves to evaluate the importance of the message for the current topic. The forum has threads, so every reply is associated with the corresponding message. The thread in which the message is involved is always visible to the reader, also when she writes a response. (fig. 5, item 3). All the messages are stored in and appended to text files, not in the database. The files have a preconfigured maximum dimension, so when this dimension is exceeded a new text file is created. This proved to be the most logical choice when taking into account the following facts:

- the number of newsgroups available: there are more than one hundred teachers and courses
- the variable dimension of the messages: in most cases the messages are short (a few hundred characters), but some messages (FAQs, for example) could be very long, so the database fields should be dimensioned accordingly, with a great waste of space.

On these text files an indexing engine makes it possible to use the traditional search and advanced search mechanisms. As mentioned in the discussion of teacher tools, in the student section it is possible to check if the teacher is on-line at that moment via videocamera, and therefore if the teacher is available for interaction in real-time (fig. 3, item 1).

Figure 5: a single message with different options

4. The administrative functions

This area includes several functions, not only related to ICT administration. It also includes functions necessary for the faculty secretary. The first important function is the change of academic year. In September of every year, the course can change teacher/s, title, group of discipline, and most of all students. So, every year in this period a specific function that allows the faculty secretary to redefine the association between the courses and the teachers must be provided. Because of the quantity of information associated with a course, this task requires the provision of several functions that could be fully automated, partially automated or completed manually. These functions are listed as follows:

- A function to transfer automatically all the materials from the previous to the current year, this in case the teacher decides to reuse the material of the previous year. Everything is therefore copied with a new identifier, so the old and the new courses have different identities but the same material.
- A function to selectively transfer materials and other information related to the course from one year to the other. The major problem is represented by the newsgroup, where threads could be in progress and therefore an automatic transfer between the two years could confuse the students on one side, and could be inconsistent with a potentially different course programme on the other. The default option is that the newsgroup remains connected only to its original course, so a new course will have a new newsgroup.
- A function to store previous courses with all the related materials so that students can access to them.

Other more traditional administrative functions are related to the ordinary activity that the secretary carries out during the academic year, especially at the beginning of the year. The main function is the management of the teacher database, with all the administrative information necessary to fulfill bureaucratic obligations. In addition, a function that assigns the teacher to courses is provided; this association is fundamental for the rest of the system, as it is used in every area that grants access to the online material. All the materials, newsgroups, links, students etc. depend on this unique association: teacher-course-academic year.

5. Feedback and future developments

The prototype of CMS we developed has been under a stress test since the second semester of academic year 2000/2001 and will be released in its final version at the end of this experimentation period. The system has
been tested with about 1,600 students and 200 teachers for one year, with a download rate of 1,300 documents per day. We submitted some questionnaires to students, both manually and via e-mail, and collected direct feedback from colleagues. From these responses we can assert that the reaction to the system has been very positive. Our main concern was the teachers with less computer experience, which meant a majority of our faculty. The system has proven very easy and intuitive to use, winning praise from everyone due to its simplicity. We must admit, however, that we made a great effort in this area, in terms of providing direct assistance to teachers, sometimes by using students to help teachers in difficulty. We also received positive comments from the students. In the students' questionnaires we asked for comments on functionality, usefulness, quality of materials and performance of the system. In short, of the approximately 200 questionnaires returned from students, 79% expressed satisfaction with the system. In particular, the contact with the professor and the availability of new material are the most welcome features. Eighty-six percent were satisfied with the quality of the material, although a few underlined the need for open (not read-only) material. The overall usefulness of the system was largely connected to the news section, where the student is notified at every connection of any new material added since his/her last connection. A second positive aspect was the teacher-student contact and the related improvement in the learning process. In this part we received 91% positive feedback, an embarrassing indication that change was definitely needed. The performance of the system was found to be satisfactory for 78% of students, while the rest were not very satisfied. An important point to note is that teachers often don't look at the amount of megabites their materials represent (they use office connections to the Web site) but students using home connection with analogic modems at 56Kbps suffer in this aspect, which should be considered more by teachers when uploading materials. As regards the frequency of use, more that 50% of students used system daily, and the rest from two to four times a week.

In conclusion, we can be very satisfied by our first experiment, though there are some points where the system must be further integrated. One important point of integration is with the student secretary database. In our university the student secretary is an autonomous entity, with its own procedures, database and technology. On one hand this allows single projects to be started without having to depend on the big infrastructure of the student secretary. On the other hand, however, there is a time where the different autonomous systems should be integrated. The simplest example regards the login and password to access the different facilities that the university offers to students, examples being e-mail, access to laboratories, account of the refectory, etc.. At the moment, the uniformity of login and password in the two systems is not guaranteed, it is up to the student to register herself in both systems with the same login and password.

In conclusion, the system presented in this paper is one alternative to Course Management Systems, built with the main target of distributing educational material to students in a uniform way. Some real-time functions have been added to the system and are currently under testing; however we believe that the basic functionalities provided by the system to distribute dynamic information and educational material are the minimum services that should be provided to students. The positive results of the first experiments seem to confirm this assertion.

Abstract: This paper will provide overview of the redesign of two corporate training programs, New Supervisor's Basics and Ethics and Compliance. These two courses are part of an enterprise wide e-learning initiative underway at Harris Corporation; a Melbourne, Florida based international communications and electronics company.

Components of successful repurposing training programs and interactive methodologies incorporated in redesign will be shared with participants. The lessons learned, and challenges encountered will also be included in the presentation. Attendees will have an opportunity to discuss the components of successful programs and uses of interactive methodologies to determine applicability to their own organizations.

Evolution of Corporate Web-Based Training

This paper presents an overview of two separate stand-up (instructor-led) courses that were repurposed into web-based training (WBT). The paper further describes the lessons learned by the Harris Knowledge Network (HKN) team during this ongoing effort. These lessons learned are not restricted to a stand-up/WBT repurposing effort; they are readily applicable to other projects in which an existing educational/training system is modified into a different delivery system.

Corporate Example

An ongoing goal of the HKN team was to create a site that supports employees’ need for training and information while maximizing return on investment with Internet technology and training. Empowering employees with the elements and tools to become independent knowledge workers was also an objective of the Harris team. Preliminary research strongly indicated that although the application of web-based training and other e-learning initiatives would play significantly in the overall organizational learning strategy, they would have to be carefully integrated into the curriculum. Adapting the blending learning methodology for two of the first courses rolled out worked well within this strategy. The initial blended model included a Bulletin Board System (BBS) and collaborative tools. These features will be added incrementally as HKN solidifies its curriculum.

Requirements

An analysis of business requirements and technical environment was performed in order to determine the best overall methodology and design strategy for these courses. The methodology had to account for multiple training and information needs within a large geographically dispersed corporation in an economic manner. A needs
analysis was also conducted to determine the skills and skill levels of the end users. This data identified what were the gaps or "holes" of knowledge. It also gave strong design clues as to which materials should be presented online and which material would be optimally delivered via live instructor.

Business requirements identified were diverse training and information needs, and personnel distributed across several states and countries. Fiscal drivers included the desire to reduce travel and training costs while improving the skills and knowledge of employees. The technological factors taken under consideration included accelerated desktop computer processing speed, improved browser technology, and such features as Java enabled client server interactivity, improved backend database technologies, the ubiquitous availability of commercial internet service providers, and improved access to the bandwidth needed for large file transmission (Wagner, 1999).

After performing a comparative analysis of business and technical requirements, as well as needs analysis of end users, the chosen methodology for both Harris' New Supervisor Training and Ethics and Compliance Courses was a blended design consisting of synchronous and asynchronous learning.

Glossary of Terms

**E-learning**: Covers a wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms, and digital collaboration. It includes the delivery of content via Internet, intranet/extranet (LAN/WAN), audio- and videotape, satellite broadcast, interactive TV, and CD-ROM.

**Blended learning**: Learning events that combine aspects of online and face-to-face instruction

**Asynchronous learning**: Learning in which interaction between teachers and students occurs intermittently with a time delay. Examples are self-paced courses taken via the Internet or CD-ROM, Q&A mentoring, online discussion groups, and email.

**BBS (bulletin board system)**: An online community run on a host computer that users can dial or log into. BBS users can post messages on public discussion boards, send and receive email, chat with other users, and upload and download files. BBSs are text-based and often related to the specific hobbies or interests of their creators

**Business requirements**: Conditions an e-learning solution should meet to align with needs of such stakeholders as content developer, subject matter expert, learner, manager, and training administrator.

**Collaborative tools**: Allow learners to work with others via email, threaded discussions, or chats

**Customer-focused e-learning**: Web-based learning programs targeted at current and prospective customers. By training customers online, companies attract new business and make people more comfortable with e-transactions.

**End user**: The person for whom a technology is designed; the individual who uses a technology for its designated purpose. In e learning, the end user is usually the student

**Enterprise-wide e-learning**: E-learning that is intended for all or most employees within a company. Often part of a strategic change of direction with a very short timeline. Also used to support a core process such as sales.

**Synchronous learning**: A real-time, instructor-led online learning event in which all participants are logged on at the same time and communicate directly with each other. In this virtual classroom setting, the instructor maintains control of the class, with the ability to "call on" participants. In most platforms, students and teachers can use a whiteboard to see work in progress and share knowledge. Interaction may also occur via audio- or videoconferencing, Internet telephony, or two-way live broadcasts.

**Ongoing Endeavor**

The New Supervisor's Basics Course initially piloted in November 2001 and is scheduled for its second session in January 2002. Ethics and Compliance Course is scheduled for initial pilot in February 2002. Also Environmental
Health and Safety WBT is scheduled for its first course pilot in January 2002 and customer focused e-learning courses are currently under development. This corporate training and information site will continue to expand as the portal to various knowledge portals for specific audiences throughout the international company. It follows the strategic plan for continually increasing the breadth and depth of information and training offered via the corporate training portals and knowledge hubs.

Harris Knowledge Network has continued to successfully integrate itself as a corporate tool as technology advances and business factors address employee needs as specialized knowledge workers. Successful deployment and maintenance of a knowledge network depends upon accurately defining organizational business goals, creating a viable learning strategy and on having a clear understanding of requirements and terminology.

Abstract: Previous research on video instruction shows that the learning is enhanced when small groups of users watch and discuss lectures and videos together. Using specialized, high-end videoconference systems, these improved results have been shown to apply even when the users are in different locations. In this paper, we explore two issues in making Digital Library scenarios widely supported at low cost. First, we explore designing of a model system that allows distributed individuals to collectively watch a Digital Library video using shared controls such as play, pause and stop. Second, we explore the impact of four alternative discussion channels on users learning and interaction behavior.

1 Introduction

This paper contains the research plan from the original project proposal. More recent ideas and progress will be periodically made available from the Yano Lab. home page. With rapid changes in technology, what we learn today become obsolete or irrelevant within a short time span. We need to continuously update our skills, and cost-effective support for such lifelong learning is a key challenge facing our education systems. To address this problem, one solution adopted by many universities has been to broadcast classes via TV networks in a Digital Libraries, and strategy Stanford has pursued successfully for over 25 years. However, much work is needed to enable a more advanced utilization of the available information and communications resources. This research focuses on the exploration of issues in develop of digital library environments that facilitate CSCL, CSCW (Computer Supported Collaborative Work) to their specific individuals needs and preferences. The strategy that Stanford has pursed as synchronous model of learning has drawbacks: it often conflicts with users’ work commitments, and the model is not scalable. Even if the class could be broadcast to a million people concurrently, there are few chances that interesting interaction would happen between specialized users and end users in such environment.

The flexibility and scalability can be solved by using Digital Library video, videoconference streaming technologies and the Internet to create an on-demand, anytime, anywhere learning model. However, research shows that learning can suffer when users watch videos individually. This concern is identified and addressed in a classic study reported in Science by Gibbons et al. (1997). As a solution, they propose the tutored video instruction model, wherein remote users watch videos in small groups with a discussion facilitator. As they watch the video, they periodically pause and discuss it. The study shows that the tutored video instruction users outperform users who attend the live class in the classroom, as well as users who watched classes live from remote locations and users who watched classes video individually. The advantage of tutored video instruction over classroom attendance was replicated at the University of Massachusetts where some users groups met without tutors (Stone, 1990). The advantage of tutored video instruction was also found by Smith, Sipusic, and colleagues (Sipusic, 1999, Smith 1999). In addition, they tested and extension of tutored video

1 http://www-yano.is.tokushima-u.ac.jp
instruction called distributed tutored video instruction, which does not require users to meet in the same room. The researchers had groups of up to seven users watch and discuss pre-recorded lectures from multiple locations. In addition to the lecture video, users were connected with a high-quality, low-latency audio and video connection. In experiments involving six university courses and several hundred users, course grades of distributed tutored video instruction and tutored video instruction users were better that those of users who attended the live lectures and were indistinguishable from one another. The success of distributed tutored video instruction and tutored video instruction is attributed to the collaboration and discussion that occurs among the users watching the video.

Distributed tutored video instruction is clearly a desirable model in many ways. It allows users to participate from anywhere, thus eliminating location constrains. It allows users to participate almost anytime, subject to finding a few partner users willing to participate at the same time. It is scalable, as hundreds or thousands of such small groups can exist and make progress independently. Best of all, it provides all these features while statically showing better learning outcomes than being in the classroom.

Given the desirability of distributed tutored video instruction, this paper extends earlier work in two principal directions, allowing for wide-scale deployment of distributed tutored video instruction in a Digital Library. First, a key component of distributed tutored video instruction is the ability to collaboratively view pre-recorded lecture video. For example, when one user presses the pause button, the video should pause for all remote users. The “what you see is what I see” principle needs to be preserved for all group members.

Second, distributed tutored video instruction results presented and Sipusic et al. (1999) were based on the remote participants having a specialized, high-quality videoconference system, e.g., the system presented four remote videos currently on a monitor, each at 30 frames per second, while also encoding the video of the local participant. Such infrastructure is unlikely to be available to most DL-users (digital library users), and past literature shows little benefit from including talking-head video in somewhat similar contexts (Boyle, 1994). Consequently, in this paper we propose a new model of communication for effective collaboration in a videoconferencing-based CSCL environment with videoconferencing, audio-conferencing, text chat and face-to-face communication. And also the question of how this model is affected if the communication channel is less rich. Does is affect learning and interaction behavior?

2 Distributed collaborative video

Enabling the distributed collaborative video instruction in Digital Library scenarios requires two components:

a) A distributed lecture video viewing system with shared controls like play, stop and pause.

b) A communication system for discussion around the library holds materials including video content.

Although the distributed tutored video instruction requirements are quite basic in many ways, today’s streaming media products and applications sharing products do not support it.

Streaming media players (e.g., Microsoft Windows Media Player) allow multiple people to watch the same stored video from a shared video server. However, users do not share the VCR controls. Users could say “pausing video” on the conference call when pausing the player, but remote users will end up pausing their video players at slightly different times. In addition to being a cumbersome process, over multiple stop-starts, they can easily get out of synchronization.

Unfortunately, this almost works, but not adequately. The remote Digital Library users can see and control the navigator or video, but the video is jittery and of low quality. Instead of the video data stream going from the Digital Library video server to all participants and being independently decoded and rendered on their workstations or PCs (shown in Figure 1), the video stream goes only to the Digital Library user who starts the media player (DL-user1) (see Figure 2). It is decoded and rendered on DL-user1’s machine, and the pixel-level screen changes are detected by the application sharing system (e.g., NetMeeting), re-encoded using a separated algorithm, and sent to others’ desktops. Because none of the application sharing products is optimized for this scenario (they are targeted towards transmitting infrequent changes to the screen as may occur during web browsing) the performance is dismal compared to highly optimized video codecs, and the
network bandwidth consumed is large. Although application sharing allows DL-users to share documents, presentations and DL web pages, current systems do not work for dynamic media like video.

To solve the above problem, what we need is a partial sharing navigation browser and media player application. We want the Digital Library content to stream independently to each users' navigation browser and media player and be decoded and rendered there (as in Figure 1), but we want to have a Navigation with VCR control UI of the browser and media player to work via our model application system. To implement this solution, we need to combine the functionality of JMF (Java Media Framework), NetMeeting SDK and JDK 1.3.

### 3 Video-communication model

In this section, we propose an interaction model that would solve the problems of distributed materials and video-communication viewing that commonly exists in others implementations, while also providing opportunities for instant communication for unintended interactions with unexpected DL-users by introducing the sense of distance among DL-users in the Digital Library environment.

In the first implementation we tried to introduce the sense of distance in a hybrid space by providing public and private places, as well as by varying the amount of digital information exchange between users (see Figure 3). Public places are used by end DL-users, while private places are used by specific DL-users. A place for DL communication consist of a public place that is shared by users as a hallway, and private places, that are used by these users as their classrooms. The hallway is provided in a virtual space on the network, while the private classroom space is located in a Digital Library. DL-users can be defined independently from their private places locations. The virtual hallway and the private classrooms are interconnected by virtual links that are provided by the messenger GUI located in their networks terminals.

When one DL-user wishes to initiate a video-conversation with other DL-users, the first user send a instant message through the Digital Library messaging service showing his or her picture and information to the DL-users group. The user caller can wait till the DL-users group is available without interrupting the activities of the group when the group looks busy. After the user decides to contact the DL-users group, the user approaches the private place of the DL-users group, then our implementation combines the Windows Media Player and NetMeeting in a manner that can be displayed the DL-video image along with the basic CVR controls start, stop and pause (see Figure 4). All events generated by the VCR controls are captured by the UI shell surrounding the media player and transmitted to remote DL-user group's media players using the T.120 data channel provided by NetMeeting, JMF and JDK.

These race conditions are inherent in distributed systems, and many classes of solutions are possible. It is necessary to give an apparent order to all tasks being issued, but without first passing them through a
central messaging service to avoid video-communication the user felt uncomfortable and the Digital Library does not know where the users are. In our first software implementation, we introduced a notion of ordering of the transmitted messages using the time stamps of the DL-user sender's video stream in each of the messages. Since the media player records the video stamps relative to the start of the video stream, these timestamps are obsolete and not influenced by the system clock. Any player that receives a message with a timestamp earlier than the one on its last sent message ignores the received message. This ensures that all the players record the message that has the latest timestamp relative to the start of the video stream.

Figure 4: User interface. The modified media player used by the participants on the left.

As mentioned in Section I, we wish to explore the impact of three digital communication channels in a Digital Library. The first, videoconferencing (transmission of life video of all DL-users) required extra work. A separate, special-purpose application was built to allow participants to see each other. This application only transmitted video; the second, audio-conference was provided by other channel. This window displayed medium quality video (full color, 15 frames/second) of all DL-users group. Each group member's image was approximately 5 centimeters wide and 4 centimeters tall. Video was captured using a camera on top of each participant's monitor. The third, text chat was supported using the standard chat, with these tools all DL-users were communicated in a network-based system.

4 Study focus

A major goal of this ongoing research is to develop a new model for effective collaboration in a videoconference-based CSCL environment examining how various communication channels affect this new model in a Digital Library environment. Specifically, we are interested in determining whether videoconferencing (audio and video) is the best option relative to text chat.

We are examining three major sets of variables to determine the utility of these communication channels. First, because this model is being designed for the educational context, we measured participant learning and comprehension. Second, because of the tight relationship between learning and discussion in our model, we measured various aspects of the users' interaction and discussion. Finally, we want to know if our new CSCL model experience is the best way for effective collaboration in a Digital Library environment. Figure 5 shows an example screen for the collaborative video viewing condition. For this first implementation, each participant was seated alone in a room with PC. All participants used microphone to communicate, but when the shared DL-video played, the sound from the computer speakers was relayed through each microphone, causing an unacceptable distraction (public place). For the second test, participants were seated together at the same room. One computer class was played using our first implementation model (private place), except the computer's screen was displayed on a projector screen at the end of the room. The professor who was teaching used a computer and mouse to pause and play the DL-video during discussions. Group members would ask the professor to pause the video if they had something to say; often they would just being talking and the professor would automatically pause the video.
Figure 5: Shows an example screen for the collaborative video viewing condition.

Although the groups of our first implementation paused the DL-video more often, the difference was not significant. In addition, both test groups felt that the number of pauses was about right, and both test groups were equally comfortable with pausing video. Both groups were also equivalent in terms of time spend discussing the DL-video and comfort with asking questions and making comments. However, the first test users felt that there was too much discussion, while second test users felt that the amount of discussion was about right.

5 Discussion

First we should note shortcomings of this ongoing study. First, the video we used for these studies was didactic material property of Digital Library. However, if the distance education takes hold, it is likely that more resources will be invested in producing materials of higher quality than a recorded lecture. Second, this ongoing research has the generalizability issues common to our lab studies. The majority of our participants were students, and although our tests settings were not very similar to a college classroom environment, it was similar to what is found in distance learning training settings. As a result, this ongoing research could benefit from future field study replication.

The first goal of this ongoing research is to build and effective collaboration model in a videoconference-based CSCL Digital Library environment on top of existing, commercial technology. Ideally, we hope to build a model that would recreate the collaboration video viewing experience for students and DL-users who could not meet in the same room. Our ongoing studies found no significant differences between the first and second test groups on most major measures, including our measures of learning.

However, our study did find one area in which the model could benefit from additional design. Distributed tutored video instruction test groups were not as comfortable with pausing and discussing the DL-video, reflected by both the survey data and the reduced time spend discussing the video when it was paused. This result is worrisome given the tight assumed connection between discussion and learning in the tutored video instruction literature. The second goal of this ongoing research was to examine the effects of using different communication channels to link DL-users together. Aside from this issue, our data suggest that providing videoconference is a helpful addition. If this is consistently replicated, it is good news for Digital Libraries implementations that wish to implement distributed tutored video instruction providing the video channel.

6 Concluding Remarks

The effective collaboration in a videoconference-CSCL environment model in a Digital Library provides significant benefits: scalability, good learning outcomes, and location and time flexibility for DL-users. In this paper we have addressed two issues that together allow our model to become more widespread. First, we have shown how a collaborative video viewing solution can be built on existing technologies by any third party. Second, we have provided results on DL-users learning, interaction, and satisfaction as a function of communication channels used for interaction. Both of these solutions illustrate that existing barriers to distributed tutored video interaction can be overcome without tremendous expense.

Abstract: Problem Based Learning is of great use in Medical Schools. This method is based on patients’ cases discussions and its success lies in the fact that it stimulates student’s investigation and critical thinking. This strategy complements the conceptual learning and allows the students to deal with real situations. This paper describes a web-based cooperative learning environment, CardioCaseDiscussion, to support the discussion of patients’ cases among medical students and professors of cardiology. This environment is part of CardioEducar, an educational meta-environment which purpose is to integrate several educational environments.

1 Introduction

Problem Based Learning (PBL) has become the outstanding method of teaching in pre-clinical undergraduate medical education (Elsner, C. et. al., 2000). PBL makes students more active during the learning process because they feel empowered to have impact on the outcome of the investigation. The web can be used to support on-line discussion in PBL approach in order to enhance the student communication. Online discussion can assist learners to interact and collaborate with peers or experts for knowledge construction purpose.

2 Cooperative Learning

Cooperative learning allows students to help each other in the learning process by working together and/or with an instructor. According to Comeaux, P. & Nixon, M. A. (2000), collaborative technologies allow the construction of common ways of seeing, act and understand. These technologies allow people to develop shared knowledge and/or new group activities. The communication technology used in the learning environment depends on the educational goals of the learning theory adopted. The web support to medical cases discussion provides a virtual environment where users can interact from different remote locations, in different or synchronized moments, and share knowledge information (Osuna, C. A. & Dimitriadis, Y. A., 1999).

CardioCaseDiscussion is designed to incorporate problem-based learning into a multi-user computer-assisted information exchange in an asynchronous communication way.
3 CardioCaseDiscussion Environment

CardioCaseDiscussion is one of the learning environments of CardioEducar, a meta-environment for cardiology education that offer computer-based support for the teaching conferences and meetings held in the Medical School and the University Hospital of the Federal University of Bahia, Brazil.

CardioCaseDiscussion supports meetings for discussion of patients’ cases. It was developed to teach medical students to analyze patient’s data (history, physical examination and tests) and to formulate a diagnosis. The environment supports cardiology cases discussion in three different situations: (i) a group of students oriented by a professor; (ii) a single student oriented by a professor, and, (iii) a group of students without the professor guidance. It can also be used by a single student with individual learning objective. In this scenario there will be no opportunity for discussion.

CardioCaseDiscussion is composed by four environments:
- **Authoring Environment**, which supports a professor when preparing the discussion of a patient’s case. It offers facilities to insert the patient’s data (history, physical examination and tests results).
- **Discussion Environment**, which presents the cases and monitors the discussion among students and the professor.
- **Meeting Environment**, which supports the case’s data presentation in a live classroom meeting.
- **Tutorial Environment**, which provides medical students with detailed information about cardiology diseases and cardiology tests.

The communication among participants takes place by means of text messages interchange. CardioCaseDiscussion uses categorization and structuring of messages in order to facilitate the argumentation and to guide the participants to reflect about their messages. The users can participate in the discussion in four different ways: (i) asking a question, (ii) answering a question of another participant, (iii) introducing a commentary, or, (iv) disagreeing of an answer or a commentary. CardioCaseDiscussion supply representative pieces of information about the message contents to help user to identify the message relevance and context. This argumentation model is used to facilitate the dynamic of the discussion, orienting the participants on how to express their opinions and ideas (Gerosa, M. A. et al., 2000). Awareness is implemented in CardioCaseDiscussion through the author identification of each contribution for the discussion. The discussions are asynchronous, which provide more flexibility to the students allowing them to use the environment according to their possibilities or preferences.

4 Conclusions

The cardiology cases discussion can be held easily with the CardioCaseDiscussion support. The benefits of this environment lie on its support to problem based learning and its ability to facilitate user’s access and cooperative work through the web. The use of an Internet browser provides platform-independent access and allows its users to participate in the discussions at different time and locations. The environment can be used in Medical Schools or as a support for distance learning and continuing medical education.

Pedagogical Agents in Virtual Reality Environments:

Do Multimedia Principles Still Apply?

Roxana Moreno, Ph.D., J.D.
Educational Psychology Program
University of New Mexico
Albuquerque, NM, 87131
moreno@psych.ucsb.edu

Abstract: In this paper, I review a set of studies that examined what students learn in various virtual reality environments (VREs) designed to promote an understanding of environmental science. The goal of the reported studies was to provide an update to the classic distinction between the role of media versus method in promoting learning (Clark, 1999). Media was varied by comparing how students learn from an instructional game delivered via a desktop display (D), head mounted display without walking (H), and head mounted display with walking (W). The instructional method was varied by comparing how students learn when words are presented as on-screen text (T), narration (N), or both (NT).

The Role of Media in Virtual Reality Environments

The first goal of this research was to examine the role of media in VREs. Thus, an important research issue concerns whether more immersive VREs (e.g., via head mounted displays) result in qualitatively different learning outcomes than less immersive VREs (e.g., via desktop computer displays). Immersion is defined as the extent to which computer displays are capable of delivering an inclusive, extensive, surrounding, and vivid illusion of reality to the senses of a human participant (Slater & Wilbur, 1997). How does immersion affect learning?

First, higher levels of immersion may promote a higher sense of presence which in turn, may promote more engagement and deeper learning. Presence is a subjective state, the psychological sense of being in a VRE (Slater & Wilbur, 1997). Past research in VREs, found that higher levels of immersion in the learning environment induce a higher sense of presence during the learning experience as measured by participants’ ratings on a presence questionnaire (Welch et al., 1996). The fundamental idea is that a higher sense of being in the environment may encourage the deep processing of the learning task by engaging students in an active search for meaning (Moreno & Mayer, 2000).

Second, more immersive VREs may improve transfer of learning to the real world because the more similar a learning environment is to a real environment, the better the transfer of learning (Durlach & Mavor, 1995). Preliminary evidence supports the idea that the richer the perceptual cues and multimodal feedback (e.g., visual, auditory, haptic, etc.) the more likely the transfer of VR training to real-world skill (Regian, Shebilske, & Monk, 1992). This idea is also consistent with one of the grand aims of VREs for learning: to provide interface transparency by making the interaction with technology more “natural”. The cognitive advantage of a transparent interface, which is generally concomitant with a more immersive environment, is that it drives students’ limited attentional resources to learning the content material rather than to the interface.

The Role of Method in Virtual Reality Environments

The second goal of this research was to examine the role of method in VREs. Method refers to the instructional method implemented in the design. For the case of the reported studies, the role of the modality of the verbal information was examined. More specifically, the instructional method was varied by presenting the words printed
as on-screen text (T), spoken as narration (N), or both (NT). How does the modality of the verbal information affect learning? To answer this question, I start with a dual-processing theory of multimedia learning.

According to dual-processing theory, students who can hold corresponding pictorial and verbal representations in working memory at the same time (such as the dynamic graphics of the VREs held in visual working memory and the corresponding narrated explanations held in auditory working memory) are better able to build referential connections between them (Paivio, 1986). On the other hand, given the limited resources students have for visual working memory, using a visual modality to present both pictorial and verbal information can create an overload situation for the learner (Baddeley, 1992; Chandler & Sweller, 1991; Sweller, 1989). Previous research in a desktop environment has shown that students learn better—as measured by tests of retention and transfer—when the instructional method involves spoken rather than printed explanations (Mayer & Moreno, 1998; Moreno & Mayer, 1999; Moreno & Mayer, 2002; Moreno, Mayer, Spires, & Lester, 2001). Similar results were obtained in an immersive VR training environment (O’Neil et al., 2000). This effect of instructional method has been called the modality effect (Moreno & Mayer, 1999; Moreno et al., 2001).

Does redundant verbal information (identical narration and on-screen text presented simultaneously) facilitate students’ understanding of an interactive VR program further? Recent findings on learning with short multimedia explanations have shown that when instructional materials contain simultaneous pictorial information such as animations, adding identical on-screen text to a spoken explanation hurts rather than helps students’ learning (Mayer, Heiser, & Lonn, 2001; Moreno & Mayer, 2002). The negative effects of redundant verbal messages have been interpreted as due to learners’ need to split their limited visual attention between simultaneous text and graphics. This effect of instructional method has been called the redundancy effect.

Media Versus Method

The decision to use different delivery media (D, H, or W) or methods (N, T, or NT) in instructional design may depend on one’s conception of learning. In this section, I consider the following two views: media-affects learning and method-affects-learning.

Media-Affects-Learning

On one hand, a media-affects-learning view is that the delivery medium can affect what is learned. Media refers to the delivery device; in this case I varied the degree of immersion by presenting the instructional program via a desktop computer screen (D), via a head mounted display while the learner is seated (H), or via a head mounted display while the learner can walk (W). For example, Seidel and Chatelier (1997, p. 2) call for research comparing how people learn from desktop workstations versus from head mounted displays (HMDs) by asking, “What is the value added by HMD, and what purposes or what types of tasks does it serve best for learning purposes?”

According to the media-affects-learning view, immersive VREs (such as in conditions W and H) have the potential of making computer-based learning feel more real by promoting a sense of presence, which in turn, could promote deeper learning. The effect of media would be reflected in superior performance on tests of retention and transfer for students who experience more immersive environments. If media affects learning, then a media effect would be expected, that is, performance on tests of retention and transfer depends on whether the instructional program was presented by desktop display, head mounted display, or head mounted display with walking. This pattern would be reflected in a main effect for media and no interaction between method and media.

Method-Affects-Learning

On the other hand, the method-affects-learning view is that instructional methods influence learning. Instructional methods can guide cognitive processing in the learner, which influences the knowledge that the learner is able to construct. According to the method-affects-learning view, it is not technology per se that promotes learning but rather how the technology is used. As long as instructional methods promote appropriate cognitive processing during learning, then media does not seem to matter (Clark, 1999). Although VR offers a compelling technological breakthrough, the medium itself does not promote learning but rather the instructional methods that it affords promote learning.

In the present review, the modality of the verbal information was used as instructional method. Therefore, the effect of method would be reflected in two ways. First, by demonstrating a modality effect, that is, superior performance on tests of retention and transfer for students who receive verbal explanations as narration (N) rather
than as on-screen text (T). Second, by demonstrating a redundancy effect. Students who receive verbal explanations as narration (N) will outperform those who receive redundant explanations (NT) on tests of retention and transfer.

The main interest of the reported studies is the general issue of whether method affects learning across media—that is, whether instructional methods have the same effects within different media environments. If method affects learning, then a modality or redundancy effect can be expected within each of the VREs examined—desktop display, head-mounted display, and head mounted display with walking. This pattern would be reflected in a main effect for method and a lack of interaction between method and media.

A Virtual Reality Agent-Based Micorworld

The learning environment used in the reported studies is a computer game called "Design-A-Plant", developed by the Multimedia Laboratory at the Department of Computer Science of North Carolina State University (Lester & Stone 1997). In this program, the student travels to an alien planet that has certain environmental conditions (e.g., low rainfall, light sunlight) and must design a plant that would flourish there (e.g., including designing the characteristics of the leaves, stem, and roots). It includes a pedagogic agent who offers individualized advice concerning the relation between plant features and environmental features, encouragement when students encounter difficulties, and feedback on the choices that students make in the process of designing plants. The program starts with the agent introducing the student to the first set of environmental conditions. Then, he asks the student to choose the appropriate root from the library of roots' names and graphics shown on the computer screen. After the student had chosen a root, the agent gives a narrated explanation for the correct root. The same procedure applies to the stem and leaves, with the agent first asking the student to make a choice, and giving the student feedback afterwards. Once the student is given the last explanation on the leaves for each environment, he is taken to the next environment. The same procedure follows for the rest of the environments.

Experiment 1: Media Versus Modality Effects

Method and Results

The participants were 89 college students. Each participant served in one cell of a 2 x 3 between-subjects factorial design, with the first factor being modality of the verbal information (narration or text) and the second factor being the level of immersion during the computer interaction (desktop, head mounted display, or head mounted display plus walking). There were 17 participants in the narration and desktop group (ND Group), 17 participants in the text and desktop group (TD Group), 13 participants in the narration and head mounted display group (NH Group), 13 participants in the text and head mounted display group (TH Group), 13 participants in the narration and head mounted display plus walking group (NW Group), and 14 participants in the text and head mounted display plus walking group (TW Group).

After interacting with the respective program, participants were tested on three important measures of learning: retention—in which memory for the basic factual information was assessed; problem-solving transfer—in which students were asked to solve new problems based on the principles learned in the program; and program ratings—in which students were asked to rate their level of motivation, interest, understanding, and the perceived difficulty and friendliness of the lesson. Participants also completed a presence questionnaire. We determined whether the groups differed on measures of retention, transfer, and program ratings by conducting two-factor analyses of variance for each dependent measure with modality (T or N) and level of immersion (D, H, or W) as between-subject factors, and retention, transfer, and program ratings as the respective dependent measure.

Do students experience a stronger sense of presence in more immersive VREs?

Consistent with past research in VREs, higher levels of immersion in the learning environment induced a higher sense of presence during the learning experience (Welch et al., 1996). Using presence as a dependent measure, a one-factor ANOVA revealed that students in D groups rated their sense of presence significantly lower than students in H and W groups which did not differ from each other, $\bar{M}_s = -2.59, 7.31$, and $8.22$; $SDs = 12.49, 10.03$, and $12.33$, for D, H, and W groups, respectively, $p = .0006$. 
Do more immersive VREs promote deeper learning than less immersive VREs?

The media-affects-learning view holds that more immersive VREs are more likely to promote students' learning of the science lesson, by virtue of inducing higher levels of presence. Using retention as a dependent measure, a two-factor ANOVA failed to reveal a main effect for immersion. Groups presented with higher levels of immersion did not differ in the mean number of recalled items about the plant library from those presented with lower levels of immersion \((\text{Ms} = 6.01, 6.50, \text{and} 5.82; \text{SDs} = 1.85, 1.85, \text{and} 2.04, \text{for D, H, and W groups, respectively})\). There was no significant interaction between immersion and modality.

Using transfer as a dependent measure, a two-factor ANOVA failed to reveal a main effect for immersion. Groups presented with higher levels of immersion did not differ in the mean number of answers from those presented with lower levels of immersion \((\text{Ms} = 31.06, 30.69, \text{and} 31.52; \text{SDs} = 9.54, 9.20, \text{and} 11.68, \text{for the D, H, and W groups, respectively})\). A significant interaction was found between immersion and modality \((p < 0.05)\). Post hoc analysis of simple effects for modality and immersion indicated that both for D and H conditions, receiving information via on-screen text rather than via narration, proved to significantly hinder students' learning as measured by transfer scores \((p = .006 \text{ and } .0001, \text{respectively})\). Similar to the case for retention, there was no immersion effect for students' program ratings and no interaction. The respective ratings for the D, H, and W groups were: \(\text{Ms} = 28.67, 31.83, \text{and} 31.52; \text{SD} = 6.61, 7.02, \text{and} 6.88\).

Do students who learn with narration learn more deeply than students who learn by reading on-screen text?

The method-affects-learning view holds that presenting verbal material as speech is more likely to promote students' understanding of a multimedia lesson than presenting the same material as on-screen text, regardless of delivery medium. Using retention as a dependent measure, a two-factor ANOVA revealed a main effect for modality \((p = .0003)\), with a mean number of ideas recalled of 6.84 and 5.43 respectively for the narration and text groups \((\text{SDs} = 1.51 \text{ and} 2.01, \text{respectively})\).

Using transfer as a dependent measure, a two-factor ANOVA revealed a main effect for modality \((p = .0001)\), with a mean number of correct answers of 36.12 and 25.57 respectively for the narration and text groups \((\text{SDs} = 8.34 \text{ and} 8.80, \text{respectively})\). Groups presented with the verbal information in the form of speech gave significantly more correct answers than those presented with the verbal information in the form of text. Groups also differed in the overall ratings for the program. A two-way ANOVA using program ratings as the dependent measure revealed that the narration groups rated the program more favorably than the text groups \((p < .05)\), with a mean rating of 32.33 and 28.72 respectively for the narration and text groups \((\text{SDs} = 5.85 \text{ and} 7.42, \text{respectively})\).

The results from Experiment 1 supported the method-affects-learning hypothesis by demonstrating a modality effect on retention, problem-solving transfer, and program ratings. No evidence was found in favor of the media-affects-learning hypothesis. The purpose of Experiment 2 was to test the alternative hypothesis using a different type of instructional method. The effects of presenting redundant verbal information by means of a VR desktop display (D) or by means of a head mounted display without walking (H) was examined. Students received explanations from an agent via narration alone (N), via on-screen text alone (T), or via simultaneous narration and on-screen text explanations (NT).

Experiment 2: Media Versus Redundancy Effects

Method and Results

The participants were 75 college students. Each participant served in one cell of a 3 x 2 between-subjects factorial design, with the first factor being modality of the verbal information (narration, text, or narration and text) and the second factor being the level of immersion during the computer interaction (desktop or head mounted display). There were 14 participants in the narration and desktop group (ND Group), 14 participants in the text and desktop group (TD Group), 14 participants in the redundant desktop group (NTD Group), 11 participants in the text and head mounted display group (TH Group), 10 participants in the narration and head mounted display group (NH Group), and 12 participants in the redundant head mounted display group (NTH Group). The procedure was identical to that of the first experiment. To determine whether treatment groups differed on measures of retention, transfer, and program ratings, separate two-factor analyses of variance were conducted for each dependent measure with modality (N, T or NT) and level of immersion (D or H) as between-subject factors, and retention, transfer, and program ratings as the respective dependent measure.
Do students experience a stronger sense of presence in more immersive VREs?

Similar to Experiment 1, the results showed that programs delivered via head-mounted displays rather than desktop displays induce higher levels of presence ($p = .03$). Students in the D groups rated their sense of presence significantly lower than students in the H groups. ($M$s = .81 and 8.73; $SD$s = 12.95 and 17.93, for D and H groups, respectively).

Do more immersive VREs promote deeper learning than less immersive VREs?

Using retention as a dependent measure, a two-factor ANOVA failed to reveal a main effect for immersion or an interaction between immersion and modality. Groups who learned in the desktop conditions did not differ in the mean number of recalled items about the plant library from groups who learned with higher levels of immersion ($M$s = 6.81, and 6.55; $SD$s = 1.55 and 1.68, for D and H groups, respectively).

Using transfer as a dependent measure, a two-factor ANOVA failed to reveal a main effect for immersion or an interaction between immersion and modality. Groups presented with higher levels of immersion did not differ in the mean number of answers from groups presented with lower levels of immersion ($M$s = 28.17, and 30.55; $SD$s = 7.47 and 7.36, for the D and H groups, respectively). Similarly, a two-way ANOVA using the overall program rating as the dependent measure failed to reveal an immersion effect. The respective ratings for the D and H groups were: $M$s = 30.14 and 28.49, $SD$ = 6.95 and 7.02. There was no significant interaction between immersion and modality.

Do students who learn with redundant explanations learn more deeply than students who learn with explanations in only one modality?

The method-affects-learning view holds that presenting verbal material as narration alone is more likely to promote students’ understanding of a multimedia lesson than presenting the same verbal material as narration and on-screen text, regardless of delivery medium. Using retention as a dependent measure, a two-factor ANOVA revealed a main effect for modality ($p = .006$), with a mean number of ideas recalled of 7.25, 6.96, and 5.88 respectively for the N, NT, and T groups ($SD$s = 1.57, 1.46, and 1.51, respectively). Supplemental Tukey tests (with alpha at .05) revealed that groups presented with on-screen text alone recalled significantly fewer items from the plant library than groups presented with narration alone or with narration plus on-screen text, which did not differ from each other.

Using transfer as a dependent measure, a two-factor ANOVA revealed a main effect for modality ($p = .0004$), with a mean number of correct answers of 32.08, 30.77, and 24.84, respectively for the N, NT, and T groups ($SD$s = 6.16, 8.15, and 5.96, respectively). Similar to the case of retention, supplemental Tukey tests (with alpha at .05) revealed that groups presented with on-screen text alone gave significantly less correct answers to problem-solving transfer tests than groups presented with narration alone or with narration plus on-screen text, which did not differ from each other. Groups also differed in the overall ratings for the program ($p = .01$), with a mean rating of 32.54, 29.31, and 26.52 respectively for the N, NT, and T groups ($SD$s = 5.36, 6.87, and 7.43, respectively). Supplemental Tukey tests (with alpha at .05) revealed that groups presented with on-screen text alone gave significantly lower program ratings than students presented with narration alone.

Overall, modality effects were obtained on the retention, transfer, and program ratings replicating the pattern found in Experiment 1 and thus supporting the method-affects-learning hypothesis. However, redundant verbal information did not hurt or help students’ understanding as compared to spoken explanations alone. A possible interpretation for NT groups performing comparably to N groups is that students in NT groups may have been inclined to attend to the narration alone due to the experiential mode of VREs. When students are exploring a VRE (either by moving the computer mouse or by moving their head), it is less likely that they will read a box containing text if they can obtain the same information by listening to a narration.

General Discussion

The present review yields evidence—based on questionnaires—that students feel a stronger sense of presence in more immersive VREs. In addition, the reported studies provide new evidence—from retention and transfer tests—that students who experience more immersive VREs do not necessarily learn a computer-based lesson more deeply than students who experience a lower sense of presence. This is consistent with past research in VREs where no
relationship between presence and performance was found (Slater & Wilbur, 1997) and fails to support a media-affects-learning hypothesis. Theoretically, this research provides one of the first methodologically rigorous studies of conditions that foster productive learning in a virtual environment. The replication of the modality effect across different media shows that effective learning depends on which instructional techniques help guide the learner’s cognitive processing of the presented material rather than on the medium per se. Importantly, this review has shown that the same factors that improve student understanding in one medium (such as modality effects in a desktop environment) improve student understanding in another medium (such as the present findings concerning immersive VREs). In both cases, ineffective instructional messages can be converted into effective ones by applying the same instructional design principles.

Finally, the conclusions drawn are limited by the nature of the learning materials. The learning materials consisted of an environmental science VRE with short agent and student interventions. It is possible that in VREs where students’ physical interventions are essential to the learning process, such as if the goal of the instructional material is to train a procedure, the use of more immersive environments might play an important role in adding psychomotor feedback to the learning experience (Seidel & Chatelier, 1997; Thurman & Russo, 2000). Because some media may enable instructional methods that are not possible with other media, it might be useful to explore instructional methods that are possible in immersive environments but not in others.

Who Learns Best with Multiple Representations?

Cognitive Theory Implications for Individual Differences in Multimedia Learning

Abstract: Who learns best with multiple representations? In this paper, I present a cognitive theory of multimedia learning from which predictions on individual differences in learning are derived and tested. Elementary students learned how to add and subtract integers with an interactive multimedia game that included visual and symbolic representations of the arithmetic procedure. They learned either with or without verbal guidance in their first language. Verbal guidance was expected to help minimize cognitive load, especially for students with low prior knowledge, low computer experience, and a less reflective cognitive style. The theoretical and practical implications of the results are discussed.

Multiple Representations for Meaning Making in Math

Multimedia environments allow learners to integrate information from different representation formats and sensory modalities into one meaningful experience (Moreno & Mayer, 2000). Therefore, when an arithmetic procedure is to be taught with a multimedia program or game, the instructional designer is faced with the need to choose between several combinations of modes and modalities to promote meaningful learning. In the present review of studies, students learned to add and subtract integers by interacting with a multimedia game consisting of symbolic representations in the traditional number sentence format. In addition, based on recent advances in multimedia learning, the computer game depicts the execution of the computational procedures as visual representations of movements along a number line (Moreno & Mayer, 1999). According to the arithmetic-is-motion metaphor, "numbers are locations on a path", "the mathematical agent is a traveler along that path", "arithmetic operations are acts of moving along the path", and "the result of an arithmetic operation is a location on the path" (Lakoff & Nunez, 1997, p. 37).

For example, students select one of eight problems to solve from the problem menu. Then, students see the problem presented in symbolic form (as 4 - -5 =__) and a number line showing integers from -9 to 9 with a bunny standing at the 0 point. A simulated joystick consisting of the following four alternative moves for the bunny appears in the lower right corner: face to the left, face to the right, jump forward one step, or jump backwards one step. Students may click on any combination of the four joystick options and instantly see the resulting change in the bunny on the number line. The program instructs learners to try to figure out the problem by moving the bunny along the number line using the joystick. When students are ready to answer, they type in a numeral (and negative sign, if needed).

If the student's answer is not correct, the student may try again or see the solution to the problem. If students type in the correct answer, they hear the word "Yes" followed by an animated sequence which consists of four major steps in solving the problem. First, the symbol "4" is highlighted and the bunny moves to position 4 on the number line. Second, the minus sign is highlighted and the bunny turns to the face the left side of the screen. Third, the symbol "-5" is highlighted and the bunny makes five jumps to the right. Finally, the number "9" is highlighted and the bunny faces forward on the 9th position of the number line. Thus, the learner sees how each step in the procedure can be represented in symbols and movements. At this point, students may click on the "Back to Menu" button which takes them back to the main menu.
Would the addition of a verbal representation in the form of spoken words explaining the relationship between the visual metaphor and the symbolic sentence help students' learning? Moreover, do all students benefit from learning with more rather than fewer representations? To help answer these questions, I conducted two studies where the learning outcomes of students who learned to add and subtract integers with symbolic and visual representations (Group SV) was compared to those of students who learned the same lesson with symbolic, visual, and verbal representations (Group SVV). In particular, I concentrated on three learning measures: learning rate, pretest-to-posttest gain, and using what they have learned to solve word problems. The overarching goal of the reported studies was to explore the cognitive implications of training students with multiple representations in a high cognitive load situation and infer some preliminary principles of instructional design for individual differences in multimedia learning. In the next sections, I provide a cognitive theory of how people learn with multiple representations, introduce three possible sources of individual differences in learning from multimedia environments, and derive predictions based on the theory.

A Cognitive Theory of Multimedia Learning

The cognitive theory of multimedia learning used in the present studies draws on two main assumptions: multiple representations help learning and cognitive load hurts learning. One one hand, according to a multiple representation hypothesis, teaching with more representations facilitates and strengthens the learning process by providing several mutually referring sources of information (Kozma, Russell, Jones & Marx, 1996; Grouws, 1992; National Council of Teachers of Mathematics, 1989). For example, past studies in multimedia learning have shown that students learn math better when information is presented in verbal, visual, and symbolic formats rather than in symbolic formats alone (Moreno & Mayer, 1999), and that students learn science better from animations that include words rather than from animations or words alone (Mayer, 2001).

On the other hand, according to the thesis that cognitive load hurts learning, students' working memories are limited in capacity (Baddeley, 1986; Chandler & Sweller, 1992; Sweller, 1994). Therefore, presenting multiple representations of the same arithmetic procedure may overload the learner by creating the need to integrate the multiple sources of mutually referring information. Students with larger capacity are better able to maintain and coordinate multiple representations in working memory than are students with lower capacities (Just & Carpenter, 1992). Thus, although cognitive theory of multimedia learning supports learning with multiple representations in general, individual differences cannot be discarded (Moreno & Mayer, 1999). What are some possible sources of cognitive load differences between students?

Cognitive Tempo

Cognitive tempo (or Impulsivity/Reflectivity) refers to a person's tendency to reflect or not reflect, before responding on a problem-solving task with response uncertainty (Kagan, 1966). According to this individual difference, reflective students make fewer errors and have a longer response time than impulsive students on inductive reasoning, recognition memory, visual discrimination tasks, and serial recall (Borkowski, Peck, Reid, & Kurtz, 1983). From a theoretical perspective, it can be hypothesized that a persistent impulsive style limits students' time to reflect on the accuracy of an answer. Reflective students take more time to develop a solution hypothesis before making a choice (clicking on the computer mouse). A consequence is that deep learning becomes less likely for impulsive than for reflective students, especially where tasks carry high uncertainty and little guidance (Jonassen & Grabowski, 1993).

Prior Knowledge

Based on a cognitive theory of multimedia learning, students with high prior knowledge in arithmetic have already built their own mental model for the presented material (at least partially, for the addition and subtraction of natural numbers). Therefore, multiple representations are easier to integrate with prior knowledge and less likely to overload their working memory (Mayer, 2001; Moreno & Mayer, 1999). In addition, computer knowledge or experience (mastery of the task-specific skills that derive from interacting with a multimedia program such as clicking on buttons, typing in numbers, etc.) may affect multimedia learning. Low computer experience may impose an extra cognitive load if students are not very familiar with computers and the tasks involved in the interaction have not become automatic yet (Chandler & Sweller, 1991). This is particularly relevant for the present study because many participants are children who come from low-income, immigrant, non-English backgrounds with very few having access to computers at home.
Language Background

What are the cognitive consequences of learning verbal materials in a more versus less familiar language? An additional goal of the present study was to examine if students would choose to learn the arithmetic procedure in their first or second language given the option to do so. Knowledge of a less familiar language constrains problem solving in that language (Duran, 1985). As the computer game used for the present studies presented verbal explanations in English with the option to listen to Spanish translations, it was expected that limited English proficient students (LEP) would make significant use of the translations during training sessions. The rationale is based on the assumptions that attentional resources are limited and that in learning situations of high cognitive load such as the present one, students will be likely to lower the attentional demands by choosing to use a more familiar language.

Predictions

Based on a cognitive theory of multimedia learning, students trained with example problems presented in three different forms encode the material more deeply than those trained with problems presented in two forms (Clark & Paivio, 1991; Paivio, 1986). Moreover, cognitive load for the SVV group is minimized respect to the SV group because the extra verbal representation guides students’ discovery of the relationship between the visual metaphor and the number sentence (Chandler & Sweller, 1991; Solter & Mayer, 1978; Tarmizi & Sweller, 1988). Consequently, it was predicted that compared to the SV group, the SVV group would show a larger pretest-to-posttest gain, faster rate of learning, and better transfer to solve word problems.

However, individual differences in cognitive load based on students’ cognitive tempo, prior knowledge, and language background were expected. Therefore, the positive effects of multiple-representation learning should be stronger for high prior knowledge or high computer experience than for low prior knowledge or low computer experience students. Second, the positive effects of multiple-representation learning should be stronger for reflective rather than impulsive students. Finally, as students in Group SVV were given the option to look up the explanations in Spanish, it was predicted that limited English proficient (LEP) learners would show a greater use of Spanish explanations over sessions compared to first English proficient (FEP) learners. The rationale is based on the idea that students who are still in the transition to becoming proficient English speakers will be likely to choose their first language to lower the cognitive load required to understand the explanation of the arithmetic procedures in English.

Experiment 1: A Low Computer Experience Scenario

The first study was conducted at the beginning of the school year in a southern California elementary school where many children come from emigrant, low-income, Spanish-speaking homes. A significant proportion of students is limited English proficient and has almost no computer experience. Training with multimedia games in this scenario is very interesting as it can be argued that the visual presentation of a mathematical procedure such as the one used in the present studies can minimize the importance of language and therefore has great potential for enhancing the learning of non-native speakers of English. Second, visual instruction can build on the existing intuitive knowledge of the learner and can be particularly appropriate for less skilled students who lack formal academic training in the subject domain (Mayer, 1997). Third, visual forms of presentation can help learners build mental models of complex systems that enable problem solving rather than being subjected to rote methods of instruction that emphasize solely the acquisition of isolated facts and procedures (Grouws, 1992).

Method and Results

The participants were 61 students from three fifth and sixth-grade classrooms of an elementary school in southern California who lacked substantial prior knowledge about addition and subtraction of signed numbers. Thirty students participated in the SV group and 31 students participated in the SVV condition. Based on the school records for their English language proficiency level, students were classified as FEP or LEP. Fourteen FEP and 16 LEP students served in Group SV and 15 FEP and 16 LEP students served in Group SVV. First, each student was given the computer experience questionnaire, the paper-and-pencil pretest, and the Matching Familiar Figures test (MFFT) to determine children’s cognitive tempo (Kagan, Rosman, Day, Albert, & Phillips, 1964). Second, they were randomly assigned to learn with either a SV or SVV version of the computer game and participated in each of
four training sessions held on different days over a two-week period during regular class time. Finally, they were given the paper-and-pencil posttest and computerized word problem test.

For each student, the number of correct answers on the pretest was subtracted from the number of correct answers on the posttest to yield a pretest-to-posttest gain score and the number of correct answers on the word problem test, the number of correct answers on each of the training sessions, and the number of times students asked for a Spanish translation was recorded from a computer-generated log during training sessions.

**Do students who learn interactively with symbolic, visual, and verbal representations show deeper understanding from a multimedia math lesson than students who learn with symbolic and visual representations alone?**

Students in Group SVV had a larger mean pretest-to-posttest gain score than students in Group SV (p = .02), a marginally larger transfer to word-problem score (p = .075), and no significant difference in the learning rate. These findings suggest that instructional programs that use multiple representations (such as symbolic representations and visual interactive metaphors) are more effective when verbal explanations are explicit. However, the benefit of the verbal representation only affects students' pretest-to-posttest gain of the arithmetic procedure itself. Providing verbal representations does not affect students' learning rate and only marginally helps students transfer the procedure to solve word problems.

On the other hand, the results on individual differences showed that although prior knowledge did not affect the pretest-to-posttest gain, computer experience showed a significant interaction with the type of treatment: Students who had low computer experience did not benefit from the verbal representations but students with high computer experience benefited considerably (p = .05). In addition, reflective students scored marginally higher on pretest-to-posttest gain (p = .06). Moreover, high prior knowledge students, high computer experience students, and reflective students learned faster and scored significantly higher than their counterparts in transferring the arithmetic procedure to solve word problems (p = .0001, p = .03, and p = .01 respectively for learning rates and p = .0001, p = .05, and p = .01 respectively for transfer scores). These results show that prior knowledge (both in content and computer skills) and a reflective cognitive style help students' learning by minimizing cognitive load in complex learning environments.

**Do students who are in the transition to becoming English proficient use verbal explanations in their first language?**

An additional issue was if LEP students in Group SVV would make significantly more use of the Spanish translations than FEP students in Group SVV. To answer this question, for each session and student, the number of times students listened to Spanish translations was recorded. Consistent with the prediction, an ANOVA with language background as a between-subjects factor and number of translations as a within-subject factor revealed a significant effect for language background, number of translations, and a significant interaction (p = 0.02, p = 0.0001, and p = 0.001, respectively). LEP students used significantly more the Spanish translations than FEP students and the number of translations decreased significantly over time for LEP students. This result is consistent with the idea that students prefer to use a more familiar to reduce the high cognitive load that results from learning with multiple representation interactive environments.

**Experiment 2: A High Computer Experience Scenario**

Experiment 2 was conducted at the end of the school year in a fifth and sixth grade classroom of the same elementary school that participated in Experiment 1. Contrary to the case of the first experiment, all participating students had been intensively trained in computer use for almost an entire school year. Therefore, the first goal of the second study was to test the prediction that due to students' training with computers, computer experience would lose its impact as a determinant factor in learning from the interactive program.

An additional goal of Experiment 2 was to investigate if transfer to word problems could be improved by providing explicit word problem training. The results of Experiment 1 showed an advantage of SVV instruction over SV instruction for only one of three dependent measures: pretest-to-posttest gain. Providing verbal explanations did not help students' learning rate or transfer to solve word problems. In Experiment 2, the learning of a group of students trained with symbolic, verbal, and visual representations (Group SVV) was compared to that of an identical group presented with an additional word problem for each problem type (Group SVVW). Based on past research on problem-solving transfer (Cox, 1997; Mayer & Wittrock, 1996), it was predicted that explicit training in solving word problems would result in better performance on this measure. However, as the treatments did not differ in any other aspect, differences in pretest-to-posttest gain or learning rate were not expected.
Method and Results

The participants were twenty-four students from a fifth and sixth-grade classroom of an elementary school in southern California who lacked substantial prior knowledge about addition and subtraction of signed numbers. Twelve students participated in the SVV group and 12 students participated in the SVVW condition. The procedure was identical to that used in Experiment 1 except that after students were given the computer experience questionnaire and the paper-and-pencil pretest, they were not given the MFFT because individual differences on cognitive tempo were not the focus of the study.

Do students who learn how to add and subtract integers with word problem examples show better transfer to solve word problems than students who are not presented with word problems?

Consistent with the predictions, students in Group SVVW and SVV did not differ in their mean pretest-to-posttest gain or in their learning rate. However, the main prediction was that providing word problem examples to Group SVVW would make a significant difference in the transfer to a word problem test respect to Group SVV. Consistent with this prediction, using transfer to word problems as a dependent measure, a one-factor ANOVA revealed a treatment effect (p = .05). Students in Group SVVW were significantly better able to transfer the arithmetic procedure to solve word problems as compared to students in Group SVV.

What is the role of computer experience for students who learn with multiple representations in a computer-trained classroom?

Due to students' overall high experience with computers, it was expected that computer knowledge would not affect overall performance because they had automated the computer skills necessary to interact with the program. Consistent with the predictions, the statistical analyses revealed no computer experience effect on pretest-to-posttest gains, learning rate, or transfer to word problems. High experience students scored comparably to low experience students on all dependent measures. As argued in the predictions, the different pattern of results between both studies can be interpreted as due to the computer training program that the teacher had implemented in the participating class. Experiment 1 was conducted at the beginning of the school year and many students reported having very low or even no basic computer experience. On the other hand, Experiment 2 was conducted in a classroom where the teacher placed priority on students’ practice of technologically based instructional materials. For example, one of the goals of the participating class consisted of having each student develop their own web page by the end of the year.

General Discussion

Multimedia programs allow students to work easily with multiple representations of complex systems. The reported studies demonstrate that presenting a symbolic and visual representation of how an arithmetic procedure works does not insure that all students will understand the explanation unless cognitive theory is applied to the design.

The reported studies have important implications. Theoretically, this research supports a cognitive theory of multimedia learning in two ways. First, by demonstrating that teaching with symbolic, visual, and verbal representations facilitates and strengthens the learning process by providing several mutually referring sources of information. Second, by suggesting that the additional cognitive load imposed on the SV group (i.e., the need for students to use their limited cognitive resources to discover the meaning of a procedure and generate their own verbal representation) is detrimental to learning by exhausting working memory capacity. Third, the results from Experiments 1 and 2 show that even when instructional methods are grounded on visual metaphors, transfer skills require explicit training. Although interactive visual metaphors may help students build connections between arbitrary sets of procedures that use symbols and their informal conceptual knowledge, this method only seems to help students understand the arithmetic procedure itself. Finally, congruent with cognitive load theory, when learners are required to mentally integrate disparate sources of mutually referring information, such split-source information may create a heavy cognitive load that disrupts learning, especially for learners who have fewer cognitive resources (Moreno & Mayer, 1999; Sweller, 1991). The present results on individual differences are consistent with the interpretation that students learn deeper in multimedia interactive environments when the...
advantages of multiple representations are not outweighed by individual differences in cognitive load (Chandler & Sweller, 1991; Sweller, 1994).

On the practical side, the overall results indicate that visual metaphors need verbal guidance and word problem examples if they are to be used as an instructional tool to foster mathematical understanding and transfer. Multimedia environments have the capability of creating dynamic visual representations of constructs that are frequently missing in the mental models of novices (Kozma, 1991). However, the present findings show that for multimedia learning to be effective it is important to design the materials in a manner that minimizes cognitive load. One way to reduce cognitive load is by providing guidance in the form of verbal explanations in students' first language. A contribution of the reported studies is to identify computer experience, prior knowledge, and cognitive tempo as important factors that help students learn from multimedia by minimizing cognitive load.

Lights and Wires: Effective eLearning

Jenny Morice
Griffith University,
Brisbane Australia
J.Morice@cit.gu.edu.au

Abstract: There exist two commonly held views regarding the use of multimedia and Internet technology within learning environments. Many educators believe that the presence of content material on CD-ROM or the Internet will help students reach their learning goals, and students 'like' multimedia and/or Internet based delivery. This paper explores these views through analysis of the design and development of an eLearning solution.

Introduction

"Television can teach. It can illuminate. Yes, it can even inspire. But it can do so only to the extent that humans are determined to use it to those ends. Otherwise, it is merely lights and wires in a box." Edward R. Murrow

While this statement is obviously discussing the use of television as a learning resource, the same sentiment can be directed toward eLearning solutions. However, the thought of an expensive eLearning solution as merely 'lights and wires in a box' is probably enough to strike fear into the hearts of most eLearning providers. Given the general view that the use of educational multimedia applications and online learning solutions enhance learning effectiveness, such a stance is akin to heresy. Instructional designers developing eLearning solutions claim 'improved learner outcomes' (Colorito, 2001) and 'more effective learning experiences' (Maki et al, 2000). These are nice ideas. Happy learners and even happier teachers skipping down the yellow brick path toward successful learning outcomes. However, not a lot unlike the young woman in the sparkling red shoes, it does not take long to discover that fantasy and reality are somewhat distanced from one another.

There exist two commonly held views regarding the use of multimedia and Internet technology within learning environments. Many educators believe that the presence of content material on CD-ROM or the Internet will help students reach their learning goals, and students 'like' multimedia and/or Internet based delivery. Many factors play a part in shaping an individual's learning experience, not least of all the assumptions of the instructional designer. For example, using Brookfield's paradigmatic assumption, learners within the university context will be predominantly proactive, highly motivated consumers of knowledge. Associated with this assumption is the prescriptive assumption that as the students are proactive, self-directed learners then the best teaching will be that which encourages students to take control over designing, conducting and evaluating their own learning (Brookfield, 1995). Therefore, if the paradigmatic and prescriptive assumptions are correct, it follows that if an environment is created to support self-directed learning such learning will (naturally) take place (causal assumption). This is largely the reasoning applied to the integration of multimedia and Internet technology within learning environments. Students 'like' multimedia and/or Internet based content therefore if learning facilitators provide such environments students will (naturally) have successful learning outcomes.

While many learners may prefer, or perhaps expect, to access content material via the Internet recent research does not support the view that students prefer this mode of delivery (McInnis, James & Hanley, 2000). New technology is seductive, this danger is especially apparent when multimedia and Internet technology are viewed as a providing improved learning experiences. However, it is important to not allow technology to overwhelm the foundations of an effective learning experience. Whether delivered via CD-ROM, the Internet, cassette or print, we should seek to provide a learning experience that is meaningful to all users. Jonassen (2001) discusses eight qualities inherent in meaningful learning environments. These are:

- Active: Learners are engaged by the learning process in mindful processing of information where they are responsible for the result.
- Constructive: Learners integrate new ideas with prior knowledge in order to make sense or make meaning or reconcile a discrepancy, curiosity, or puzzlement.
- Collaborative: Learners naturally work in learning and knowledge building communities, exploiting each others skills while providing social support and modeling and observing the contributions of each member.
- Intentional: All human behavior is goal directed.
- Complex: Unless learners are required to engage in higher order thinking, they will develop oversimplified views of the world.
- Contextual: A great deal of recent research has shown that learning tasks that are situated in some meaningful real world task or simulated in some case-based or problem based learning environment are not only better understood, but also are more consistently transferred to new situations.
- Conversational: Learning is inherently a social, dialogical process. ... Technologies can support this conversational process by connecting learners across town or across the world.
- Reflective: Learners should be required by technology-based learning to articulation what they are doing, the decisions they make, the strategies the use, and the answers that they found.

(Jonassen, 2001)

In view of these effective practice guidelines and qualities as articulated Jonassen (2001) the challenge for educators and eLearning providers is to build in to the distributed educational context dynamic, collaborative, and conversational environments. However, integrating collaboration and conversation within a distributed learning environment is easier said than done. The following case study explores the way in which these guidelines informed the development of an eLearning environment for a core subject for second year university computing students.

Case Study - ‘Issues in the Design and Delivery of Multimedia’ eLearning resource

History: The subject content and Internet site were partially developed in 1999 and both were extensively revised in 2000. The structure, sequence and content of the subject and the Internet site have been used as teaching and learning resources for two years (2000 and 2001).

Subject: ‘Issues in the Design and Delivery of Multimedia’ focuses on examining and analysing ethical, legal, social and professional issues in the development and delivery of multimedia. In this subject issues such as software piracy, computer crime, online pornography, professional ethics and the impact and implications of the use of technology are critically analysed.

Learners and Mode: Typically the student cohort comprises (generally) motivated adult learners from a variety of experiential and cultural backgrounds. Approximately 15% of learners are international students and between 20% and 40% are aged over 25 years. The subject is delivered in on campus mode. An extensive Internet site was developed to support lectures and workshops.

Methodology: The creation of educational environments, both in class and online, that fostered collaboration, conversation and activity (Jonassen, 2001) underpinned the philosophical orientation of the instructional design process. In many respects, the process of designing and developing online instructional materials closely resembles a software development life cycle model in that the instructional design process is an iterative one. Progression relies on analysis and evaluation of the objectives and outcomes of the preceding phase. The instructional design process used in the development of the eLearning environment relied on four primary phases that guided and shaped the development process. The phases are illustrated in Figure. 1.
Phase 1: Front end analysis. What do we currently have? (What are the global aims and specific objectives? What resources can be utilised to achieve those goals?) In this phase, existing subject content was reviewed to update specific content areas. This phase examined the current teaching and learning process and specifically analysed the assessment instruments in relation to the stated subject aims and objectives. Feedback regarding content and teaching strategy was sought from learners and colleagues. The major focus of the review concentrated on addressing three primary areas identified in the initial problem analysis:

- Explicitly stating global aims and specific objectives and strengthening the relationships between aims, objectives and content.
- Identifying learner entry and exit points (including assessment) and the relationships between them.
- Addressing inconsistencies in delivery media and identifying opportunities for implementation of innovative delivery strategies.

Global aims: The solution sought to incorporate the following global educational aims in order to strengthen the relationship between aim, objective and content. At the completion of the subject learners should:

- have developed an awareness and understanding of the concepts, practices and ethical codes and conventions regarding the design and delivery of multimedia applications and technology generally
- have developed an understanding of the issues and implications regarding management of knowledge
- exhibit high level critical thinking and problem solving skills
- have developed high level verbal and written communication skills and be encouraged to think critically about the uses (and abuses) of multimedia and information technology generally
- exhibit responsible and discerning use of technology in general

Specific objectives: Further to strengthening the relationships between aim, objective and content in relation to global educational aims, the following areas were identified as desired specific objectives of the subject. Accordingly, at the conclusion of the course, learners should:

- have detailed understanding of the composition and application of their personal ethical framework
- have detailed knowledge of the concepts and principles regarding the ethical, legal, social and professional issues relevant to the development and delivery of multimedia and an ability to apply these concepts and principles in practice.
- be competent in making informed judgments about the impact of multimedia and information technology on the individual, organisation and society
- understand the 'current state of play' of the information economy in Australia and understand the strategic direction of state and federal governments with regard to the information economy and understand the role of Australia in the global information economy
- understand and engage in the discourse surrounding: Ethical codes for computing and information technology professionals; International domain name control and registration; Domain name registrar accreditation; Disability discrimination in online environments; Digital image manipulation; Content control; Online pornography/erotica; Privacy, security and encryption; Hacking and cybercrime/terrorism; Copyright and intellectual property law
- effectively incorporate ethical practice in the design, development and evaluation of multimedia solutions
- apply knowledge of the ethical, social and legal impact of the use of multimedia applications and technology to a business situation in the form of specific analysis and recommendation.

Resources: The resources developed exist primarily in an online format. Resources for in class workshops were developed in hard copy. Workshops in weeks 2,3 and 4 concentrated on exploration of personal ethical frameworks and utilised scenario analysis as a delivery strategy. Student seminar and discussion sessions were scheduled to take place in weeks 5 – 14.

Phase 2: Knowledge/content analysis. What do we want to achieve? (What is the terminal objective? What type/s of knowledge does the learner need to develop?) In this phase, subject content was analysed and evaluated in relation to the stated aims and objectives of the subject, and to ensure that a variety of learning approaches were appreciated. The teaching strategy adopted included lectures, workshops and online fora, integrating scenario analysis, and facilitating formal and informal discussion. As part of this process major learning goals and objectives were defined -(i)...the terminal objective of instruction" (Taylor, 1994) and subject content was assembled from multiple sources and evaluated -(ii)...analyse the underlying declarative
knowledge base of an expert (or experts)” (Taylor, 1994), and arranged into relatively broad topic areas. The broad topic areas comprise four main modules, providing multiple entry points for learners.

**Entry points:** Four primary organising factors were identified and implemented to provide overall structure to the subject content. These were: Module 1: Ethical considerations; Module 2: Social factors; Module 3: Legal framework; Module 4: Professional issues. Students are required to undertake all four modules of study. Initial modules are presented linearly to enable learners to progressively develop understanding of primary concepts and principles (Figure 2 — Detail ‘Gov.au’).

**Exit points:** Four assessment items were specified. They are: Participation in online fora; 20 minute seminar with oral defence; Academic paper - Article reflection; Consultancy report for ‘real world’ client.

As the subject is taught as part of an undergraduate program exit points are prescribed in that learners must undertake all assessment items. However, learners have control over a number of aspects of assessment. For example, at the commencement of the semester students submit suggested fora topics. Students then ‘vote’ for four preferred fora topics. When selecting seminar topics learners can select from a provided list or negotiate a topic of choice. Articles for reflection are supplied, however learners are also able to analyse (approved) articles of choice. Further, students are encouraged to self select a client partner for the consultancy report.

**Knowledge:** In order to achieve desired learning outcomes learners needed to develop (at least) two types of knowledge - explicit and implicit (Sternberg, 1998, p 13). For example, as primarily novice learners, the students require explicit knowledge “... knowledge of the facts, formulas, principles, and major ideas of a domain of inquiry.” (Sternberg, 1998, p 13), in this case knowledge of ethical, social, legal and professional issues required to function as multimedia designers, they also required high levels of implicit knowledge — tacit knowledge of the domain (multimedia) and the social organisation (their classroom and the University) (Sternberg, 1998, p 13). According to Gagne et al, the locus of control in learning rests with the learner, in that the learner brings to the process of learning inherent cognitive strategies that facilitate understanding (Gagne, 1987, p66). This view is shared by Simonson and Thompson when they discuss cognitive theory and computer based instruction “CBI needs to be organised and delivered in a way that complements the cognitive structure and level of sophistication of the learner “(1994, p36). Further, Gagne states that learner’s process information according to the cognitive strategies used by the learner, and when new strategies are acquired metacognition takes place. That is the process of “learning to learn” is analysed and edited by the learner, increasing the level of understanding (Gagne, 1987, p66). Similarly, Bruner discusses the concepts central to cognitive theory as being: how knowledge is organised and structured; readiness for learning; intuition; motivation (in Simonson & Thompson, 1994, p37). Hypermedia is used as an example of a “powerful tool” in computer based instruction “that is non-linear and non-sequential … [and] used by cognitive scientists to examine how students interact with instruction during the process of learning” (Simonson and Thompson, 1994, p37).

**Phase 3: Sequencing/synthesising content. How can we get there? (What are the major instructional strategies? What are the learning activities that will be used? )** In early iterations of the subject, any opportunity for peer to peer discussion in any formal or semi formal educational environment was non-existent. The opportunity to provide students with content in a way that integrated their areas of professional interest...
(computer mediated communication, multimedia and the Internet), and directly related to content issues they were discussing (legal, social, professional and ethical issues in a networked multimedia environment) was identified. Students were encouraged to learn through understanding by articulating and defending their views through delivery of a student seminar with oral defence and to become proactive learners by setting their own research direction within the criteria for the major assessment item. In addition, tailoring delivery of resources in this way also provided opportunities to help learners identify and expand bridging points between subjects being studied simultaneously. For example, students are required to complete the subject ‘Computer Mediated Communication’ in the same semester as ‘Issues in the Design and Delivery of Multimedia’. ‘Computer Mediated Communication’ requires students to examine and apply concepts and principles related to communication in ‘virtual’ environments while ‘Issues in the Design and Delivery of Multimedia’ provides such an environment through the online fora.

Instructional strategies: Instructional strategies were identified “strategy and role-playing games, intentional learning environment, case studies, coaching and scaffolding, learning by design, group, cooperative, collaborative learning” (Wilson, 1997). In practice teaching strategies focusing on the needs, preferences and expectations of the learner were implemented. These instructional strategies were modelled on the effective practice guidelines and qualities as articulated by Collins (1998) and Jonassen (2001) and comprised:

- striving to create a classroom atmosphere (both on campus and online) that is conducive to collaborative learning and is supportive and inclusive of all learners
- encouraging learners to form learning alliances with their peers in order to share information and knowledge within a peer supported learning framework
- promoting strategies that foster a sophisticated level of understanding of subject content and related concepts by encouraging learners to relate content to personal schema.

Early modules utilised short video segments to coach and support novice learners, and to 'personalise' the eLearning environment (Figure 3.). Students were given simple instructions and study direction for the module.

The rationale for using the online fora was based on two concepts. Firstly, high level understanding of the subject content and specifically complex ethical issues, comes not through transmissive teaching but from engagement with the discourse surrounding specific issues. Secondly, based on anecdotal evidence suggesting a high rate of usage of computer mediated communication technology among multimedia students it seemed that multimedia students would adapt quickly to the medium and engage readily with the concept of an online discussion environment. This view has been supported by the subsequent rapid development of the fora into a dynamic ‘virtual’ discussion environment where students feel comfortable in forming and expressing their opinions on issues related to the subject content. Evaluation feedback showed that 69% of respondents stated that they would have contributed to the fora even if it were not assessed.

A further area of innovation in this subject involved the use of a 20 minute seminar with oral defence to assess student understanding of specific concepts. As multimedia students are, in general, high achieving students the seminar was implemented as an assessment item to provide a high level of cognitive challenge and stimulation for second year students. This aspect reflected one of Jonassen’s (eight) qualities of meaningful learning environments - namely the provision of a complexity (2001). Additional challenge was provided in the form of
weekly reflection questions. The questions were designed to provide extension to in class discussion and activity.

**Phase 4: Evaluation. How do we know we have achieved our aims? (What are the results of formative and summative evaluation?)** Students were surveyed (informally) at the start of the semester "[to]... measure the extant knowledge bases of the relative novices..." (Taylor, 1994). The purpose of the survey was twofold. Firstly, it was important to discover existing levels of knowledge and expectation, and for students to begin to examine the validity of their assumptions and expectations. Students were asked to examine: what they knew now, what they hoped to know and what they thought the subject would help them learn. Based on the outcome of the survey, the subject design focussed on taking the learners from where they were situated at the start of the subject (self identified novices) to where they expected to be (more or less) at the conclusion of the subject (multimedia producers cognisant of ethical and professional issues related to the field). This progression reflected Taylors "... gradual elaboration of a series of organisers..." (Taylor, 1994).

**Conclusion**

The use of a supported eLearning environment for the subject ‘Issues in the Design and Delivery of Multimedia’ provided students with a valuable learning resource. While students enjoyed ease of access, intellectual challenge and willingly contributed to the online fora, the majority of high level discussion and complex reasoning still took place within the on campus classroom.

Within distributed learning environments, multimedia and Internet technology provide a vehicle for the transmission of content material, in the same way print materials, and audio/video cassettes have traditionally done. Technical capabilities aside, it matters little whether content is delivered via CD-ROM, the Internet, audio or video cassette, or even print based materials, as these technologies merely provide the substrate to the learning resource. Unless the subject structure and content is based on sound pedagogical theory, and sits within a coherent, supported learning framework, it will make no difference whether cutting edge multimedia and Internet technology have been used. The content will make little sense to the learner.

Information and Communication Technologies in the Teaching and Learning Process: Does Online Professional Development Make a Difference?

Donna Morrow
Christchurch College of Education, Christchurch, New Zealand

Abstract
This study is an ongoing examination of the effectiveness of an online professional development course designed to examine the connection between learning theory and technology used to support learning in the classroom. The course was taught by three methodologies: a traditional face-to-face class that used the online materials as a resource; an online class that received all instruction via the Internet; and a hybrid class that used the online resources in addition to meeting weekly for teleconferencing with the instructor. At the completion of the course, data was collected from the participants relating to course design and implementation resulting in positive feedback from most students. To ascertain changes in attitude and classroom practice, further data was requested from the students six months after completion of the course. This study focuses on the second round of data collection and examines the changes in attitude and practice reported by the teachers.

Introduction
Information Technology in the Teaching and Learning Process is a core course in a seven course Diploma of Information and Communication Technology at the Christchurch College of Education in Christchurch, New Zealand. The diploma attracts practicing teachers who want to upgrade qualifications and gain skills in using information and communication technologies (ICT). The course is designed to examine the connection between learning theory and technology used to enhance learning in the classroom, and was formerly taught as a face-to-face course with provision for the occasional distance student made available through teleconferencing. At the beginning of 2001, an increased demand from students around the country wishing to enrol in the course as distance learners led to the decision to develop the course for online delivery. Due to the configuration of students requesting enrolment in the course, three different methodologies were identified: a traditional face-to-face group that would meet bi-weekly with the instructor on campus and use the online materials as a resource; an online group that would receive all instruction via the Internet; and a hybrid group involving a group of teachers in a remote location who would use the online resources in addition to an initial two-day, face-to-face start to the class with the instructor. A weekly phone conference between the instructor and the assembled group was also a dimension of this hybrid class. The existence of the three methodologies presented a unique opportunity to explore how the use of telecommunications impacted each of the groups as they interacted with the course materials, the instructor, other class members and with the technological interface used to deliver the course. Also of interest was the impact that this class had on the teachers' attitude and practice in their individual classrooms.

Literature Review
Online professional development is a new methodology that is increasing rapidly. New demands are being placed on teachers and school as an outgrowth of the demands of the knowledge age society, new understandings of the teaching and learning process, and an upsurge in the design and availability of new technologies. These new demands are forcing changes in professional development (Moon, 2000; Trewern, 1999) and have contributed to the growth of professional development offered through telecommunications (Bates, 1995; Blanton, Moorman, & Trathen, 1998). One such change is the availability of professional development presented to practicing educators online, allowing them to take advantage of new interactive technologies that offer study at a time and place convenient to them (Leonard, 1999; Mclsaac & Gunawardena, 1996).

Berge (1998) describes two major frameworks from which to view instruction. The first is a transmission framework, examples being lectures, textbooks and videotape and is based on theories of positivism and behaviourism. The second, a transformation framework, in which the learner transforms information by generating hypotheses, making decisions and constructing knowledge either individually or through a social interaction with others, is based on the theory of constructivism. Contrasting these methods as
teacher centred versus learner centred, Berge states that instructors have implicit or explicit personal theories about good instruction and will choose teaching methodologies and technologies according to these preferences. Bates (1995) cautions that the transmission model no longer meets the changing needs of the knowledge economy workers, where communicating effectively, working in teams, analysing information and generating new knowledge are creating complex new educational needs.

The design of online instruction needs to shift from prescriptive, directed learning situations to environments that allow learners to solve real-world problems and engage in dialogues with a community of practitioners (Jonassen, Davidson, Collins, Campbell, & Haag, 1995). Describing constructivist environments as those that “engage learners in knowledge construction through collaborative activities that embed learning in a meaningful context and through reflection on what has been learned through conversation with others learners,” (p. 13) Jonassen et.al suggests a framework of context, construction, collaboration and conversation to facilitate the making of meaning for learners. Within the online learning environment, this framework can be mediated by a variety of technologies. Computer-mediated communication is available through electronic mail, computer based discussion and conferencing. Collaboration is available online through the ability of the technology to support groups across a distributed environment where learners can actively work toward a negotiated meaning. Using situated, case-based learning to give authentic contexts in which students can work, is supported by both video and hypermedia environments and gives learners an opportunity to reflect, communicate and negotiate a shared meaning within the group (Jonassen et al., 1995). Wiggins (1993) defines the characteristics of good learning environments, both distance and local, as being centred on worthy problems or important questions, including tasks that are replicas of real-world problems faced by professionals in the field, providing access to resources commonly available to those professionals, and presenting problems that require a repertoire of knowledge, judgement and skills. In defining the constructivist online environment Jonassen et.al (1995) states: “Constructivism can provide theoretical bases for unique and exciting distance learning environments. These environments should emerge from authentic tasks, engage the learners in meaningful, problem-based thinking and require negotiation of meaning and reflection on what has been learned” (p. 21).

Design and Implementation of the Course
The outcomes of this course required that students examine a variety of learning theories and teaching strategies, look at current research in the field and apply practical skills. To accomplish these goals the instructor used a combination of directed, transmission oriented learning such as lectures or explanatory content, practical activities and readings; and more transformational, constructivist approaches such as reflection, evaluation and discussion. To give the students a chance to work through these concepts and make personal meaning from the idea presented, students were asked to reflect on what they had read, apply the learning to their own situation and/or evaluate materials within the context of their own teaching situation. Questions were posed through the discussion forum where students could offer opinions, solutions and share experiences based on their personal reflections and interactions with the course materials.

Methodology
This study was begun in February 2001 during the first semester of the academic year in the southern hemisphere. Twenty-nine students enrolled in the course with 14 in the hybrid group, 8 in the online group and 7 in the on-campus group. To evaluate the effectiveness of the course design and understand the students’ perceptions and satisfaction with the course, the following data from the hybrid, online and campus groups was available: initial survey of online students, statistics from the courseware used to present the course materials, e-mail between lecturer and students, discussion board archives and end of course survey.

Since the data collected during and immediately after the course reflect only participants perception of the design and implementation of the course, further data was needed to examine any change of attitude or practice in the teachers’ classroom practice. Six months after the end of the course, students were asked to reflect and comment on changes in attitude or classroom practice that they could attribute to their participation in the course.
Results

Results of the end of course survey showed that students reacted positively to the structure and design of assignments, with only one campus student marking 'disagree' to the question "Assignments were of definite instructional value," and all others marking either 'strongly agree' (33%) or 'agree' (62%). When asked to comment on the effectiveness of the instructional methods used in the class, 62% of students marked 'strongly agree' and 38% of students marked 'agree.' Students were equally positive about the student-student interaction and student-instructor interactivity, and 100% of the students felt that the course helped them to see the relationship between learning theory and information and communication technologies, with 57% marking 'strongly agree' and 43% marking 'agree.' Students felt that the course would help them integrate ICT into their classroom activities with 62% marking 'strongly agree' and 24% marking "agree." Overall, differences in satisfaction between the participants in the three course methodologies, although they did exist, were minor and not statistically significant due to the small sample. The majority of the students were positive about their participation in the course, their interactions with the instructor and the other students, their success with the technological interface and the knowledge gained about teaching and learning with information and communication technologies.

While these results showed that students responded well to the combination of both directed and constructivist instructional methods, and were pleased with the content of the course, these findings did not indicate whether the course would have significant impact on the attitudes and classroom practice of the teachers involved. To determine the impact of the course content six months later, answers to an e-mail questionnaire were examined. Ten teachers returned the questionnaire, which represented a third of the participants.

The first question asked the teachers to comment on any change in attitude or perception about either technology, learning theory or teaching in general that they attributed to the content or interactions in the course. The answers to this question fell into three categories: confidence, leadership and teaching/learning.

Confidence

All the teachers reported feeling more confident. Four teachers mentioned specifically that they felt more confident about their own use of information and communication technologies. Four teachers reported that they were more assured about their own academic abilities or more confident about taking part in discussions about learning theory and/or research relating to the use of technology in the classroom.

"I also feel that the research we had to do, as part of the course, was good for me personally, as it made me feel more confident in myself. Doing the readings, the bibliography and the presentation were all hard work, but I felt extremely pleased with my efforts and finished products."

"I’ve certainly gained more direction and confidence to mix it with those whom I perceive to be more technologically literate ..."

"... and being able to wax eloquent with such terminology as constructivism and scaffolding while discussing lesson plans proves that my IT self-confidence has gone up the scale tremendously."

Several teachers noted that they found themselves more confident as they planned instruction.

"This has helped me to have greater confidence in using ICT with my classes and to be less concerned about not knowing how to do everything."

"It has also helped me to become more comfortable in an ICT environment where collaboration and teacher facilitation are often the most effective strategies to use when managing a class."
But more so, the readings have given me the confidence and knowledge to trial things. The stress seems to have alleviated when setting up items for the class, eg. Hyperstudio stacks at the beginning of the year were effortless. I now think the big stresses came from me, as the children pick it up so quickly.

Leadership
Several teachers commented on leadership roles they had assumed. Some of these roles were formal such as becoming the technology coordinator for the school, running professional development sessions for staff or posting technology rich lesson plans on a website; while others were more informal:

“This course has also made me think more closely how to regard computer skills – or lack of them – amongst colleagues and how to extend the common pool of knowledge within the school.”

“I read information [in the course] that I have referred to since and passed on to other teachers I work with.”

“Attitude was positive to start with, but knowledge gained has led to informal discussion with peers and increasing their options.”

Teaching/Learning
Comments were mentioned by the teachers that pointed out changes in perceptions toward teaching and learning.

“I have found myself looking at the work that I am preparing and presenting, and reflecting on whether the knowledge fits the constructivist, directed or behaviourist style and in this reflection I guess comes an improved evaluation of the product as well as a question of the value of the work and how it is presented.”

“One of the perceptions that I have become more aware of is sorting out whether the computer is a tutor, tool or tutee. It has made me look closely at what the computer in each situation requires of the learner.”

“Whereas I used to be fascinated by what computers and technology could do I am now (since the course) refocussed on the fascinating business of learning and how to set up the optimum conditions for it to take place.”

“I have found it vital that I know what research says.”

The second question focused on the practical classroom applications. Teachers were asked to comment on any activities they had implemented or changes they had made resulting from the knowledge gained in the course. Some answers focused on changes in the classroom that involved the use of technologies.

“I have focussed on information literacy in our library and tried to refine the library use to include the Internet.”

“I taught and used PowerPoint and Internet skills in my IT701 assignment. I have since gone on to teach spreadsheets, databases and HTML in basic ways.”

Teachers also reported making changes in the way they approached the teaching task, taking the learners’ needs into consideration. The following quotes are examples of this.

“My focus with ICT now is to get the children asking focus questions that they will be able to answer.”
This course has made me think about direct instruction and how I can present it when teaching computer skills to ensure that the students' learning styles are used and higher order thinking skills are stimulated.

"Probably when I analyse the impact of IT701 on my teaching practice, I believe it has given me ideas on how I can make better use of the computer as a tool and how it fits with learning theories."

Conclusions
From the ten questionnaires returned there is evidence that the course has had an impact on teachers and they way they approach teaching and learning. Many teachers report increases in confidence in computer use, planning for classroom instruction and academic abilities. Some mention increased leadership within their educational communities. All teachers noted changes in their perceptions and attitudes about using information and communication technologies in the teaching and learning process. These included a new appreciation of constructivist versus directed approaches to teaching and learning, fostering higher order thinking, catering to individual learning styles, the teacher in the role of facilitator, an increased appreciation of the benefits of research findings on classroom practice and reflection and evaluation of their own teaching methods. One teacher described the changes in this way:

"I don't know sometimes I think that I must have been walking around teaching with my eyes closed. Not realising why I am teaching this way, where did these teaching strategies come from and what was I trying to achieve in the class. This course has opened my eyes - even though it is just now that I have realised how much I have changed over the year - it's quite exciting!"

Results from the questionnaire about changes in classroom practice are less clear. Some teachers reported on specific practices they had changed while others reported on changes in focus. In general, the responses from the second question were extensions and variations of the responses to the first question and did not list explicit changes. A limitation of this study is the low number of questionnaires that were returned and the limited scope of the questions asked. Further study would be required to determine the long-term impact of the course content and methodology on the participants' classroom practice.

Multimedia Magic: The Design and Development of a Programme in Applied Serology

Dr El-Marie Mostert
Department of Telematic Learning and Education Innovation
University of Pretoria, South Africa
emostert@postino.up.ac.za

Abstract: This multimedia programme consists of colourful animations and video footage, supplemented with commentary, text, slides, and photographs. It is used for training students and laboratory personnel in basic serology. The educational rationale behind the design and development of this programme is discussed. The compilation of the project team and the roles and responsibilities of each member is presented and the programme will be demonstrated.

Introduction

The development of Applied Serology programme was initiated by the Department of Veterinary Tropical Diseases, Faculty of Veterinary Science, University of Pretoria. Multimedia development is a costly procedure, but due to funding from a German institution, it was possible to obtain the necessary resources to develop this programme.

Educational rationale

The aim of the programme is to present students and laboratory personnel with a multimedia tutorial on adapted serological techniques for use in undergraduate as well as post-graduate teaching in Immunology, Applied Veterinary Immunology and Serology.

Practical serological procedures as used in diagnostic and research laboratories, are relatively complicated tests that require dedicated and expensive apparatus and reagents. To demonstrate these procedures is labour-intensive and costly. Therefore it would be prudent to utilize communication and information technologies to provide cost-effective and innovative learning opportunities in applied serology and immunology. The nature of serological techniques requires that students be afforded maximum visual exposure and hands-on training. By developing a programme richly illustrated with diagrams, video clips and structured animations, it will provide opportunities for students to be repeatedly exposed to procedures that would otherwise only have been demonstrated once, in a teaching laboratory.

A self-assessment question databank was included to provide the students the opportunity to assess their own level of competence. A student can do the self-assessment as often as he/she wants to – the questions for each exercise will differ because it is drawn from the database of questions.

Planning phase

The content of the programme is based in part on a book compiled by C. Staak, F. Salchow and N. Denzin – "Practical Serology – From the Basics to Testing". The rest of the content was added and it was very well structured before the development of the programme started.

Collaboration between the Department of Veterinary Tropical Diseases of and the GTZ-BgVV Service laboratory in Germany exists and the development of this project was made possible by the generous financial support provided by the German Ministry of Economic Cooperation and Development through the GTZ. Although some services needed to be paid for, the Department of Telematic Learning and Education
Innovation provided the services of the instructional designer and programme developer. A project team consisting of members of the Department of Telematic Learning and Education Innovation, lecturers from the Department of Veterinary Tropical Diseases and the GTZ, was compiled.

The subject matter experts from the GTZ and the University of Pretoria compiled a very extensive storyboard even before the project proposal was submitted to the Department of Telematic Learning and Education Innovation of the University of Pretoria. This department is responsible for the development of different forms of electronic educational media used in the different faculties.

**Project team**

The project team for this project consisted of a project manager, content specialists, an instructional designer and a programmer, a graphic designer, a sound engineer, a photographer and video photographer. Each team member played a significant role in the success of the final programme.

**Design phase**

The design phase consisted of the development of an appropriate “look and feel” and the selection of an appropriate development platform. QuestNet+, an authoring tool was used for the development of the programme. The functional utilisation of different media e.g. animations, voice-over, video, graphics etc. was very well researched by the appropriate members of the project team. The design of the processes and procedures demonstrated by the programme, was based on the fact that the principles applied in serological techniques are often very difficult for students to understand and it also takes a lot of time and laboratory equipment to perform the different tests. The programme provides the student with a graphic and animated explanation of each test principle. The test procedures are explained in systematic animations and are supplemented with video footage. The aim is to expose the learner as much as possible to the real-life situation in the laboratory. Photographs, slides and other graphics are used to present results.

**Development process**

Numerous obstacles had to be overcome during the development process e.g. the distance between one of the subject experts (in Germany) and the developers (in South Africa). Failure of technology at a crucial phase of the project, also hampered the continuity of the project. Emphasis was placed on the effective utilisation of resources and time management. Quality assurance strategies were also implemented to ensure that all the team members were involved with the testing and evaluation of the programme and everybody was satisfied before the next phase commenced. Technical aspects as well as content matter were thoroughly assessed. A lot of time was devoted to these quality assurance strategies.

**Demonstration**

The programme will be demonstrated to provide examples of:

- The functional use of the different media.
- The content of the programme.
- The self-assessment exercises.

**Conclusion**

Applied Serology is an excellent example of the power of multimedia. During the design and development phases of this project many valuable lessons were learnt that will be implemented in the process of developing of future multimedia programmes. It was surely a worthwhile experience.
Abstract: This paper discusses the growing need for a virtual university facility in Lebanon and the creation of a system (VUSIL) to meet this need. Although general public access to the system is possible, the prototype server was designed with two main user-groups in mind: students and professional engineers. The system was designed to provide lifelong learning opportunities based on the potential of the Internet and the World Wide Web to deliver distance education. A needs analysis was conducted and the results were used to inform the design of the VUSIL system. This paper describes the results of the needs analysis and outlines the design of the system.

Introduction

As we enter the 21st century and embark on the Information Age, there is a growing belief that learning is the key to economic success and competitiveness. This belief is developing at many levels – within individuals, organisations and nations. In a fast changing world, knowledge rapidly becomes outdated. Employees therefore need to enhance their employability through ongoing self-development. Furthermore, employers need to continually update the skills of their workforce in order to remain competitive. Bearing this in mind, Keeling et al (1998) suggest that 'learning in the workplace ... is essential to promote a more highly skilled, flexible workforce and economic stability'.

Over the last few decades a new approach to learning has evolved in order to overcome the problems outlined above. This new approach is often referred to as 'continuing professional development' (CPD). CPD is just one aspect of the broader field of lifelong learning. The development of lifelong learning has taken place in two basic stages. The first of these was initiated in about 1970, when a number of international organisations such as UNESCO, OECD, the Council of Europe and the Standing Committee of European Ministers introduced the concept of lifelong learning into international discussions and committed themselves to its realisation. In the next decade, interest in lifelong learning waned but it still retained its importance (Peters, 1998).

The second stage in the development of lifelong learning started in the mid-1990s. Interest in the concept is now greater than ever before and is of a completely different nature (Knapper and Cropley, 2000). The economic, technical and social changes and the new challenges set by the Information Society have made this possible.

The lifelong learning approach to educational provision is important because it can facilitate the realisation of the 'education-on-demand' and 'just-in-time' training paradigms. These techniques are increasingly being implemented through the use of appropriately designed web-based systems (based
on both intranets and the Internet). Web-based training (WBT) is a method for the delivery of training, assessment and reference material via the Internet or an intranet (Steed, 1999). Like computer-based training (CBT), it is self-directed and self-paced. It allows students to access training material on their own personal computers. Unlike CBT, web-based training materials may be rapidly changed and delivered to students, without the cost and 'latency' involved in creating and mailing out a computer diskette or a compact disk (CD-ROM). Another important facet of WBT is that it allows the tracking of course use and the assessment of users' progress — in order to better determine the success of the training course. In addition, WBT provides interactivity through online communication and multimedia techniques such as chat rooms, e-mail, discussion groups and audio/video presentations (via the Internet). Some of the benefits of web-based training include: reduction of training expenses and training time, ease of delivery, ease of updating content, multimedia capabilities, controllable access and accessibility - anytime and anywhere.

A genuine virtual university has no physical place where people go to attend classes. The classrooms are nowhere and everywhere at the same time. Indeed according to Donoghue et al (2001), it is anticipated that 'virtual classrooms will take the place of the solid buildings where students currently attend lectures, at set times in set rooms'. Within these systems, the lecturer is the instructor and facilitator who are trained to use networking facilities to teach and lead interactive discussions (Duggleby, 2000; Barker, 2002a; 2002b). Furthermore, the class materials, books and other products can be ordered via the telephone or on the Internet. These books may be conventional paper-based publications or they may be electronic documents that exist within a digital library facility. These resources can be augmented by the use of email and other means of electronic communication such as video conferencing. The students and facilitators communicate with each other - just as they might if they were meeting in a student lounge, a library or during a lecturer's office hours. Emerging Internet technologies can be used to create online learning communities that are not restricted by geography.

Project scope

The fundamental issue that this research is intended to address is the impact that digital electronic libraries, and hence, virtual university facilities are having on post-compulsory educational provision within the professional sector of the Lebanese community. Particular emphasis has been given to exploring the implications of realising the education on demand and just-in-time training paradigms through the utilisation of a distributed digital library system based on the use of a globally available digital information superhighway. A cyber café was used as one of the access options. Other access possibilities include home PCs, libraries and conventional universities.

The initial work in this research project involved identifying the needs of particular sectors of the Lebanese professional community and designing a prototype virtual university facility to meet those needs. Courseware materials have been designed, and are in the process of being implemented and evaluated. These materials are to be delivered using the prototype VUSIL facility. Subsequently, they will be employed as a basis for an empirical study of lifelong learning in Lebanon. As well as courseware creation, particular emphasis was given to mechanisms for course accreditation, skill assessment and the mechanisms underlying the optional award of 'digital diplomas'. A critical evaluation of the potential advantages and limitations of the system was conducted from two perspectives: those involved in using the system; and those responsible for maintaining it.

Needs Analysis

The needs analysis was undertaken within the Internet café ('the PC club') in Beirut, Lebanon; most of the participants were students at universities and professional people (mainly engineers). The main aims were: (1) to identify the need for a prototype system, VUSIL; and (2) to explore different topics of interest that would become subjects of study. Because the intended users of the system are both students and professional people, the perspective of both of these groups were studied. For this purpose, an online questionnaire was used; this could be accessed via a URL that was embedded in an electronic message that was sent to members of an electronic mailing list. This contained 337 addresses. In some situations, 'follow up' face-to-face interviews were carried out in order to clarify issues in order to obtain more information about potential study areas.
Seventy-seven responses were received. Sixty-three percent of the respondents were males; thirty-seven percent were students, twenty-eight percent were professionals (mainly engineers). The rest followed a range of careers such as computer-related, management, self-employed and consulting. Amongst those who took part in the survey, nearly 45% held (or were studying for) an undergraduate degree and 32% possessed (or were eligible for) a graduate degree.

The results of the needs analysis survey for VUSIL were encouraging. This is reflected by the fact that more than 75% of those who responded reported a positive interest in online learning. Further interest was shown in obtaining a qualification through the Internet. Four levels of online qualification were distinguished: diploma or certificate, technical degrees, undergraduate and post-graduate degrees. A diploma/certificate represents one or a set of modules relating to a subject of study; at this level, a full degree is not aimed for, only recognition of successfully completing the required modules. A technical degree is based on a highly specific set of modules. Undergraduate (BSc) and post-graduate (MSc/PhD) levels represent normal degrees. The majority of respondents (61%) showed an interest in the post-graduate degree level, while 19% and 12% expressed an interest in studying at diploma/certificate and undergraduate levels, respectively. Only 8% were interested in further study leading to a technical degree. These results demonstrate the need for and the potential importance of an online learning system (such as VUSIL) in Lebanon.

The survey has demonstrated the need for a wide variety of subjects of study. It revealed that information technology topics were amongst the most popular subjects of interest. Computers and the Internet were the most popular topics - accounting for more than 25%. There was also considerable interest in other subjects - such as e-business (11.5%), money and finance (10.7%), science and nature (9.9%) and health and fitness (9.1%). Based on these findings, appropriate topics were chosen for delivery through VUSIL.

An attempt was made to study the reasons behind respondents' choices relating to the selected areas of interest. The reasons were divided into four main categories: 36% for new skills relevant to jobs, 25% for current topics of importance, 25% for personally relevant topics and nearly 6% for particular leisure interests or hobbies. Other minor reasons given amounted to 8%.

The findings from the survey we have conducted fall in line with the results of other research in this area - see, for example, Sinitsa (2000). Our results provide a sound justification for the development of the VUSIL system.

**Development of the Prototype**

The VUSIL project involved a number of different design and development stages. Following on from the initial design, the first prototype was programmed. Table 1 shows the functions that were included in the first implementation of the VUSIL prototype. The next stage of the development involved producing two short courses and mounting them on the server. At the conference, further progress on the development of the system will be reported.

The main aims of our study are to test the first prototype virtual university in Lebanon, to help tutors perform their teaching tasks and activities and to assist students and professionals in their learning activities. As can be seen in Table 1, the system supports six main functions. Each of these is briefly discussed below.
The Administration Office performs the tasks of a university's registration facility. This includes the ability for users to register for online courses, view and edit their personal profiles, and view their transcripts. The Lecture Hall is the place where users who are registered for a module can go in order to take the corresponding lectures. The Library provides two main facilities: first the provision of access to electronic documents relevant to particular courses of study (for example, course specifications and course notes); and second it provides a bookshop facility. As VUSIL does not handle commercial transactions, there are links to Web sites (such as www.amazon.com) where students can buy books for the courses. Students and online-tutors can enter the Library in order to purchase required books for courses, university merchandise, souvenirs, etc. These can be placed in a shopping cart and purchased from third-party suppliers. The Course Catalogue provides users with general university information along with a list of available modules. Upon choosing a certain module, users are presented with a more detailed description. The Forum gives users the ability to post questions and information related to the modules they are taking. Modules are automatically added to the Forum once they have been entered in the Administration Office. In the Forum, users can select the module to which they wish to post questions and comments. In turn, learners and tutors can reply to these posted items. The Forum also serves as a place for tutors to post information about modules such as test dates, assignments, and so on. The Manager's Toolbox is primarily intended for course instructors and managers. It enables new courses to be added to the system and, if necessary, old ones to be deleted. In addition, particular parts of any given course can be modified and deleted and new parts added. New functions can be added to the toolbox as needs arise.

**Future Developments**

VUSIL has been designed and built using a basic set of requirements. There is therefore still a number of features and improvements that need to be incorporated into the system. These fall into short-term and long-term development goals. Three of the most important short-term developments that should be included in the system are: (1) the addition of a 'user-friendly' help system that is capable of providing new users with general help, guided walk-throughs and advice related to using the system; (2) the provision of a topic index and a search facility to enable students to search the VUSIL web in order to locate particular items of interest - software to perform each of these latter functions is available commercially; and (3) linking the VUSIL system to external academic support sites. This is discussed below.

For the last eighteen months, the University of Teesside (UK) has been, evaluating the use of a commercial software package - called Blackboard - to create an online learning environment. Blackboard (www.blackboard.com) offers a complete suite of enterprise software products and services that provides online education infrastructure for schools, colleges, universities and other education providers. Using the power of the Internet, it provides software solutions that facilitate the management of the many diverse demands of an academic organisation and helps to bring educational experience online. One of Blackboard's important features is its forum facility. As a further development of the VUSIL system, we plan to provide our users with access to Blackboard's forum - thus giving them the ability to access some of Blackboard's facilities.

From the perspective of long-term developments, there are three important enhancements to be made to the system. First, the addition of a large variety of subjects of study; this would cover most of the topics in which students have expressed potential interest (based on the survey). This variety of subjects would attract more users, thus adding to the overall utility of the whole system.

The second main development would involve the incorporation of XML as the basic mark-up language (Mans, 2000). Use of XML is important because it facilitates the preparation of the catalogues and indexes needed in order to implement efficient and effective searching for material and modules in the system. It also simplifies data exchange with respect to the administrative tasks associated with monitoring and assessment – and subsequent reporting of feedback to both students and staff.

The third enhancement would involve the addition of streaming audio and video facilities (Beckstrand, Barker and van Schaik, 2001). This type of technology does not require files to be downloaded before use. In addition, the use of streaming technology does not require specific class meeting times while still simulating on-campus presentations.
Conclusion

Computers and electronic communications technologies are increasingly being used to provide mechanisms for the support of open and distance learning. These technologies make it possible to provide mechanisms to facilitate an ‘education on demand’ approach in a variety of different situations. This can occur at home, in the workplace, in libraries and in colleges. Of course, through the use of mobile computing facilities (such as notebook computers and hand-held devices), there is no limit to where electronic learning can take place provided a wireless signal of some sort can be received. This approach to learning using mobile technology is illustrated by the use to which devices like Compaq’s iPaq hand-held computer are now being put – see, for example, Schneider (2001).

There is now a significant number of virtual university systems available to support open and distance learning - particularly in the UK and North America. We have designed and developed a prototype virtual university server system to support the needs identified in this paper. Quite naturally, these systems are based on (and embed) ‘Western culture’ as they are primarily designed to serve American and British societies. However, within Europe, the use of ‘all English’ material is problematic because of the many different languages and cultural differences that exist. This too is a problem in many Middle Eastern countries where Arabic is the predominant language. Although the VUSIL project is currently being developed in English, a long-term objective of the project is to create an online system that can be used by both English and Arabic speaking people. Naturally, two important aspects of this work are the development of a bilingual facility both in terms of the end-user interface to the system and its academic content. Such a development is quite challenging and makes it different from many of the other monolingual virtual university systems that currently exist. For Arabic speaking nations, this is an important development because although many students and most professional people in Lebanon can speak and use English, there are many other people in the Middle East who are likely to want to use lifelong learning opportunities but who are unable (or unwilling) to use English as their mode of communication. The VUSIL system could easily cater for this type of audience.

A Neural-Network system for Automatically Assessing Students

D.J. Mullier
1Faculty of Information and Engineering Systems
Leeds Metropolitan University
United Kingdom
d.mullier@lmu.ac.uk

Abstract: This paper is concerned with an automated system for grading students into an ability level in response to their ability to complete tutorials. This is useful in that the student is more likely to improve their knowledge of a subject if they are presented with tutorial material at or just beyond their ability. However, dynamically responding to a student’s changing knowledge about a subject usually requires the presence of a human teacher, an altogether expensive resource. The system discussed here can grade both a student and the questions in a tutorial with minimal input from the human teacher. In order to accomplish this a specialist neural network is employed. The design and operation of our system is discussed along with arguments as to why a neural network approach is suitable for this problem.

Introduction

The Tutorial Supervisor (TS) is an automatic system for grading a student into an ability level in response to the student’s interaction with tutorial questions. Once the student has been graded then a question or tutorial can be selected which is inline with best pedagogic practice (Bergeron 1989). Our TS is an expansion of the TS designed by Bergeron et al (1989). Our TS improves on Bergeron’s original specification by having the additional ability to adapt to both students and questions/tutorials as the system is in use, as opposed to requiring the system to be taken off-line and reprogrammed/trained. The TS’s ability to respond in real-time to a student’s changing ability and how a population of students perceive a particular tutorial or question is brought about by the use of a specialist neural network device that is able to learn and adapt without human intervention. A thorough description of our TS along with complete details of its design and testing can be found in Mullier (1999).

Operation of the Tutorial Supervisor

The TS is simple in operation. A set of questions to be given to the student is recorded in a database and is graded with a difficulty level by the author of the question. A student can then be given an appropriate question, depending upon the student’s ability and the difficulty of the question. However, in order for a student to progress in their learning it is necessary to pitch questions so that they sufficiently tax the student without it being impossibly difficult (Bergeron 1989). Therefore it is necessary to track the student’s change in ability as they progress through the learning material. Our system achieves this by recording the student’s interactions with questions and mapping this onto an ability level. The system is robust to exceptions in the student’s behaviour, since a student may generally perform well but make a mistake with one particular question. Similarly, the system is able to regrade questions in the question database. For example, a question may have been graded by the author as being relatively easy. However, it may transpire that a population of students actually find it difficult. This will be borne out by most students who should have performed well with the question actually performing poorly. Such a situation negates the pedagogy stated above. Our system is able to statistically determine that a question has been misgraded and is able to remedy the situation. The remainder of this paper will discuss the issues relating to the design and implementation of our TS system.

Rationale for Using a Neural Network

A neural network is an Artificial Intelligence (AI) system that is able to learn rules in response to being presented with many examples. The neural network is said to learn the rules from the examples. In contrast a traditional rule-based system would have rules encoded within it that a designer has previously identified. The advantage of neural network systems is that it is not always possible for a human designer to express and encode rules in a reasonable time frame or even express them at all. A
further disadvantage of rule-based systems is that if the rules change for some reason then it is necessary for the designer to reincorporate the new rules within the rule-base (Hagan et al. 1996).

A further reason for choosing a neural network for the TS in preference to a rule-based system is that, unlike a rule-based system, a neural network can be domain independent. It is unlikely that, for example, a high level student produces results in the same range for every type of domain. Thus the rule "IF SCORE >70 THEN LEVEL 10" is only likely to apply to the domain that it was initially defined for. This is the reason why Bergeron et al. (1989) use a neural network for their Tutorial Supervisor. Their neural network holds the rules that it has learnt from its training data (the first domain). It is then able to change its rules in response to new data (new domains), by retraining off-line. In this manner the neural network can adapt to misconceptions or inaccuracies in the original rules and adapt to new situations. This would be a difficult and time-consuming process for a symbolic rule-based system, since it would require the re-engineering of the rule-base by a designer, in that the new rules would have to be identified and then encoded. In essence, the neural network is doing the job of the human rule designer. Designing such rules is not necessarily a simple matter, since it requires the human designer to examine many student interactions with various questions and tasks so that a valid grading of each question can be made (e.g. this question was answered well by novice students, it is therefore easy and can be presented to other novice students). The situation is further complicated by the possibility that different populations of students (students from different classes or tutorial groups) may have different previous knowledge of the domain and therefore the initial question gradings may not apply to them. It would therefore be helpful if an AI system could be employed to accomplish the task of dynamic question grading and therefore remove some burden from the author. However, Bergeron et al.’s (1989) TS is unable to readapt to different domains without being manually provided with new training data and then retrained off-line. The remainder of this paper describes the neural networks used for our Tutorial Supervisor, which improves upon Bergeron et al.’s (1989) design by allowing the automatic on-line adaptation to different domains.

**Tutorial Supervisor Architecture**

The Kohonen self-organising map is a specialist type of neural network with the ability to learn without a designer specifically indicating that the networks results are right or wrong, this is termed unsupervised learning (Callan 1999). This is useful in our system since the distinction between a novice student and an expert student, in terms of marks at tutorial nodes, may be small, or may vary significantly from domain to domain. For example, the majority of students may achieve marks between 50% and 60%, with a few results between 60% and 75% percent and a few between 40% and 50%. There are therefore two large ranges of numbers that occur infrequently (0-40 and 75-100). If a standard type of neural network, such as a backpropagation network which is the most commonly used neural network, were to be used to model the above problem then these mark ranges must be identified beforehand or the neural network’s outputs would have to be designed to produce student ability levels between 0 and 100, in order to accommodate a broad range of scores. Identifying scores beforehand is not likely to be practical since it would require the collection of a large amount of data (with no initial benefit for the student). Designing such a generic neural network also introduces the following difficulties. A back-propagation neural network must have enough ability levels (outputs) to clearly demonstrate the distinction between students in these highly clustered areas, necessitating an increase in outputs for all areas to cover for all possibilities, even those that are unlikely. The increase in outputs renders the neural network more complex, resulting in a network that is more difficult to train. Further, and most crucially, once the trained back-propagation neural network is used for different domains, then there is no direct correspondence between an ability level for one domain and an ability level for another. This is because an output of the back-propagation neural network does not correspond directly to a student ability level, since the student ability level may vary between domains. The upshot of this is that the back-propagation neural network would require complete retraining for different domains.

A Kohonen network can solve the above problem by continually adapting to input stimuli whilst it is being used by students. This is because of the way a Kohonen network operates. A Kohonen network is given a number of outputs by the network designer, representing the number of categories that the network designer wishes the network to identify (the number of required student levels in our case). It is then left to the network itself to sort the input data into this number of categories, since it is not made explicit by the training data itself. In the case of the back-propagation neural network it would be required to include an example solution with the training data. If there are ten or more distinct patterns in the data then a correctly trained Kohonen will learn by itself to distinguish them (Kohonen 1989, Callan 1999). Therefore, it is irrelevant to the network if the actual values of the input data change; it will still attempt to separate them into the number of categories represented by the number of
outputs that it has. The outputs of a Kohonen neural network therefore behave as fuzzy sets, whose boundaries may change over time. The Kohonen neural network is therefore simpler than the standard neural network for the TS in this case, since the number of outputs can be kept small since it is not necessary to design for all unlikely possibilities (the network will adapt to them if they occur).

Training Data

A neural network has a number of inputs, which in our case represent the student’s responses to questions and a number of outputs, each one representing a unique ability level. The inputs to the Kohonen neural network must incorporate history data in order to make a more informed evaluation of the student and therefore avoid a restriction of Bergeron at al’s (1989) neural network, namely reacting to a one off error (or success) from a student. History data can be used to prevent the TS from making snap judgments of the student. For example, if the student is generally performing well, but gets one question wrong, then if no history data is taken into account the TS is forced to make a decision based only upon the most recent presentation and the student is likely to drop a level. The student ability itself represents a degree of history data, in that if a student is regarded to be an expert student, then they must have performed well in the past. However, the direct incorporation of history data prevents a continual changing of levels based upon one interaction only. The incorporation of history data can be achieved by presenting a number of previous interactions with tutorial nodes to the neural network. Each time a new interaction is presented the previous interactions are shifted along the inputs to accommodate the new input and the oldest interaction is lost. Training data supplied to the neural network are figures that represent a percentage value of a student’s interaction with a tutorial. For example, if the student achieved a 50% success level with a tutorial question, then it is this figure that is passed to the TS.

Re-grading Questions Using Fuzzy Logic

Each question level is generally presented to a student of the same level, or just below, a pedagogy used with success by Bergeron et al (1989), in that a level x student should be able, overall, to answer a level x question. A question may however, be graded incorrectly by the domain author. This can be determined by the system after a number of interactions with different students (a population of students who should be, generally, getting a question right are getting it wrong or vice versa). It is not suitable to immediately re-grade a question with respect to an interaction with one student, however. As has been discussed earlier, a student is a complex entity and it is difficult to formulate rules describing them accurately. In order to resolve this problem, each question level is modeled as a fuzzy set. This allows a question’s level to be adjusted slightly, within the level, without necessarily affecting the overall level (as presented to the student), thus there is a buffering effect and the question does not rapidly leap back and forth between levels. The use of fuzzy sets also provides a mechanism for allowing a question to belong to more than one question level set, providing a smoother transition between levels. This differs from Bergeron et al’s (1989) approach in that they collect data from the students and then periodically use it to update the training of the neural network. There is therefore a delay, which ensures that the question levels do not suddenly change, which could potentially result in the question level continually changing and thus be distracting to the students. However, the drawback is that this is a manual process that requires the direct intervention of the system designer. The process for regrading questions described below is achieved automatically, whilst still maintaining the delay between the question being presented to a student and changing its level.

A question is re-graded by a population of students’ interactions with the question being determined as incorrect by the TS, for the reasons described above. Such erroneous interactions cause the question ability to move within the fuzzy set until it crosses into a different fuzzy set. A question’s ability level is therefore only changed after a number of erroneous interactions with students, the actual number being dependent upon the size of the fuzzy set, the fuzzy set is therefore acting as a buffer. A simple fuzzy processor accomplishes question re-grading. The fuzzy processor compares the level of the current question and the student level output of the TS neural network. The buffer can be implemented using three fuzzy rules (Kosko 1996):

1. IF S_LEVEL > Q_LEVEL THEN Q_LEVELf = Q_LEVELf + 1
2. IF S_LEVEL < Q_LEVEL THEN Q_LEVELf = Q_LEVELf - 1
3. IF S_LEVEL = Q_LEVEL THEN Q_LEVELf = Q_LEVELf (remain unchanged)
where

$S_{\text{LEVEL}}$ is the level assigned to a student

$Q_{\text{LEVEL}}$ is the level of the question, used to decide whether it is suitable for the student.

$Q_{\text{LEVEL}}f$ is the fuzzy membership number of the question.

![Figure A Membership of the fuzzy sets](image)

Using figure A, a question may belong to one or two of four levels. If the question has a value of $Q_{\text{LEVEL}}f$ corresponding to $x$, then the question is regarded as both level three and level four. If however, as a result of interactions with several students, rule one is repeatedly fired, then the value of $Q_{\text{LEVEL}}f$ will increase and the question will become graded as level four only. Conversely, if rule two is repeatedly fired then the value of $Q_{\text{LEVEL}}f$ will decrease and the question will be graded as level three only. Such changes may result in further increases or decreases in the value of $Q_{\text{LEVEL}}f$, which may become any of the levels available. The utilisation of this fuzzy system ensures that the level of a question is not changed (in terms of presenting to students) in response to individual interactions with students. The fuzzy logic is able to distinguish overall trends and is therefore robust in the presence of exception data.

The changing of levels is dependent upon the size of the fuzzy sets, since the size of the fuzzy set directly affects how many interactions are required before a question migrates from one level to another. These start and end points also define whether a question can belong to more than one level or not. It is intuitively sensible to provide a small overlap of neighbouring fuzzy sets. This provides a simple buffer that will help the question to find its true grade. For example, if fuzzy sets were to be defined separately (or as a discrete set) then a question may be presented as a difficult level but become graded as an easier level after several interactions. Once this change has occurred then the question is no longer presented to the original class of students that graded it. This may result in the question becoming stuck at a particular level. If instead the question is presented to both the original class of student and the new class of student, then a smoother progression from one level to another may result and the extra information enables the question level to settle more easily. If the fuzzy sets are defined so that a question may belong to more than two levels, then the question level may not settle at all, as one level of student may push the value of $Q_{\text{LEVEL}}$ one way and another level may push it in the opposite direction.

**Experimental Trials**

Our TS was designed using a Neural Network package, NeuroShell2 by Ward Systems. Several configurations of neural network were built and tested with both simulated data and real student interactions. The most successful architecture is discussed below. A full description of the experimental trials can be found in Mullier (1999).

The Kohonen neural network proved to be a successful architecture for the problem of grading students into ability levels. Most permutations of parameters produced neural networks that converged upon a solution. A fast and reliable neural network could be produced with between five and twenty inputs or outputs. It is possible to increase this number, but this is unlikely to be required, since it is not desirable to use information from too far in the past, since the network does not have any knowledge of time. It has been experimentally determined that the number of outputs should not rise above twenty. If more levels are required then the outputs may be combined to form fuzzy sets.

Parameters for a generic Kohonen Tutorial Supervisor, i.e. one that will converge on a solution and provide a high degree of student grading for a variety of domains are suggested as the following:
• 5 Inputs – this has been found to provide the network with enough information with which to evaluate the student. It is suggested that an input filter, a simple algorithm that combines many history elements into the five required, is employed if more than this number of inputs is required.

• 10 Outputs – corresponding to ten student levels, if more levels are required then it is advised that thirty levels is the upper limit, beyond this the neural network becomes less likely to activate all of its outputs.

• Any form of data extraction may be used to form the training set, however a large number of examples are required to produce a fully trained network. One thousand student interactions provide enough examples. Note therefore, that for a network to be trained with real student data is probably impractical. However, since the Kohonen network is fully adaptable, it is suggested that a network be trained upon generated data and then allowed to adapt to real students. The generated data could be designed to represent realistic but uncomplicated situations. For example, training the network to model simple rules such as "If result in the range 40-50 THEN set student level to 5". The neural network is then able to adapt to any misconceptions present in these rules. Once a neural network has been trained it may be saved and replicated.

Discussion and Conclusion

The Tutorial Supervisor is intended to be an automatic system for gauging a student’s abilities with tutorials. This imposes a restriction upon the kind of material that can be offered in a tutorial, since it must be suitable for automatic assessment. Automatic assessment effectively rules out assessments that cannot be graded in a relatively simple fashion. For example, it would not be possible, with current technology, to have an essay automatically assessed, since this would require a complex understanding of the essay on the part of the assessor. Automatic assessment is limited to tasks that can be broken down into elements that can then be individually marked. A tutorial may, for example, take the form of ten questions, each of which could be answered by the student and graded as right or wrong, or graded as containing relevant keywords. However, assessment is not the role of the TS, which is presented with completed assessments (results). Assessment is therefore limited to multiple-choice questions or identifying that the student has visited certain nodes (or a combination of both).

A key issue of concern regarding the TS is the number of student levels that the TS is to recognise and output. Each student level should have tutorial material generated for it; since it is important to target tutorial tasks at the student’s ability, this is seen as being of more educational benefit than offering the same tutorials to all students and then assigning a student level based upon the grade that the student achieves (Bergeron 1989), although there is no technical reason why the latter could not be done. The number of student levels therefore may change between domains, since some domains may have a richer set of assessment questions than others (for a number of possible reasons). A possible conflict therefore could arise between the number of student levels that has been designed into the TS by the system designer and the number of student levels that are required by the current domain author. A possible solution to this problem is for the system designer to provide a TS that is capable of outputting a large number of student levels and then each domain author can allow it to adapt to their domains and ignore the inactive outputs from the TS that will naturally arise if there is not sufficient input student levels. The benefit of this approach is that one TS configuration could be used for many domains without the need for reconfiguration. However, the drawback is that some outputs of the TS will always remain inactive, although the experiments carried out as part of the research demonstrated that active outputs tend to cluster together and so are easily identifiable. A problem related to the number of outputs is the number of inputs.

The amount of history data presented to the TS directly affects the grading of the student, in that the more history data presented to the neural network, the greater the effect of previous results with tutorials. This is a similar situation to that of the number of student levels, in that it is possible to design a TS with a large number of inputs and then use only the required amount. However, it is not a simple matter to determine how much history data to present to the neural network in order to aid the student the most. This issue is difficult to reconcile without extensive trials with real students and even if this were done it would still be unlikely that any real conclusions could be drawn since proving the effectiveness of educational systems is notoriously difficult in the educational field (Dillon and Gabbard 1998). The purpose of the TS here is to explore the technical issues relating to the feasibility of providing an automatic student grading system. Whether this facility is useful is open to educational debate. However it is likely to be the case that it will be useful should the correct set-up of the TS be achieved during trials with real students, since Bergeron et al (1989) found their TS to be useful.
Further issues arise concerning the adaptability of the neural network used for the TS. The neural network architecture used by Bergeron et al (1989) requires off-line training and is therefore under the control of the system designer. The drawback with this approach is that it requires the manual intervention of a person who can interpret the student interaction data with tutorials and determine whether it should be represented to the neural network. The advantage of the Kohonen neural network architecture is that it is able to train continually without any intervention from a human. However, there are situations where this adaptation is undesirable, most notably when different skill levels of students use the same domain at different times. For example, if a class of first year students use the system followed by a class of final year students. However, this is not a problem if the questions and tutorials have been adequately assigned a difficulty level, since the first year students will only be offered easier tutorials and so can be graded only as lower level students (although they can still progress if they continue to achieve success with the tutorial). Problems can arise only if both the student abilities and the question difficulties are unknown beforehand. This is because the TS acts as a bi-directional mapping device, in that if either the student abilities or the question difficulties are known beforehand then the TS can produce the unknown parameter. It is not, however, able to produce values when nothing is known beforehand. The TS’s ability to re-grade questions automatically is an exploitation of this bi-directional mapping facility, in that the student ability can be changed in response to improving results and the question difficulty can be changed if a significant proportion of students who should get the question right in fact get it wrong.

Research into the TS has demonstrated that a fully adaptable system for automatically grading students is possible and practical. The approach of using an automatic tutorial supervisor has been practically justified by Bergeron et al (1989). However, their system requires manual periodic retraining which renders it unsuitable for a generic tutorial system, or a tutorial system that can be used without the need for reprogramming or otherwise rearranging the program code of the system.

Further research is concerned with incorporating the TS within a hypermedia tutoring system (Mullier et al 2002, Mullier 1999) so that the students’ interactions with the TS can be studied. It is anticipated that such a study will prove useful for determining how the TS reacts to different domains, where the rules that describe ability are different, with a view to reengineering the TS so that it is able to learn such a vast set of rules without conflict. A “superTS” such as this would be useful in a more generic tutoring environment such as may become more prevalent on the WWW.

seirikss@uwf.edu

Abstract: A variety of attempts have been made to address the concerns of new teachers as they enter the profession. A meaningful support system has been recommended as a key component to guiding new teachers as they become socialized into the profession. Professors realize the gap between theory and practice is never perceived as wider than perhaps during this period of a novice teacher's career life. Two professors decided to explore if technology could be used to enhance their senior seminar programs for student teachers. The project designers were interested designing a format where student teachers could participate in an interactive telementoring experience. A pilot program was implemented to determine the interest, use, and benefits of an interactive website for new teachers.

Introduction

Numerous studies have identified the most critical issues that cause teachers to leave teaching before they complete three years. Concerns particularly associated with novice teachers include those of classroom management, overwhelming job responsibilities, and finding meaningful methods of support (Nelson & Low, 2000). A variety of attempts have been made to address these concerns. School districts, regional service centers, and university induction programs have all struggled to develop programs to help support new teachers, particularly in that first critical year of teaching (TEA, 2000). Providing some type of a support system have been recommended by many as a key component to guiding new teachers as they become socialized into the profession (Cole & Knowles, 2000).

Conceptual Framework

Support systems for new teachers take on many forms and designs. Various configurations include individual outside mentors assigned to new teachers, seminars, and other opportunities for professional dialogue and development (Cook-Sather, 2001; Cole & Knowles, 2000).

Emergent issues resulting from related research indicates that perhaps there is a vital need for support in areas other than those traditionally focused on: teaching skills and knowledge. Successful retention of teachers may need to reach beyond the first year and attempt to help teachers develop internal resources necessary to pursue a long and satisfying teaching career (Cook-Sather, 2001).

Designing effective student teacher experiences and induction programs are of primary interest to schools of education. Professors realize the gap between theory and practice is never perceived as wider than perhaps during this period of a novice teacher's career life (Posner, 2000).

Providing structured meetings or seminars are invaluable ways of allowing new teachers a way to schedule and prepare for discussions about teaching. However, with new technologies continually emerging, there may be additional ways in which professionals can connect without the structure of brick and mortar (Harris & Figg, 2000). As new teachers graduate with more skills in technology use and awareness, other avenues could be included in meaningful teacher induction programs.
The Study
Two professors decided to explore if technology could be used to enhance their programs for student teachers. The project designers were interested designing a format where student teachers could participate in a telementoring experience. A pilot program was implemented to determine the interest, use, and benefits of an interactive website for new teachers.

Each group of student teachers was enrolled in predominately rural serving settings. Students in both of these programs had completed a traditional teacher education program. Regionally, both groups were located in similar, rural areas. Participation in the pilot project was voluntary, with a total of twenty-three student teachers enrolled on the website.

The site includes resources for teaching strategies, such as lesson plans, journals, and classroom management ideas. Additionally, the site has a link to an interactive component where participants have access to a discussion board, email, and a virtual chat room. The purpose of the interactive component is to provide student teachers a way to communicate at times other than during scheduled seminar opportunities. Participants have the capability to share experiences, reflect on their own experiences, and have other students with which to discuss ideas and concerns.

Implications
By incorporating technology into a peer mentoring program, students could have the advantage of a “just in time” format for addressing their needs. If it appears this type of interactive site is beneficial to participants, the benefits may expand to others outside of our two programs. Introducing a telementoring component into the final semester of student teaching may be one way to encourage new professionals in establishing supportive relationships early in their careers. These first year teachers would already have established a network of colleagues to continue sharing concerns, issues, and challenges during this critical point in their careers.

Conclusion
Those entering the teaching profession are benefited by various methods of mentoring and support as they navigate the routines of daily classroom life. Emerging technologies can be integrated into existing mentoring programs as a method of extending support systems. Data collected from student teachers who participated in a pilot project of an interactive website reported benefits in both reflective practices as well as valuable dialogue between others experiencing similar situations. Of the twenty-three eligible participants, eight students were classified as frequent users of the interactive portion of the site.

The authors propose that teacher retention begins even before teachers step into their first classroom. If support programs can be implemented during the final semesters of teacher education programs, it may be possible for novice teachers to build support systems and professional development resources early in their careers. Developing resiliency skills through telementoring may be one avenue to enhance first year experiences.

Abstract: This paper describes a research project, which seeks to showcase the experience of educators with technology-enhanced teaching and learning. A particular focus of this investigation is on how the use of information and communications technology is influencing teaching practices and students' approaches to learning at the University of Melbourne. As such it comprises a naturalistic inquiry into the experience base of practitioners who have been engaged in technology-enhanced teaching and learning. Our goal is to look beyond objective data and examine closely how information and communications technology is fundamentally influencing the nature of the teaching and learning transactions. As such we are interested in the "untold" stories of practitioners and participants in this work. Data that is collected is archived on a website, and used in a variety of ways for faculty development.

Aims and Outcomes

Educational institutions all around the world are beginning to pay greater attention to the improvement of their teaching and learning practices with the innovative use of information and communications technology (ICT). Although a great deal of work has gone on in the investigation of the effects of computer-based learning, there is a lack of reliable knowledge about what works, why and in what ways? This paper describes a research project that is trying to seek for some answers to the foregoing questions from the perspective of practitioner experiences. The goal of this investigation is to look beyond survey data derived from questionnaires into the experiences of practitioners, to ascertain how ICT is fundamentally influencing the nature of the teaching and learning processes in various subject matter domains. As such the aim is to tell the "untold" stories of practitioners and participants. The stories we are collecting, and the profiles of practice that we are developing will comprise the data for the development of conceptual models of best practice. These models may then form the subject of empirical study in the future.

The outcomes of this research are expected to be a deeper level understanding of how the use of ICT is influencing teaching and learning in fundamental ways. In that regard, this is "exploratory" research as it seeks to compile stories of the experiences of teachers and students with technology-enhanced teaching and learning. As an immediate output, these "stories" or "vignettes" of practitioners will be used to build a "gallery of stories" on technology-enhanced teaching and learning that will be accessible on a website for the benefit of all, but most importantly, for novices. Furthermore, models of behavior and practice derived from this research will provide the context for more empirical studies in the future, such as the study of any correlation between innovative teaching and learning designs and specific learning outcomes, and/or approaches to learning and teaching.

Context and Scope

The application of ICT in teaching and learning has the potential to change educational practices in significant ways (Ben-Jacob, Levin, & Ben-Jacob, 2000; Rogers, 2000). For example, the integration of email and computer conferencing with multimedia databases and electronic libraries has enabled the emergence of a whole new kind of educational activity, namely eLearning. Information and communications technology is also enabling established campus-based providers to rethink and re-engineer the nature of their teaching and learning...
practices. The University of Melbourne, like many other educational institutions, is currently involved in just such a process as part of a strategy to position the University as a global player in higher education. As a direct result of this and along with the adoption of ICT, innovative approaches to teaching and learning such as problem-based learning and collaborative learning are being encouraged. These initiatives have led to the rise of new roles for teachers such as "facilitators of learning" as opposed to "deliverers of content" (Evensen & Hmelo, 2000; de Vreede & Berge, 2000; Salmon, 2000). They have also exposed students to new models and approaches to learning such as "computer supported collaborative learning" (Dillenbourg, 1999; Koschmann, 1996; O'Malley, 1995), and "computer supported problem based learning" (Bernard, Rojo de Rubalcava, & St-Pierre, 2000; Koschmann, Kelson, Feltovich, & Barrows, 1996).

While interest is growing in the integration of technology in learning and teaching, there is still very little known about how the use of ICT is changing teachers' approaches to teaching, and students' approaches to learning (Rumble, 2000). The need to investigate what is happening with technology-enhanced teaching and learning is now imperative. This includes, among other things, understanding how approaches to teaching are being impacted, how teacher-thought about teaching and learning is being modified, how students' approaches to learning are changing, and how student support is changing with the use of ICT?

Methodology

The research described in this paper set out to seek some answers to the foregoing questions from the practitioners' perspective. It comprises a naturalistic inquiry into the modus operandi of educators (Lincoln & Guba, 1985). Naturalistic inquiry is particularly suited to questions and settings such as this where the context is heavily implicated on meaning. Such a contextual inquiry demands the use of human instruments for gathering data, as humans have the capacity to use their tacit knowledge with qualitative data gathering tools such as interviews, direct observations, self-reporting and think-aloud, and document analysis. Once in the field, the inquiry takes the form of successive iterations of these elements: purposive sampling, inductive analysis of the data, development of grounded theory based on the inductive analysis, and projection of next steps in a constantly emergent design (Lincoln & Guba, 1985; p. 187). Throughout the inquiry, and especially at the end, the data and interpretations are continuously checked with respondents, and differences of opinion are negotiated until the outcomes are agreed upon or differences of opinion are understood and reflected as such. This information is then used to develop a case report or profile, which is tested for "credibility" and "confirmability" (Lincoln & Guba, 1985; p. 189). This testing begins early in the study and continues throughout, culminating in a final representation of what was observed.

Data Gathering

Interviews are being used as the principal instrument for data gathering in the first instance. The initial sample comprises practitioners who are known for spearheading the use of ICT into teaching and learning at The University of Melbourne. This sample will grow to include other practitioners at the University of Melbourne. There is a possibility that this may grow even further to include practitioners from other organizations including tertiary educational institutions, and also commercial enterprises. In the spirit of naturalistic inquiry, interviews are being conducted on location. An interview protocol has been developed which sets out the goals of the interview and trigger questions to guide the interview (see boxed text below).

Teaching and Learning Experiences with Educational Technology

We are interested in your story and your experience with technology-enhanced teaching and learning. We would therefore like you to reflect on your experience with technology-enhanced teaching in terms of the following:

Planning
- What are your goals and motivations?
- What aspects of your teaching and learning are you trying to influence (e.g., approaches to subject matter content representation, activation of learning, assessment, socialization, or provision of feedback)?
- Why are they important, to whom and to what?
Interviews routinely begin with a discussion of this interview protocol and the trigger questions. This is to ensure that interviewees understand the questions, and are comfortable with their motives. With the permission of the interviewees, interviews are audio taped and subsequently transcribed. These transcripts comprise the raw data for the development of profiles of practice. The interview protocol follows the action research methodology, which comprises planning, doing/taking action, observing and reflecting.

Developing Profiles of Practice

Excerpts derived from the interview transcripts comprise the raw data. Researchers sift through these transcripts to develop individual profiles of practice along the lines of the interview protocol. These are then presented to each interviewee to allow the filling of gaps in the profiles, verification of existing materials and addition of any other thoughts on the matters raised during the interview. This in itself is an iterative process and involves further consultations with interviewees. The profiles are entered onto the database only when complete agreement has been reached between the interviewee and the researchers on the content of the profiles.

Development of the Database

The database is used to generate profiles of practice for a website that is available to all University of Melbourne academics. Data is entered using a simple web-based form to populate the following fields:

<table>
<thead>
<tr>
<th>Planning</th>
<th>Doing</th>
<th>Observing</th>
<th>Reflecting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Summary</td>
<td>Summary</td>
<td>Summary</td>
<td>Summary</td>

<tr>
<td>Approach to learning</td>
<td>Influences on choice of tools</td>
<td>What did not work</td>
<td>Impacts on your student's approach to studying</td>
</tr>
<tr>
<td>Limitations of the approach</td>
<td>Challenges in selecting tools</td>
<td>What criteria for success were used</td>
<td>What did you learn</td>
</tr>
<tr>
<td>Challenges</td>
<td>Limitations experienced</td>
<td>How those criteria were measured</td>
<td>What you would do differently next time</td>
</tr>
</tbody>
</table>
Data is also included for standard project details such as the names and affiliations of faculty and project leaders, date of implementation, and project type. Each profile also contains a brief summary of the project and current issues in the discipline. There is no requirement that all fields contain data.

Where appropriate, data can be provided in formats other than text. The database is used to generate a showcase of academic practice. Users of the site can customize the display of stories by focusing on a particular action research process, group of trigger questions, faculty or the complete profile of a particular project. Display options include a choice of predefined categories, as well as browseable lists and individually constructed searches. Browseable lists allow the display of projects by faculty and department, as well as by action research process, including approaching the data from varying perspectives. Search functions provide for user-constructed views of the data that enable investigation based on specific interests. Keyword searching is also available across all fields of the database. Each story segment is displayed with fully linked metadata for the corresponding project. This provides a link to departmental databases containing other project information, and also to academics involved with the project. Links are provided to live course content where possible.

Summary of Project

Reason!Able is a stand-alone PC package designed to assist students at all levels, including those with no explicit training in logic or argument, to acquire general informal reasoning skills. We looked at research about critical thinking courses and it showed that they just weren’t having the effect that they were claiming to have had, and were perhaps actually hurting students’ critical thinking.

Planning: Summary Comment

We wanted to help students to learn to acquire general and fundamental skills of reasoning and argument. We teach general skills that can be applied in any domain whatsoever e.g. in students’ other academic subjects and in their chosen profession.

Planning – Goals and motivations

We wanted the students to go through a certain fairly standard, straightforward routine. We had initially used a HyperCard stack, but wanted to come up with a dynamic forming type of software tool, that would simultaneously teach the students all the concepts and procedures that they needed to know.

Planning – Approach to learning

I was fundamentally concerned with the problem that the students did not learn. They were trying to learn, but not succeeding, and not reflecting on the fact that they weren’t succeeding. If you want to acquire skills, you’ve got to practice. It’s true for cognitive skills just as much as practical ones. But it’s not just any old practice; it’s got to be the right kind of appropriately guided, scaffolded, and motivating practice.

Planning – challenges

The idea that targeted practice will lead to an improvement in skills is the one thing that has been absolutely constant. What we were trying to create with the Reason!Able software is what I have come to call an ‘environment tool’ for quality practice in reasoning.

Doing – Summary Comment

Teaching is still a cottage industry where a whole lot of people are just assumed to be able to do it and they go by unquestioned. There hasn’t been the pressure to force change.

Doing – Choice of tools

We thought that maybe there were more ways of representing complex structures of reasoning, which take advantage of representational resources, which for practical reasons couldn’t be used very effectively. In Reason!Able you’ll see an almost complete switch from a HyperCard approach to an all-in-one workspace. All the information is at all times is available on the screen.

Doing: Challenges in selecting tools
Despite difficulties, it was the first time ever that somebody had built a way of handling argumentation that made it visual, manipulable, and graphical. It's a real turning point.

Doing - Limitations experienced
In a certain sense, we failed in our first attempts, because we found out that the task was a lot more difficult and challenging. I don't think it was a success from the point of what we said we would do at the beginning and what we delivered at the end. Although, I think that we've succeeded at the end of three attempts.

Observing - Summary Comment
We are dealing with a huge spectrum of intuitiveness and familiarity. It is very interesting, that many university students are having difficulty with critical thinking skills and yet, elementary school students are coping with it.

Observing - What did and did not work
Students have been more successful in learning how to think critically because of these visual elements. It is the visual element that is having the most impacts.

Observing - What criteria for success were used?
So far, our students gain three to four times as much as any other students in the world, in terms of critical thinking skills. The studies showed that this technology helps people learn critical thinking skills.

Observing - How those criteria were measured
Last semester, we did a number of studies, comparing the results from the University of Melbourne, with that from Monash University in Melbourne and McMaster University in Canada. Their results were only half as good as ours. There was something about our approach, which was working much better.

Reflecting - Summary Comment
It has changed me a lot, there's no question about that. We don't think hard enough about effectiveness and quality. We inherit a framework of practices and assumptions and we work within that so that what everybody else accepts is deemed fair and reasonable practice is what obviously I would accept as reasonable practice.

Reflecting - Impact on your view of teaching and learning
The software is tapping into a much larger set of brain resources than the typical ways of presenting arguments. We are getting students to use more of their brain. The software is partly visual, partly manipulable and that helps them and it makes life easier for them. It reduces the cognitive burden.

Reflecting - Impact on your students’ studying and learning
The students are being affected far more than they realize. At a deeper level, they are being exposed for the first time to what it is to be critical and what it is to have a rational opinion. They’re getting an understanding of what it takes, how complex the world is, what the issues are and how much work is involved in actually thinking through an issue.

Reflecting - What you learnt
If the primary role of this course is to improve students' critical thinking skills, then yes, I think I have become better at it. I am using better methods, better tools, and getting better results. I have also learned that if you’re engaged in a challenging project, you have got to expect that it may not pan out the way you think it will. You have got to be prepared to change your direction, re-conceive the project, and keep pushing the boundaries.

Concluding Remarks
The work that is described and discussed in this paper grew out of a growing call for "evidence of the impacts" of information and communications technology in tertiary teaching and learning. While this is a question that has been asked many times before, answers to it have not been conclusive one way or the other. There is a lot of evidence to suggest that the use of information and communications technology in tertiary teaching and learning has many advantages. There are also suggestions that these benefits do not justify the cost,
time and effort that this kind of work entails. Many of these findings are however, problematic as they are based on neither reliable nor valid research techniques. The work that is reported in this paper incorporates investigation techniques that depart from the commonly used approaches to the quantification of user perceptions with questionnaires and surveys of sorts.

Our goal in this work is to capture the experience base of practitioners with the use of a range of data gathering techniques that are grounded in the principles of naturalist inquiry. We realize that data derived from these kinds of approaches are not easily "generalizable" to other contexts. Among other things, generalizability is a function of sampling and we expect that over time, we will have in this gallery, the amount of information and data that is necessary to make meaningful generalizations from it to similar situations and contexts. We anticipate that this gallery will grow into an extremely rich resource of the experience base of not only many of our pioneering efforts but some of the most innovative work that is being undertaken in this regard at the University of Melbourne and elsewhere. A larger collection of profiles in the database would enable the examination of patterns and models of behavior among practitioners that could become the subject of study further down the road. Questions that might seem relevant would include: the reasons for particular approaches to teaching, and prominent approaches to student study behavior. We are hopeful that these questions would make interesting study towards explaining how the use of technology is impacting teaching and learning.

References

Abstract: The desire to learn and teach in an online setting often presents great difficulty for students and instructors due largely to the lack of face-to-face interaction. Online instructors are continually looking for methods to improve student engagement without monopolizing instructional time. Students desire feedback on their progress in a non-test setting. Using JavaScript and html to develop client-side online testing fulfills both of these goals and provides instructors and students with better tools for successful online education.

Introduction

One of the most significant challenges experienced by instructors of online courses is keeping students engaged and confirming that students are making satisfactory progress throughout the semester. The lack of face-to-face interaction makes it difficult for the instructor to determine which students are fully participating and comprehending the materials, and which topics are causing particular difficulty. Minimal interaction between the instructor and an individual online student could mean that the student has grasped all concepts and needs no further assistance, the student is inactive and will remain so until a mandatory deadline occurs, the student is unaware that he or she is not grasping the course material, or that the student is overwhelmed by the material and needs help to succeed.

In addition, the lack of immediate feedback from the instructor often leaves students in a quandary with respect to their current progress in the course. Frequently students receive minimal feedback in an online setting until an examination is graded, at which time it is too late to take remedial action. While these problems can also exist in the traditional face-to-face classroom, the misperceptions caused by the lack of mandatory meetings between the students and the instructor is magnified in the virtual classroom. To combat this, scheduled intermediate quizzes, perhaps weekly, can be created which measure the students' progress in a non-threatening environment, and let the students know which concepts the instructor feels should be emphasized to better meet the educational goals of the course. The benefits of the quizzes for the instructor and student are many.

1. Students are engaged weekly in verifiable activities.
2. Instructors can identify problem areas where more examples or clarification are required.
3. The quiz process is asynchronous so students can schedule time appropriately.
4. Students can measure their progress against a course standard.
5. Each student can take the individual time required to complete the quiz without fear of being judged.

It is certainly possible to meet these goals by merely posting a series of quiz questions for the students to answer, and then manually grading the responses. However, the use of automated grading on the client-side reduces the workload for the instructor while allowing the students to receive immediate feedback on their quiz. By providing results in this manner, the students have the opportunity to further research the questions they answered incorrectly while the topics are fresh in their minds.

Online Testing

In order to solve the problem efficiently and effectively in an online setting, content-specific quiz questions were selected and put in a standard format, an html version of the quiz was produced, a JavaScript program to grade the quiz was produced. To optimize the above, the system was prototyped once, and then automated to save the instructor time and minimize any associated errors. In this case Microsoft Excel was used to store the content-specific quiz questions.

Question Selection

Although a variety of formats for creating online quizzes exist, the system implemented includes html, Visual Basic and JavaScript. Prototypes were developed and then Visual Basic was used to generate future quizzes. The format for the example questions is multiple-choice, although any method that can be graded algorithmically is theoretically programmable.
Html Prototype

Prototype quizzes were created for online graduate courses. There are three buttons at the end of the quiz that provide students with the options to Check Answers, Submit Solutions, and Clear Quiz. The three options provide students with the capability to check their answers in a non-threatening setting. They can check their answers as many times as they like prior to submitting their answers. The amount of information provided in response to selecting the Check Answers button is controllable by the instructor, and can range from merely reporting the number of correct answers to detailed information about each question that was answered incorrectly.

JavaScript

The immediate feedback to the student is provided through JavaScript. The easiest method of using JavaScript on a web page is to embed the code in the html source. However, this allows anyone to view the JavaScript, which in this case will include the quiz answers, simply by viewing the page's html source. Since allowing the user to view the web page source is a basic function supported by all popular browsers, embedded JavaScript is not particularly effective for online quizzes. To ensure that the quiz answers are not trivially accessible, the JavaScript can be stored in a separate file on the server, and that file is then referenced from the html document. Anyone viewing the html source in this case will no longer have immediate access to the JavaScript code. Unfortunately this does not completely solve the problem. The file in which the JavaScript is now stored is likely saved in the browser's local cache directory, and can be opened by the student using any text editor, revealing the JavaScript source. However, it is likely that storing the JavaScript in a separate file is a sufficiently secure solution for most quizzes, while still providing the benefits of a client-side controlled interactive page. In the event that a more secure system is required the interactivity could be controlled on the server-side using CGI programming, which would also require a greater level of client-server communication.

Quiz Generation

The extensive ability inherent in current technologies to automate redundant tasks can greatly simplify the quiz construction process. The html for a collection of quizzes varies only in the quiz question contents, and any header information that the quiz creator chooses to include for supplementary information. The JavaScript varies in the construction of the answer array as a list of correct solutions. Thus for the collection of quizzes associated with a particular course, the html and JavaScript files should be identical except in the references between the files, question contents, and header information. The references between the files include the items necessary to correctly name the files and to associate the correct JavaScript file and path with the correct html file and path. The question contents include the textual questions and associated solutions. The header information includes quiz-specific information such as quiz number, course, etc. With so much similarity between these items, it certainly is possible to create one html and JavaScript prototype and modify each to create subsequent quizzes. With the ease of automation, this process can be greatly simplified with the possibility of associated error being minimized as a side effect. Perhaps one of the simplest methods is to put all of the content questions and associated solutions in a file, and then use Visual Basic to generate the associated html and JavaScript files. In fact, that is how the files in the figures above were generated, with minimal effort on the part of the quiz generator.

Conclusions

The client-side quizzing has been tried in several courses with very positive results. At first consideration, many students have difficulty immediately seeing that they can determine the correct answers to all questions by checking answers for each question individually. Beginning students, and those with minimal experience in the area of combinatorics change multiple answers at once, thereby greatly complicating the process of determining which answers are correct. The option to submit the answers has met with mixed results. It requires the students to remain connected to the server for submission and also increases the possibility of submitting answers before the student is ready through accidental means. Using client-side quizzes created by combining html and JavaScript provides students with the capability to measure their progress each week. The instructor can also choose to verify the results depending on the needs of the particular virtual community. This can guide the instructor in developing content focus areas, and can provide a valuable means to ensure that students are engaged throughout the course.
Promoting Active Learning Strategies: *Doing* Economics in the Lab

Laurence Miners, miners@mail.fairfield.edu
Kathryn Nantz, nantz@mail.fairfield.edu
Department of Economics, Fairfield University, Fairfield, CT USA

This case study reviews a new model that we have developed for our introductory economics courses that focuses on the use of technology to engage students in active learning strategies. This project is the result of a three-year grant awarded to the Economics and Mathematics departments at Fairfield University by the Davis Educational Foundation. Under the grant, each department has restructured the way it teaches introductory courses. The objective has been to use technology to improve quality and lower the costs of delivering high-quality learning opportunities to students. In this paper we discuss the economics portion of the project.

Our contention is that students can learn about economics, but to understand and use the theoretical models and quantitative techniques that we teach them, they must also do economics. Economics texts often say that students need to be able to understand the "economic way of thinking"; we argue that they also need to experience the "economic way of doing", to pose interesting questions, formulate hypotheses, collect data, analyze the data, and generate conclusions regarding the results of their experiments. In order to make this environment both active and effective in improving student learning outcomes, students need to be engaged in the process. Our solution is to infuse technology into the activities of the course so that it becomes the common denominator around which the course is constructed. Though our colleagues in the natural sciences have had students working in labs as active learning environments for many years, social scientists have not had easy access to similar settings for students. Computer time was expensive, and data files were often difficult or expensive for students to retrieve. The recent explosive growth in computer technology now makes it possible for economists to get students into a meaningful learning-by-doing environment in a cost effective way.

Introductory economics classes at our school have traditionally been taught in a 3x50 minutes or 2x75 minutes per week lecture format. Since the demand for introductory economics is great (the courses are required for our School of Business students), faculty members in economics often teach two sections of "intro" each semester. To give our students the opportunity to do economics we restructured our sections of introductory economics in the following way: Two sections were combined into one large (60+) student lecture. The class meets as a "large" lecture twice a week and in smaller groups (20-22) once a week in a computer classroom. There are two practical advantages to this restructuring. The first is that students are able to use the technology within the format of a three-credit course. No extra lab meetings or outside class assignments are needed to "add on" the technology. Rather, the technology has become an integral part of the class. Second, the instructor saves one class meeting per week. Typically, the two sections would have six 50-minute meetings per week; with the new model, there are two 50-minute lectures and three 50-minute labs.

Outside of class, we have two important assignments that engage students with course material using technology. Our department has used spreadsheet exercises in introductory-level courses for many years. These spreadsheet exercises, written by department members, guide students through introductory and then more complex spreadsheet operations in the context of economic problem-solving exercises. Students learn to use technology as they would paper, pencil, or calculator, as a tool to aid in their understanding of sometimes complex economic concepts. As students move into upper-division economics courses, additional spreadsheet concepts (like regression analysis) are added, and they learn other statistical software and simulation packages (like E-Views and the Fair model). We believe that this has become a distinctive component of our departmental curriculum; technology is infused into the learning process from the introductory level on so students are able to engage actively in the learning process.
To further enhance student engagement with technology outside of class, students in our sections participate in online threaded discussions on issues of their choosing related to the course. This allows them to continue to develop discussions that started in class but that were cut short as the class period ended. It also encourages them to try out new terms and ideas that they are applying to the economic world around them. The discussion board encourages students to experiment with new economic ideas and applications in a non-threatening environment.

There have been several challenges, particularly during the pilot phase of the project. Our computer classroom facilities have a high level of utilization and there was no guarantee that we would receive priority. Our restructured format has also required that students who enroll in our sections have two free time codes in their schedule—one for the lecture and one for the lab. This has perhaps deterred students from enrolling in our sections. We have also experienced our share of technology-related "glitches", which frustrate and discourage students and instructors alike.

Also, the students themselves were not always as receptive to the technology and hands-on learning environment as we had hoped they would be. Acquiring some "ownership" of the learning environment was not a concept that they universally desired. We need to do a better job of refining our lab materials so that the students are more engaged and eager to complete them. To do this, we have developed exercises that must be completed outside class and we have provided "homework" credit. This form of reward often works with our students, who like to know what the "payoff" is to their effort and attention.

In terms of the course material itself, "losing" a third of our lecture time presented a challenge. During year one of the grant we wondered how we could cover the same amount of material and still provide students with the hands-on experience we so valued. What we learned is that some concepts are covered better in the lab and we were able to eliminate or greatly reduce discussion of them in the lecture. Experiential learning is a much more efficient way to deliver some course concepts, we just need to understand which concepts these are and develop lab materials that encourage students to take more responsibility for their own learning. We realized that we were initially thinking of the lab as a place to work on material that we had already lectured over; what we realized was that students did not need to be "briefed" before they entered the lab. The lab exercises could be structured as self-contained units, presenting students with entirely new concepts and applications.

As yet, assessment results regarding improvements in student learning are inconclusive. We are administering pretests in introductory micro in the fall semester, the same multiple-choice questions will appear on course final exams. We hope that we can use the results of these tests to gain insights into how student-thinking processes are affected by our technology-enhanced approach to the courses relative to more standard formats. We are using the Flashlight cost assessment model, which has allowed us to track resources allocated to this project. We have concluded that extensive use of technology for teaching is a time-intensive activity.

In terms of student satisfaction, results have been mixed. Some students embrace the technology and enjoy working in the lab environment. Others see the lab work as an "add on", or as extra work, and prefer to take strictly lecture sections. Going into the project we assumed that since students are using computer technology to shop, to communicate with their friends, and to download the latest music they would recognize the importance of using technology to analyze data and enhance learning. We have found, however, that we have to work hard to convince students of the importance of using technology in their academic lives. In terms of instructor satisfaction, having the opportunity to develop a new course with a colleague has been one of the most rewarding aspects of this project. We have also found that this sort of project has encouraged us both to think carefully about the goals that we have for our courses and students. In order to center our pedagogy around technology and active learning, we have relinquished "center stage" and find ourselves playing the role of co-learner and coach rather than all-knowing sage. This has at times been difficult, but we believe that our students will benefit by better retaining what they learn about the economy. We also believe that these active learning skills will serve them well as they move through the rest of their academic and work place lives.
Computer Information Literacy Modules (CILM): Educating Online Users about Computer Crime Prevention, Ethics and Morals in Digital Communities, and Effective Information Processing

Dr. Bizhan Nasseh
University Computing Services
Ball State University
United States
bnasseh@bsu.edu

Abstract: This paper describes the need for and the creation of an innovative, web-based learning tool intended to provide interactive, hands-on learning opportunities for students and employees in various institutions and businesses. Specifically, the Computer Information Literacy Modules (CILM) educate people about the relevant topics of computer crime prevention, ethics and morals in digital communities, and effective information processing. Each module provides basic information about the subject matter, interactive case studies and simulations, a self-evaluation, and a test to evaluate the learner's competency.

Introduction

Computer and communication technologies continue to be at the heart of both changes and important development in the new century. It is vital to our global educational and economic systems that online users gain knowledge about computer crime prevention, ethics in digital communities, and effective information processing. This knowledge becomes increasingly important considering the number of people entering the online community, as well as the number of problems reported as a result of computer crime and misuse. The Pew Internet & American Life Project reports that the "online adult population has hit 56%, totaling 104 million, and 16 million new users ventured online in the last 6 months (USA Today Website, 2001). A 1997 Computer Security Institute survey indicates that “75% of US institutions, corporations, and government agencies reported financial losses in the past year as a result of computer crime” (McKenzie 1998). While many isolated web sites cover these issues, they do not provide an interactive, hands-on, problem-centered, and competency-based learning opportunity for online users. The Computer Information Literacy Modules (CILM) learning tool assures employers and educational institutions that every employee and student has an equal opportunity to learn a basic level of competency about healthy participation in digital communities and effective utilization of computer and communication technologies in one comprehensive package without limitation of time and place. The CILM has the potential to be a learning tool not only for all incoming freshman classes at Ball State University, but also for students in high school systems, students in other higher educational institutions, and employees in different branches.

The web-based Computer Information Literacy Module was chosen because 1) there are national concerns and demands for today's online users in general and students in particular to have adequate knowledge and skills about computer crime prevention, ethical and moral issues, and information processing; and 2) there is not a comprehensive, web-based, interactive learning tool similar to CILM on the market. The Internet technology fits well with most learners, who have other responsibilities and concerns such as job, family, distance, and insufficient time. In 2000, grant money was provided in order to design and develop phase I of the CILM project.

A Description of the Computer Information Literacy Modules

The initial design of the CILM project includes the following four modules: Module 1, Computer Crime Prevention, is intended to help learners understand the main issues of computer crimes and their prevention in
computer and communication technologies and digital communities. Module 2, Ethics and Morals, is intended to prepare learners in the areas of resource utilization, privacy, intellectual integrity, copyright, and other common standards in open-access environments and digital global communities. Module 3, Information Processing, is intended to help learners gain needed knowledge in searching for resources, selecting needed resources from overloaded databases, and processing vast amounts of information for needed knowledge. Finally, Module 4, Ball State University’s Infrastructure, is intended to provide an opportunity for students to gain needed knowledge about Ball State University’s technology-based facilities and resources, procedures and standards for their utilization, and available support systems. This module can also help new faculty and staff members to learn about technology infrastructure and support systems at Ball State University.

The instructional design of these web-based learning modules is based on the constructivism model, which supports the active participation of learners in learning activities. The subject matter, case studies, and simulations are designed and developed based on current issues, events, concepts, models, and concerns at local and global levels. Each module has four sections. The key elements of each module’s four sections include the following: 1) A description provides basic information about the subject matter of each of the four modules for learners. This section helps learners to develop theoretical knowledge about the subject matter and prepares them for activities in the next section. 2) Rich interactive case studies and simulations help learners to gain practical skills and knowledge about the subject matter through hands-on activities. This section of each module has several case studies and simulations to cover a variety of situations. 3) A self-evaluation provides learners with an opportunity to evaluate their level of knowledge about each subject matter. If a learner does not meet a certain level of readiness, then he/she will be advised about necessary additional study. 4) Finally, a test section evaluates the learner’s competency in each module and permits the learner to advance to the next module. A central database system records all learners’ test results. The results of each module can be available to various academic departments for class credit and to organizations for future planning and action.

The instructional design of the CILM is perfectly suited for an audience with different styles, backgrounds, abilities, locations, and commitments. The asynchronous learning modules will provide learners with the flexibility to complete each module at times that are most convenient for them. Individual participants will gain adequate skills and knowledge from the CILM learning tool through varying amounts of effort and time. The World Wide Web is perfect for the Graphical User Interface (GUI) design and interactive multimedia programming of the CILM project. Today, any reasonably equipped PC with a basic connection to the Internet provides a good platform to access the CILM learning tool from anywhere at anytime.

Conclusion

The four sections of each module are designed in a way that serve all different learners’ basic needs. The description section will help all participants gain some theoretical knowledge about subject matter in each module. The case studies and simulations section will help learners gain practical knowledge in addition to theoretical knowledge. The self-evaluation section will help learners to evaluate their progress in each module and, when needed, advise them about additional learning activities. Finally, the test section will certify their adequate competency in subject matter and will record the results in a database.

Ball State University’s Information Technology Office, Student Affairs Office, University Computing Services, College of Continuing Education, and Computer Science Department already support the development and implementation of the CILM project for students at Ball State University and online learners in different branches in Indiana. The quality of the modules will be ensured by adherence to the formative evaluation plan and content review by experts in the field. For legal issues and accuracy of the content, local experts will be asked to review content before it is published on the Web. Phase I of the CILM project, completed in December 2001, can be found at <web.bsu.edu/cilm/>.

LEARNING FROM E-LEARNING: TRANSFORMING CONFERENCES

Lisa Neal

Abstract: Effectively applied, the lessons the e-learning community has learned about designing and delivering education and training at a distance can enable organizations to evolve new and potentially better ways of conducting conferences. Travel's high cost and inconvenience have often been cited as the impetus for rethinking the role of the classroom. These reasons, coupled with the economic downturn, have led to rethinking the need for and the role of professional gatherings. Technology has transformed education and training, and similarly has the potential to transform conferences in ways that can be beneficial both to participants and those who would like to participate.

Acknowledgements:

My deepest gratitude to Jeff Green, EDS, and Ken Korman, ACM, for their extensive help and feedback.

INTRODUCTION

Based on the number of e-mails I've seen recently offering extended deadlines, it seems that a lot of conferences are not attracting as many submissions or advance registrations as they would like. It made me wonder if conferences are evolving in a way that parallels corporate training in that dwindling enrollments, budgetary pressures, and new technologies have led to an interest in online alternatives. Will the same factors lead to the emergence of the "blended conference"?

I can track much of my professional career by conference attendance — absorbing as much wisdom as possible at the early ones and eventually networking and presenting with relative ease. I find conferences a source of ideas and inspiration, as well as a way to assess trends and the state of the art. I like writing conference papers and giving talks, because it forces me to reflect and think clearly about a subject. The conferences I like best are the ones where I know a lot of people and meet new people with interests similar to mine. I collect business cards and stay in touch with people, and have even made some close friends at conferences.

Today's lower attendance levels — caused by security issues and the economic recession — concern many of us who savor the learning and networking opportunities conferences represent. Now, these circumstances have brought us to a crossroads where the basic model for conferences is being reexamined. For example, instead of being multi-day events at a convention center or hotel, some conferences are conducted online. Many more take a "blended" approach, using technology for submissions, registration, and advance programs, pre-conference activities, and broadcast or archive sessions.

To look at the effectiveness of online or blended conferences, you first have to consider why people attend conferences in the first place: To learn and network. They're a break from work, and they offer a chance to meet people, get new ideas and insights, reflect, have a change of scenery, and eat good food. These are the same

[1] "The many manifestations of organizational change - downsizing, outsourcing, merging, splitting, acquiring, partnering, and the constant redrawing of internal organizational charts" — have led to a situation in which workers become more dependent on personal social networks that cross organizational boundaries. Conferences are among the best ways to establish and refresh the "intensional networks" defined in http://www.firstmonday.org/issues/issue5_5/nardi/index.html.
reasons employees like off-site training. Conferences are also an immersive experience where people focus on conference activities and other attendees while professional and personal concerns are largely left behind. Conferences foster a sense of membership or belonging in a professional society or discipline. None of these attributes requires technology.

MOVING CONFERENCE ACTIVITIES ONLINE

Methods can be developed and refined for integrating online and in-person conference components in a kind of blended-learning approach. Teachers are well aware of the advantages of combining online and classroom activities: Pre-class activities reduce the quantity of in-class time spent covering basics, and they help level the playing field on which students tackle a new subject. Classroom time is spent on activities where face-to-face contact is most beneficial. In theory, these advantages can be applied to conferences.

When conference Web sites link to abstracts and papers, attendees can plan their schedules better and prepare for sessions. Both attendees and people who can't attend the conference can participate in e-mail discussions, virtual meeting places, or discussion forums. One blended-learning-like result is that actual conference time is used more efficiently. ASTD, www.astd.org, for example, has successfully implemented some of these components for its annual conference.

CHI 2002 offers CHIplace, www.chiplace.org, where anyone can set up a profile, see who else is there and what their interests are, preview and comment on papers, and discuss conference-related topics. I'm sure the most heavily accessed part is the personal profiles. I especially like the feature that generates random pictures of participants. It's similar to the serendipity of running into someone at a conference break. Unfortunately it doesn't provide the interaction or awareness indicators that make breaks so much fun.

MOVING CONFERENCE SESSIONS ONLINE

Some conferences Webcast sessions, which is not unlike COMDEX's broadcasts of popular sessions to overflow ballrooms. Some conferences archive sessions online as well. When I consider the benefits of Webcasting and archiving, I am reminded of my experiences teaching online: In general, it's hard to engage both present and distant audiences. The one time I was Webcast while presenting at a conference, I had trouble ignoring the cameras and focusing only on the audience. Then there are the speakers who present by videoconferencing to a "live" audience, which rarely is the same as being there for speaker or audience. However, I imagine the people "watching" — hard to call it participating — these sessions think it's better than not being able to listen to the talks at all.

PUTTING A CONFERENCE ONLINE

How can fully online conferences be made effective? Ultimately, the answer parallels the familiar e-learning/classroom debate: Rather than trying to figure out how to reproduce a conference as an online event, we should try something different online that exploits our delivery technology's capabilities for superior results. Cost, comfort, and convenience are potential benefits of the online format.

[2] David Eastment, in the Guardian, http://education.guardian.co.uk/eleaming/story/0,10577,603226,00.html wrote about attending a fully online conference and thought it was "better online because you can flip forward and back through the presenter's screens rather than simply follow what is being said, and you can get up and stretch when you want" and switch sessions without stepping on toes. Eastment pointed out that "only a few presenters had had previous experience of speaking to an unseen audience," but, in general, conference presenters vary widely in how good they are, and there may be better opportunities to provide coaching for first-time online presenters.

[3] In some recent experiences organizing an online seminar (Kim Vicente speaking about Cognitive Task Analysis, www.ctaresource.com) feedback was largely positive, including "I thought that it was a great way to hear a speaker. No
How much are people willing to pay for an online conference or online portions of an in-person conference? Online conferences and seminars are usually free, although I have seen a few charging high fees. There is a cost to using technology, and conference organizers may fear that, in using a blended approach, they lose attendees who prefer to participate online. Over time we'll find out if online programs provide a viable option for those who wouldn't otherwise attend a particular conference at all, or if these programs are most successful at getting people excited about in-person attendance.

THE FUTURE OF CONFERENCES

Let's go back to my original list of reasons people attend conferences in person: education, networking, break from work, chance for reflection, new ideas, a change of scenery, good food, and a sense of connectedness.

I got my job by networking at a traditional conference, and it's hard to imagine replicating that experience online. And what's the likelihood of an online conference giving you a break from work and a chance for reflection? Limited, at best; in fact, the opposite is probably true. Because online conferences are typically crammed into existing work hours, frustration and fragmentation are the likely outcomes. The change of scenery and good food I can get on my next vacation. But the sense of membership or belonging is harder to acquire online. In-person conferences excel at promoting connectedness, scheduling breaks and receptions to increase physical presence, and using badges, t-shirts, and bags for a sense of inclusion.

Where can technology help further? At any multi-track, in-person conference, it would be great to know more about what you missed. I'd like to be able to replay some sessions, although I understand the dilemmas conference organizers face in determining how to price those capabilities and offer them in a way that doesn't lower registration numbers. I miss sessions because I'm talking to someone in the hall, and that experience is much harder to facilitate with technology.

Since I'm not great at standing up during sessions to ask questions, I'd like the opportunity to make queries online and see others' questions and answers. Presenters, attendees, and people participating at a distance could all use such a resource. While the prospect of piled-up work and full in-boxes may inhibit participation in post-conference discussions, extending the conference experience online may be the best way of increasing conferences' relevance back in the "real" world.

Based on where technology is now and how people and organizations respond to technology-delivered courses, I don't believe that online conferences are a substitute for on-site ones. Online conferences may be valuable for what they do offer: more diversity in the participants and more flexibility to reflect on and apply concepts. Current technologies, even telepresence, cannot replicate the immersive experience of in-person conferences.

We are still at an embryonic stage in the application of technology to conferences. Conference organizers are experimenting with and evaluating different approaches; the results to date have been interesting, as have been the diversity in their approaches. People's expectations of and comfort levels with technology change over time, and this, in conjunction with further experimentation and innovations, may be what ultimately leads to new and more successful models for technology-enhanced conferences.

[4] Duke University's Fuqua School of Business charges more for their online MBA program because people are willing to pay for the convenience. When they started their online MBA, they must have been concerned about it drawing students away from the campus program.
Implementing Technology Integration at the University Level: A Case Study of Changes in Faculty Behaviors and Attitudes

Introduction

Modeling of technology integration by university faculty into their respective course delivery structures is a crucial element in the preparation of technologically proficient teachers (OTA, 1995; Topp, Mortenson, & Gradgenett, 1995; Wetzel, 1993). These "teachers in training" need to experience technology within the context of both their learning opportunities at the university and their student teaching experiences in the field setting. In order to model this type of framework within their pedagogy, university faculty must change attitudes and behaviors toward the use of technology (Joyce & Showers, 1983; Schrum, 1999). As Strudler and Wetzel (1999) assert, the "goal of technology integration is a moving target" (p.80), and therefore cannot be studied in a vacuum. Rather, faculty must be dedicated to beginning and/or continuing professional development of their own technology proficiencies within the dynamics of their learning organization. Furthermore, they must be cognizant of the extensive technology proficiencies required by state teacher certification standards. The following proposal details a local experience relating to a technology integration project designed to support the ongoing refinement of faculty technology skills within the context of the teaching and learning situation.

Important Features of Project

The Learning and Integrating Knowledge and Skills (LINKS) project is a three-year technology project is designed to integrate established and emerging technologies into the teacher preparation curriculum at Texas Woman's University (TWU) and is supported by a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology (PT3)
implementation grant. The LINKS program supports both changes in university faculty roles and changes in curriculum content and delivery.

This paper addresses two primary questions: (1) how were the development of faculty technology proficiencies supported and (2) what was the progress of the participating faculty in infusion of technology in university web-based course delivery? To address these questions, second year findings regarding the examination of changes in faculty attitudes and behaviors and the effectiveness of the implemented LINKS project are provided.

Description of Problem

Integration of technology into university course delivery provides an essential model for pre-service teachers. Pre-service teachers recognize that, throughout the teacher preparation required coursework, they are expected to demonstrate technology integration skills prior to student teaching. Therefore, these future teachers expect university faculty to model these behaviors within the context of their university learning experiences. Increasingly, faculty from Arts and Science as well as from Teacher Education recognize the need to model within their own course delivery a variety of ways to integrate technology into teaching and learning. This faculty challenge encompasses both the new technology proficiencies and contemporary issues in pedagogy.

Description of Need, Population, and Implementation of Project

Need

A needs assessment from a purposive sample of current faculty addressed faculty needs relating to the integration of advanced technology tools into course delivery. Their perceived critical needs were in four areas of: (1) productivity; (2) connectivity; and the integration of technology.

Faculty members see productivity as a priority including support in development of their skills related to multi-media presentations and the creation of a professional web page for use in classroom instruction and communication with pre-service teachers. The survey data indicated the need for training to extend their multimedia presentations with more advanced media tools and the use of connectivity tools such as the World Wide Web and asynchronous and synchronous forms of communication.

In order to provide a model for our pre-service teachers, faculty must integrate technology into the design and delivery of all instruction. Advanced forms of technology must be infused throughout all courses, not just a separate technology method course, as transparent tools for thinking, learning, and constructing new knowledge. According to survey data, support for the use of web-based curriculum and instructional materials were high priorities for the faculty. They identify their need for training in evaluation and utilization of advanced forms of media, of content related Internet resources related to content areas, and of appropriate CD-ROMs and content-specific software.
Beginning in the spring of 1999 the LINKS program for faculty was created and implemented to respond to these perceived needs.

Population

Faculty volunteers from a variety of disciplines were recruited to attend technology-training sessions began September 2000 and were completed in April 2001. These faculty members were recruited from the group responsible for coursework within the teacher education sequence. Their only compensation was the use of a University laptop outfitted with web page browsers, Microsoft Office, multimedia software, and Ethernet connections for the duration of their participation in the LINKS project. This volunteer sample of university faculty (N=20) registered for each LINKS training session one week before the session date. If vacancies became available for any session, the training on that day was opened to interested faculty from the College of Professional Education and the College of Arts and Sciences. At each session data were collected on faculty stages of concern, levels of use, and perceptions of the effectiveness of the training they had received.

Implementation of Project

Training Goals. The primary training goals were: (1) the introduction of LINKS standards and resources, and (2) support for faculty delivery of web-based courses as models for future teachers. The goals were addressed through two types of sessions. Hands-on professional development sessions focused on specific areas for remediation or for more advanced work and whole-group development sessions addressed broad topics essential to all participants.

Training Session Overview. All sessions served as an orientation to the required technology proficiencies Texas pre-service teachers are expected to master and demonstrate. To provide a cohesive model, faculty were encouraged to integrate technology into the design and delivery of their instruction. These sessions also served as a training vehicle for the preparation of web-based course delivery via Blackboard, the University’s web-based course delivery template.

Fourteen sessions were available throughout the 2000-2001 year, seven per semester. These two-hour sessions were delivered in a University computer lab providing Blackboard access. All materials were available on a “class” Blackboard site for later reference. By using a web-based course delivery system to communicate with faculty participants, meaningful learning was integrated into their own web-based course development.

LINKS infused advanced forms of technology throughout training sessions as transparent tools for thinking, learning, and constructing new knowledge. Integrating technology as a transparent tool includes the use of advanced forms of media such as optical technology, scanners, video and sound, digital and document cameras, and streaming video.

Many sessions were designed as hands-on workshops. Faculty were encouraged to bring course materials, syllabi, graphics, and other materials to use as they converted traditional courses to the electronic medium. LINKS provided practical printed reference materials, related web page URLs, and individual assistance as needed. Additional one-on-one assistance was available from
LINKS staff by request. Personnel from Information Technology Services (ITS), the Distance Education Support Team, and from the library services collaborated with LINKS personnel in organization and implementation of the training.

Training Session Topics.

- **Session I: Orientation and Data Collection.** A whole-group session which served as an orientation to the LINKS project and PT\(^3\), including student and faculty benefits. The research methodology was outlined, and data was collected via online tools.
- **Session II: Exploring Internet Resources.** A whole-group session designed as an orientation to TWU Library resources, search engines, and other tools.
- **Session III: Searching Without Losing Your Composure.** A hands-on session with step-by-step procedures for searching the Internet using tools available on the Internet.
- **Session IV: Getting Your URLs Organized and Creating a Virtual Office.** A hands-on session designed to organize favorite and frequently used resources into directories for Bookmarks or Favorites.
- **Session V: Introduction to Blackboard.** A whole-group session designed to address questions concerning the creation of courses, getting access from a remote location, and managing information and sharing information in the course.
- **Session VI: ABC’s of Preparing Documents for Blackboard.** A hands-on session which discussed the philosophy of organizing course materials.
- **Session VII: Shortcuts and More.** A hands-on session with an emphasis on keyboarding and toolbar shortcuts in Microsoft Word and PowerPoint.
- **Session VIII: Exploration of Blackboard.** A whole-group session which covered upgrades from Blackboard 4.0 to 5.0. Collection via online tools was also administered.
- **Session IX: Adventures in Uploading for the Tentative.** A hands-on session that related to the uploading of documents into Blackboard for the novice user.
- **Session X: Cliff Walking on the Rocky Blackboard Range.** A session for the more experienced user that related to uploading different document types.
- **Session XI: Refinement of Blackboard.** A whole-group session specifically related to information dissemination addressing pedagogical issues pertaining to Blackboard. Speakers discussed recent finding from EduTex, a regional conference of EDUCAUSE, in San Antonio. Spotlighted were best practices and how other TWU faculty members are using Blackboard.
- **Session XII: Beyond Simple Documents.** Adding PowerPoint presentations and graphics to online classes.
- **Session XIII: Braving New Frontiers.** Using HTML coding.
- **Session XIV: Symposium and Data Collection.** A whole-group session that consisted of closure, overview of lessons learned, best practices models and presentations, and online data collection.

Data Sources. The purpose of related research inquiry and associated program evaluation of the LINKS project was to assess the changes in faculty behaviors and attitudes related to the integration of technology and to measure the effectiveness of training. Intrinsic to the examination of behaviors and attitudes of participating faculty was the use of the Concerns Based Adoption Model (CBAM). The module was developed by Hall, Wallace, and Dosset (1973) at the University of Texas at Austin Research and Development Center for Teacher
Education. Because the faculty could be followed and supported as they adopted the innovation (i.e., use of a web-based course delivery system), the CBAM model was implemented with this population through the Stages of Concern Questionnaire (SOCQ) and the use of a modified online survey structured from the Levels of Use (LoU) interview process.

Hall et al. (1973) discovered that an individual progresses through three clusters of concern as she or he adopts an innovation--self concerns, task concerns, and impact concerns. Three diagnostic dimensions were identified that are used to monitor a person’s progress through these stages: Stages of Concern Questionnaire (SoCQ), Levels of Use Interview (LoU), and Innovation Configuration (IC). Both the SoCQ and the LoU were used to assess progress toward innovation adoption or the IC.

To gauge the effectiveness of the provided training opportunities, faculty completed evaluation questionnaires at the end of each two-hour session. The evaluation questions related to the session’s impact on their motivation to apply new knowledge and skills and the ability to use technology more effectively in the classroom. Additionally, an overall perception of session quality was obtained. The evaluations of individual training sessions were utilized to refine management and enhance training in subsequent semesters.

Analysis. Pre- and posttest data were collected for the SoCQ and Levels of Use. Parametric paired-sample t-tests assessed differences across time. Qualitative analyses were conducted for open-ended items on session evaluation forms.

Implications for the Local Setting

The primary goals for the university faculty were introduction of the LINKS standards and resources, and support for faculty delivery of web-based courses as models for the future teachers. Descriptive statistics and profiles for the SoCQ suggested that the faculty had high informational and personal concerns as well as increased consequence and collaboration concerns. These types of concerns are consistent with movement through the change process. Analysis of the LoU revealed that all individual faculty made significant progress in levels of use, although they began at different levels. Qualitative analyses of open-ended evaluation questionnaire items suggested issues related to individual technical ability, to the time needed for implementation and integration of technology, and to the applicability of new learning to specific teaching situations. Additional analyses of implementation data have been conducted and will be reviewed during the course of this paper presentation.

The LINKS project provided a wealth of training opportunities for TWU faculty volunteers relative to the teacher preparation program. The following are key findings:

- Personnel from various campus departments collaborated to deliver staff development for faculty.
- LINKS training was tailored to accommodate faculty’ broad range of technology abilities.
- LINKS activities raised university faculty’ awareness of technology proficiencies needed by future Texas teachers.
• LINKS training positively impacted university faculty' motivation to use and capacity to integrate technology.
• Suggestions for training improvement centered on the individualization of training to meet faculty’ particular needs.
• Faculty’ main concerns centered on time, personal skill proficiency, skill retention, and resources.
• Faculty’ concerns with web-based course implementation, as measured by the SoCQ, changed over time.
• Progress toward higher levels of web-based course delivery use varied for particular faculty.

Implications for External Settings

Even though the benefits of technology integration has been well established in the literature, the United States Department of Education (USDE) finds that “relatively few teachers (20%) report feeling well prepared to integrate educational technology into classroom instruction” (2000a). In a separate report, USDE suggested that “teachers have been prepared for a model of teaching dramatically out of step with what is needed to prepare the nation’s students for the challenges they will face in the future” (USDE, 2000b). Findings presented regarding the implementation and effectiveness of the LINKS project has implications for increasing the technology proficiencies of entry-level teachers as well as providing a model for other universities undertaking similar changes and institutionalization efforts. Findings have particular relevance to explain how university faculty can be nurtured and supported as effective models of technology use in web-based course delivery and electronic communication with students.

Through the examination of the change process and the utilization of this information to support faculty to become users and modelers of technology, multiple benefits are evident. By providing a supporting scaffold, university faculty become less fearful of change and their attitudes take on a willingness to engage in increased learning experiences. When pre-service teacher witnesses technology integration within the auspices of their university coursework they are more likely to adopt the same technology integration and model that back to their future students thus encouraging a true technology integration model.

First Steps in Telelearning —
Simple and most flexible ways to realize distance-learning with children at the age of 6 – 10 years

Newald Martin (wseper@paed.asn -wien.ac.at)

Abstract: First steps in Telelearning is the title of our project (started at the beginning of the schoolyear 2001/02) in which we try to evaluate methods of telelearning for children at the age of 6-10 years. We are interested in the aims, chances and borders of telelearning at this age.

1. Introduction and Basic Information

Our main intention is to find out, how models of telelearning could be adapted for children at the age of 6 to 10 years: We try to find out, which basic-skills are absolutely necessary to enable children to use telelearning tools. We are interested to find and evaluate ways to guide children to a self-motivated and self-guided learning and try to find out the limits of telelearning-projects for children at this age.

2. First steps: Training of basic competences in using IT

Before starting the telelearning-project itself, we had to train the kids (and some teachers) the basic skills in using computers and modern IT. To motivate children we always start with very simple and easy computer games and similar things: Using Windows and its basic functions, use of very simple standard-software (wordpad, paint, ...), first steps in handling data, ...

3. Network-Technology

First steps in understanding network-technology: Right from the beginning we are using the network: We "force" the children to save their data on network-drives. Beside that we begin to communicate using the LAN. Then we start the first steps in the www ("guided tours", finding & saving information, ...) with a short basic training. After that children should find different informations (using different search-engines). While training the basic internet-skills children are also learning to use mailing to communicate: Each child creates his own mail-account (webbased) and sends/receives emails. Another part of our "basic-training" is to use chat-engines: Pupils begin to chat using an Austrian chat-engine, created by Prof. Dr. Rita Humer (Pedagogic Academy) especially for children (www.antonwelt.at).

4. Netmeeting

As a consequence of our idea to base our project on standard-software and very common used tools, we mainly use software-products of Microsoft. MS Netmeeting enables us to communicate in a simple way in our LAN as well as in in the www.

5. First Telelearning-Projects

Our first projects & tests were based on projects and contents of regular lessons: The pupils began to use MS Netmeeting as a part of the "daily school-life": Contacts to parents, contacts to different "professionals": The
first challenge was to take part at the "Interpaedagogika 2001" (November 8th–10th, 2001) with 20 of our pupils: Ten pupils in Linz (at the fair) and ten in Vienna presented how to communicate with netmeeting & "antonchat" (www.antonwelt.at). As a consequence of the special knowledge of those children, they could also present the possibilities of application-sharing and worked together with different software-products (to show, how to solve several problems together using the web). Another part of the presentation was working with word and excel in a "long-distance-team". In the future we plan to establish National & International Partnerships: We initiated a partnership with a small school in Salisbury (country). Now the children have the opportunity to learn to communicate with "strangers": They have to get to know each other by the web-based communication. The latest project and next step is to organize an international partnership with schools of other European countries: The "Comenius-Programm" is the basis for this plans. - We are interested in establishing a longer lasting partnership: Pupils of the different countries shall learn about each other and about the different hometowns-countries.

6. Accompanying projects and outcomes

Another part of our work concerning our telelearning-project is to enable the pupils to use the opportunities of modern distance-communication and IT for their school-duties, their individual learning and their daily life. "Learning at home" - Home exercises, using e-mail, encourage special interests: We noticed, that some pupils began to communicate with members of their family, they did not see every day: For instance there are some children, whose parents are divorced. They by themselves began to communicate by using e-mail, chat-engines and MS Netmeeting to establish contact.

7. Problems & Limits

First there are technical and software problems: e. g. bandwidth; most of the user-interfaces (hardware and software) are not created for children’s use. On the other hand there are problems and limits of telelearning especially for children at this age (6 – 10 years) as there are:

Usage of the mother tongue: Children are taught to read and to write at the age of six years. But this culture technique is the minimum base for the use of "usual" tools of modern IT and web-based communication:
- Capability of reading: Reading speed of pupils at this age is very low; so they need much time to read the informations they are given by the computer-human-interfaces.
- Capability of writing: Children are able to type letters, but they are typing very slowly – the speed of text-based communication often is to low. Therefore it is very important, to work with video-/audio-support or by using very intuitive graphic-interfaces (bandwidth!).
- Language-style of the children: The development of the language-style is very intensive at this age. So children are often not able to express what they mean. While they mostly can speak out their thoughts orally, they are not able to do this by written language in the same way).

Foreign language: The most important "computer-language" is English - but usually children begin to learn this foreign language when they start school. But most of the the web-information is in English and so our German speaking children are not able to use them!

8. Accompanying Measures

Teacher education and advanced classes for teachers with experience in working with computers: We always try to involve students of the Pedagogic-Academy to our project: It is also a very important aim for us, to motivate and enable them to use IT for their future educational work. Another very significant part of our project is to teach the teachers: Most of those teachers were able to handle their computers but did not have the necessary skills to train their children in using web-based communication tools. So we had to organize special workshops and lessons to train teachers. Since that we are organizing special workshops in cooperation with the Pedagogic Institute of the Archdiocese of Vienna.

Abstract: This work stems from a project funded by the Arthritis Research Campaign (ARC) to develop a web site, JointZone©, for the study of Rheumatology for both undergraduate medical students and practicing doctors. The educational application incorporates both declarative and procedural knowledge, providing students with a chance to acquire knowledge on rheumatic disorders as well as develop clinical reasoning skills through a series of graded case studies. In order to enhance learning and reduce cognitive overload, which can be associated with hypermedia environments, adaptive hypermedia techniques (Brusilovsky 2001) have been integrated into the core of a web-based learning environment. This paper discusses the adaptive features employed and the pedagogical rationale involved in developing the web site.

1. Introduction

Resources in an information-rich hypermedia environment allow users to browse the material in an informal way until something of interest commands greater attention. Alternatively, they may search the material in a goal-directed manner to find the information they need. The former is analogous with an informal learning environment (Duchastel 1989) where one's attention skims a wide range of information. However, a corpus of information in a hypermedia environment is not necessarily an ideal learning environment as it is essentially 'non-pedagogical', and generally provides minimal structural support (Duchastel 1992). However, this mode of learning can be effective if the reader already has a fairly well developed schema (a personal construct of related information) for the material being read. A schema acts to filter incoming information and provides a framework for processing information. For a well-developed schema, paying scant attention to material as often happens when browsing, is very often enough to modify a schema, and hence learn. Practitioners, or those knowledgeable in a field therefore, may use this technique in a casual manner and informally upgrade their knowledge of a subject. Novices on the other hand, with less well-developed schemas, are more easily overwhelmed and quickly suffer from cognitive overload. General browsing therefore is not necessarily an effective learning method for them (Mayes et al. 1990). Goal-directed learning on the other hand is more focused, affording a greater opportunity to attend to the material. It is important therefore to provide guided support, or scaffolding for novices while allowing the more advanced reader to move more quickly through the material. The nature of hypermedia as a searchable network of information can enhance goal-directed learning through effective search facilities while also allowing easy access to a wide variety of material for browsing. However, both these functions of hypermedia can still lead to a cognitive overload (Thuring et al. 1995) as even with goal-directed learning a vast array of linked resources can be presented to the learner. Adaptive hypermedia is one approach that takes into account the reader's knowledge level and can present an appropriate selection or an adapted set of content nodes - adaptive presentation. It can also provide adaptive navigational support offering a selection of links based on reader knowledge and, or readers' browsing history (Brusilovsky 2001). In both these cases, adaptive mechanisms support the reader by offering a guided set of documents/ or links with the aim of reducing the cognitive overload, thus enhancing the reader's ability to attend to pertinent documents and learn. In view of these issues, our task within this Rheumatology project has been to place learning materials online which ensure coherency and a good accessibility to information without causing...
disorientation. Since we are using a closed corpus of information, we are able to collect information from the user on entry which is used to develop a supportive learning environment through adaptive hypermedia techniques.

Three major roles have been involved in the development of this project to encourage effective web-based learning. There is the web author, whose major responsibility is to develop a coherent information model employing adaptive hypermedia techniques, changing a static website into a dynamic one with tailored links and navigational aids to enhance orientation and reduce cognitive load. There is the domain expert, whose role is to provide information (declarative knowledge) on various topics within the domain, and learning material that encourage readers to structure this knowledge by constructing relations between pieces of information (structural knowledge). In addition, an opportunity is provided for readers to interpret various elements within a virtual clinical interview (procedural knowledge), emulating the activity of an expert practitioner (Jonassen 1991). Finally, there is the education expert, whose role is to understand the structure of the domain, anticipate the needs of readers and their potential understanding of the content at any given point. This role offers advice on learning support and scaffolding strategies that enhance readers' ability to develop their current schemas, construct new ones and develop cognitive skills that allow them to apply the knowledge they have within their professional context.

In this paper we shall first outline the implementation of JointZone© and our pedagogical approach in developing readers' procedural knowledge through a cognitive apprenticeship model. Then we shall explain the adaptive mechanism employed in JointZone.

2. Implementation

When constructing a framework for the JointZone© application, an information model (see Fig. 1) was developed to feature three types of 'separation' (as described in (Lowe & Hall 1999, p.67)) namely: the separation of presentation code from information (content), the separation of links from content, and the separation of logic from information.

These three features were taken into consideration in the design in order to reduce the authoring effort by re-using the resources and to facilitate the maintenance of the application. As shown in Fig. 1, the information model outlines the different entities in the application (content, user data, link data, presentation code and logical data) and they are implemented using different web technology to emulate the notion of separation of concerns.

![Figure 1: The information model of the JointZone© application](image)

The latest web technologies such as XML\(^1\), XSL\(^2\) and JavaServer Pages™ have been used to implement the model. XML is used to store and structure the content while XSL is responsible for its presentation style. This allows data to be separated from information and encourages information re-use. For example, the same copy of XSL style sheet

---

\(^1\) XML (Extensible Markup Language) is the markup language that provides a mechanism for inventing new elements.

\(^2\) XSL (Extensible Stylesheet Language) is the style sheet that renders the presentation of XML on a web browser.
can be used to display more than one XML page. Likewise, only one copy of XML content is maintained even if it is presented in different ways in the browser. On the other hand, the logical bits of the web site, i.e. session tracking of users' activity, the adaptivity engine and the search mechanism have been implemented using JavaServer Pages™ (JSP). The JSP technology allows the integration of Java™ codes into HTML pages to facilitate dynamic content generation, which makes the adaptation of links and contents possible. In short, all the components described above contribute to the notion of separation of concern, which facilitates maintenance.

We employ link databases or linkbases (Hall et al. 1996) to store links separately from the documents to which they refer. This implies the separation of links from content. Links are not only a means to traverse the web site but also embody the semantic relationship between the nodes (web pages). Proper link management therefore is essential for the orientation and usability of the application. From the perspective of learning, good management of links can reduce users' cognitive overload that can result from poor orientation and navigation facilities. Hence we employ the use of different types of links to better manage the linking of information pieces. We adopted the following link taxonomy from (Lowe 1996, p. 33):

Structural links illustrate the structural layout of the web site. These include 'jump' links within a page to provide direct access to page fragments, 'next' and 'previous' page links that ensure coherency between the documents, and the provision of the 'table of contents' to give a meaningful overview of the information site.

Referential links are essentially glossary links that relate a word in context to its definition. The main difference between structural links and referential links is in their linking mechanism. Referential links are abstracted from the idea of generic linking (Hall et al. 1996) where links are not embedded inside the documents but stored in the link databases. They can appear anywhere in any document where a glossary word exists. Hence these links are not handcrafted but automatically generated using an offline pre-processing mechanism, another feature that eases authoring effort. The glossary links are highlighted in green and are resolved in real time from the link database once followed by the users. The effect will be a pop up window explaining the word that a user has selected. From the learning perspective, the glossary links are useful for learners to expand their knowledge of the terminology within the knowledge domain.

The idea of generating associative links comes from the usual phenomenon of users browsing in the current context to find more information about a particular concept. For example, when users are reading a document or solving a problem that concerns concept 'X', links to other documents are suggested, which they could find out more about 'X' in other documents (Lowe & Hall 1999). Hence, these links are called associative links because they associate two or more documents based on a common concept. Associative links are stored in a linkbase where each of them is indexed or retrieved based on a keyword or concept. From a learning perspective, this link type is used for goal directed learning where the user will search on a concept to find a series of related documents.

3. Learning Issues

JointZone© provides a rich source of material to enrich users' domain (declarative) knowledge in: basic science, rheumatic disorders, approach to patient, investigation and disease management. This network of information can be used by all readers in a browsing or goal-directed learning mode and is suitable for medical students and practising doctors. Information can be found using the site's internal search engine or selecting sections from the side menu bar to reveal documents, and as documents are selected, their linked structure becomes visible on the side menu. However, domain competence is more than domain knowledge, it also comprises a whole range of skills and for medicine, skills based competence is vital. These skills are: a) physical, e.g. equipment and procedures and, b) cognitive, e.g. analysis, interpretation and decision-making. It is the cognitive skills that demand a more sophisticated learning process if they are to develop (Kinshuk 2001) and with adaptive hypermedia mechanisms we are able to match the content level with the student's knowledge through interactive case studies. A case study approach was adopted for JointZone© as it can holistically represent the complexity of clinical reasoning. Students are then able to develop their procedural knowledge, which elaborates how doctors approach problems, interpret clinical information and make decisions (DesCoteaux & Harasym 1998).

3.1 Developing Cognitive Skills through Procedural Knowledge

Some of these critical skills and processes that medical students need to learn are decision-making, reasoning and problem solving (Greening 1998); essentially skills that relate to a clinical diagnosis and management which is a pivotal activity for all physicians (Nkanginieme 1997). To develop these skills, it is important for students to practice relating disparate pieces of information from a patient within the clinical context. The graded case studies
in JointZone© provide clinical medical education that develops students' clinical reasoning skills within the domain of Rheumatology.

The advanced case studies were developed to encompass a wide range of information available in the clinical context. These were generated following a heuristic analysis of the clinical decision making process by an expert practitioner. Our analysis reflects the cognitive skills identified by Nkanginieme (1997), namely that physicians: a) obtain and recognise symptoms in the patient, b) identify the appropriate system involved, c) speculate on the pathological processes, d) differentiate pathological processes, e) identify the possible causes of the pathology, f) evaluate all pieces of information and make a clinical diagnosis. To support student development of these cognitive skills, explicit procedural steps for the clinical interview were presented: the referral letter, patient history, the examination, investigations, diagnosis and clinical management. On working through these stages, students are confronted with a wide range of options, such as results from investigations: diagnostic imaging, haematology, immunology, microbiology, serology, and synovial fluid aspiration, which give students information pertinent to the case under study. The clinical observations they gather by working through the case study are recorded so the student has ongoing access to this information as they proceed. At the diagnostic stage, students are given a complete record of the examination findings and investigations. If the system feels insufficient or inappropriate information has been gathered this will be pointed out to the student. From a list of possible diagnoses, students select their preference based on their interpretation of clinical information gathered. They then obtain subsequent feedback on why that diagnosis is likely to be appropriate. This feedback, and the feedback across all case studies, makes explicit the expert's heuristics of clinical reasoning. This is an attempt to share that clinical expertise through a modelling or a cognitive apprenticeship (Collins et al. 1989) approach, and it displays the underlying principles and rationale of the clinical diagnosis and completes the process. This enables students to develop their cognitive skills, providing a framework for problem solving and hence clinical reasoning.

Case studies for beginners and intermediate level students are much narrower in scope and the choices are more restricted. However, as with the advanced case studies, the feedback mechanism serves to model expert thinking in how to solve these problems. The goal for beginner case studies is to recognise the value of particular pieces of clinical information, identify the pertinent investigations and make a diagnosis. For the intermediate students, the goal is to reassess a case in which the original diagnosis is under question. For both these levels, students are given scores on their performance in reaching a diagnosis. A random selection of items is penalised. Through these case studies, students learn to recognise and interpret the value and relevance of disparate pieces of information that are integral to any clinical scenario. In this way students construct their own understanding of the relationship between the pieces of information rather than having it imposed upon them. This encourages a cognitive flexibility (Spiro et al. 1992) that is vital for the complex world of the physician.

3.2 Bridging the Declarative and Procedural Knowledge Adaptively

At the end of all case studies, students have access to an 'adaptive reading room' (see section 4) where links to pertinent domain knowledge are made available. This adaptivity feature gives advanced users a wider range of pertinent documents than those with lesser knowledge. An example of this is for the concept 'osteoporosis', advanced students have access to the following sub-concepts: osteoporosis, crush fracture, densitometry, bone scan, and corticosteroid while intermediate students have access to osteoporosis, crush fracture and densitometry, and beginners have access simply to osteoporosis. However, there is no restriction to information for any user group should they wish to investigate further. The list of suggested reading titles is identified for each case study and presented adaptively. Each document title in the list will indicate the amount of attention that reader has already paid to the particular document through a green icon indicator alongside the title, (see Section 4). Hence, the 'adaptive reading room' and the textual glossary links throughout all cases act as a bridge between declarative and procedural knowledge in the application.

4. Integrating Adaptive Features

We have briefly mentioned adaptive case studies (for beginner, intermediate and advanced level) and the adaptive reading room in the previous section. For some background, adaptive hypermedia (AH) (Brusilovsky 2001) systems essentially revolve around the idea of adapting information to users' differences (knowledge, background, interest etc). One of its aims is to protect users from getting lost in hyperspace by limiting their browsing space or providing advice. In our case, the integration of adaptive hypermedia will hopefully counteract some of the negative effects of self-exploratory learning on the web.

Our main reason for integrating adaptive features into a web-based learning environment is to cater for users' needs that arise due to individual differences. This can be accomplished by adapting information to users in
several ways. Firstly, their knowledge level, where information is presented based on users’ current level of knowledge. Each user’s knowledge level is evaluated by means of either a prior knowledge test upon initial entry to the application or a self-selecting level based on registration details. Secondly, the user’s browsing history provides personalized browsing aids for individuals, so that they can concentrate on pages they have not read adequately. The browsing history is a record kept by the system to keep track of pages that have been read by the users and how much time they have spent on those pages. The system estimates the degree of effort a user has spent on a particular page by comparing an optimal reading time (set by the system on each page) with the actual time spent by the user on the page. In order to make the estimation more accurate, the system will consider the individual’s effective reading speed (Jackson & McClelland 1979) and the length of the page when estimating the effort that has been spent on each page (Ng et al. 2001). Thirdly, the goal of the user is employed, by pointing users to pages based on their selected reading goals. These short-term goals are captured explicitly from the users’ input, when they select a reading goal. From a learning perspective, short-term goals provide guidance in a self-exploratory learning environment where the user’s declarative knowledge of the domain can be enhanced. Instead of free browsing, users can therefore focus on a topic or goal.

In JointZone© we have used adaptive features based on users’ knowledge level, browsing history and reading goals mentioned above. In adaptive case studies (as explain in Section 3.1), users are directed to the graded case study section based on their current knowledge level. The personalised site map (see Fig. 2) provides an overview of the web site showing all the web pages and their physical layout (headings, subheadings) on the site. Once a user has registered with the system, their browsing history and time spent on each document is logged, enabling this personalised site map to be presented. Pages are annotated with a three-color-band code to indicate their reading gauge—a visual representation of the amount of time a user has spent reading individual pages. The personalised topic map is similar to the personalised site map, but instead of showing all pages on the site, it shows only the pages that are related to the current reading topic. To initiate this, a user is required to choose a reading topic from a pull down menu, for example ‘gout’. A topic-based map will then be presented showing only pages that are related to the reading topic and the pages are highlighted adaptively according to the user’s browsing history. Finally, the adaptive reading room supports user-driven tasks. Unlike the two navigational maps mentioned above, which apply to general free browsing, adaptive reading hints are integrated with the interactive case studies. When a user has finished working on a case study, he or she might want to know more about the concepts related to that case study. The adaptive reading room hence offers a reading list that is adapted to the user’s knowledge level, as described in section 3.2.

6. Conclusion and Work

The overall aim of this web-based learning environment was to provide a rich source of information that effectively supports the learner through the adaptive features and allows users to engage with material more effectively. We set out to achieve this through careful hypermedia authoring while maintaining a constant awareness of users’ needs. Our main strategies for developing an effective learning environment on the web were to:
• provide a personalised information delivery system that through adaptive hypermedia technique, allowed users to maintain an overview of the documents they had read or not read. We have also linked the procedural and declarative knowledge in the application adaptively, to prevent cognitive overload and facilitate the process of learning.

• design learning materials that develop medical students' cognitive skills in clinical reasoning via, graded interactive case studies.

• reduce authoring effort and increase maintainability of the application through the separation of concerns in authoring.

• increase the usability and accessibility of information through various linking strategies.

A comprehensive evaluation of the adaptive features is currently being undertaken to scrutinize their effectiveness in terms of learning and information access. This evaluation will give us some insights into whether adaptive web-based learning really benefits the students or whether it is a mere technology-driven technique in a learning paradigm.

Integrated Environment for Web-based Experimentation in Engineering Education

Anh Vu Nguyen, Yassine Rekik, Denis Gillet
School of Engineering
Swiss Federal Institute of Technology in Lausanne
Switzerland
{Anhvu.Nguyennogoc, Yassine.Rekik, Denis.Gillet}@epfl.ch

Abstract: The Swiss Federal Institute of Technology in Lausanne is currently developing an environment for Web-based experimentation in engineering education. This environment aims at providing students with the facilities to reinforce their learning process by carrying out practical experimentation. This paper focuses on the concept of Laboratory Journal, a component of the environment, which has been developed to support knowledge acquisition and reinforcement in a collaborative way. The Laboratory Journal is designed and implemented as an integrated space that supplies the needs for collaborative learning and fulfills hands-on session requirements, using the latest communication and information technologies. It has been developed as a Web-based application with client/server architecture. The implementation is based on the use of Java and XML technologies.

1. Introduction

The rapid development of computer networking and the Internet in the last decade has provided new possibilities and also new challenges for designing and deploying distance and collaborative learning systems. Nowadays, one of the useful and interesting trends to support active learning is to expand the available educational resources by providing virtual and real experimentation facilities (Gillet, D. & Farkas, G., 2001). This is especially important in engineering education where the practical approach to learning is as necessary as the theoretical one. Thus, there is now a growing demand of developing remote experimentation environments for educational purposes.

The deployment of Web-based experimentation facilities is carried out at the Swiss Federal Institute of Technology in Lausanne (EPFL) in the framework of the eMersion project. This project aims at providing an environment for engineering education based on new learning technologies resources, which facilitates experiments through Web-based simulation and/or remote manipulation of laboratory setups. eMersion proposed an integrated environment that allows students to execute remotely Experimentation Modules over the Internet to support their learning activities. The environment has a Cockpit-like graphical user interface. This so-called Cockpit environment contains all the components necessary to complete successful experimentations. In particular, the Cockpit includes three main parts: the Experimentation Console, the Toolkit Console and the Laboratory Journal. The Experimentation Console can be regarded as the interaction part that enables the actual realization of experiments. The Laboratory Journal constitutes the collaboration part that facilitates reporting as well as knowledge integration and sharing. The Toolkit Console provides students tools to carry out interactive design and analysis activities related to the experiment. The portal of the Cockpit environment for automatic control modules is shown in (Figure 1). Currently, the environment is used for pilot-courses in automatic control, fluid mechanics and biomechanics at the EPFL.

This paper introduces the collaborative part of the Cockpit namely the Laboratory Journal. It is organized as follows: section 2 discusses about the concepts of collaborative learning in engineering education. Sections 3 and 4 present the features and implementation of the Laboratory Journal. Section 5 shows the user case validation. Section 6 talks about the future work and section 7 concludes the paper.
2. Collaborative Learning in engineering education

CSCL (Computer Supported Collaborative Learning) studies how computer science can support learning processes promoted by the collaborative efforts of students working on a given task (Santoro, F. M. et al., 2000). CSCL supports active collaborations. That means it not only provides the delivery mechanism for collaborative interactions provided by CSCW (Computer Supported Collaborative Work) but also provides additional controls and services required to guide collaborative learning in an active fashion, based on the requirements of the peers involved in the interactive learning (Clemson University Notes). Collaborative learning not only helps group works but also encourages individual’s activities and contributions in the group. Each member in a group has some specific authorities, responsibilities and roles when taking part in the group's activities.

Taking ideas from CSCL, many collaborative learning environments (CLEs) have been developed and proposed for the tutor and student to work together. These CLEs are generally made of a collection of tools and services that supports teaching and learning processes to help tutors and students show their opinions without face-to-face judgement. Nowadays, the WWW is becoming an ideal platform for developing CLEs.

In engineering education, the practical part is as important as the theoretical part. In the spirit of flexible learning (Gillet, D. & Farkas, G., 2001), the students should be allowed to carry out the experimental work in laboratories as well as from distance. Hence, to facilitate the practical learning, the physical and virtual experimentation setups should be both supported. Those are used by the tutor for demonstrating and also by the students for hands-on exercises (Gillet, D. et al., 2001). The virtual experimentation could be a combination of graphical animations and numerical simulation tools. During the experimentation process, students need a shared working space (or shared workspace), i.e. the collaborative space, where they can take notes about their experimental works, store results and observations, discuss, share information and materials, ask or provide assistance with other students.

In academia as well as in industry, there are a lot of simulation tools, which support practical activities in engineering education. For example, in (Mateos et al., 2001) PROSIMAX, a Windows based tool for testing control programs implemented on different control devices, is presented. It is intended to minimize the main drawbacks of classical tools used for test in educational environments. DEVRE is presented in (Ridao, P. et al., 2001) with the aim to assist engineers during the software development and testing in the laboratory prior to real experiments. (Sepe et al., 2001) has constructed VE-LAB, a Web-based virtual engineering laboratory for collaborative experimentations on a hybrid electric vehicle starter. Using these environments, users can perform virtual experimentations. DEVRE and VE-LAB are built in a distributed environment (Web-based environment in case of VE-LAB). However, users have no way to collaborate (the collaboration is poor supported in VE-LAB) and/or to share, to exchange their ideas, experimental results and information. In other words, these environments don’t support working in groups.

Recently, there is a growing interest to support collaborative work over the Internet. Maybe one of the most popular collaborative tools in academia is BSCW (Basic Support for Cooperative Work) (Klöckner, 2000). This is a shared workspace where users can share information; collaboratively perform their activities over the Web. However, BSCW doesn't support task manager; i.e. the capability of the supervisor to fragment a big project into small tasks and distribute to different groups, assign responsibilities to group members, monitor the progress of groups when performing tasks. In addition, the synchronous collaboration among users in BSCW is not much either supported.

The goal of the INVITE project (Bouras et al., 2001) is to build a platform for synchronous tele-learning that can be interfaced with standardized content management and/or industrial management system.
3. Laboratory Journal features

The Laboratory Journal is developed based on the concept of electronic journal. Normally, text, sketches, graphs, tables, signatures, images and other kinds of data are “written” (or “recorded”) on electronic journal “pages”, which can be read and navigated (Daniel C. Edelson, D. Kevin O’Neil, 1994). The electronic journal allows easily input of scientific data (for example, the experimental results in the form of image or mathematical formula). As indicated in (Al Geist & Noel Nachtigal, 2001), an electronic journal has many advantages, it can be shared by a group of users, can be accessed remotely, cannot be lost (if carefully backed up but this task is easily done), can be searched for information, can include multimedia or hyperlinks to other information, etc.

In our system, the Laboratory Journal is constructed as a collaborative working space (or collaborative workspace for simplicity) for students when performing Web-based experimentations. In other words, it is a Web-based medium where engineering students can remotely record aspects of experiments that are conducted in the framework of a virtual practical exercise. The Laboratory Journal lets students access their preparation materials, store and post-process their experimental results. Logically, we have two different spaces for working. The private Journal components can only read or modified by its single owner, and group Journal space is the shared space for a group. The student and tutor can work on their private Journals before sharing them with others. Each group Journal is dedicated to one group for one experimentation module. Authorization or access rights relate to the operations available to the user. The authorization is changed from one Journal to another. It depends on the role as well as on the context. To prevent conflicts when co-editing the Journal, the locking mechanism is provided.

The Laboratory Journal provides the possibility for documenting and reporting, and it facilitates the key activities of knowledge integration and knowledge sharing (Gillett, D. et al., 2002). It takes many advantaged features from structured document concepts (Adre, Furuta & Quilt, 1989). The structured document permits the flexible reuse of the document and of its elements. The relationships between elements are based on the document’s logical structure and not the physical appearance of the components displayed on the page. Students just concern with the content of the document. In the Cockpit environment, they use the Laboratory Journal to collaboratively prepare reports. Thanks to the hierarchical structure of the Journal page, users can co-edit the whole or just some parts of the report. Also thanks to the DTD (Document Type Definition) (Harold, E. 1999) defined for the Cockpit and the Laboratory Journal interface, the Laboratory Journal’s views can be changed depending on the user’s profiles and the report can be automatically generated based on the inputs from the user.

In the Laboratory Journal, many kinds of elements can be defined, for instance: text, image, table, etc. The artifacts in the workspace are called fragments, which can be composed of objects and used to construct the report. The text fragment can be edited by hand or extracted from documents imported by different students. The imported documents are transformed into structured document format. When the imported documents cannot be
transformed, they remain as attached documents. Other kinds of fragment can be uploaded from a file server or transferred from the Experimentation Console using the Data Tunnel, which is constructed as a tunnel for data transmission between different parts of the Cockpit environment. In addition, the student can create and edit notes, which will be used in the report, to memorize the observations or anything else when performing the experiment.

The report is constructed by inserting fragments. The fragment is chosen in the workspace and then inserted to the report. The delete, modify possibility is also allowed in the report editing space. Every time the report is modified, the previous version is saved. This version control functionality helps students to review their working history. After being edited, the report is sent to the tutor as HTML or PDF file by email. After being submitted to the tutor, the group report cannot be modified anymore.

The member of a group communicates with other members in the same group or with the tutor either directly through message exchange or indirectly through annotations, which are added to the fragments (or the shared artifacts) in the workspace. The annotation provides the meta-information about the fragment. For example, it could help students and tutors know that this fragment was created by whom and when. Different annotations from different users can be attached to the same fragment. The communication between members is also enabled by the way the student provides the "write" permission to other members in the same group or the "read/write" access to the tutor. Thus, the tutor or other members can also modify the fragment or to give some feedbacks to the student-author. The communication mechanism is in fact provides students and tutors the awareness information in collaboration process. The general concept of awareness was defined by (Paul Dourish and Victoria Bellotti, 1992) as an understanding of the activities of others, which provides the context for each member's activities.

A group task manager is also constructed to solve the need to fragment a whole task (for example, group 1 prepare a report for experimentation module A) into specialized smaller sub-tasks that are to be performed by different students working within a single group (for example, who does what). Common tasks may be shared and manipulated independently by a number of users with different kinds of access control. With this tool, students monitor their progress or organize cooperative tasks; for example, create, refine or modify a task. To create a task means to define this task, to allocate some resources and assign it to some specific students.

4. Laboratory Journal implementation

(Figure 2) shows the Cockpit environment when performing experimentation module about electrical drivers. In the top of the figure is the Navigation and Supervision Area. In this part, we could find the objectives and the status of the task currently being processed (for example, the task is finished or currently implemented). The Protocol space in this Area describes step-by-step procedures necessary to perform the experimental work. The Navigation and Supervision Area also provides the possibility to access other relevant supplementary information such as reminders or links representing the theory, a description of the environment, etc. The bottom left of the figure represents the Experimentation Console (the higher part) and the Toolkit Console (the lower one). The Laboratory Journal is showed in the bottom right of the figure.

![Figure 2: The Cockpit environment for the automatic control module.](image-url)
To represent the concept of structured document, XML (eXtensible Markup Language) (Harold, E., 1999) is chosen. It is the universal format for structured documents and data on the Web. XML data only contains data; that means what is to be presented. The presentation part is done by stylesheets. Using a stylesheet, the correct style will then be generated in different formats such as PDF or HTML.

The Laboratory Journal is constructed using Web-based client-server architecture. Users can use Java-enabled browsers to access Web pages, which contain codes (Java codes and scripting codes such as Javascript) used to invoke services. The Web pages in our system are in fact the JSP (JavaServer Pages) (Aveda et al. 2000) ones. JSP pages can provide the full power of the Java language to process and transform XML documents. The DTD (Document Type Definition) is defined at the server side. The server side is an extended HTTP server, i.e. an HTTP server with some application servers (written as Java applications) to enrich processing functionalities. In the Cockpit environment, a TOMCAT version 4.0 from the Apache Software Foundation is used as the Web server. A relational database (mySQL (see MySQL) in our case) and a file system are used to store data in the central server. Depending on the requests from the clients, the appropriate XML files are created. The XML files are then transformed by XSLT stylesheet (see XSLT) into formatting object trees. The object tree is parsed by Java codes to create objects in the Journal.

5. User case validation

Since October 2001, a group of 25 EPFL volunteer students for each semester has used the Cockpit environment to carry out laboratory assignments in automatic control under observation. They were asked some preliminary questions listed in the Cockpit protocol and then the answers are added to the Laboratory Journal by creating notes or attaching documents. This is considered as the pre-lab task and when finished, it is made visible (by providing permissions) so the tutor is able to grade it.

The answers are corrected and annotated by the tutor within the Laboratory Journal context. The students are then authorized to perform the practical part of the experimental assignments using the Experimentation Console. (Figure 2) illustrates a laboratory assignment, in which the student performs the experimentation in modeling and digital controlling of servo drive.

During performing experimentations, the student takes notes in the Journal. The experimental results and observations are saved in the workspace in order to create the reports.

The volunteers have been observed and interviewed by pedagogues to evaluate their reactions regarding the Web-based environment and the flexible learning approach. The evaluation detail is described in (Gillet, D. et al., 2002).

6. Future work

Currently, the Laboratory Journal is in the phase of design and implementation. There are still many theoretical and technical problems to deal with when developing the system. The future version of the Laboratory Journal will fully support the collaboration when performing activities on Journal pages and Experimentation Console. The ability to generate automatically the report based on the user's inputs (thanks mainly to the well-defined XML files stored in the server) will be implemented as well.

7. Concluding remarks

In this paper we described the Cockpit environment as a paradigm introduced at EPFL in engineering education to sustain hands-on learning activities. We have defined the Laboratory Journal, the collaboration part of the Cockpit, as an infrastructure that supports collaborations among students when performing Web-based experimentation. Our system relies on a variety of flexible, scaleable and platform independent components. We have shown the concepts related to the Laboratory Journal, its features and implementation. Currently, the environment supports three courses taught to students in automatic control, biomechanics and fluid mechanics. An evaluation is currently carried out in collaboration with a usability team and pedagogical experts in order to assess the effectiveness of the deployed solutions.

Abstract: This paper describes the design and implementation of a real time on-line collaboration tool, EDUCO. The main focus is to demonstrate how the tool is applied to a real life on-line distance-education course, discuss the preliminary research findings of qualitative empirical study, and propose directions for future work and implications. The preliminary results show that some of the features used in this tool can be directly applied to a wider context of modern computer-based learning environments.

Introduction

The main objective of the EDUTECH project is to develop methods for applying probabilistic modeling techniques, such as Bayesian network models, in building and using personalized, adaptive software components for digital learning environments. The research focuses on developing intelligent autonomous but interoperable modules for educational purposes from assessment techniques to the support of co-operative activities and personalized adaptive learning materials.

The first phase of the EDUTECH study period (1999-2000) concentrated on the development of intelligent questionnaire software EDUFORM (Kurhila, Miettinen, Niemivirta, Nokelainen, Silander and Tirri 2001). EDUFORM allows for an adaptive and dynamic optimization of questionnaire propositions and profiling of learners on-line. This software module is applied to varying types of assessment applications both in business and educational domains.

The ongoing second phase (2001-2002) of the project has two sub-phases. Firstly the research group has developed an experimental version of a tool for on-line computer supported collaborative learning. The latter ongoing part of the research is focused on utilizing and combining the co-operative aspects of profiling information gained from EDUFORM by providing mechanisms for intelligent matching with co-students.

The major goal of this paper is to describe the design and implementation of a real time on-line collaboration tool, EDUCO. The main focus is to demonstrate how the tool is applied to a real life on-line distance-education course, discuss the preliminary research findings of qualitative empirical study, and propose directions for future work and implications.

The Role of Real Time Interaction in Web-Based Learning

The concept of computer supportive collaborative learning (CSCL) consisting intentional active learning, process aspect knowledge and methods of knowledge-building resources necessitates a flexible and synchronous learning situation (Scardamalia and Bereiter 1994). When we compare these conditions for learning and the implications from CSILE and Knowledge Forum to modern platforms for web-based learning, such as WebCT and Learning Space, we must admit that the real time component of on-line learning process is still very static and inflexible.

How, then, the task-related social interaction, which should play a significant role in a learning process, is implemented in available educational software? Comparison between the software is relatively simple to carry out due to the fact that popular platforms have relatively similar functionality. They all provide the learners with tools to go through the learning material, perform tasks like answering to quizzes and submitting assignments, and communicating with peers or teachers (see e.g. Landon 2001). However, in these “traditional” web-based learning environments the real time social interaction is limited to a simple chat and web board services. When a user is actually using the platform, the learning experience can be perceived as a lonesome activity, since there is no feeling of
other live learners or teachers within the environment. The concept of social navigation (Munro, Höök and Benyon 1999) provides one viable solution to the problem.

Considering social navigation from the standard perspective, the concept means providing the users with information from the actions of other users of the environment. For example, showing the hits for different web pages is a simple form of providing means for social navigation. In the seminal book of social navigation, Munro et al. (1999) use an on-line grocery store as an example: if people visiting the store are given recommendations what other people have bought, it is a form of indirect social navigation. If a shopper in the grocery store has a sense of other people moving about the store and can engage in seeking e.g. assistance, it is a case of direct social navigation.

Experiments with social navigation have mostly fallen into the category of indirect social navigation. Still, in some sense the feeling of other users can be achieved even if the actions are not delivered to other users in real time. For example, in CoWeb (Dieberger 1999) the feeling of aliveness is carried out with persistent discussion spaces that allow any user to modify any hyperdocument. CoWeb uses indirect social navigation in generating footprint markers that indicate the amount of recent traffic to pages and when the pages were last modified. The markers provide an additional sense of awareness of activities in the information space and thus increase the sense of the CoWeb as a social "place".

However, the indirect social navigation approach does not add to the need for really live users. Therefore, we have implemented a tool for real time on-line collaboration called EDUCO. EDUCO appears to the users as a visual collection of web sites, where the users can navigate the documents and see when other users are navigating those same documents. Users can engage in chat simple by clicking the dots representing users in EDUCO. Furthermore, EDUCO users are able to set "alarms" which are triggered when a certain person, group member (Hoppe and Ploezner 1999) or any user arrives to the systems or to a certain document. Search functions to locate users or documents with desired keywords in the title exist as well.

The Design of the Study

The first experiment with EDUCO was a course given at the Department of Computer Science, University of Helsinki, Finland. The topic of the course was Web-based learning. The first meeting was an introduction to the topic and to EDUCO. The following weekly or bi-weekly sessions were carried out on-line with EDUCO as an interaction tool until the final day when students presented their papers. Students (N=24) taking part of the course were expected to form a group of two, pick a topic in the field of web-based learning and prepare a paper and a presentation about the topic. In addition, there were several time-limited mini-tasks given by the teacher on-line, and tasks where the students were supposed to comment on research papers on web-based learning. The data set was gathered in three stages: (1) pre test on the first day of the course measured motivational level and learning strategies, (2) user log was gathered during the course, and (3) post test after the course measured how students' expectations faced the reality.

Pre Test

Motivational profiling in this study is based on the Motivated Strategies for Learning questionnaire (MSLQ), which is developed on the basis of motivational expectancy model (Garcia and Pintrich 1994). MSLQ measures both motivational factors and learning strategies and has been adapted to the research field of Finnish vocational and higher education (Ruohotie 2000). The motivation section (A) of the questionnaire consists of 17 items that were used to assess students' value for a course, their beliefs about their skill to succeed in the course, and their anxiety about tests in the course. The learning strategy section (B) includes 13 items regarding student's use of different cognitive, metacognitive and resource management strategies. A 5-point Likert type scale ranging from 1 ("Not at all true of me") to 5 ("Very true of me") was used for all items. Students were divided into three groups based on their motivational level scores from "A" section of the questionnaire: Group 1 (blue, N=10) characteristics: Extrinsic goal orientation, test anxiety and meaningfulness of studies, Group 2 (green, N=8) characteristics: Efficiency beliefs, intrinsic goal orientation and meaningfulness of studies, Group 3 (red, N=6) characteristics: Control beliefs and intrinsic goal orientation.

Data Collection During the Course

User log from EDUCO (time stamp, user id, action) was recorded during the course from September 24 to November 20, 2001. (Figure 1).
Figure 1: A sample of EDUCO log file.

Post Test

An email survey consisting of 15 open propositions (10 responses out of 24) was conducted two weeks after the course in December 2001. Propositions measured users experiences and expectations towards computer supported education together with EDUCO-related attributes (usability issues, user interface, features etc.).

EDUCO Architecture

From a technological point of view, EDUCO consists of a server, a Java applet for every user and several cgi-scripts. The server tracks the state of the distributed system and informs the clients as changes occur. Examples of possible changes in the environment are users moving to another page and initiating a chat. The implementation of this kind of a scheme in real time requires the clients to maintain an open connection to the server throughout the session.

To avoid any copyright or other intellectual property right issues we have taken the approach that the documents (i.e. HTML files) chosen to be part of a particular instance of EDUCO are not copied to our server. Instead, they can be located anywhere on the Web. This being the case, the server needs to know which page each user is viewing. We have solved this problem by using our EDUCO-server as a kind of proxy, which means that the documents are routed through our server instead of being sent to the client directly from their actual location (Figure 2).

EDUCO User Interface

The EDUCO user interface consists of six elements of which only one is concurrently visible: (1) Map, (2) Chat, (3) Search, (4) Alarm, (5) Preferences and (6) Help. The EDUCO interface is small, only 200 x 300 pixels, and thus placed into the left-hand side of a www-browser frameset. The right-hand side of the browser frameset, usually more than 440 pixels, is reserved for the content (i.e. hyperdocuments) and the space below EDUFORM is reserved for the document specific comments. Commenting is based on ordinary html-forms. Each document has an associated comment file, which is opened to its designated frame and can be updated by the users. The server keeps track of modifications and the visits of individual users. This way the documents that have been commented after the last visit can be distinguished visually from those that contain only comments the user has already seen. (Figure 3.)

“Map” is a view to a visualization of the hyperdocument structure and the people present in the learning environment. The material is organized in clusters consisting of related hyperdocuments. People are shown as coloured dots. Colour indicates different group membership or types of user
profile, and the location of the dot depends on the document the person is currently viewing. When mouse is placed on top of the symbol of document or person, a tool tip appears showing the name of the person or the document. Clicking a symbol selects it for further use; double clicking a document opens it in the browser window. The documents change their colour on the map depending on how much they have been read relative to the others. The total time all users have spent reading each document is recorded by the server on an hourly basis. The change in the colour of an individual document is determined by the distance of its moving average for the last 24 hours from the same average for all documents. (Figure 4.)

Figure 3: EDUCO user interface with Map view active and open document with related comments.

“Chat” enables synchronous communication with other peers. EDUCO Chat sends messages only to those people sender has actively contacted by e.g. clicking dots on the Map. The number of participants in the discussion is unlimited, but one person may use only one chat channel simultaneously. (Figure 4.)

Figure 4: EDUCO Map (left) and Chat (right) views.

EDUCO “Search” is useful for finding people or documents. The search is targeted to the titles of documents and names (and nicknames) of users online. Search selection affects also to the other views (“Map”, “Chat” and “Alarm”). “Alarm” defines a condition to be monitored by the system. If a user wishes to seek for a work mate who is also interested in certain document (or topic), he can tell the system to send a notifying message to the title bar of EDUCO when predefined conditions are met, i.e. other person arrives to the document specifying the task. Alarm is helpful when user wishes to conduct a collaborative time-related assignment with a friend who has not yet logged into the system. See Figure 5 for screen dumps of Search and Alarm views.
Results

The main focus of this study is on the design and implementation of EDUCO software and thus profound analysis of the empirical results of all three forementioned stages is unbearable to carry out. Next we will present some preliminary results of the post test. Seventeen respondents (71%) out of 24 replied to the email survey. In this paper we analyse briefly following four propositions (Table 1):

Table 1: Selection of preliminary propositions of the post test.

<table>
<thead>
<tr>
<th>Proposition</th>
</tr>
</thead>
<tbody>
<tr>
<td>5. What is your opinion of the essential added value of EDUCO compared to traditional computer-based learning?</td>
</tr>
<tr>
<td>9. Give your comment on the Map view’s functionality considering it as a tool for a) navigating from one hyperdocument to another, b) commenting (annotation) hyperdocuments, and c) social navigation and interaction.</td>
</tr>
<tr>
<td>10. How relevant the Chat was to you?</td>
</tr>
<tr>
<td>11. What was the relevance of EDUCO’s profiling info to you when you were seeking for work mate(s) to carry out collaborative tasks?</td>
</tr>
</tbody>
</table>

Preliminary results of the post testing show that the EDUCO was found to be a useful tool in the matters like adaptation to respondents learning, cognitive and motivational strategies, and means to implement collaborative actions.

"It was very useful to see what documents other users were reading ... it gave me many hints and saved time."

"It was truly nice to be able to see what is the most interesting document at the moment and who is reading it."

"Actually, in several cases I wanted to start a chat conversation with someone reading same hyperdocument with me ...I guess this is social navigation?"
Presence of EDUCO increased task-related participation and was valued tool for those who had difficulties to participate in face-to-face meetings:

"Learning material was easy to access."
"EDUCO gives more flexibility to studying process."
"It was possible for me to participate to this course and carry out all those tasks regardless of my domicile."

Real time interaction of EDUCO also elicited negative comments:
"EDUCO hindered formation of REAL social contacts!"
"Chat never beats traditional face to face meetings."

EDUCO’s tools for seeking work mates (group membership, search function) were truly useful for most of the respondents:
"I was in a blue group, and when another blue was looking for a mate, I replied instantly. He had already chosen an article, I glanced at it and found that it was suitable for me too."
"I had a group proposal via email message. As my forthcoming work mate had the same colour than I did, it was easy to make the decision to start collaboration. Afterwards I thought that I agreed so quickly because of the same motivational group, normally it takes more consideration. But to be honest, the topic was the most important factor."

Conclusions

The paper has described the design and implementation of a real time on-line collaboration tool. EDUCO was build to seek solutions to some unsolved problems concerning real time collaboration between live users in both traditional and modern web-based education platforms. The main focus of the study was to demonstrate how EDUCO was applied to a real life on-line distance-education “Web-based learning” course. The preliminary research findings of small-scale qualitative empirical study indicated that some of the features used in this restricted evaluation task, namely “motivational group membership information”, “graphical view to the hyperdocument space”, “hyperdocuments that change their colour depending on the popularity”, can be directly applied to a wider context of modern computer-based learning environments (see e.g. Dillenbourg 1999).

A Study of Changes in Attitude Towards Science in a Technology Based K-8 Preservice Preparation Science Classroom
Rena Faye Norby, Assistant Professor, Black Hills State University

The purpose of this study was to identify and analyze changes in attitudes towards science in a technology based science content course for K-8 pre-service teachers. Given a science classroom where Internet research, hands-on science activities, cooperative group work and a constructivist learning environment is promoted, research can identify how students’ attitudes towards science change before and after taking a technology integrated class. Technology is required in standards based teaching, and the science teacher needs guidance in integrating technology into her teaching while continuing learning experiences that work in her classroom. A positive attitude towards different components of science in pre-service teachers can facilitate more effective learning in science in K-8 classes.

Attitudes associated with science appear to be affecting student participation in science as a subject (Koballa et. al., 1990) and impacting performance in science (IAEP, 1992). An international assessment of nine-and-thirteen-year-old students in twenty countries (IAEP, 1992) revealed that positive attitudes toward science were related to higher student performance.

Science teachers in grades K-12 have developed hands-on, experiential methods that have been effective without adding in the mix of technology. Teacher accreditation agencies are requiring technology literacy for teachers, but the connection to improving attitudes towards science, perception of the science teacher, and the value of science in society, had not yet to be analyzed. The hands-on science teacher has some real questions about the value of replacing class time spent in practicing the processes of science with computer and other technology based experiences.

For this study twenty-nine students in a one semester four hour class took the “Test Of Attitude Towards Science” on the first day of the Earth and Physical Science for K-8 Teachers at Black Hills State University. These students spent 4 hours per week for 15 weeks in a university computer lab that

---

provided Internet access, and use of standards software packages. Students studied a science textbook outside of class, and completed project based activities in earth and physical sciences during class. They used the Internet to research science content, lesson plans for K-8 teachers, and to access state and national science standards, including STS standards. The students took the same survey as a post assessment in the last week of the class.

The pre and post responses were analyzed using nonparametric statistics. The perception of the science teacher was the variable that showed the smallest increase between pre and posttest. Other subscales on the instrument showed decrease in anxiety towards science, and increases in motivation and enjoyment of science. More than 80% of the students indicated that their overall attitude toward science had increased appreciably since the beginning of the course.

The students were pre-service teachers so it would be expected that they already had a fairly positive perception of science teachers. On a formative assessment that asked the students about their most positive experience in science learning, almost all of the individuals who responded to this question described hands-on activities and an enthusiastic science teacher. Adding in the use of technology in this class appears to have been the cause of a significant increase in feelings of motivation and enthusiasm about science, since so many pre-service teachers are uncomfortable with the requirement that they teach science after obtaining employment. Further research with similar classrooms that are taught without the presence of extensive access to technology could make an even stronger case for integration of technology into science teaching.

In this study, hands-on, learner-centered classroom activities as well as the use of technology, provided interesting and motivating experiences for the students at the same time that their attitudes towards science improved. Results of this research can be generalized and validated for larger populations and can encourage science teachers to use technology and Internet access in their classrooms for other purposes than record keeping and word processing.

---

A Framework for Online Professional Development

Online professional development serves the needs of individuals as well as organizations. Professional development can be viewed from these two perspectives: the individual who plans to participate in additional education and training opportunities and a system that provides those opportunities to its workforce (Bellanca, 1995). Adding an online perspective to professional development activities provides an individual with the chance to participate in education and training opportunities at times and places that are convenient. Systems benefit from online professional development by reducing travel and absent employees (McCampbell, 2000). This proposal explores a framework of designing, developing, maintaining, and implementing an online professional development program for educators who are challenged by national and state reform and accountability initiatives. The example OPD workshops described in this paper have been developed and implemented. As part of the framework for OPD, issues related to Accountability and Reform Initiatives are addressed. In addition, a set of guiding questions that focus on High Quality Course Design, Course Management, and Learner Support/Course Facilitation are used to design, develop and implement the OPD. Before these questions are addressed, however, let us begin by defining OPD.

The Challenge of School Reform and Accountability

During the past decade, many states across the country have engaged in rigorous school reform and accountability efforts, most in direct response to the national Goals 2000 initiative. In some states, high-stakes testing accompany rigorous standards, all with the hope of transforming education and improving student performance.

Ultimately, the improvement of performance comes down to how well teachers understand the reform efforts, the standards, and the content for which they are being held accountable (Sparks & Hirsch, 1997). Teachers must have the tools, support, and training to radically change teaching and to infuse change at the school level (Darling-Hammond & McLaughlin, 1995; Sparks & Hirsch, 2000). Schools trying to improve must consider professional development as a cornerstone to success (Fullan, 1999) with strong linkages between professional development and the reform agenda (Darling-Hammond & McLaughlin, 1995). In the past, fragmented approaches to professional development have yielded minimal progression toward a clear, compelling vision for the future (Fullan, 1991). This vision, apparent in most school reform agendas, should be considered when linking professional development with reform. By linking professional development with participants' ongoing professional practice, the effects may begin to visibly move the reform agenda in a positive direction, thus promoting change within the educational system as a whole (Sparks & Hirsch, 1997).

Lieberman (1995) suggests that a radical re-thinking of professional development must occur. Given that learning
occurs through active engagement, it is time to consider alternatives to more traditional direct-instruction approaches. With a national average of only 1% of the budget slated for staff development, with less than 50% of teachers receiving release time for professional development, and with nearly 25% of teachers given no time, credit or support (NCES, July 98), rethinking the practice of professional development, as well as the mechanism for delivery, is critical. It is no surprise that teachers report increased use of strategies and change in their teaching practice with increased professional development (NCES, July 98). Thus, support for professional development is a most important variable in school reform.

**Defining Online Professional Development**

Online Professional Development (OPD) is the delivery of professional development where participants and instructors are separated by time and usually by distance, using the World Wide Web as the tool for instruction, communication, and collaboration. As with all forms of distributed learning, there are a variety of learning goals and approaches used within various OPD settings. Based on the learning goals, the available technologies, and the level of interaction that is deemed necessary, an appropriate model or combination of models may be selected. With interaction being a significant contributor to the success of online learning, it is important to consider the levels of interaction being used. Both social and instructional interactions contribute to the success of online learning. Social interaction promotes communications and collaboration, while instructional interaction promotes interaction with the content. Three levels of instructional interaction are commonly discussed for distributed learning, to include: (1) interaction with the content, (2) interaction with the instructor, and (3) interaction with peers (Moore, 1989; Northrup, 2001; Rasmussen & Northrup, 2000). Models of Online Professional Development will vary in their type and amount of social and instructional interaction. Models for OPD that encourage various levels of interaction include: (1) Self-Paced, Individual Study, (2) Lecture-Discussion, and (3) Learning Community.

**Self-Paced, Individual Study**

This model of OPD has low levels of interaction and closely resembles a correspondence course. Interaction would most likely occur between the student and instructor and between the student and the course materials. This self-paced model may be "open-entry, open-exit" where participants log on and complete their course using their own time table rather than a specific beginning and ending date for the course. For participants who are very motivated and self-directed, this model may yield successful results. For most, this is a difficult approach. In addition to being difficult for students, instructors/facilitators have no boundaries and find it hard to communicate, assess assignments or to establish a relationship with students.

**Lecture-Discussion Model**

Typical lecture-discussion models provide online lectures via PowerPoint, streamed video, or even through videotapes delivered via surface mail. This approach, if deemed appropriate, may provide the typical lecture discussion approach where students are encouraged to read materials, view lectures, and respond accordingly through listservs, chat rooms, or via threaded discussions. The levels of interaction in this model would include instructor-to-student interaction, student-to-materials, and student-to-student interactions most closely aligned to discussion of given content. Less social interaction would occur in this model.

**Learning Community Model**

This model places its emphasis on interactions among participants, instructors, and facilitators. Many learning community models rely on activities to spark ideas and generate collaboration and sharing. This many-to-many model makes use of listservs, threaded discussion, and chats, with a focus on collaboration and communications. Success with this approach requires embedded scaffolding of expectations, guidelines for setting up teams, and some general rules of dialog. Interaction in this model heavily emphasizes social interaction as well as student-to-student and student-to-instructor instructional interactions. What's missing in this approach is the tutorial-focused instructional component of instruction, as most assignments are centered around activities. Depending on the instructional content, this may or may not suffice as the sole vehicle for instructional delivery.

**Guiding Questions for Online Professional Development**

As a result of the need for radical rethinking of professional development, this paper documents how Online
Professional Development (OPD) can be used as one of many professional development strategies within a school district. This paper advocates OPD as one solution; however, there are several other learner-centered approaches that should be considered when developing a school or district-wide professional development plan. The guiding questions addressed in this paper center around the elements of professional development, whatever the medium (EDC Center for Online Professional Development, 2000). The following guiding questions form the basis for High Quality Design, Course Management, and Learner Support/Course Facilitation of OPD:

- How do we provide equal professional development opportunities for all teachers at a time and place convenient for them?
- How do we provide opportunities for collaboration and sharing among faculty?
- How can we provide a forum for inquiry, reflection, and mentoring?
- How do we model successful practice?
- How can professional development translate into professional practice?
- How can we promote ongoing communication and conversation among educators?
- How can we foster “deep” understanding of the subject matter and its relation to the school reform and accountability agenda?
- How can we instill confidence in participants who are not familiar with online learning?
- How can we scaffold strategies for time management and for embedded support throughout the professional development experience?

Using the Framework for OPD Development

*Information Engagement: Reading in the Content Area* and *The Making of a Technology-Rich Classroom* are two Online Professional Development (OPD) workshops designed and field tested through grants in collaboration with The University of West Florida's Division of Technology, Research and Development and partnering Florida school districts. In response to standards-driven reform, these OPDs provide opportunities in continuous improvement of professional skills as teachers participate in an active, engaging learning community. The OPDs are highly interactive, activity-focused, and rich in collaboration and discussion among participants, instructors, and facilitators.

Each of these OPDs are four-week, 10-hour workshops (approximately 2.5 hours per week) designed to guide teachers through related processes and content. In the *Making of a Technology-Rich Classroom* (http://mentor.coe.uwf.edu/onlinepd/) the goal of the workshop is to provide teachers with knowledge, skills, and abilities that are needed to successfully integrate technology into the teaching and learning environment which, in turn, will enhance the overall learning environment and, ultimately, increase student performance. Similarly, *Information Engagement: Reading in the Content Area* (http://dev.ibinder.uwf.edu/cybersphere/profdev/onlineindex.cfm) is designed to provide middle and high school teachers with the skills they need to effectively integrate reading techniques and strategies into content area classes with the objective of increasing reading scores.

The OPDs combine elements of the lecture-discussion model (i.e., information acquisition) and the learning community model (i.e., discussion-based, sharing of experiences, both prior and current). The OPDs were systematically designed to promote exploration and discovery, encourage experimentation, and to provide rich examples and opportunities for practice. In addition, the OPDs are designed to be highly interactive and visually rich, taking teachers into others' classrooms via online video examples.

Information is presented over the four-week period (see Figure 1 for the main site of *The Making of a Technology-Rich Classroom*) to the teachers in manageable, small chunks that focus on specific objectives through several delivery methods: text, graphics, and video. Teachers are guided through the workshop by a facilitator. The facilitator promotes interaction in threaded discussions and through the listserv, and serves as an expert for individual questions, offering advice and best practices.
Research on traditional teacher staff development suggests that typical in-service activities for teachers is faulty – teachers spend isolated time, away from their classroom, learning the topic and never fully implement, either by choice or by situation, the changes into their classroom. These examples of OPD combat these issues by enabling teachers to participate in the workshop at times that are convenient for them and by, more importantly, guiding the teachers in a step-by-step processes that are immediately implemented. In other words, teachers field test techniques and strategies suggested by the OPD and other teachers in their own classroom laboratory. This integration of implementation into the workshop environment provides teachers with the motivation to start to implement and then, hopefully, to provide them with enough support so that they may continue the implementation after the workshop is completed. Teachers then reflect with other learners and facilitators as to what worked through communication activities (chats, listserves, and threaded discussions [see Figure 2]) which also permits them to learn about challenges and successes experienced by their colleagues. The structure of the OPDs, over an extended period, require that sharing and reflection take place – giving teachers the time that they need to actually try out innovations in their classrooms and evaluate the success of that innovation.

Field Testing the OPDs

Information Engagement: Reading in the Content Area and The Making of a Technology-Rich Classroom have been developed and implemented with teachers. An evaluation was conducted after each field test. Both evaluations yielded
positive results, with teachers focusing on the convenience of the OPD and applicability of the strategies to the classroom. Teachers were able to integrate innovative strategies into their classrooms with little disruption or interference in the day-to-day operation of the class. Using anecdotal data from the four-week period, teachers believed that student performance would be improved with continued use of the new strategies.

Addressing the Guiding Framework Questions

The questions outlined earlier relating to High Quality Course Design, Course Management, and Learner Support/Course Facilitation are extremely important in the ultimate success of the OPD participant. The first area of concern that needs to be evaluated is the course quality. Without a strong foundation of quality, the professional development will not meet the needs of the participants. Learning outcomes are aligned to relevant standards (e.g., NETS, NCTE/IRA). In addition, throughout the OPDs, teachers align their own revised curriculum, using suggested strategies that focus on improving student performance. Materials, including web pages, activities, supporting resources, have been created by professional instructional designers in consultation with subject matter experts who are experts in their fields. The instructional materials contain web links, readings, and assignments that are aligned to standards and workshop goals and objectives. Information is presented and activities are incorporated in a variety of fashions to meet a variety of learning styles. All activities are designed to be able to be immediately used in the classroom with a minimum of disruption. The weekly activities are designed to take no more than the allocated time of 2.5 hours, which includes the time set aside for chat sessions, threaded discussion responses, and listserve communication. All elements of the OPD are designed to promote effective and efficient learning that meets the needs of the teachers and the goals of the workshop.

Expectations for teacher performance are clearly outlined in the first week—the final outcomes are outlined and teachers immediately begin to work on their final projects, which are based upon implementing topic strategies by the end of the OPD. Facilitators communicate with teachers at least twice a week to make sure that they remain motivated and on track.

Course management issues revolve around two major categories: Administrative (for the providers of the OPD as well as for those who supervise professional development activities at the district- and school-level) and the Participant. Concerns of registration, recognition and notification, cost, and alignment of the OPD to the district schools' accountability and improvement initiatives must be addressed. Districts handle these issues differently. In some cases, teachers register through their home districts. At other times, participants will register through the OPD web site. At the completion of the workshop, teachers are provided with a certificate and the district staff development office is notified via e-mail that the teacher has successfully completed the OPD. Costs are negotiated with the district for district-sponsored workshops. Some districts may choose to negotiate to implement the OPD and assume the responsibilities for access and facilitation.

OPD can, in many cases, be overwhelming to participant on several levels. Even expert technology users must become comfortable with the delivery system and the demands of learning at a distance. Novice users face the challenges of learning both to learn at a distance as well as being able to efficiently and effectively use new technologies. Teachers should have a basic level of technology literacy, including the ability to use the Internet, email, and use basic application software. An online orientation assists teachers in developing the skills they need to be distance learners. In addition, the first week serves as an orientation to the content of the OPD. When districts participate in the OPD, face-to-face orientation meetings can be held. For teachers who may not possess all of the technology skills, tutorials are available to provide them with additional support (which may require additional time on the teacher's part).

Before a teacher participates in OPD, they must commit to the time required for the workshop and have access to the minimum technology resources needed. They should also accept the philosophy of the OPD in terms of interaction and relationship development. In the example OPDs, teachers commit to accessing the site at least two to three times a week as they actively share their experiences and implement technology-rich activities in their own classrooms. Teachers work in groups and must be able and willing to participate in group activities. The final area of concern when considering OPD involves learner support and course facilitation. First, teachers should evaluate the level and amount of support and determine whether it fits their style and needs. The accessibility of the facilitator and experts should be evident—both facilitators and experts should be available at various times throughout the OPD to offer support and guidance. Responses to questions should be returned to the teacher within 24 hours at most. Online support, such as tutorials, coaching, embedded assistance, and other resources, should be available to supplement needs of the distance learner. Student-to-student interaction should be encouraged to promote and develop an active learning community that
will continue beyond the OPD experience. The learning environment should be non-threatening and supportive to permit teachers to explore and discover strategies that are meaningful to their own instructional situation. Finally, the site, or resources from the site, should be available so that teachers can revisit resources as they follow-up and continue to implement strategies from the OPD.

Support and facilitation are of utmost importance. In the example OPDs, extensive web resources including tutorials, web resources, activity databases, standards, and previous teacher ideas are available whenever the teacher needs additional information. Teachers are encouraged to share via the listserve new sites that might also interest their peers. These new resources are captured by the facilitator who then improves the web resources by new relevant sites. Facilitators are themselves expert teacher who successfully integrate technology in their own classrooms and serve as active participants, sharing their own experiences, as they encourage and motivate the teachers. After the OPD concludes, the facilitator maintains contact with the teacher participants for a period of two months, providing follow-up information and encouraging the teacher to continue to integrate technology into his or her classroom. In addition, teachers are encouraged to keep in contact with their new peers to develop their own learning community that promotes technology integration.

Conclusion

Online Professional Development is an effective way to provide teachers with the new skills that they need to meet the challenges of state and national accountability and reform initiatives. Available at their convenience, teachers can take advantage of OPD workshops that meet their needs. The appropriate design and development of a workshop, in conjunction with learner support of the OPD, facilitates participant success. Following the framework for online professional development ensures a successful OPD experience.

Learner Perceptions of Online Interaction

Dr. Pam Northrup  Mr. Russell Lee  Mr. Vance Burgess
University of West Florida

Interaction has been defined from many perspectives. Most simply stated, interaction is engagement in learning (Hillman, Willis & Gunawardena, 1994). It is agreed that interaction must be designed into an instructional program and that it is an important variable for online learning. Berge (1999) suggests that interaction is important to learner satisfaction and that it assists in maintaining student persistence in courses. With retention in online learning programs being as low as 50% in some cases and course completion rates in traditional courses at 10-20 percentage points higher than in online courses (Carr, 2000), learner satisfaction is a key variable. With interaction being a component of overall student satisfaction, interaction should be considered when trying to increase retention in online courses. However, from the online learners point of view, too much interaction may be perceived as busywork and lead to frustration, boredom, and overload (Berge, 1999); while too little interaction may result in student isolation. Both are considered frustrating and a balance has to be found.

Several interaction frameworks and taxonomies are available as guidelines for designing for online interaction. Moore (1989) identifies three types of interactions: (1) interaction with the content, (2) interaction with peers, and (3) interaction with the instructor. Gilbert and Moore (1998) view the process from a different perspective indicating that interactions encompass both instructional and social situations.

Sorting through interaction frameworks to determine the most appropriate interactions for given learning outcomes is difficult at best. Northrup (2001a) provides a set of interaction attributes that can be used to select strategies and tactics to facilitate online interaction. The attributes encompass levels of content interaction, types of dialog through communications and collaboration, levels of student self-directedness, and types of support for the learner anytime, anyplace.

With most research on interaction focused on classifying the types of interactions or building frameworks from which designers would select appropriate interactions for given learning outcomes, it seemed apparent that there should be an upper and lower limit to the types of interactions used for a given set of instruction. Additionally, with student perception of interaction being complete as such an important variable for ongoing participation in the course (Zhang & Fulford, 1994), the relationships of student perception to the attributes of interaction should be considered.

Purpose of the Study

The purpose of this study was to investigate the types of interactions that students perceived to be important for online learning. The interaction attributes investigated included content interaction, conversation and collaboration, intrapersonal/metacognitive skills, and need for support. Also investigated were reasons why learners were taking online courses. It was presumed that students taking courses for convenience, flexibility, or preference would likely be more pleased with interaction in online course than those required to take an online course because it wasn’t offered on campus.
Method

Introduction

The purpose of this study was to investigate the types of interactions that students perceived to be important for online learning. Interaction attributes studied in this investigation included content interaction, conversation and collaboration, intrapersonal/metacognitive skills, and need for support. This study was an initial investigation of learner perceptions of online interaction. Data were collected through the administration of the Online Learning Interaction Inventory (OLLI) (Northrup, 2001b).

Participants

This study consisted of 52 graduate students in an online masters program in instructional technology. Thirty-four of the students were female and 18 were male. Students were selected to participate in this study based on where they were in the program of study. Intact classes of students were selected from two courses at the beginning of their online learning sequence and two courses at the end of their online learning sequence.

Instrumentation

The instrument used for this study was the Online Learning Interaction Inventory (OLLI), with a reliability coefficient of .95. The OLLI focused on the four interaction attributes of content interaction, conversation and collaboration, intrapersonal/metacognitive skills, and need for support.

The OLLI was divided into six sections with a total of 50 items. Section 1 dealt with demographic information. Section 2 included five questions on reasons why students selected to take an online course. Section 3-6 addressed each of the interaction attributes and were rated on a five point Likert scale with 1 representing strongly disagree to 5 representing strongly agree. Section 3 dealt with Content Interaction. There were 13 items relating to the indicators of content interaction. Section 4 addressed Conversation and Collaboration with 14 items relating to the indicators of interaction. Section 5 addressed Intrapersonal/Metacognitive Skills with 7 items relating to the indicators of interaction. Section 6 addressed Support with 7 items relating to the indicators of interaction.

Procedure

In the current study, students from four online classes were sent a detailed email stating that the purpose of the Online Learning Interaction Inventory (OLLI) was to gather information to continue to make the online courses and the program more appropriately interactive. The email indicated that data would be reported and used as research as well as be used for formative evaluation purposes. Students were provided with the url to take the OLLI online. In two of the four courses, the OLLI was posted as a weekly assignment. In the other two courses taking the OLLI was optional. Students were provided with one week to complete the 50-item instrument.

Data Analysis

Data were analyzed by item using frequency, means, and standard deviations to report areas of interaction that are perceived to be valuable or a hindrance to success for online learning. Research questions for the study are as follows:

Question 1: Why do students learn online? Question 2: What interaction attributes do students perceive as important for online learning?
Results and Discussion

Data collected from the OLLI were analyzed by attribute, with frequency, means and standard deviations reported. Reported first will be responses from the first research question related to students learning online. The second research question related to the interaction attributes will be reported by each of the four interaction attributes.

Learning Online

Learning online is related to the first research question, *Why do students learn online?* The majority of students selected to take online courses for convenience ($M=4.13$, $SD=1.14$) and flexibility ($M=4.65$, $SD=1.33$). Most of the students reported that they could attend school even if the course was campus-based ($M=3.58$, $SD=1.58$), indicating that many of the students lived close enough to the campus to take campus-based courses. Only 12 students (23%) reported that it would be impossible to take the course if it were not offered online.

Interaction Attributes

There are four interaction attributes related to the second research question. Attributes included: (1) content interaction, (2) collaboration and conversation, (3) intrapersonal/metacognitive strategies, and (4) support. Responses are included by attribute for the following research question: *What interaction attributes do students perceive as important for online learning?*

Content Interaction. In general, it appears that students agree that interacting with the content is important to their online learning experiences. Overall, they report that they like partially individualized courses with some instructor direction ($M=3.77$, $SD=.85$). Participants also reported a desire to interact with content delivered via audio-narrated online presentations ($M=3.65$, $SD=1.22$). Interacting with innovative instructional strategies also was reported to be important to their online experience. Strategies such as case studies ($M=2.83$, $SD=.92$); structured games ($M=3.10$, $SD=1.11$); and readings followed by online discussion ($M=4.56$, $SD=1.09$) were all rated popular with participants. Interestingly, participants expressed strong frustrations about being required to participate in too many interactive assignments in a weekly segment of the course ($M=4.08$, $SD=1.06$).

Interacting with the content is a major component of an online course and the primary location where new knowledge, skills, and abilities are presented. Typically instruction online is presented as instructor-centered or student-centered. Both are appropriate given the learning outcome and topics of the course content. Students in this study seem to prefer a variety of techniques, yet seem to feel most comfortable with the “feeling” of a traditional class. With the highest reported perceptions of positive interaction in the areas of audio-narrated presentations and readings text followed by discussion. The lecture itself (the audio-narrated presentations) can provide a foundation for other attributes of interaction including conversation, collaboration and informal discussion.

Conversation and Collaboration. Results of the interaction attribute of conversation and collaboration indicated that participants rely on their peers and their instructor in forming and maintaining the online learning community. The majority of participants ($M=4.94$, $SD=1.06$) reported that it is essential to build a community of learners in the online environment. Participants reported liking to discuss ideas and concepts with peers ($M=4.00$, $SD=.71$) and also perceive that sharing information with
peers is important (M=3.83, SD=.71). In relationship to teaming, participants reported that working in teams was difficult for them (M=3.08, SD=1.19) and that once a team is formed; they prefer to maintain the same team for the entire semester (M=3.62, SD=1.05). In terms of innovative instructional strategies for interacting online, participants reported liking online debates (M=3.04, SD=1.12) and posing questions to experts (M=4.02, SD=1.02). Students weren’t as receptive to the idea of posing as the guest presenter in class (M=2.71, SD=1.18). Finally, in terms of feedback from the instructor, participants reported that it is important to them (M=4.35, SD=76) and that the instructor should make every attempt to provide some kind of feedback to them at least two times per week (M=3.77, SD=.85). Interestingly, participants reported that it was unnecessary for instructors to provide feedback on a daily basis (M=4.25, SD=.84).

Promoting collaboration and conversation online is an attribute of online learning that participants considered important. Overall, forming the community of learners, collaborating with peers, and getting feedback from the instructor were the most highly rated indicators of this attribute. Given that groups of students do not just become collaborative because they are assigned together (Johnson & Johnson, 1994) means that designers and instructors should provide clear expectations for collaboration online.

Interestingly, note the positive responses on innovative instructional strategies. The variety of strategies presented within the confines of a course appears to yield positive perceptions among students. Providing both synchronous and asynchronous conversation and communication online can extend learning and at the same time motivate the learner (Sherry, 2000).

Intrapersonal/Metacognitive Skills. Analysis of items related to intrapersonal/metacognitive skills suggest that self-directedness and embedded cognitive strategies designed into the online learning environment are perceived to be important to participants. Participants reported that it is important to monitor their own progress each week (M=4.58, SD=.72). With regard to embedded cognitive strategies, participants reported that it is important to have structured times that assignments are due (M=4.33, SD=.83), to have an advance organizer to assist them through the assignments each week (M=4.10, SD=1.00), to provide graphical representations of the steps that should be taken to complete assignments (M=3.96, SD=1.31), and to have notetaking guides to accompany audio-narrated presentations (M=4.04, SD=1.12).

Overall, self-regulating one’s own learning is an important aspect of online learning. Not only do students need to monitor their progress in an ongoing fashion and adjust their strategies for learning based on their progress, they also need to maintain a time management schedule in order to complete online learning activities in the allotted timeframes. To assist and guide learners through online learning, strategies like advance organizers and graphical representations are used to guide the learner through assignments, while notetaking guides and posted times for assignment due dates are also included.

Support. Results indicate that support is also a key attribute in the success of online learning. Designing online learning with a solid support system in place enables timely responses to questions, mentoring, tutorials, and tips from peers. This support system may very well provide a foundation for successful learning. Participants report that timeliness of response (M=4.48, SD=.64) is a major indicator of support. Most participants reported also that having a mentor in place to provide assistance is also
important ($M=3.52$, $SD=1.35$). Participants also reported that having tutorials available as needed ($M=3.12$, $SD=1.55$) will assist them in performing tasks such as being in a chat room, posting to a threaded discussion, etc. And no surprise, participants report that when the technology doesn’t perform as intended, they are extremely frustrated ($M=4.17$, $SD=1.15$).

**Overall Perceptions of Interaction**

Overall, participants provided the reasons why they chose to take courses online. They also rated items in each attribute of online interaction as important to their success as online learners. The top reason for taking a course online was the flexibility ($M=4.65$, $SD=.74$) followed closely by convenience ($M=4.13$, $SD=1.14$) With regard to the interaction attributes, Intrapersonal/Metacognitive had the most highly rated indicators with self-monitoring of individual progress ($M=4.58$, $SD=.72$) rated at the highest frequency. The support attribute also rated at the top with timely responses by the instructor ($M=4.48$, $SD=.64$) rated as the number two indicator of an interactive online course. Although indicators exist in each of the interaction areas, the idea of self-regulating learning and having timely feedback from the instructor was reported as most valued by participants.

**Conclusion**

In conclusion, it is agreed that interaction should be designed into online instruction. It is also agreed that interaction is an important variable for learning, primarily because it is important to learner satisfaction and motivation (Berge, 1999). In this study, online learners echo the importance of interaction by requesting interactive elements in their online experiences. Participants in this study are still most comfortable with the idea of simulating a campus-based class online, as reflected in their statements regarding the desire for instructors to use online audio-narrated lectures, provide notetaking guides, and discuss learned experiences in some type of online conversation. Although their comfort is with the “known” they still favorably rated using more innovative strategies in the online environment including case studies, debates, role-plays, and gaming. The foundation of the online learning environment however, included the notion of solid student support and self-directedness. Participants strongly stated that the need for timely responses from peers and from their instructor was of utmost importance. They also indicated that it was essential for students to self-monitor their progress for survival in the online course.

This study was an initial investigation into the perceptions of online learners’ interaction needs. Future studies should consider other variables that may affect the individual learner, the learning environment, and instructional strategies that may be most appropriate for specific learning outcomes.

Beyond Animation and Simulation: 
Teaching Mechanics with Explorations

Olaf Nowaczyk
Heinz Nixdorf Institute, University of Paderborn,
Computers and Society, Paderborn, Germany
nowaczyk@uni-paderborn.de

Abstract: The groundwork for interactive learning applications at the Laboratory for Technical Mechanics, begun ten years ago, has led to a new type of highly interactive application called an Exploration. Explorations combine aspects of construction, modeling, and simulation; they allow students to graphically create their own constructions, and supply the corresponding mathematical description. The program executes the necessary calculations and displays the results in graphs and as analytic equations. The idea behind Explorations was to support learning by constructions and immediate response by the system. In cooperation with the research group Computers and Society of the University of Paderborn, a number of Explorations were built for student use.

Introduction
The problem that arises in learning Technical Mechanics is finding the connection between mechanical structures and their complex mathematical and physical relations. The practice of teaching shows that especially for visual conceptualization, both of static and of dynamic mechanical processes, the use of animation and simulation programs can be a good extension to the classical method of presentation with chalk and blackboard. Even for mechanical problems covering static structures, an animation effectively shows how one can find a solution. The necessity for the visualisation of mechanical effects was the internal spark for developments of simulation programs at the Laboratory for Technical Mechanics of the University of Paderborn.

In the following paragraph is given a historical overview about our approach and our previous experience in the development of animations and simulations.

The second part of this paper will introduce a new kind of interactive learning application, the Exploration. These applications have capabilities that are in many ways more powerful than the capabilities of animations and simulations. They give students the ability to build constructions in a graphical way while construction, simulation, visualisation and analytic description of technical models are linking.

Previous works in the field of animations and simulations
In 1991, the Laboratory for Technical Mechanics procured its first PC systems, leading to the development of computer programs for instruction purposes. The first application (see Ferber et al., 1992) was a program for image processing, simulation and scientific visualisation. This program created simulations of experiments done by students in the laboratory section of a technical mechanics course. The shadow-optical images created by students during these courses are digitized and analyzed by image analysis algorithms¹, thereby allowing the unknown parameters of the experiment to be determined. With these parameters, based on the fundamental equations of optics, numeric simulations will be carried out. The pictures gained by visualization of the simulation results are compared with those pictures which are experimentally obtained, and students discuss the variations. Even the testing of parameter combinations before carrying out

¹ In this basic experiment, a specimen of a transparent composite material containing an existing crack is illuminated with light generated by a point light source. The stress intensification in the region surrounding the crack tip leads to a reduction of both the thickness of the specimen and the refractive index of the material. As a consequence, in the transmission case, the light passing through the specimen is deflected outwards, and a dark shadow spot is formed on an image plane behind the specimen. The spot is bounded by concentration of bright light, the caustic. This caustic contour determines the properties of the material.
time-consuming experiments is thus made simple. In hindsight, the longevity of this application is remarkable. Function libraries which were developed in the programming language FORTRAN can still be used by modern compilers to simulate complex mechanical processes. Between 1994 and 1998, several applications and non-related animations were created. The didactic goal was to offer a means beyond mere text and visuals by which students could prepare for this infrequently offered course.

**mechANIma**

With the mechANIma project (see mechANIma, 1998 and Keil-Slawik & Nowaczyk, 2000), which began as a co-operation between the chairs of Technical Mechanics and for Computers and Society, the efforts within the area of the new media which focus on new concepts of multimedia teaching were resumed and strengthened.

The acronym mechANIma establishes a connection between “mechanics” and “animation”. However, mechANIma is not only a computer program or a collection of different materials for a mechanics course, but rather a new method for teaching and understanding mechanics. Our biggest concern in the project was the inclusion of students in the production of materials. This goal led to the phrase, “Software created by students for students”, which remains an objective for us today. This phrase can be realized in auxiliary worker activities or as a part of seminary- and diploma theses. It was important to us that the chosen programming language was easy to learn and use, so even students without extensive programming knowledge could obtain a quick and easy introduction to programming. The programming language should not contain pitfalls which normally lead to errors, and should be capable of calculating complex simulations. Indispensable are extensive documentation and code samples which can be understood by the non-expert programmer. It should also contain programming examples for typical problems which arise in the development processes. Therefore, the suitability of a number of popular programming languages and environments has been evaluated and tested for our special purposes. Because of its popularity as a teaching language, it is assumed that future generations of students will use Java. Therefore, following the creation of independent modules in Visual Basic and Borland Delphi, Java was finally selected as the favoured programming language for this project. Because of the availability of different development environments without license fees, Java is also well suited for usage at universities. Its extensive standard class library allows Java to be used for developing user interfaces. Another advantage is the availability of Java for all four significant operating systems (Windows, Linux, MacOS and Solaris) used in university computer labs. The desire to more clearly elucidate complex mechanical processes by suitable visualization methods was the main motivation for the creation of animations and simulations for learning purposes. The most important aspect is that all our animation systems visualize the precise effects and parameters addressed in the lectures and tutorials. Hence, by modifying these parameters in animation systems, students get a much better idea of the underlying physical and mathematical effects.

In general, the interactive capabilities of simulation programs are limited. Only particular simulation parameters may be modified but the mathematical model of an experiment is fixed by the program and cannot be changed. Normally even small changes by the user are not possible.

With the intention of building a new kind of interactive digital media, we began the creation of mechADO (Hampel, 1999), a construction environment which covers the topic of static analysis of plane trusses. With mechADO, students are able to construct a truss and apply forces to it in an interactive way. The program then automatically calculates internal and external reactive forces of the construction. Even if mechADO lacks some important aspects of current Explorations, it was an important step towards the development of the Explorations-concept. This concept comprises the core of this paper, and is further described in the following paragraphs.

**The Exploration Concept**

Explorations are a new kind of highly interactive learning application which combine aspects of construction, modelling and simulation. They allow students the graphical creation of their own constructions whose mathematical description and calculation are executed by the program. The results are shown graphed and as analytic equations. The basic idea was to support learning by construction and immediate response from the system. Designed as modular units, a single Exploration always covers one well-defined topic. Those modules should be usable in different contexts: e.g. lectures, tutorials, individual self-instruction, or even in an internet-based cooperative learning environment.
A piece of software comparable to the Explorations in that it links construction and simulation is Interactive Physics 2000 (IP), a commercial application produced and sold by MSC Working Knowledge (see http://www.krev.com/products/ip.html). IP is suitable for simulating a wide range of physical topics such as kinematics, kinetics and rotation dynamics. Virtual experiments covering the elastic collision of masses are especially easy to simulate with IP. It was created as a monolithic application to cover all the above topics in one program. The disadvantage of this is that it may take the user longer to discover all the features of construction and parameter in- and output.

We tested IP as an authoring environment for building animations, but soon reached the limitations of the system. It was proven to be quite difficult to precisely reproduce the exercises which students had been solving for years with pencil and paper. However, the main reason for developing Explorations rather than using IP in the teaching of engineering was its approach to mechanics. In IP, a physicist’s point of view is taken, whereas the Explorations view mechanics from an engineering perspective.

However, the major difference between IP and Explorations is that IP has no means of describing the constructed experiment with an analytic equation.

The ambitious goals of the Explorations were fulfilled in a two-year project. Applications which are now in use have been developed for fundamental topics in mechanics, including statics, dynamics and failure theories. It was not our aim to create an entire multimedia script, but rather a few modules which cover significant topics and are usable in a highly interactive way. That is why the Explorations are not bound to a specific learning medium, but can be used in many different environments. In an internet-based usage, such as in our prototypical environment, the Explorations can be started using Java Web Start in the browser. On a CD-ROM, the Explorations can be started immediately without any further software. Two out of eight constructed modules are presented in detail below.

**Example of an Exploration: one-dimensional spring-absorber-mass system**

A fundamental topic in the study of engineering are vibratory systems. In electrical engineering, they can be implemented using a combination of inductive and capacitive components, and in mechanics they can be implemented with masses and springs. For this part of a mechanics course, the Exploration Swingx should enable free construction of a vibratory mechanic system with various components.

![Exploration Swingx](image)

**Figure 1: Exploration Swingx (one-dimensional spring-absorber-mass system)**

With this Exploration, it is possible to demonstrate the element which mainly describes such a system; that is, the connection between drawing, equation of motion and the motion itself. The picture above shows one
Multi-level representation in learning modules

Technical systems can be described not only with drawings, but also through mathematical notation (e.g. an equation). Because the mathematical notation can automatically be deduced from some kind of construction, it is possible to transfer this work to a computer program. Thus, the most important feature of an Exploration beside the visualisation of the numeric solution (i.e. in a graph or animation of the drawing) is the ability to depict the analytical solution. These two ways of representing a mechanical system can be viewed simultaneously in order to help the student comprehend the complex structures.

The multi-level representation and the ability of the student to change the construction with its components and connections demonstrate the correlations that describe the system. Thus, different points of view can be developed for a single task and set in correlation to one other. This will help the student to gain a deeper understanding of the topic.

In a nutshell, the main task of an Exploration is to simulate and animate systems constructed by students and to ensure consistency between the different ways of describing this mechanic system.

Example of an Exploration: Calculation of internal forces for straight beams

A comprehensive topic in technical mechanics is the static analysis of plane trusses. An introduction to this topic generally uses the example of straight beams. Therefore the Exploration Beamex is a learning tool in which students design the load and bearing of beams. Afterwards the resulting internal forces are visualised.

Figure 2: Exploration Beamex (internal forces in a beam) with an example construction

A selection of bearings is given, and the correct combination placed under the beam allow the calculation of the internal forces. Such an example is shown in the picture above. Distributed forces can be combined and superposed in various ways on the beam, leading to different internal forces. In a frame beneath the designed structure it is possible to visualise different internal force diagrams. Particular to the Exploration
is not only the depiction of reactive forces in the schematic as force vectors, but also a corresponding calculation formula. It is possible to change the construction even after the calculation. As a result, the student can continuously vary the loads and simultaneously observe the new diagram. To summarize, Explorations have capabilities which surpass those of previous tools in several ways. They allow students to design on their own, with error-checking by the system to prevent impossible constructions. They enable the student to observe and link both the visual and mathematical descriptions of mechanical systems. Furthermore, they can be integrated into different learning environments.

Conclusion
With the Explorations, a new kind of highly interactive learning application was developed for engineering science which allows the construction and simulation of virtual experiments by the students themselves. What is more, the Explorations represent a new quality of learning program; they combine the graphical representation of technical systems with their corresponding mathematical equations and numerical simulations.

Future Work
The discoveries made during this two-year project are entering a new stage of development, forming the basis for cooperative Explorations. After implementing a communication interface, these Explorations will become a part of the cooperative learning environment sTeam (see Open sTeam 2001 and Hampel & Keil-Slawik 2001). Explorations which implement the so called sTeam module framework could use components for synchronous and asynchronous communication as well as awareness components directly from the sTeam environment.

With cooperative Explorations, distributed teams of engineering students can be formed, allowing them to receive feedback from each other, as well as from the simulation system.

Collaborative Learning with Dynamic Business Game Simulation –
Innovative Learning Environment for Business Education

Abstract: Business organizations and their employees face ever-increasing complexity and accelerating changes in their everyday work. This brings along the need for training models able to facilitate the development of knowledge and skills needed in this kind of environment. This paper introduces a certain computer-based, continuously processed business simulation. The purpose of the described learning environment, created with the use of highly interactive simulation, is to represent a realistic view of business processes to the students and enhance students' perception of business processes as a whole. We introduce some pedagogical and theoretical guidelines for designing of this business game, and describe also an example of a learning environment based on the use of this game. Some preliminary results from the research based on an example course are also presented.

Introduction

Modern, so-called knowledge society induces many new challenges to human competence and skills required for learning and working. As a result, the ways of working, studying, and collaborating are changing dramatically. Work is increasingly becoming organized in teams and groups, and often supported by technology. Other main characters of the modern work are the distribution of expertise and working in networks, both of which require social and collaborative skills to share and construct together knowledge, ideas, symbolic artifacts etc. (Lehtinen, 2000). From the pedagogical perspective, students need to learn to learn, develop metacognitive capabilities and construct meaningful knowledge in interaction with others and with tools afforded by activity environments. This is true especially in the fields of science, but also in business world.

Our rationale for using a dynamic simulation in teaching within the domain of business comes from the alarming findings from previous studies. Namely, the biggest challenges and obstacles in business education as well as in other subject domains are difficulties in applying theoretical subject knowledge in real life settings, inability to handle complex and ill-defined problems, and lack of consistent and holistic conception of business processes. All of these problems are more or less connected to the question of contextualizing the content being learned. It’s been found that graduate students of business management are not well prepared for the complex problems and situations they will face in real-life working contexts. That’s partly due to the traditional teaching methods, which don’t help students to face the complexity and cope with ambiguity and uncertainty of real business world they will inevitably face when taking positions in working organizations (Aram & Noble, 1999). These traditional forms of instruction (e.g. lectures) are often found to produce inert knowledge, which cannot be applied in complex situations (Bransford et al., 1991), and even intermediate experts of economics may have enormous difficulties in applying their knowledge and skills in realistic problem-solving situations (Mandl et al., 1994). One of the main reasons for the inability of traditional teaching methods to facilitate the development of flexible and useful knowledge and skills is the lack of contextualizing or anchoring the content being learned. If content is separated from its authentic context where knowledge and skills are used in real life, it will produce inert or impoverished knowledge. In such impoverished environments, learning becomes the memorization of seemingly abstract, self-contained entities, not useful tools for understanding and interacting with the world (Barab et al., 2000). Furthermore, there exists a lack of integration between different functional areas of business studies (e.g. accounting, marketing, management), which makes it very difficult for students to
develop coherent mental models about the business world and strategies in whole (Selen, 2001). This is a clear example of stripping content out of context and conditions in which it is used; separating different domain areas from each others and from their realistic intertwined existence. Walter and Black (2000) have recognized similar problem: what is needed in business education is a process approach. They state that the flexible and organizational understanding of the business world can only be accomplished by presenting the study of business as a series of integrated activities (c.f. connecting the areas together in realistic way). However, all of this embedding of learning experiences in practical situations or contexts must not neglect the learning of formal knowledge and construction of abstract ideas (Lehtinen, 2002). On the basis of the issues discussed above changes are definitely needed in the teaching methods in the domain of business studies, and one possible answer for these problems might be the use of a dynamic computer simulation. The main reason for this simulation use is to create an authentic and collaborative learning environment, where computer simulation is used as a tool for situating the business content being learned in its authentic contexts in challenging way.

The Case of Dynamic Business Game

We assume that the potential of simulations and games in business education is not fully exploited. One of the reasons for this is that present, traditional batch-processed business games neither realistically represent the actual processes occurring inside and outside organizations, nor correspond to the real-world decision-making situations. However, there are no technical obstacles for constructing continuously processed business simulations that differ from the main stream of business games by how the participants experience the subject matter of the learning session. So far the computer based business games have worked in batch-process mode. Whicker and Sigelman (1991) describe how ‘business strategy games’ are processed: “Typically, the player feeds information into a computer program and receives back a series of optional or additional data that are conditional upon the player's initial choices. The game proceeds through several series of these interactive, iterative steps.” The problem with the batch-processing method is that world very rarely works in such a pure sequential order. There are hardly any business areas where the decision makers first enter all their decisions for the next budgeting term, then rest during all the actual term, and enter again the business in the end of the term to analyze the term results executed and to prepare the next budget.

The simulation, Dynamic Business Game (DBG), we are introducing in this paper is in several ways a typical business game, and the aim of the new construction is the same as with the conventional business games: to increase business perception of the participants. However, as the new construction is operated in a different way compared to conventional games, it brings along some advantages not met in conventional games. What is suggested here is a real-time processed business simulation. Decision-making and having results from the decisions made should be in interactive real-time mode as they are in the real-world environment. Interactive mode means that decisions are made continuously when in the game model and game market situations occur which need to be reacting to by the participants. In the interactive model decisions are made as soon as they are needed or at least as soon as the decision-maker notices that the market situation needs actions from him.

DBG is a computer-based simulation, which creates a complex and authentic-like environment for learning of business studies. It’s developed by one of the authors of this paper. DBG models the managing of a manufacturing company with main decision-making functions, and a market engine creating demand and supply. This is done by a computer model representing realistic contexts, in which students are required to perform complex problem solving and discover functional market strategies when running their virtual company. Therefore DBG can be defined as certain kind of a hybrid form of simulation between typical types of conceptual model and operational model simulation as classified by de Jong and van Joolingen (1998). On one hand DBG requires discovery inferring the simulation model as a way to achieve functional business strategy (conceptual model), and on the other hand it urges an active functioning and responding to that model (operational model). DBG can also be seen as a combination of educational games, experiential and conceptual simulations as divided by Gredler (1996), because DBG environment contains competition between participants, it places students into responsible roles in complex situation, and requires discovering, predicting and developing of mental models about business functions. What makes DBG very special is the changing nature of its business model as a result of all participating companies' actions. That's why this game is called as dynamic.
Theoretical Principles of Dynamic Business Game Simulation

The most important theoretical principles that have guided our efforts to design DBG can be described as follows:

- **PROVIDE REALISTIC AND COMPLEX MODEL OF BUSINESS FUNCTIONS.** DBG provides dynamically changing, rich information about the current situation of companies and market trends in whole as a reaction to the students' actions and decisions made in the managing of their firms in an interaction with other companies' inputs. The main idea is to embed learning in realistic and relevant contexts.

- **USE AUTHENTIC TOOLS AND MULTIPLE REPRESENTATIONS.** There are realistic tools to examine this rich information provided by the simulation (e.g., different market and cash flow reports), which might support the understanding of the business functions more deeply and facilitate interaction between students (DBG is functioning as a shared frame of reference).

- **FACILITATE CONTINUOUS PROBLEM SOLVING.** DBG is functioning in real-time - based virtual market in LAN network. Therefore the time to react and make decisions is an essential element of successful business functioning, and the students need to continuously watch the market, interpret available information and if necessary change their strategies.

- **EMBED LEARNING IN SOCIAL EXPERIENCE.** DBG is designed to be used in small groups, because learning by its very nature is a social and collaborative process. DBG tries to facilitate task-oriented interaction, social negotiation and collaborative meaning making by demanding the students to discuss about their decisions in the management of their company.

- **SUPPORT STUDENTS' LEARNING BY TAILORING THE GAME.** There are opportunities to adjust the simulation to support the needs of learners (e.g., the speed of game clock can be changed or stopped, the model can be made more complex during the gaming, the company context with all of its variables can be modified, the supply and demand of the market can be changed, economical depression is possible to model etc.) (c.f. de Jong, 2001)

The objectives of using DBG can be very diverse and versatile. For example the students can learn substance knowledge and skills of business studies, enhance their collaboration and interaction skills, learn to face and master the complexity of real economical world, and acquire flexible and robust competence which is transferable to other contexts and real-life situations. In short, the working with simulation aims to facilitate both formal and informal knowledge. The main pedagogical basis behind this kind of a learning environment is the idea of "learning with technology" (Jonassen et al., 1999), which is congruent with constructivist perspective as seeing learning as an active meaning making and knowledge building in an interaction between learner, available tools and his/her social and physical environment. In this view the role of computer technology is to encourage the thinking of the learners, facilitate the mindful engagement with a deeper level of learning, support the collaboration between participants, and function as a cognitive partner of learners. The essential feature of this learning environment is the use of simulation in small groups (or teams), in such a way that every small group manages their own company. Collaborative action becomes very important, because every decision has to be discussed and processed in small groups the same way as in real business contexts.

DBG is highly interactive in several ways (see Fig. 1). First, there is collaboration between the participating students within each team around the same computer. Secondly, the participants enter their decisions to the game decision-making application (computer model of manufacturing company) in their computer. Thirdly, each company application is in continuous interaction with the market server. Actually simulation does not operate in true real-time processing. However, the processing is continuous in the sense that the game time is clock-driven, smallest increment of time being one hour, and the participants are not tight to make decisions in specified points of time but can make decisions whenever during the game they choose. Fourth, all the companies are indirectly in connection to each other through the market server. So, the market server with the contributions and actions made by each participating company form a kind of a virtual market. This virtual market with its human component is much richer and more authentic than a pure computer-based model of the functioning of the business world alone. DBG includes all the major business decision functions, which correspond to the realistic contexts found in business world. The idea is that students can use any of the tools and information resources available at any time. Also multiple tools can be used simultaneously. In a way the working with DBG resembles continuous problem solving. Figure 2 represents the game user interface (company decision-making application).
However, to overcome the difficulties in simulation environments found in previous studies (e.g. de Jong & van Joolingen, 1998) it is also possible to arrange other instructional supporting activities besides mere simulation working. Our own approach was home assignments which supported and focused student processing towards the relevant contents and variables in business simulation. A typical assignment was, e.g., to carry out different business analysis and designing future business strategies for their virtual firm, and then to apply these in the next simulation session. We also assigned them to create an Excel spreadsheet (which they could use afterwards during working) for calculating profit and other key figures. These additional arrangements were to engage the students in a deeper processing of the substance area. Other supporting feature which was build in this simulation was so called model progression (e.g. White & Frederiksen, 1990) method, which means that the complexity of simulation is gradually increased. This was done by accelerating the game clock speed and adding more market areas into the game during the course. We hypothesize that this would help students in the beginning to get used to the simulation and to decrease their cognitive load. In all, we assume that with DBG it is possible to create a learning environment, which supports constructive, situated and social processes of learning (Nurmi & Jaakkola, in press).

Overview of the Research

Our first research of a DBG based learning environment was conducted in autumn 2001. The study course was arranged in higher education level, and 19 students of information systems and computer science participated in the course. The course consisted of 24 hours of working with DBG (6 sessions of 4 hours) and in addition to several home assignments. The DBG was used in the groups of three students, so there were seven companies in virtual market competition. We have collected large amount of both quantitative (financial figures, attitudes towards ICT, teamwork and business studies, feedback from the course, log data from simulation, and scores of pre- and post-tests of substance knowledge) and qualitative data (observation data of group working, reflecting the roles of group members). The purpose of our research was to understand the actual collaborative learning and working processes with simulation, and to find out what are the effects of simulation course on students substance knowledge and attitudes towards ICT, team work and business studies.

Preliminary Results and Discussion

At the moment only part of the data is analyzed. Qualitative process data from the observation of small groups will be analyzed in the near future, as well as companies' log data and financial progress in the game. These preliminary results are based only on the effects of simulation working and feedback and experiences from the students. When reviewing students' scores on pre- and posttest questions, it can be seen that simulation course had statistically significant (T-test p < .01; Wilcoxon test, value of z = -2.672, p < .01) effects on scores of substance knowledge (see table 1). The effects of playing to scores were significant, but the overall increase in score was quite modest, average scores increased only from 12.7 to 13.9 points (max 21).

Table 1: Effects of simulation course to the scores on pre- and posttest of substance knowledge.

We were not quite satisfied with our test questions, which were concentrating too much on fact knowledge, and the content of our problem solving tasks didn’t match too well with the issues students had to face during simulation working. It seems to be the case that by its very nature the results of simulation working are so qualitatively different from just acquisition of new factual knowledge that those effects cannot be detected by traditional knowledge tests (c.f. Swaak & de Jong, 1996). Swaak et al. (1998) concluded that it is not clear how the effects of learning from simulation are to be measured. Further they inferred that simulation working produces intuitive (or implicit or tacit) knowledge, which tends to be difficult to verbalize and to measure. As a consequence in following studies we have changed our test questions much more towards problem solving and knowledge applying tasks as well as concept mapping assignments, because simulations are more valuable in facilitating deeper understanding and complex problem solving skills than in teaching factual knowledge. In future it would also be interesting to compare DBG with more traditional batch-processed business game.

We also ask participating students to reflect their experiences and give feedback from simulation course and especially from the simulation itself. According to these comments several conclusion can be made. First of all, all the respondents regarded DBG as authentic. They thought that the questions and problems they were dealing with during the game can also be faced in real working-life context of any manufacturing company. Participating students evaluated that DBG represent authentic and complex business processes rather realistic way. For example one claims that “Situations and problems faced while playing felt very realistic. Also game business model looked like real, but someway it’s little simplified (e.g. customers are not always so rational etc.). However, I think that it is impossible to model all the factors in business world in computer game”. The complexity of business world was also seem to transmitted to students, which can be seen from these comments: “What made this playing to felt so real, was that you had to take care so many things simultaneously to get the firm do well” and “I realized that enterprise is always a risk. You can’t be sure that even considered decisions will lead to anything but a loss.”

Secondly, the simulation was valued as very engaging (or immersive) and the working with it was experienced as meaningful and interesting. Once the game started some of the students didn’t want to stop playing when the course ended. “I could say that I was little addicted to game, it would be fun to keep on playing longer” said one participant. Especially real time element of the game was seen as very important feature which affects on authenticity and engagement, because real timing “makes it possible to see the consequences of own decisions and actions”, “…shows how important it is to make your decisions as quick as possible and before your competitors”, and “…forces to observe the market situation, analyze the actions of other companies and revise your strategy”.

Thirdly, especially participants assessed the collaboration around simulation as very fruitful and useful. They said that simulation can function as a shared frame of reference which allows talking about difficult issues even without correct concepts. This can be seen e.g. from this response: “Our team work succeeded well, and we were all aiming to get our company to show a profit. I could say that the working was very intensive during the whole course and the game inspired our discussion”. Basically one can claim that the collaboration in small groups brought additional value to wholeness of simulation working. Collaborative processes seems to be much more than just a sum of its parts (the characteristics and abilities of group members), because none of the background variables (attitudes to ICT and team work, learning orientations, scores of pretest) couldn’t clearly explain the successfulness of small groups in the virtual market of game. It clearly seems that in order to understand learning with simulation, we have to concentrate on analyzing the collaborative processes around computer occurring in small groups.

Students also saw DBG as very motivating teaching and learning method for business education – especially compared to more traditional instructional methods, and based on their opinions it can be said that simulation could maintain task related orientation during the whole course. For instance one student said that “...maybe the
most motivating aspect of the game was the competition against other companies”, while some other regarded the meaningful problems and situations as the real source of motivation. However students also saw the importance of traditional teaching methods: “Although playing is fun and it gives the big picture of business processes, it’s not enough. It would be good to combine theoretical lectures and concrete playing in the same course”. One suggested mode to use this simulation was the knowledge applying approach: “...game is a perfect opportunity of testing what you know before in a safe environment. It lets you simulate different approaches and their effects”. When asking students to reflect, what the most important thing they have learned during the simulation course was, majority stated that it was acquiring the consistent conception of business processes as whole. They said that they could now understand how many different factors are affecting to successfulness of business company. For example one stated that “…the most important thing that I have learned is how different parts of a company interact and what kind of things you have to take in considerations in such a company as this” which he explained, was because “…you could see the flow of the whole process of the product from the raw materials to the end product and the different procedures in between”. Unfortunately this development of holistic picture about business processes could not be catch in our test questions. In all, the overall responses about the whole course were very positive without exception.

In conclusion, on the basis of this research, we state that simulation working can be regarded as authentic and very engaging as well as meaningful and motivating for students, and it could facilitate the development of deeper understanding about realistic business processes as whole. However, our qualitative analyses about small groups’ working processes are not done yet, and they will shed new light on many of our research questions and conclusions in future.

At the moment we have conducted a follow-up research where students with different levels of expertise have been compared. We examined how novices and intermediate experts are working with simulation. The research focus is on the questions such as: does the students with different level of substance knowledge and expertise in economics work and use DGG differently, does they use various business strategies (e.g. trial-and-error experiments or planned theoretical strategies based on the theories of economics) during the game, does they succeed differently in the competition of virtual market, and does they benefit equally in tests as an effect of experiments or planned theoretical strategies based on the theories of economics) during the game, does they succeed differently in the competition of virtual market, and does they benefit equally in tests as an effect of playing? The results of this study are reported in future.

Abstract: Retention has been indicated as one of the greatest weaknesses in online instruction. While a preponderance of literature about online instruction is available, concrete ideas about how to retain students are lacking. A DHHS grant for over $1 million dollars has made it possible for us to provide an Internet option enabling registered nurses to obtain a bachelor's degree. Now in the third year of the program, we have maintained an excellent retention rate ranging from 85 to 93%. Factors found to positively influence retention included: enhancing the comfort level of students with the technology, creating a sensitive online faculty persona generating trust in the environment, and addressing safety and security needs to support highly interactive experiences. These strategies promoted the development of relationships with “classroom” colleagues and fostered linkages necessary for students to remain connected to the learning experiences and continue to degree completion.

Student Retention in the Web Environment

Despite great attention to appropriate design for online courses, high student attrition and/or lack of re-enrollment continues to be the dominant concern about web-based learning. The literature addressing web-based learning contains few practical suggestions for connecting with students online to retain the high-touch in a high-tech environment. A study conducted at one small liberal arts university (Lynch, 2001), reported student dropout rates from Internet courses were as high as 35-50%, compared to 14% for traditional classes. Lack of feeling connected to other students has been cited as a major reason for students dropping out of online education. “This feeling of isolation is credited for the high attrition rates of this type of instruction.” (Link & Scholtz, 2000, p. 275) Obviously, poor retention would preclude the viability of online learning unless strategies to increase student success and control costs related to student attrition can be reversed. How good can the method be if students do not to continue in the environment?

A DHHS grant for over $1 million dollars provided the opportunity to develop an Internet option enabling registered nurses to obtain a bachelor's degree in nursing. Analysis over three years of program delivery has demonstrated a remarkable retention rate of 85 to 93%. What factors affect student retention? We need to attend to preparing students for this brave new world of learning. Greater attention needs to be paid to directing the students' earliest online experiences. In redesigning this program for web-based delivery, it was rapidly discovered that student comfort levels and faculty persona made a tremendous difference in the student’s perception of their potential for success. Students must feel safe and secure in the environment before they can develop the level of trust needed for positive learning and growth to occur. Trust is more difficult, but not impossible, to achieve when the learner is virtual. Trust is also essential for engaging students in highly interactive learning experiences. Students must feel free to take risks and challenge assumptions. Without this level of comfort between the student and faculty, they will be reticent to dispute ideas and stretch their thinking.

1517
They will also find the learning experience very isolating and many will retreat to the comforts of a classroom setting or be lost to continuing education entirely. This presentation will describe the strategies found useful in establishing trust and comfort that is essential for student retention.

Comfort Level with Technology

One challenge of online learning is the lack of learner familiarity with the delivery system. Therefore, it is important to remember that transitioning courses for online learning requires far more than a simple conversion to a web-based format. Lack of face-to-face contact with the learner requires new ways of thinking about how to connect with students. One of the first priorities for faculty is to assure that the technology does not get in the way of establishing this connection. "Comfort with technology is key to whether collaboration takes place." (Boettcher & Conrad, 1999, p.90) Students need to focus on the learning and not be distracted by the underlying technology. Therefore, faculty need to generate ways of assisting students to become comfortable with the delivery system. An important and useful method for achieving this goal was the development of a technical training manual. This manual contained step-by-step instructions for activities that students would perform in the online courses. These activities, or "boot camp challenges", gave students practice taking online quizzes, using the e-mail system to introduce themselves to their classmates, posting messages on a discussion board, discussing group assignments in the chat room, and uploading assignments to the course faculty, etc. These exercises enabled students to become familiar with and reasonably comfortable in the learning environment. A second method was the early inclusion of an informatics course that incorporated the essential computer skills that students would need to be successful throughout the program. Students acquired basic skills in computer application software (Word, Excel, PowerPoint, and Access) and information literacy skills (use of electronic resources available through the library and the World Wide Web). To provide relevance and to help students more easily acquire these skills, exercises using technology were designed especially to give students the opportunity to apply their newly acquired skills to their discipline. Facilitating the use of the technology will prevent frustrating technical dilemmas that interfere with learning.

Course Design and Instruction

Many factors related to good online course design and instruction apply when addressing the issue of student retention. A well-designed course is satisfying to the learner and will encourage return. Some factors not commonly published include the fact that not all faculty are well suited for the online instruction. Students will not hesitate to drop a traditional course when a favorable impression of the faculty is lacking. Online students look for several factors in their virtual faculty including flexibility, personal credibility, and the willingness to consider other perspectives without injury to the contributor. Nowhere is an instructor more vulnerable with this type of student critique than in the online environment. As such, instructors must be carefully selected for online teaching assignments. Faculty must be able to view their teaching from the student's perspective. The ability of the faculty to effectively communicate in the written format quickly becomes transparent to all. Attention to clarity, grammar, spelling, and punctuation are essential. Therefore, faculty who harshly criticize students' written work, when their own skills demand attention, may unwittingly establish an adversarial relationship with students. In addition, the communication of complex concepts necessary for critical thinking requires clear, concise, yet innovative teaching strategies because faculty are not able to evaluate non-verbal clues to comprehension online. Those who consider teaching online an easy contrast to the drudgery of the classroom, should carefully be evaluated. Simply posting PowerPoint content outlines used in traditional classroom presentations has little meaning in the online environment. Conversely, posting extensive lectures notes that do not contain material significantly different from the textbook is a time-consuming, boring approach. "A well designed distance course that has a focus on interactivity includes many topics for discussion, feedback from students as well as experts, and finally links to sources of pertinent information. Literature citations, journal articles and URLs are a few of the possibilities" (Parker, 1999, p.16). Developing content to foster interactivity is essential. Strategies for effective interaction online are varied but not limited. Most adult students desire interactive learning. We are reminded that "The web may be a great medium for discovery learning, but there has to be substance for the student to discover!" (Carlson & Repman, WebNet Journal, 2000, p.11). Without the credible faculty, retention will be a moot point.
Many factors influence the initiation and maintenance of trust in this environment. Assigning "busy work" is inappropriate in any learning environment, but it is particularly destructive in online education. The product of online learning is written. Students submit their work in the time intensive and laborious manner of a written format. When that product is perceived as "busy work", trust in the faculty member's expertise is quickly eroded. Students are less likely to become disgruntled with time spent in high-level, interactive activities that challenge their comprehension of materials through analysis, application, or synthesis strategies than with activities that require them to regurgitate what they have read. Therefore, online faculty must become designers or managers of learning experiences, shifting the work of learning to the student. "The students become the center as interactive collaborative learners." (O'Leary, 2000, p. 28) Students must feel confident that the faculty will not humiliate them by diminishing their contributions in the face of their peers. This degradation is preventable, but is devastating to continued progress once the student has experienced it.

Both boredom and extraordinary demands (far beyond the expectations for traditional education) are primary concerns for students considering continuation in the online learning environment. Flexibility should be considered the hallmark of effective, interpersonal communication. Rigidity becomes very evident in online education. Faculty who are insensitive to subtle cues about student needs will struggle to establish a trusting relationship with their students. Awareness of students' work at the beginning of a course can provide clues to changes in behavior later on. These behavior changes can include decreased activity level, diminished quality, and delayed responses. These are critical cues. They should alert the faculty member to solicit student responses regarding the meaning of the new online behavior pattern. However, when students provide feedback about the instructional methods, faculty must be flexible and willing to evaluate the validity of that input so that they can make meaningful adjustments in the course. Results of a study conducted by Indiana University Bloomington to profile the innovative teacher using technology concluded that all of the teachers who had changed their teaching with technology shared what one might call an "innovative personality". "They were willing to remain flexible and to modify their innovations as they received feedback from their students." In addition, they found that innovative teachers "liked changing things mid-stream to make them work better, not having to wait for the next time they teach the course." (Energizing the Innovative Teacher: Technology's Role, http://www.indiana.edu/~ltl/energy.html) One must also keep in mind that it is easy to become so enthusiastic about the endless possibilities of activities for online instruction that one creates an overwhelming workload for the students. Identification of this factor demands the flexibility to adjust the assignments appropriately. Teaching online can be far more demanding than classroom instruction. It is expected that the faculty will gain a close association with each student and must be responsive to their individual needs or risk losing the student.

**Risk Taking**

Online learners are subjected to a different set of stresses than those in the classroom. Writing in the online environment creates feelings of vulnerability in both the students and faculty. Written communication is perceived as a more permanent form of self-exposure than is typical in the conversational environment of the traditional classroom. Thus, faculty need to take the lead in setting the example for risk-taking online. This is particularly true if your subject matter involves sensitive, personal expressions or examples to make a point. If faculty want students to apply learning to personal experiences as a demonstration of a concept under discussion, it can be invaluable for the faculty to provide the first example. Openness on the part of the faculty can facilitate honest communication from the students. Faculty leading the way in risk-taking activities enables the braver students to test the waters and others will follow. If risk-taking is an expectation, then it must be handled carefully or students will not return to the setting.

**Feedback**

Retention is related to the development of a connected relationship between the faculty and the student. One mechanism for linking to the student is feedback. In the traditional classroom, faculty are able to respond to students immediately. In the online environment, this response time is likely to be delayed. However, the delay should be minimized as much as possible so that each student perceives the faculty as truly committed to their
learning. Timely review of materials supports student progress in a course. Long delays translate into student concerns about whether the faculty received the information or, if received, cared enough to review it. The literature suggests that the feedback time to online learners should not exceed 48 hours. A student who logs into a course on Sunday and has questions about the following week’s assignments, will become very frustrated if the faculty does not respond to these questions very early in the week. The more connected the adult student feels to the learning situation and their faculty, the more likely they will be to continue in the course and to consider enrolling in future online courses.

**Tone of Written Communication**

Online students can be particularly sensitive to the tone of the written communication that they perceive between themselves and the faculty. Tone can be an elusive factor in written communication. However, it is a very important variable. How students interpret what faculty have written may be very different from the message that was intended. Most problems occur when faculty forget that it is imperative to be able to stand back from the message and view it from the students' perspective. This view relates not only to the content, but also, perhaps more crucially, to the nature of the message. Sensitive critiques including attention to word choice, understanding student perspectives, openness to errors in thinking, and warmth are factors that reflect the online faculty persona. For example, an authoritative style can easily be communicated to and resented by adult students online resulting in the inhibition of trust. When this occurs, students begin to produce what they believe the faculty wants rather than challenging their own thought processes. On the other hand, an investment in the creation of an overall trusting atmosphere will allow the students to perceive the safety net required to step-out-of-the-box and work to improve their critical thinking skills. The use of humor, especially, if it is self-directed and not sarcastic, can be an effective method for engendering trust. "Humor can lighten the burden of the learning curve for both the student and faculty and can generate a felling of sincerity among those in the class. (Parker, 1999, p. 16) But, any method that communicates a non-judgmental, open approach will assist the students to view the faculty as human and trustworthy. In any case, attention to the tone of each message requires additional time and effort on the part of the faculty. Lack of attention to tone, often will send learners running away from the experience.

**Collaboration in Online Learning**

Faculty who are successful in establishing an online learning community encourage student participation and discourage lurking behavior. Eisley (1991) and Schmier (1995) identified that learning is best accomplished when the learner is actively engaged in the process. Knowlton, Knowlton and Davis (2000) indicated that online discussions help students understand that there are real people that they are communicating with in cyberspace and that discussions facilitate the formation of an educational cyber-community of learners. Harasim (1989) pointed out the benefit of knowledge building that occurs when "students explore issues, examine one another’s arguments, agree, disagree and question positions. Collaboration contributes to higher order learning through cognitive restructuring or conflict resolution, in which new ways of understanding the material emerge as a result of contact with new or different perspectives. (Harasim, 1989, p.5) This type of online teaching requires emphasis on quality rather than efficiency. A high level of interactivity allows faculty to quickly identify when students are confused or need additional information and gain a greater understanding of individual students' performance abilities. As noted in the University of Illinois Faculty Seminar Report (2000), "You get to know your students' minds, not just their faces". "Collaboration is an integral component of higher education not only because it supports active learning, but also, because it is required for the workplace for which students are prepared (Ben-Jacob, Levin, & Ben-Jacob, 2000, p. 8). It must be remembered that participation is not likely to happen unless it is deliberately planned. This format defines a learner-centered educational model where students operate in a more self-directed mode and have greater control of their own learning. It encourages student success and connectedness that in turns fosters retention. Again, these strategies are time consuming and require committed and dedicated faculty.
Conclusion

Clearly, many factors influence student retention. Initiation and maintenance of trust in the online environment is essential. Collaboration is essential for active learning and gives students valuable practice of skills that can lead to advancement in the workplace. Faculty contemplating teaching online must be cognizant of the need to prepare students for this new learning environment. Beyond technology preparation, faculty need to learn how to establish credibility with the students. Major factors that affect credibility include written communication skills, use of higher level teaching strategies, flexible approaches to learner concerns and needs, setting an example for risk-taking, timely feedback, and setting a tone that promotes open and honest interaction. These factors positively influence the development of mutual trust between the faculty and their students. Online education truly demands high-touch and requires selection of faculty who are able to demonstrate the qualities of excellence described above as well as dedication and commitment to student learning.

Teaching and Learning Activities in the Online Classroom: 
A Constructivist Perspective

Jaishree K. Odin
Liberal Studies Program
University of Hawaii at Manoa
United States
odin@hawaii.edu

Abstract: To establish standards of quality in online courses developed through the University of Hawaii’s Asynchronous Learning project funded by the Alfred P. Sloan Foundation, a preliminary study of courses from various disciplines was conducted. The aim of the study was to identify teaching activities that contributed to the creation of a high quality interactive classroom where students were actively engaged in the process of learning. The study showed that a direct relationship exists between the teaching activities and the frequency and quality of collaborative learning in the online classroom. Carefully crafted teaching activities contribute toward creating the social presence of the teacher, which directly or indirectly shapes the learning environment and thus significantly impacts the desired learning outcomes.

Introduction

A number of recent studies on the online teaching-learning process have specifically dealt with the role of the online teacher as a facilitator (Salmon, 00; Palloff et al, 01; Collison et al, 00). Such studies through their exclusive focus on the role of the teacher as a facilitator often lead to the misperception that online teaching is merely facilitation. The role of the online instructor is also to create a “teaching presence” through appropriate instructional activities which include lecture notes, teaching commentaries and individual or collective discussion responses to guide students toward critical exploration of the content (Anderson et al, 01).

Studies have shown that the constructivist model in instructional design based on active learning is capable of providing an effective theoretical framework within which to analyze the teaching-learning experience in technology mediated instruction (Bednar et al, 92; Gold, 01). Knowledge construction has been described as a social process (Dewey, 96). Learning involves construction of internal representations of knowledge which can best be accomplished in a collaborative situation where learners encounter other knowledge representations or perspectives, which allow them to review, evaluate and assess their own perspective, and revise it if the revision is more meaningful (Bednar et al, 92). In an effective learning environment, the instructional tasks are contextualized in authentic situations and students are given opportunities to construct knowledge as they test their ideas on others and evaluate other perspectives. The social negotiation of meaning is enhanced when the role of the teacher is seen as a coach and a facilitator in the learning process (Vygotsky, 78).

Current research on online learning shows that new technologies allow course participants to engage in meaningful discussions so knowledge is not transmitted from the teacher to the students, but rather discovered as individual perspectives are shared in a collaborative learning environment (Hiltz 97; Harasim, 90; Joy et al, 00). Students acquire knowledge in a social context where they are given opportunities to articulate and express their views as they construct knowledge that is personally meaningful to them. The teaching-learning process is thus seen as a shared transaction in which the learners assume responsibility for their learning and the teacher shares with students the control of the nature and content of the activities in the classroom as he/she ensures that any new knowledge created meets the shared disciplinary standards (Garrison et al, 00). As the content expert, the teacher thus guides the learners as they negotiate the exploratory learning environment. The direct and indirect teaching acts performed by the
teacher in the online classroom are thus critical in shaping the collaborative learning process in the classroom to achieve the desired learning outcomes.

Research Method

In order to determine the relationship between the diverse teaching and learning activities in completely online courses offered at the University of Hawaii at Manoa, a detailed study was conducted of six courses from a variety of disciplines: information and computer sciences, music, family resource management, anthropology, political science, and interdisciplinary technology and culture. The six online courses were taught in Fall 2001. The primary aim of the study was to find the set of teaching-learning practices that were conducive to creating an active collaborative learning environment. In order to collect data on the courses, the study employed a detailed worksheet listing various teaching and learning activities possible in the online classroom. Teaching activities which were examined in each course included course overview documents, lecture notes/content overviews, interpretive teaching commentaries, discussion/study questions, and teacher’s facilitative discourse. Learning activities that were examined included weekly responses to the reading assignments or individual work assignments, online discussion, group projects, and students’ leadership discourse. After collecting data on the teaching and learning activities included in each course, the relationship between the two types of activities was examined. The impact of the teaching acts on the learning acts was studied through analyzing the quality of the work produced by the students in terms of online class discussion, group discussion (if included), as well as individual work assignments submitted as weekly responses to the readings. This study did not include the work students submitted directly to the instructor in the form of short or long research papers or quizzes.

Data Gathering and Analysis

Teaching Activities

The courses included in the study were taught using a course management system, either WebCT or Blackboard which provided an almost complete transcript of course documents, course activities as well as strategies the instructor used to manage the course on a weekly basis. The course overview documents along with the weekly introduction of materials by the instructor provided a good perspective on how the course was designed. Courses studied were labeled A, B, C, D, E, and F in order to maintain the anonymity of the instructors who taught the courses.

All instructors had gone through a tutorial on online teaching, which went over the effective strategies to organize and manage an online course. With the result all courses included good course overview documents, which provided a detailed description of the syllabus, schedule, course procedures, requirements, and grading system. The courses A, B, and C included either an introductory student tutorial on online learning or detailed technology tips for students to access the course.

In courses A, B, and C the instructors rethought the traditional lecture presentation. The weekly reading assignments were introduced in a non-linear manner through lecture notes, content overviews, and web-based resources. The purpose of lecture notes or content overviews was to facilitate students’ access to weekly readings and work assignments.

Whereas lecture notes served the purpose of introducing the course materials, the interpretive teaching commentaries used in the courses A, B, C, D, E, and F served to provide a platform through which the instructor as content expert responded to discussion posts and/or individual responses to the readings in the form of weekly collective postings. Different instructors used teaching commentaries for different purposes. In all cases, the teaching commentaries became for the instructor one of the ways to assert his or her presence in the electronic classroom. The commentaries served to contribute to the dynamic nature of the learning environment as these were not pre-scripted, but tailored to the particular learners and the learning environment. The instructors who provided interpretive teaching commentaries thus made their presence felt in ways other than discussion facilitators.

In order to make the course materials more meaningful to students, the instructors who taught the courses A, B, and C made use of study questions or discussion questions to guide students to think of the ideas or the subject matter covered in a broader context. They also encouraged students to apply the ideas under discussion to real life situations. The discussion questions in courses A, B and C became the basis for
the instructor-led component of class discussion that also had a broader student-led discussion component. No discussion/study questions were included in the weekly activities of the courses E and F.

The success different instructors had with the efficient management of the classroom was studied through the examination of the facilitative discourse which was present in all courses to a greater or a lesser extent. The facilitative discourse included any direct or indirect teacher intervention to efficiently manage the course and make it run smoothly through enforcing deadlines and providing guidance when needed. It included the comments to generate enthusiasm or to promote self-motivation and self-direction among students. The examination of the facilitative discourse was restricted to what was revealed in the course transcripts and not to any individualized feedback that the instructors might have provided students through private e-mail.

Learning Activities

All courses included both individual as well as collaborative learning activities, which were designed differently in various courses. Students were required to submit weekly individual responses to readings in the courses A, B, D, and E, whereas in the course F, they were asked to submit a biweekly response to the readings. The courses C and F made use of weekly quizzes to assess if students had learned the material.

The instructors used various methods to collect the responses submitted by the students. In the course F, students were divided into groups and the responses were discussed in the group working area. In the course D, students were asked to post their responses on the class discussion board. In this course, the responses had to include discussion questions framed by students. In the course B, students were required to send the weekly responses privately to the instructor. After students had submitted their responses for a particular week, the instructor of this course made the responses public so they were available for everyone to read.

Online class discussion was used in all courses, but its effectiveness as a collaborative learning tool varied from course to course. In the courses A, B, C and D, the discussion served the purpose of helping students validate each other’s learning. Different perspectives helped them understand ideas that they had missed or not understood in their own reading. Students in these courses responded thoughtfully to each other’s comments. Such exchanges created a shared context for learning. In the courses E and F, the discussions were very superficial.

As far as the incorporation of group projects was concerned, only courses A and B incorporated group projects. The group project served as the focal point around which the group members in these two courses did research, gathered information, and jointly created a product.

Giving students a leadership role in course activities was used by most of the instructors as an effective way to get actively involved in course activities. Though all courses had this feature implicitly embedded in the course activities, only the course B had explicitly organized the groups in such a way that both the groups and the individual group members were given opportunities to engage in leadership discourse as they initiated weekly discussions and managed weekly group activities on a rotating basis.

Results

The detailed analysis of the course transcripts showed that selecting a course management system and creating the course overview documents is only half of the project of creating an effective online course; the other half is the content and organization of weekly multi-modal teaching and learning activities. The study indicated that the teacher’s implicit or explicit teaching philosophy directly impacted the nature and the number of teaching acts performed on a weekly basis in the online classroom. Different instructors integrated various teaching and learning activities into the course environment to different degrees. It was obvious that the presence or absence of teaching activities shaped the learning environment in each course. There was a direct relationship between the nature of direct and indirect teaching activities and the frequency and effectiveness of collaborative learning activities.

Given below is a chart that shows the relationship between the teaching and learning activities and the resulting active or passive collaborative learning environment. Courses labeled A, B, and C showed
maximum multi-modal teaching and collaborative learning activities involving discovery or active learning. Courses labeled E and F showed minimum teaching activities with very little active collaborative learning. The collaborative learning activities in these courses were merely a cosmetic addition to the class activities. The course D fit somewhere between the two as far as the effectiveness of collaborative learning activities was concerned.

Courses A, B, & C: Multiple Multi-Modal Teaching Activities

The three courses labeled A, B, and C with multi-modal teaching activities produced a learning environment where students were engaged in the construction of knowledge as they worked collaboratively. The more the teaching acts, the greater the frequency and higher the quality of collaborative learning acts performed by students.

Course D: (Constructivist Model) Reduced Teaching Activities

The course D occupied a position somewhere between the highest and the lowest in terms of the quality of online discussion. Students were required to write a weekly response to the readings and formulate two to three discussion questions related to the readings. Both the response and the questions were posted on the discussion board. Students then responded to each other's discussion questions as well as responses. The quality of discussion in this course was good. The instructor provided feedback primarily...
through a collective weekly discussion posting, though occasional responses to individual postings were also made. Students in this course, however, were on their own as they tackled the assigned readings on a weekly basis unlike in the other three courses A, B, and C where the instructors had provided lecture notes or content overviews on a weekly basis. Since students were more or less on their own in the course D as far as accessing the content was concerned, it is unclear if they could engage the texts as intensively as they would have done if the instructor had provided more guidance.

Courses E and F with Minimum Teaching Activities

In courses E and F with decreased teaching acts, it was obvious that the instructors implicitly based their courses on the traditional instructional model. Even though the instructors used the suggested online course design for incorporating collaborative work, it was against the background of the assigned course activities where students were primarily asked to basically read the materials, complete the assignments and send the completed assignments to the instructor. In these two courses, no specific instructions were given to students as to how they should conduct their discussion activities. In the first course, students were simply asked to discuss the readings with other group members. In the second course, each student had to complete a biweekly assignment. This assignment was in the form of a commentary on the readings, a summarization of the main points along with some comments on what transpired in the discussion amongst the group members. Group members were encouraged to discuss the work in the chat room, rather than through asynchronous discussion. Both the chat room archives and the asynchronous discussion, when examined, reflected very superficial interaction.

In the above two courses with decreased teaching presence, the teaching activity was thus confined to the minimum and appeared only in the form of the instructor’s collective response to discussion postings. Students found themselves in a very open learning environment, as they had to rely on their own resources to comprehend the materials for which they were unequally prepared. The discussion transcripts of the two courses showed if the instructor is not clear about the purpose of the group work and how it can be used to encourage students in constructing knowledge or transferring new knowledge to other contexts, online discussion is bound to focus on the reproduction of ideas. In the absence of any explicit guidance from the instructor through discussion questions or well-integrated interpretive teaching commentaries or lecture notes or content overviews, students were very much on their own as they went through the course materials. They were thus more intent on merely learning the material as it was presented to them in the textbooks, without critically evaluating the ideas they encountered using their higher order thinking abilities. The only collaborative work, the online synchronous and/or asynchronous discussion, seemed to be just an “add on” activity. It seemed the “real thing” students were asked to do was the assignments (responses or quizzes) they worked on independently which they sent to the instructor. Both these courses thus retained the traditional model of instruction where students primarily wrote for their teachers and reproduced what they learned in textbooks. It was also clear that just as an exclusively teacher-centered model is not educationally effective in making knowledge meaningful to students, so is the other extreme of learner-centered model where students are expected to work in a very open learning environment with little guidance from the teacher.

Conclusion

The above study showed that diverse multi-modal teaching activities with corresponding learning activities are successful in creating an effective learning environment where students are engaged in the process of learning. The teacher’s presence, generated through multi-modal teaching acts, promotes self-motivation and self-direction amongst students as they are guided to actively engage in collaborative learning activities. In establishing quality standards in the online classroom, therefore, the role of the instructor in creating an integrated teaching-learning environment must be emphasized. The electronic medium is unique in that it can be easily transformed into a dynamic electronic space that is capable of sustaining the social presence of both the teacher and the students. The instructor’s expert guidance manifested through multi-modal teaching activities is indispensable in creating a shared context of learning where students are engaged in both constructing knowledge and applying it to other contexts. The diverse teaching-learning activities promote a complex mode of multi-level interaction amongst the learners, the
instructor, and the content of the course, which creates a social context for constructing, exchanging and transforming knowledge.

Rethinking multimedia teaching: examining developments in multimedia course provision.

Michael O’Donoghue, University of Lancaster, UK
Carole Potter, St. Helens College, UK
December 2001

Abstract
This paper provides an initial examination of over 614 multimedia courses now available in the UK with discussion centered on reasons for recent course expansion. Areas of specific growth and issues of course design are presented in the analysis and discussion. Changes in the application of multimedia from subject-specific to second subject contextualisation are also discussed with reasoning to support learning benefits to be derived from this approach, and implications for course designers and providers are concluded.

This paper will be of interest to multimedia and online course designers, managers and tutors, instructional designers, and those involved in institutional curriculum planning.

Introduction and motivation for this work
The motivation for this study arose early in 1999. Our study centre, CSAL1, had successfully run an MSc in Advanced Learning Technology since 1993 and we started to give serious consideration to a course for undergraduates which married learning technology with learning theory. Our objective was not only to equip a graduate with educational knowledge and awareness, but to support this with a range of information and communication technology (ICT) and multimedia production skills in order to prepare them to make better use of educational technology already available in many educational settings.

Our first step towards this objective was to review existing course availability in this field. The University and Colleges Admissions Service (UCAS) in the UK at that time offered 53 courses related to the themes of ‘educational technology’, ‘multimedia technology’ and ‘learning technology’. We also noted that approximately 250 courses were then running which included the term multimedia in their title. Given that competition between Higher Education Institutions (HEIs) in the UK can be very high, the relatively low provision of courses in the educational technology area suggested a yet-to-be exploited area for development. Consequently the authoring of course rationales and modules commenced.

The first working title for the new degree was ‘Multimedia and Online Learning Technologies’. This changed to ‘Multimedia Learning Technologies’ within a week or so as we felt the first title to be too long and we also embraced the idea that “... the term multimedia is used to encompass both online and offline projects” (England and Finney, 1999) from one of the identified course books.

In the Spring of 2001 the degree scheme cleared the last university approval committee, though several changes had taken place by this point, not least to the title. The term ‘Learning Sciences’ now replaced Learning Technologies in order to emphasise that theoretical aspects of learning played an equal role to those of technical production and realisation. The second title change was the removal of the word multimedia completely to leave a new title of ‘Learning Sciences & Technology’. This latter change caused more than a little concern between the course authors and validators over what potential students- and tutors - may understand as the focus of the degree.

With this latter question in mind we decided to again examine the availability of multimedia and learning technology related courses offered through UCAS commencing in 2002. To our great surprise 614 courses were available across the UK which included the term multimedia in their title. This caused pause for thought for fresh questions came to mind, not least:

- What were the causes of so much expansion in multimedia course provision so quickly (around 160% increase in 2 years)?
- Had the definition of multimedia evolved to include many more new options?
- What aspects of multimedia or skills were students learning in these courses?
- Though we had removed multimedia from the title of our own scheme, was this perhaps the most appropriate thing to do, both for marketing and pedagogic reasons?

Multimedia course analysis
In order to understand this change it was necessary to review multimedia course availability on a year-by-year basis. Had this change happened gradually, or was it sudden and dramatic due to improvements in access to and in the performance of technologies associated with multimedia? An analysis of this data (table 1) showed a dramatic increase in multimedia course provision between 1997-98 and 1998-99 with 179 new courses running, compared to 95 new courses running in 1997-98 and 56 in 1996-97. The data also showed a decline in the number of multimedia courses running in 2000-2001 (105 discontinued courses and 76 suspended from the previous year) though projections had once again picked up for 2002.

As a next step we made a provisional examination of these multimedia combined courses in order to identify any specific areas of growth or

period between our initial analysis and contacting the UCAS for a statistical search.

We then examined the courses in more detail in order to identify those courses relating to our own course which originally combined multimedia with learning and technology. This inspection highlighted a number of variations on the use of the term multimedia itself. Ten variations were identified including ‘Creative Multimedia (MM)’, ‘Interactive MM’, ‘MM Communication’, ‘MM Computing’, ‘MM Electronic Technology’, ‘MM Studies’, ‘MM systems’, ‘MM Technology’, ‘MM Visualisation’ and ‘MM web production’. Some discussion took place as to what these terms may actually mean, what the courses which used these titles focused on, and whether students would necessarily understand differences between the various titles.

The next stage of our investigation focused on the placing of the word multimedia or one of its curriculum variants in the course title; some courses offered multimedia or a variant alone, some offered multimedia or a variant with a specific topic (e.g. Multimedia systems and theology), and some offered a specific topic with a multimedia or variant (e.g. Chemistry and Multimedia Technology). A classification system was drawn up to structure course titles in order to identify any development patterns (table 2). The data from this examination indicated that, in the vast majority of cases, the term multimedia or variant had been coupled with another subject study area to create a combined degree (over 478 courses from 614 making 78% MM course provision coverage).

Table 2. Course titles and place of 'multimedia' i.e. Multimedia and topic, 'Topic and multimedia', or 'Topic, topic and multimedia'. HND courses usually cover a period of pre-university study up to and sometimes including the first year of a degree level course.

As a next step we made a provisional examination of these multimedia combined courses in order to identify any specific areas of growth or development. This activity proved to be very subjective and whilst coupling multimedia with some subjects seemed to make some rational sense (e.g. Multimedia Communications & Business Studies, or Multimedia and Internet Technologies) others proved to be more taxing on our immediate understanding (e.g. Geratology and Multimedia Systems). We were particularly curious about ‘Complimentary therapies and aromatherapy and Multimedia systems’ insofar as whether the course utilised the sense of smell alongside text, images, audio and graphics.

In order to limit subjectivity we established a Faculty classification system. Taking the Faculty and Department structure at Lancaster University as a framework, each course was placed in the Faculty which would best provide a home for its study; for example, Mathematics and Multimedia Communication was placed in Applied Sciences due to the mathematical and possible technical components of what may be meant by Multimedia Communication. This classification system resembled the hierarchical classification systems used in phenomenographic

2 The figure of 617 reported here shows an increase on our earlier reported figure of 614 due to 3 new courses becoming available in the period between our initial analysis and contacting the UCAS for a statistical search.

3 We refer to these as Multimedia offspring or Multimedia variants

4 Further Education (FE or tertiary education) is usually the stage before Higher Education (HE or university) for many UK based students.

5 Foundation Degree (FD) is sometimes referred to as a Year 0 course and can be taken prior to University (HE) study.
The analysis of this data highlighted three areas of interest and discussion:

- That over a quarter of all multimedia related degree schemes and modules were related to Arts and Humanities
- That ICT and Applied Sciences (including computing and networking) accounted for less than 15% of multimedia degree and module related delivery
- That expansion of multimedia courses related to Business and Management and, in particular, the emergence of e-business and e-commerce courses, were higher than expected.

Diagram 1. Faculty distribution of multimedia related courses highlighting areas of highest course provision. Our own newly developed course, Learning Science & Technology, was not included in the statistical analysis but would be placed in Social Sciences (indicated by *) or video related [9].

In consideration of this result we are aware of the subjectivity involved in the Faculty placing of each course, even allowing for judging and co-judging described. In order to refine these results it became necessary to examine the rationale and structure for each course provided. However, before setting out to complete such a detailed analysis for all 614 multimedia related schemes specified, we felt an examination of a sample of these courses would help us to best determine how to go about this task and what such an analysis may yield. This led us naturally into the second of our initial questions as to whether the definition of multimedia had evolved and how it may have done so.

Initial course rationale analysis
In our previous examination of course titles we took care to track Higher National Diploma (HND) courses separately from degree courses. HND courses tend to be delivered by colleges with a Further Education (FE) focus or those which may not be able to resource and staff a complete degree course. This is illustrated in the data (table 1) where 62 of 90 HNDs are offered by FE focused establishments. One further difference is that HNDs have tended to be skill or vocational orientated qualifications, compared to HE awarded degrees which may comprise levels of reflection or meta-cognitive components. To examine this situation for multimedia related qualifications we acquired details of a number of schemes for analysis.

The first HND in Multimedia in FE in the United Kingdom was produced at Halton College and validated by the Business and Technology Education Council (BTEC) in Summer 1996. The rationale for this course states:

6 With Dr. Michael Pengelly, CSALT, Lancaster University
"The proposed course in multimedia has been developed to provide students seeking a career in multimedia with experience, knowledge and awareness of production, management and technical aspects of the relevant environment. It is expected that students following the course will leave well prepared for further study in higher education or for working life in a commercial or business setting.... Construction of the course has been centered around multimedia production, authoring, design and management, forming the main themes of study for both years."

(O'Donoghue, 1996: 5)

The course made use of 12 key modules which covered aspects of design and production equally and was delivered by a team of tutors drawn from the cross-college multimedia department. The emphasis on "production, authoring, design and management" provides an indication that the course was skills focused. This can be compared to a degree scheme in multimedia produced at the same college the following year whose rationale had a wider developmental focus:

"? [to] create a core of multimedia activities, projects and studies compulsory for all students
? [to] create a progressive system of study and workshops moving from the skill based to the academic and abstract
? [to] create a series of options to facilitate general awareness of the changes in multimedia developments (both physical and in thinking), and to support future career choices."

(O'Donoghue, Potter & Molyneux, 1997)

The scheme also called for "Project deconstruction and critical analysis of multimedia work [as] essential components of each area of work", a mechanism for meta-cognitive activities and reflection within the scheme as a whole.

An examination of an HND provided by the University of Huddersfield in 1997 stands in comparison to these two schemes as an HE rather than FE provider of this qualification. This course developed and taught by the School of Computing & Mathematics offered the following rationale:

"Information (text, images, audio and video) is increasingly being presented in digital form for delivery by computer based systems. The pathway is concerned with applications of the converging technologies of computing, communications (including cable) and digital media, and with supporting the design and production of attractive and imaginative vehicles for learning, entertaining, marketing, information provision and cultural exchange."

(Topping et al, 1997)

Documentation suggests that design activities follow-on in year two from earlier computer related activities in year one, such as resource database management. However two specific aims of this course indicate a mixture of skills training coupled with reflective practices:

"? To provide an environment for students to develop technical and design skills in producing, and supporting the production of multimedia.
? To produce diplomats who understand the importance of multimedia in today's world, and have the technical and design skills to communicate effectively using the tools and structures of the new media."

(Topping et al, 1997)

Comparing these schemes to more recent activities allows us to investigate the possibility of a development in understanding or an evolution in what is understood by multimedia.

One related module to an existing degree programme in Educational Studies at Keele University, UK, is called 'New Learning and its Technologies' and is designed to:

"...develop the skills and theoretical knowledge and understanding necessary to produce interactive multimedia (IMM) resources for educational purposes. The two main aims of the module are: to introduce students to rationale for the use, design and creation of interactive multimedia resources intended for use in higher education; and to assist students to create an IMM resource that exemplifies good practice in the design and evaluation of such materials."

(McLean and Denning, 2000)

Whilst the paper reports a variety of findings on how students progressed with the module and took on a variety of roles to complete their tasks, from the course design viewpoint it is interesting to note that the multimedia component forms part of the context for the subject matter, i.e. multimedia is not studied alongside other subject materials independently, but is used to produce and reflect upon course materials as a means of providing a deeper insight into or to offer a new viewpoint towards subject based theoretical knowledge.

Further evidence of multimedia production, design and evaluation used to exemplify subject skills has also been identified in other schemes, including a degree scheme in 'Interactive Multimedia Arts and Animation'. (Potter et al., 2000).

As a result of these reviews there are indications that a number of multimedia related courses may have moved from a position of relatively independent study of technical skills and creative design to one of contextual support and communication embedded in other subject domains. The extent to which this situation is supported is, as yet, undetermined, and it seems likely that some HEIs will offer multimedia with a subject option with little thought of cross-over of context or reflective practices for financial reasons. However, these glimpses of change add purpose to a more detailed study of all 617 course structures and rationales available. This work is currently in progress."

(We expect to be able to report on this work during our presentation.)
Learning outcomes from multimedia course provision

With such a wide array of multimedia and subject topics available it seems appropriate to question the learning outcomes from such studies. As many of these courses are new there are few students who can yet be questioned on their experiences, skills and concepts of multimedia as a result of their study. However, one such evaluation on students perceptions of multimedia allowed us to make an initial examination of possibilities.

The evaluation was carried out with 12 students participating on a HND in Multimedia course at Knowsley Community College, UK (O'Donoghue and Machell, 2000). During the first year of the course students were asked to define multimedia. Answered tended to focus into two groups;

- those which split multimedia into components for production and integration, e.g. "Visual, sound, text and video, within a digital format that can be accessed and navigated by the user";
- those which were more generic by nature, e.g. "Multimedia is the ways in which to communicate, changing a situation by decision", "A computer course with a bit of everything".

The course design consisted of a six month period of intense skills development with a range of authoring tools, graphics packages, and audio-video software, followed by a period of project work which included industrial work placements and transnational project visits. When the students were interviewed one year later their definitions of multimedia were now related to their project work and their experiences which they used as a frame of reference to explain applications rather than the stand-alone definitions previously reported.

In his examination of learning towards a synthesis for networked learning environments and online communities, Goodyear (2002) provides an account of three kinds of knowledge (academic, generic and reflexive). In doing this he introduces the term 'Working Knowledge' to which he assigns a number of attributes including "knowledge which is relevant to one's own work (when the work may be in academia or in what other people take to be the real world)" and "the idea of knowledge and knowing as an active and dynamic rather than passive and static". He goes on to add:

"Learning in higher education should be imbued with a belief in the particular value of 'working knowledge'. Understanding and engaging with different 'ways of knowing' is key to effective action in academia and in the workplaces of today's knowledge economy."

(Goodyear, 2002:55)

Developing Goodyear’s theme to contextualised multimedia learning, it is possible to suggest that the skills of manufacture and production with a variety of contexts become a ‘working knowledge’ which the multimedia graduate can build on, in which case, the study of multimedia within a hybrid course or alongside a subject base may have many benefits, especially in meeting employers’ expectations (see Harvey and Mason, 1996). However, there are also other themes and issues to consider, not least those of Wild and Quinn (1998) who “… advocate the development of a coherent model or models of instructional design in multimedia”, and those of McLean and Denning (2000) who have adopted a constructivist approach to Interactive Multimedia Learning. More data is required on student’s ideas and abilities in multimedia as a consequence of the many courses now available in order to determine the relationships between course design, rationale, tuition, and skills and concept development.

Summary

In this paper we have provided data and analysis on 617 courses available in the UK which make reference to or use of the term ‘multimedia’. A large number of such courses (78%) offer multimedia or one of its curriculum variants with a specific topic. Whilst many of these topics appear to complement the use and application of multimedia and its associated technologies, other do not appear to do so immediately. This gives rise to speculation that some HEIs may be offering courses with a component of multimedia to attract students who may not otherwise attend specific courses or institutions. Analysis of course provision suggests that multimedia related courses have increased in Arts and Humanities subject areas, and in Management and Business related subject areas, more than in computing or other ICT related areas, though the authors acknowledge limitations due to subjectivity of classification.

A limited examination of course rationales suggests that multimedia course design may have undergone a shift of focus, from an almost independent skills-based and technology-led provision, to one in which multimedia is used within a specific subject context. The benefits of this kind of course provision in relation to learning have been briefly discussed, though it is recognised that this area is worthy of more detailed debate and was not intended as a principal focus for this study.

Implication for multimedia course designers and tutors

If such a shift in the focus of multimedia learning has taken place, perhaps in other countries as may be happening in the UK, a series of questions arise with broader implications for tutors, course managers and students, not least with assessment procedures, quality of tuition and work produced, teaching strategies, and whether industries dependent on students emerging with a multimedia qualification, especially in a subject related variant, find such graduates preferable to those with perhaps a single technical or design focus. There are also implications for resources which multimedia course managers need to contend with, such as access to equipment, actual time spent in multimedia production activities, and staff training for non-technical tutors asked to participate in forms of multimedia production or learning activities⁸. Perhaps the area with the greatest implication we are currently examining relates to what we may think of as the essence of multimedia; if our indications of the movement of multimedia from independent subject to embedded communication and reflective medium for other curriculum subjects are true, then perhaps a rethink of multimedia teaching is required in order to best suit the needs of students, employers, and academic non-multimedia subject specialists.

---

⁸ Some of these issues are raised by McLean and Denning (2000) and we expect to report on this situation in more detail during our presentation.
Finally, on completion of this study, we asked ourselves the question whether it was appropriate to remove the term multimedia from the title of our own new degree scheme. Insofar as we have given the multimedia components much thought and considered constructive and re-constructive methods for employing multimedia in the communication and the contextualisation of theories of learning, replacing multimedia in the title would seem to be a more accurate description of the content and activities of the course. Additionally, in marketing terms, given the relatively few courses we were able to identify within Social Sciences with a learning component (see diagram 1), the inclusion of the term, within the multimedia learning arena as a whole, would appear to represent a purposeful promotional opportunity for the department and the university, but we consider this secondary to the quality of course provision and the course design.

Continuous Zoom applied to texts

Abstract
The amount of text that we are required to read in the present days is amazing. One of the reasons for a poor performance of electronic text systems may result from the fact of users to avoid reading the whole text and make decisions mostly based on their headings (Fox, 1992). Aiming to minimize this problem, we have developed a computer-based tool for continuous zoom interfaces (graphic interface that allows a text to be continuously magnified or decreased). Prior to displaying the text, this tool performs a previous analysis of the text, taking into account its grammatical classification. Then, the text is displayed in its most condensed format and lowest zoom level, where only the most important words are shown. For that, the tool uses the artificial intelligence technique (pattern recognition). The text is then displayed in its most condensed format and lowest zoom level. As zoom increases, more elements of the text become visible. It should be highlighted that the tool deals with language “traps” and whenever the pattern recognizer fails to classify a certain word, it makes that word visible in its most reduced zoom format.

Introduction
Zoomable User Interfaces are a kind of information visualization [2]. Ken Perlin of New York University defined the concept of Zoomable surface [1]. Ben Benderon designed and implemented PAD++ tool, which in Maryland University gave rise to Jazz [2], which in turn provided a Java API to develop the Zoomable User Interfaces (ZUI). When working with version 0.6 of Jazz, we had to make several extensions to its original format.

The objective of this work is to contribute to reduce the effort to read general electronic documents; to produce and test new ways to analyze texts and identify patterns of sentence constructions, as well as to classify grammatically each of their components. One of the most important questions about electronic documents lies in the research of their usability, which advantages will be provided and how they will be [4].

The idea is that the tool is able to analyze any type of electronic text under the most diverse formats, such as .doc, .html, etc, and then handle the text through a continuous zoom interface. Each text would be submitted to both a standard dictionary (an inference motor) of a specific natural language, and another zoom-related dictionary. This latter dictionary would be specific for each style of text and would serve to define the right zoom time when a certain class of elements (text) would be displayed in continuous zoom interface. At all times, text integrity would be preserved. In other words, should the inference motor fail to “find out” the class of the element, this will be visible from the first zoom level.

Pattern Recognition
Natural languages constitute a number of traps for any pattern recognition tool; for instance, a Word may have several meanings under diverse contexts. Such meanings could lead to a different grammatical class. In English, the word Kiss analyzed separately can be either a verb or a noun. The final definition will depend on the context it is employed. In other words, almost always it is necessary to analyze a whole sentence to be able to define the grammatical class of each of its components. Sometimes, the definition of a particular element of the text can influence that of another text. This problem may lead the inference algorithm to an endless loop condition. In this case, after a certain number of attempts, our program ends by classifying the word as "indefinite classification". This special class is given a differentiated treatment. Should a second element, in order to obtain its classification, need the classification of another element in the same sentence and the latter is defined as "indefinite classification", the former also assumes this condition.

Therefore, as shown below, at constructing our patterns, we should be more economic in generic expressions, that is, we should use to the extent possible rules that should not depend on others. The more indefinite classification we have, the poorer the results obtained. There is also the problem of verb conjugations. Here, the existence of a rule to deal with them is indispensable. Otherwise, we would fall into the "indefinite classification" condition. Word classifications may be constant, such as adjective, adverb, definite article, verb, etc., or indefinite.

Also, there is a special treatment for abbreviations. Our program tries to identify them as soon as possible, at an early stage as we separate the sentences. This process is important because the context to be analyzed is always that of a sentence. Likewise, punctuation is also viewed in a
special way. There are marks that serve to end sentences and other do not. We list below a punctuation table used by the program.

Finally, there is the dictionary itself, which is constituted of lines of a text file. Each line represents the definition of a rule for word classification. Therefore, each dictionary line follows the following formation law:

\[ \text{<word>:classification1(context1)}|\text{classification2(context2)}| \ldots |\text{classificationN(contextN)} \]

"word" is the term that we are trying to classify; "classification" (shall obligatorily be in the classification table); and "context", has its own structure:

\[ \text{(element1,element2,...,elementN)} \]

Element includes: classification (as defined above), point, word, or reserved words (**) meaning that it does not matter how many and which elements appear in that context position; (qq) means that it does not matter which type of element appears in that position, however the quantity should always be match the number of occurrences of the expression (qq). The examples below illustrate how such rules work:

Example:

\[ \text{KISS: VERB(*,PRON,KISS,**)} | \text{NOUN(*,KISS,**)} \]

The word KISS appears in the dictionary under two possible classifications, depending on the context. It is a verb when it is preceded by a pronoun, regardless the rest of the sentence or what comes before of after the binomial "PRON", "KISS". In cases where this rule fails, the dictionary will try the next one, which will classify it as a noun, under any context. It is if we were working with the structure: Exception1, Exception2, ..., ExceptionN, General Rule.

Obviously, the more and better the dictionary is worked out, the better the program performance. We find that the construction of this base of knowledge is a good exercise for subjects related to the teaching of natural languages. Upon analyzing a text, the program produces two files as processing byproducts. In the first file, each line represents a word, its classification and the sentence of the text where it appears.

This means that the word He was classified as a pronoun in the sentence He gave a pie, and so on. The second text file list the expressions that could not be classified and need be defined or better worked.

Finally, after all this analysis, the main output of the program is a list of sentences of the text, where all their components are classified in a way or another.

**Continuous Zoom Interface**

Of all extensions, that dealing with the management of the zoom stands out. Since we are working with text, each element will be assigned its particular zoom control. This is due to the fact that we will control the exact time when the element (text) will be visible to the final user. That time basically depends on both its classification defined as above and the text style.

To address this issue, the program will be provided with a zoom dictionary specific for each style. Note that while the pattern dictionary defined in the previous section is generic for a given natural language, our Zoom dictionary is more specific. This way, the program can work with any combination of both the dictionaries predefined by the final user.

Specifically, zoom dictionary adopts the following format for each one of their lines in the text file:

\[ \text{<classification>}: \text{magnitude level1(Context1)}|\text{magnitude level2(Context2)}| \ldots |\text{magnitude levelN(ContextN)} \]

Where:

Magnitude level is of java float type, which determines the time when elements under that classification used in that context become visible. Zero value indicates that said element will become visible right at the first moment and is therefore an essential part of the sentence. Its suppression will make the sentence senseless, or worse, it may change its meaning.

Concluding, we would like to add that, for aesthetic reasons, the automatic realignment of lines as the different elements of text appear and disappear has not been yet implanted. It is worth stressing that the user can magnify the text (zoom in) or reduce it (zoom out) at any time.
Learning management Systems: One Size Fits All?

Learning management systems such as WebCT and Blackboard are rapidly becoming the principal systems behind institutions' moves to technology-based learning settings. In settings where lecturers have had no or limited exposure to ICT as a teaching tool, LMSs pave the way for quick introduction and eventual adoption of technology-based teaching practices. Many lecturers quickly progress and grow in the field. But there are those who argue that the use of LMS tend to be counter-productive and that in their current forms, they cannot be used effectively as a learning tool. Critics argue that they support only traditional forms of teaching and encourage poor learning designs in their implementation. This panel will explore LMSs as they exist today and will explore whether they are the solution to a pressing problem or in fact problems within themselves.

The Panelists
1. Allard Strijker from University of Twente in The Netherlands whose interest is in the concept of learning objects and reusability.
2. Duan van der Westhuizen from Rand Afrikaans University in South Africa with an interest in staff development and ICT adoption within the University.
3. Tom Reeves from the University of Georgia, USA, has expertise in the evaluation of technology-based learning;
4. Barry Harper from Wollongong University in Australia who is working on a large project exploring the development of generic learning designs for Web-based teaching and learning; and
5. Ron Oliver from Edith Cowan University in Australia will chair the panel session.

Session Summary
Duan van der Westhuizen (South Africa): LMS as successful change agents for HE
The use of LMS with their seamless and intuitive support for Web-based learning has helped to pave the way for institutions and organisations throughout the world to adopt ICT as a support for teaching and learning. They necessarily lack some flexibility and openness in their design so that they can be used by novices and experts alike. Duan will argue their strong influence and obvious success with some data showing the level of use and uptake in the short time they have been around.

Allard Strijker (University of Twente): "One Size, but still growing, LMSs: up to the next generation"
I think the current forms of LMSs are a solution that will not last long. The information that is retrieved form the objects are most of the time not useful or needed for standalone bases. LMSs will be incorporated within overall management systems and will be a feature that can be added to the existing Human Resource Systems. The weakness at this moment is that LMSs are used as a combination between portals and extended logging systems. The information that comes available is most of the times not used for adaptive learning or for management decisions.

Barry Harper (University of Wollongong). Designing Learning with LMSs
While many criticise LMS because they don't provide any learning designs, in many cases they don't need to. With the development of generic learning designs, the various LMS become very powerful tools and their flexibility and apparent lack of structure is perhaps their most powerful attribute (not the weakness that many claim). LMS serve very useful purposes if they are designed to be able to deliver resources of many forms to the users, coupled with powerful communication supports and learning management supports.
High quality assessment is the lynchpin in an effective learning environment. Although LMS provide opportunities for alternative forms of assessment that faculty may fail to utilize, they also have their limitations. Tom's stance will be both critical and constructive.
Online Learning Design For Dummies: Professional Development Strategies For Beginning Online Designers

Abstract: Much of the conventional development of Web-based learning environments stems from design strategies that are based on providing delivery of the course content. Contemporary courseware delivery systems encourage teachers to see the design of online learning as settings as a process of electronic delivery of content and information. As a consequence Web-based courses have tended to display limited evidence of an underpinning learning design and varying degrees of use of the opportunities and affordances of the new technologies. This paper provides an overview of instructional design principles that can guide beginning designers in the creation of Web-based learning materials that support learner engagement and knowledge construction. The paper suggests strategies for professional development activities that can help beginning designers to reconsider their pedagogy and to understand the processes required to design effective settings for online learning.

Introduction
Despite modest gains and often questionable achievements, there is still unbridled interest and enthusiasm among institutions and organizations for online learning and e-learning as the means for the presentation and delivery of higher education. Online learning has been mooted as the solution to many of the problems that face institutions of higher education. Many writers have argued the use of e-learning to attract new markets and new students. Others have argued its capacity to increase levels of equity and access for existing students, while some see the new technologies as capable of reducing the costs of delivery of programs and courses (eg. Holt & Thompson, 1998; Fraser & Deane, 1997; Nunan, 1996). While many of these claims and potentials have yet to be verified the one thing we have learned from our activities in this domain is that e-learning, when done well, can improve learning and deliver enhanced learning outcomes and has the prospect to transform the way education is conducted in these settings (Biggs, 2001)

The criticisms that many people hold for much of the current effort in the design and delivery of online learning stem from the narrow instructional design models upon which much of the material is based. The design models in use appear often to have evolved from the economic, efficiency and marketing imperatives (eg. Dehoney & Reeves, 1999; Mioduser, Nachmias, Oren, & Lahav,1999; Burbules & Callister, 2000). With on-line delivery it is possible to pursue these imperatives and at the same time to pursue such goals effective teaching and learning.

Staff development for online learning
Much of the development of online learning settings is currently undertaken by academics with little experience or expertise in this field. The skills and understandings of learning that many teachers develop through their face-to-face teaching are often insufficient to support their needs in online learning settings. Those academics who feel comfortable working with technology in online environments are rare, and there is generally little transference of expertise to their colleagues (Bennett, Priest, & Macpherson, 1999), a situation compounded by an increasing number of sessional and part-time teachers (Van Dusen, 1997).
There is often a resistance to technology amongst university staff. Factors include a lack of experience or confidence in using technology, caution about methodologies teachers regard as unproven, and a belief that computer-based options threaten the human interaction teachers value in face to face teaching (Sparrow, Herrington, & Herrington, 2000). In particular, the speed of adoption of the Internet in higher education has caught many teachers unaware and unprepared to face the challenges required to succeed.

A crucial aspect of effective online learning may hold the key to the changing role of the university teacher. Wade (1994) argues that the promotion of learner autonomy means increased responsibility for the student which, if it is to succeed, requires ‘a strong framework of support and guidance for the student from the outset’ (p. 13). In designing effective online learning materials, perhaps the most important first step is to create a role for the teacher as one of coaching and scaffolding as an alternative to the more commonly used didactic forms of teaching. Novices frequently fail to achieve this in the online learning designs.

**Changed roles for the teacher**

A traditional approach to the design of learning environments proposes that the best way to deal with complexity is to simplify a topic by breaking it down into its component parts. However, Perkins (1991) suggests that the temptation to over-simplify learning environments should be resisted, and instead designers and teachers should search for new ways to provide appropriate scaffolding and support. In this situation, the teacher provides the skills, strategies and links that the students are unable to provide to complete the task. Gradually, the support (the scaffolding) is removed until the student is able to stand alone.

Many designers and administrators of online units believe that they should be self-contained resources that include everything the student needs to learn a particular topic. However, teachers who expect students to work individually on online units are not only denying them the benefits of collaboration, but also the benefits of expert assistance—providing hints, suggestions, critical questions, and the ‘scaffolding’ to enable them to solve more complex problems. Collins, Brown and Newman (1989) point out that coaching is highly situation-specific and is related to problems that arise as students attempt to integrate skills and knowledge, a role that is still best performed by the teacher. Instead of providing and delivering information, the lecturer’s principal function is to create collaborative, challenging and supportive learning environments within which the learner operates.

**Instructional Design for Web-based learning**

Conventional approaches with their content-based approaches can be difficult molds for many teachers to free themselves from. In our work with such teachers we have developed strategies that we have found quite successful in assisting this move. In previous research, we have described a framework for designing online learning settings (Table 1). The framework comprises three interconnected elements which are presented as critical components for the design of learning settings. In particular, the framework highlights various distinctions between the elements involved in the design of online learning settings (Oliver, 1999).

<table>
<thead>
<tr>
<th>learning design elements</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>learning tasks</td>
<td>The activities, problems, interactions used to engage the learners and on which learning is based</td>
</tr>
<tr>
<td>learning resources</td>
<td>The content, information and resources with the underpinning knowledge and with which the learners interact</td>
</tr>
<tr>
<td>learning supports</td>
<td>The schedules, scaffolds, structures, encouragements, motivations, assistances and connections used to support learning</td>
</tr>
</tbody>
</table>

The framework provides a means to identify the various elements within learning settings and suggests emphases which can be made in the instructional design process. Contemporary learning theories posit that the forms of learning design most appropriate to higher education are those based on constructivist learning principles. The above framework takes on particular and discrete forms when applied this way.

**a. Learning Tasks**

Most beginning online learning designers commence their planning by considering the content to be learned. Such approaches are very common and characterize online settings based on pages of text and images which
learners are required to read and follow. The learning activities in technology-based environments play a fundamental role in determining learning outcomes (Wild & Quinn, 1997). They determine how the learners will engage with the course materials and the forms of knowledge construction that will take place. Contemporary thinking suggests that the activities must be active and engaging (eg. Wild & Quinn, 1997).

The beginning online learning designer must be encouraged to think not about content but about how learners will be required to use the content. They need to consider ways to engender cooperative and collaborative activities among learners which provide opportunities for reflection and articulation. The selected activities need to provide the purpose and the context for learners to deal with the content and information (Duffy & Cunningham, 1996). The designers need to plan activities with an active role for the learners in which there is encouragement and provision to take control, make decisions and act in a self-directed fashion.

b. Learning Supports
While considering the forms of learner activity the beginning online designer must also plan ways for the setting to support the learner. This critical design element involves the provision of the support necessary to guide learners and to provide a feedback mechanism which is responsive and sensitive to their individual needs (eg. McLoughlin & Oliver, 1998). A number of writers have developed frameworks to describe the ideal forms of support required for on-line learning environment and in each case, there is usually a strong argument made for an active and involved teacher (eg. Laurillard, 1993). The role of the teacher needs to be planned as that of a coach and facilitator in place of the more didactic style often assumed. In contemporary settings, this form of learning support is called scaffolding in recognition of the way in which it helps to build knowledge and is then removed as the knowledge construction occurs.

c. Learning Resources
In choosing the learning activities and planning the supports for learning, the requirements for the forms of course content required will become evident. In learning environments based around learning tasks, learners will need access to a variety of forms of content. The materials need not all be on-line. The use of conventional materials along with electronic sources can provide the diversity often required. Previously designers created course materials where the content was rigidly organised and presented to the learners in a strict sequence. Today it is recognised that learners need to be able to access resources in a variety of ways and from a variety of perspectives (Herrington & Oliver, 1995).

An Approach to Web-based Instructional Design for Beginners
Putting these elements together in a meaningful and effective fashion is aided considerably if beginning online designers follow the 6 stage process outlined below. This process provides an organizational framework that can assists novice designers and teachers to focus on strategies that create learner-centred settings which can engage and support student learning. The framework helps to remove the attention away from the content as the organising element towards learning tasks. The provision of such a framework for the novice designer provides a strong scaffold for their learning, particularly if models and exemplars are also provided for them to follow. It is often a very simple process to model the form of professional development provided around this framework as well.

Table 2: Task-based design strategies

<table>
<thead>

</tbody>
</table>

1. Planning the intended learning outcomes
The best place to commence the process of developing the online learning resources is by considering the intended learning outcomes. The beginning designers need to recognize that intended learning outcomes need to be expressed in terms that describe the learning that will be achieved. For many courses, it is possible to express objectives in terms of the learner performance or competency.
It is important that the learning outcomes are not expressed solely in terms of learning process or strategies. The processes and strategies are the means by which the learning will be achieved. It is important for the beginning designers not to confuse the activities, which are a means to an end, with the intended learning outcomes.

2. Planning the learning tasks
Once the learning objectives have been stated, beginning designers need to consider and plan the learning processes that will provide learners with the experiences that will help them to learn. The learning processes need to be carefully planned with the intended learning outcomes in mind. Planning the learning experiences involves consideration of ways to engage the learners in ways that will cause the required forms of cognition and thinking. The learning activities need to involve a variety of processes that will cause the learners to deal meaningfully with appropriate resources and information.

The best forms of learning activity to consider are those that are authentic. Authentic activities have been described earlier and usually involve the development of a product or an artefact in much the same way as the learner will need to demonstrate and practice in real life. Effective learning designs often involve forms of communication and collaboration, activities that encourage the learners to reflect on their learning and to articulate their ideas in ways that strengthen and assist the knowledge construction process. Some examples of typical learning designs include:

- Having learners design and evaluate a project plan or proposal. To complete the design the learners need to develop skills and competencies in the underpinning knowledge and concepts;
- Having learners work collaboratively to develop a solution to an ill-defined problem. The learners need to plan the problem solving process, gather the necessary information, decide on the steps to be taken, suggest a solution and demonstrate the reasoning;
- Having learners assume the roles of particular players in a role-playing setting. This involves exploring the person whose role they are playing, understanding the context and the issues and acting in scenarios in ways that use this knowledge to build a further understanding of the person and the setting.

The critical factor in planning the learning design is to consider activities that are independent of the learning resources. It is important when planning the design not to be concerned with the content and resources and to see these as completely independent elements in the design process.

3. Choosing assessment strategies
At the same time as the learning activities are being planned, it is important to decide how the learning outcomes will be assessed. The use of authentic learning activities provides a sound basis for assessment since the outcomes from the activities often demonstrate the extent and scope of the learning that has been achieved. The assessment strategies need to be derived from the stated learning outcomes. It is important that the forms of assessment not only provide evidence of the extent of learning but also provide guidance to the learners in ways that can model and demonstrate areas where further activity is still required.

4. Planning support strategies
Online learning is best designed with deliberate and intentional support mechanisms for learners. There are many possible support strategies that can be implemented and these include roles for the teacher, other learners, workplace associates, peers, and mentors. It is also possible to plan the learning activities so that they have inbuilt supports and to provide resources which can assist in supporting learners.

The purpose of any support in an online setting is to enable learners to undertake the activities that have been set in ways which assist their independence and self-regulation. With authentic learning settings, students will require a range of supports to assist them as they develop their knowledge and skills. Many of these supports, scaffolds, can be reduced as the learning process progresses to the point where the learners develop the capacity to cater for themselves. Beginning designers can be encouraged to plan the supports as they plan the learning tasks. Often the tasks suggest the forms of support that will be required.

The planning of support strategies should be a part of the planning of learning designs and learning resources, both of which have the capacity to provide supports for the online learner. Learning activities that provide learning support include collaborative settings, settings involving workplace activities, involvement of buddies...
and mentors. Learning resources that provide supports include such items as templates, checklists, learning pathways, and performance support systems.

5. planning the resource needs
In order to complete the learning activities, the learners will need access to a variety of resources and information and part of the design process is to decide the forms and extent of the resources that will be needed. Learning resources can take many forms including such information sources as textbooks, newspapers, journals, and online information sources. The beginning designers need to select resources from a variety of settings. They should be discouraged from considering writing and developing the resources themselves. They need to be encouraged to consider reuse and choosing from among those that already exist.

Depending on the forms of learning activity, the resources might also include documents and manuals from industry settings, legislation, rules, procedures, and policy manuals. In online settings there is considerable scope for the use of existing documents and resources. Often the environment will include resources that have been specially built for the learning setting. For example, examples of previous students' work, interviews with experts, selected readings, compilations of resources. It is not uncommon for the resource sets to contain tutorials and learning modules to assist students to acquire some of the underpinning skills and knowledge.

Part of the design process is to determine what resources students will need to complete the activities that have been set and to collect (and make) these resources for the learning setting. As more and more resources are being placed on the Web, the need for developing resources is diminishing and many learning settings are able to be resourced almost entirely from existing materials. The majority of the resources in online settings should have no instructional elements. It is best to separate the learning activities from the learning resources so that both the resources and the activities can be modified and customised and reused. When the resources are also instructional elements, the capacity for customisation and reuse is significantly hampered.

6. planning the organization strategy for the online materials
Once the learning activities, resources, and supports have been designed, the final stage is to consider an organisational and contextual strategy that will provide a natural and intuitive setting for them. There are many ways to organise online learning settings. Many teachers will have access to powerful online courseware delivery systems such as WebCT and Blackboard. These tools provide their own organisational frameworks for the learning setting. In some cases, it is possible and useful to design a unique interface and organisational structure, for example, a virtual setting reflective of the learning context.

Beginning designers with access to courseware delivery systems are often able to play a significant part in the process of developing the online setting. The critical factor in organising the setting is to ensure that all aspects of the learning designs, the learning resources and the learning supports are clearly evident to the learners and freely accessible. The site needs to enable learners to move freely within and to know at all times where they are in the hyperspace and how to get to all other places.

Summary and Conclusions
We have been working with beginning online designers for some years now across a variety of projects and educational sectors. Many of those looking to design and build online courses for the first time, have preconceived ideas about how the setting will be formed and many times these ideas are based on very conventional views of teaching and learning. The strategies we have presented in this paper provide a strong framework to guide the professional development of these teachers. The framework provides a structure which causes the teachers to rethink their pedagogies and to plan engaging and active learning settings where the role of the teacher is more a coach and facilitator than an expert delivering content. As well as providing a mechanism to assist in a pedagogical rethink, the framework also provides a form of blueprint and template to guide effective design strategies.

The biggest challenge we have found in providing learning support for beginning designers is to help teachers reconsider and to alter the pedagogical viewpoints they hold. Strategies that assist in this endeavour are tasks and activities that provide the learners with models and exemplars to follow. It is very important for the professional development exercise to practice what it preaches and for it to be an example of best practice.
are now many examples and cases for teachers to use for this purpose and the success of these endeavours is now
becoming evident in the growing number of quality online learning settings that are beginning to emerge.

Abstract: Maps are used to display information for educational and scientific purposes on a daily basis. The capability of generating web-based interactive maps by non-specialists and non-programmers is of great convenience. The map generating system described in this paper can handle any arbitrary map, including those with embedded and disjoined regions. The resulting web-based interactive maps can be used in many different applications requiring color-coded display of quantitative data.

1. Introduction

The Digital Flora of Texas (DFT) project has been actively pursuing the construction of biodiversity informatics tools for use by interested biologists, students, scholars and researchers. One of the browsing tools that has been used extensively is the Herbarium Specimen Browser (HSB), originally developed in 1996 and modified based on user feedback over the last five years. The HSB allows users to survey the content of collections from various herbaria throughout the state of Texas. It supports fast access and dynamic filtering of data on the fly. Information related to any combination of counties, herbaria and specimens can be displayed in real time by merely clicking on the interface shown in Figure 1.

The HSB also provides an interactive map that dynamically displays the density and distribution of herbarium specimens based upon user selections of plant families, genera, or species (Fig. 2). Clicking on a county displays the characteristics of the plant specimens that have been collected from the county by the selected herbaria. The HSB supports three mapping options: counties of the state of Texas; counties of the states of Texas, Oklahoma, Louisiana, New Mexico and Arkansas (shown); and, states/provinces of North America. Lastly, it allows users to query the collection using any combination of search terms such as name of herbaria, specimen accession number or country.

Of course, for this mapping system to work properly, someone must generate the map and associate commands that make it respond to users’ requests. In the original HSB, one had to obtain a map in PBM format, convert the map into Run-Length Encoding (RLE) format, and associate region names with the pixels in the image before the map could be used. The entire process was tedious and error prone.

The objective of this project was to simplify the process of generating a mapping system by providing a web-based automated tool that accepts some of the widely used graphics formats for the PC. In other words, given files in GIF, JPEG or BMP format, the system automatically generates the RLE file needed for the HSB or other run-length encoded mapping system. To remove the burden of manually associating region naming with the map regions, the system allows users to name map regions easily and generates the required files that allow the browser’s mapping system to recognize the regions being selected by the user.
A verifier is also provided that allows users to check and correct errors in their naming schemes and serves as a prototype for interactive mapping routines.

QIICC - Using Technology to Involve Students In Assessment

The objective for this session is to show participants a new and innovative way of involving students in the assessment process. Participants will learn how to incorporate the QIICC Analysis protocol into everyday assessment strategies. This lecture and presentation will include a demonstration of the QIICC analysis protocol utilized in a web-based quizzing system called Telequiz. During this presentation, the theory of the QIICC Analysis protocol will be discussed. This theory dictates that each question on a quiz be rated on several variables: Quality, Interest, Importance, Confidence and Challenge.

Qualities, Interest, Importance are measured in a straightforward manner. For each question a student answers on a test or quiz, they are asked to designate the quality of the question, their interest level in the content of the question and their impression of how important the question is to the learning of the course. Each of these variables is designated using a three-level scale: High, Medium and Low.

The next variable indicates the confidence students have in the accuracy of their answer. This is gathered using the same three-level scale, and affects the score that the student receives on each question. Maximum points are awarded for a question that is answered correctly with high confidence. On questions that have been answered accurately, scores fall as confidence levels fall. For those questions that are answered incorrectly, question score rises as confidence levels fall. This is due to the fact that if someone states high confidence in a wrong answer, or low confidence in a correct answer, there is a disconnect between what the student knows and what they expect to know. If a student indicates high confidence in a correct answer, or low confidence in an incorrect answer, there is no such disconnect. That student possesses a realistic understanding of their knowledge.

The final variable is challenge. In the QIICC analysis protocol, each student is allowed to challenge a certain number of questions per testing cycle. Any question that is challenged does not count against the score. This allows students to think critically about the form and content of a question, and take a more active role in the outcome of the quiz or test.

The QIICC Analysis protocol is designed to elicit student feedback on the quality of items found on a quiz or test. By doing so, it allows the instructional staff to better analyze the effectiveness of the individual elements that are included in the assessment process. More importantly, the QIICC Analysis helps students analyze their own knowledge levels, and by doing so, understand “what they know, and what they do not know.” In the QIICC protocol, students are scored on not only how accurately they answer a question, but also on how confident they are in the accuracy of their answer. This capability is a powerful tool for assessing student learning. Through the confidence variable, students are asked to take a much more critical role in the development of their knowledge. By asking for a confidence level and incorporating it into the grading rubric, it is much more important for a student to “know what they know” than is seen in other assessment strategies. By allowing for challenges, QIICC empowers students to feel comfortable with the assessment process and take control of the knowledge that is deemed important or worthwhile for learning.

Patrick O'Shea is an Instructional Technology Specialist in the Brunswick County Public School system. Currently, Mr. O'Shea is working on his Doctorate in Urban Services at Old Dominion University. Dr. Dwight W. Allen is the Eminent Professor of Educational Reform at Old Dominion University. Simon Richmond is a Doctoral Candidate at Old Dominion University, who has been responsible for overseeing the implementation of the Telequiz Assessment Tool. Dr. Allen and Mr. O'Shea envisioned and designed the Telequiz and QIICC Analysis protocols together, and piloted the protocol in Dr. Allen's Educational Curriculum and Instruction Courses for pre-service teachers at Old Dominion University.
Virtual Knowledge Communities in an Industrial Environment

Nelly Osorio, Honeywell CA*

Introduction:

Honeywell CA is a worldwide company leader in industrial automation. As a high tech business, needs to have its employees on the top of the technological advancements which means permanent training and development. Also it is going through a process for making digital all the activities including employees training. The strategy being used is the creation of a Knowledge Communities (KC) portal in the Intranet. This strategy is being supported and implemented in order to achieve the most of the employees learning by using the many opportunities available in that site. In this paper, the emphasis is the learning processes, cost reduction and goals. There will be also analysed the pros and cons of that modality of training for one Latin American affiliated.

Knowledge Communities at Honeywell IA Portal:

A KC is a remote virtual space for communication, problem solving, lesson learned sharing, training and knowledge building among Honeywell employees. It is a very rich learning environment represented in a portal that includes: 1) Knowledge Communities on products, markets, disciplines, roles and methodologies, and certifications. 2) templates, video tutorials, tips and tricks. 3) Training by using online presentations, video tutorials ordered and schedule. 4) Links. 5) e-Library. 6) Other key information resources.

The Knowledge Communities: There are 60 knowledge communities in the industrial portal by disciplines, products, markets, roles and methodologies. Each KC has a similar structure: members, best practices, tools, topics, lesson learned. The rationale behind each one is: sharing knowledge, problem solving, challenging our professionals and collaborating to improve and innovate for the generation of new knowledge. Each one has a Knowledge Manager.

Training: The Employee Learning Portal includes courses, links for training, video tutorials, online presentations, technical support and certifications. This is one the portal most important features for the digitization of the company. It is expected to reduce in a very significant amount training investment. Benefits expected: maintain people up dated on products and technology in a more effective way. On line training sessions are available to people anytime. Distance learning on line is also scheduled. The training opportunities and options are renewed and scheduled maintaining people up dated.

E-Library: people can find documents, resources and e-books in digital format. Key to Honeywell digitization initiatives as well as efforts to reduce paper copies.

Links: There are 60 links to possible sources of information, tools and key sites.

* Honeywell Andean Region Training and Development, Knowledge Community Manager in LAR.
Other Key Information Resources: there is available a diversity of information from airlines, dictionaries, people, search engines, writing guide, business, organizational charts, news, etc.

Cost Reduction Measures:

The system implemented in the portal permits to measure cost reduction by asking questions regarding: the number of people being trained, T&L costs if the training was taken in another place. That information is recorded and reports presented to the site administrator.

Some Advantages:

Sharing of knowledge at most, that was not done before.
Lesson Learned sharing between world wide affiliates
Improving of communication
Cost Reduction

Challenges:

Creation of the distance learning culture among employees.
Creation of the knowledge sharing among people
Creation of incentives for training on the web achieved
Learning Collaborative Learning: A Distance Learning Project in the DUSC Programme

Leif Erik Otteraa

Anja Stofberg
Cultural and Social Education, Rotterdam University of Professional Education, The Netherlands j.stofberg@hro.nl

Ida Margrethe Knudsen
Faculty of Education, Bergen University College, Norway imk@hib.no

Sija Geers van Gemeren
School of Health, Haarlem University of Professional Education, The Netherlands s.geers@hshaarlem.nl

Abstract: A joint Dutch-Scandinavian distance education project, part of the DUSC Programme, was carried out from November 1999 to the summer 2001. The aim of the project was to develop a module to train lecturers in how to develop a course based on using the concept of collaborative learning in distance education, and to test and evaluate the module. In the developing process, the authors themselves, from two different countries and four different faculties, went through a collaborative process, exploring different aspects of communication and collaboration at a distance. The main communication tool was the asynchronous German BSCW system, but also the synchronous tools NetMeeting and videoconference, and face-to-face meetings were used.

Introduction

The DUSC (Dutch Scandinavian Cooperation in Higher Education) Program was an initiative of four Dutch universities of professional education to develop expertise with Scandinavian institutions of higher education. A number of projects were outlined, and Information and Communication Technology (ICT) was an explicit sub-component of these.

One of the project groups was called CLiDE (Collaborative Learning in Distance Education). The aim of the project was to develop a module to train lecturers in how to develop a course based on the concept of active learning in distance education. The idea was that up to now lecturers have been trained to develop an active learning course in a classroom situation, but often do not have the skills to develop such a course for their students at a distance. After the development of the module the module was to be tested and evaluated by running it with a selection of interested lecturers within the educational institutes of the DUSC network.

The objectives stated in the project plan clearly divided our work into two different phases: Firstly, to develop the module, and secondly, to test and evaluate the module. Accordingly, the first few months we were supposed to cooperate and collaborate in a creative design and development process, and then, for the next months, try out our results with a group of students. Most of the collaboration was to be mediated by means of electronic networks. This way of organising a project work seemed very useful and interesting, because by developing a course in a collaborative way (phase 1), we would go through processes similar to our students when the developed module was to be tested and evaluated (phase 2). We believed that this experience would make us better teachers and tutors for our students. For distance education courses in general, this way of developing a course may prove to be successful.

The Project, Phase 1

This was in fact a distance project group, with members in two different countries (The Netherlands and Norway). We had to rely on electronic communication, and decided to do the greater part of our collaboration based on the asynchronous system BSCW (BSCW 2002). BSCW is a computer-based conferencing tool, developed at German National Research Center for Information Technology (GMD), and have facilities for a
great range of functionalities in the area of managing discussions and collaborative processes. We found this tool to be a good place for our discussions and contributions toward our final product: The module. We could all reach our common space in BSCW from wherever we were in the world, and so our project work, as far as this collaboration is concerned, was distance-independent.

Our Plan of Activity outlined four different elements or themes to be worked out by the project group: A: The concept of collaborative learning, B: The choice of the digital learning space, C: The practical experience and D: Critical success factors. Each of the project group members was assigned the role of moderator for one of the themes, and thus our responsibilities were shared by all of us. It was also our intention that being in charge in the moderating role would provide us, the project group members, with valuable experience in this aspect of conferencing and collaboration work. By doing this in phase 1 of the project, we felt we would be better prepared for the testing and evaluating part (phase 2).

We also planned other activities, other ways to do part of our project. In theme B, The choice of the digital learning space, we used a videoconference session, in addition to BSCW. In theme C, The practical experience, we used a synchronous, computer-based conferencing tool (Microsoft NetMeeting), and after theme C, we planned and carried out a face-to-face meeting in Bergen. See the complete report (Stofberg, Otteraa, Geers van Gemeren, Knudsen 2001) for experiences with these different sessions. A web-site (CLiDE 2000-01) was also established for the project; there we gathered some overall information, plans, links to literature, etc.

Our collaborations in phase 1 of the project resulted in two papers, The Concept of Collaborative Learning and The Tools, given as appendices in Stofberg, Otteraa, Geers van Gemeren, Knudsen (2001), meant as background material for the students in phase 2.

The Project, Phase 2

We defined four main tasks for our students, 1) Familiarising with the BSCW system and the group, 2) Problems and possibilities in digital learning environments, 3) About different tools and 4) Synthesizing and elaborating on different aspects of web-based collaborative learning methods. For each of the tasks, we specified certain learning objectives and a number of assignments. It was decided that the moderation was to be done by tutors in pairs. The two tutors would then take turns in taking the leading role in the moderation of the course, and would turn to the other if he/she needed advice or support in the moderation task.

Studying the contributions from our students, there are definitely a number of evaluative remarks worth mentioning. The tutors would corroborate that many of the issues were also the issues that affected the process and product of their collaborative work while designing and working out the course (phase 1). For the evaluation, we refer to the report (Stofberg, Otteraa, Geers van Gemeren, Knudsen 2001).

Conclusion

Keeping a long-term international relationship or collaborative project going is not an easy matter. Nevertheless, the special nature of this project made it possible. Building up expertise together, developing yourself and the group as a whole by going through a number of separate and clearly structured stages with each other, taking rotating independent responsibilities (to keep each one of us alert and motivated), pooling resources and knowledge, making joint selections, and then taking these personal learning experiences even further by putting them to use in the same project: this variety of elements and tasks kept the project alive and contributed highly to our achievements. All in all, we feel we have greatly benefited from this unusual experience provided for us by the DUSC programme.

Abstract: Multimedia elements addressing mathematical problems serve as an alternative or addition to classical forms of learning and teaching. Within the project math-kit we are developing a web-based toolbox to provide teachers and students with multimedia support to existing topics in maths. In this context, the integration of a computer algebra system (CAS) as a 'mathematical expert' offers many promising opportunities for the creation of internet-based learning units for undergraduate students. In this paper we show two examples of how the CAS MuPAD is used to create web-based mathematical drills with instant feedback.

Introduction

Mathematics is crucial for the understanding of many scientific fields especially the technical sciences. However, the level of abstraction of mathematics poses considerable problems for many undergraduate students. math-kit, a joint project of the four German universities Bayreuth, Hagen, Hamburg and Paderborn, as well as SciFace Software, is intended to offer support: we are developing a web-based toolbox to provide teachers and students with multimedia elements addressing mathematical problems.

The aspects of math-kit are many (see Bungenstock et al. 2002, Mertsching et al. 2002). In this brief paper, we concentrate on a single feature, namely the integration of the computer algebra system (CAS) MuPAD in some of our learning units. In particular, we show two examples of how the CAS can be used to create web-based drills with instant feedback.

Using a Computer Algebra System on the Web

MuPAD is a CAS which offers several powerful libraries for symbolic and numerical computing. Furthermore, all MuPAD functions can be used in internet-based applications. The main components of this model of web-based computing are a Java client applet (e.g. Terminal or Session Applet) and the MuPAD Computing Server, with JavaScript serving as the means of communication between input/output components of the web page and the client applet (Sorgatz 2001).

The Terminal Applet allows an online MuPAD session where the user can enter CAS commands as usual. Alternatively, the Session Applet is invisible to the user and can be considered merely as a means of communicating with the Computing Server. Here, HTML forms serve as input and output components whereas the CAS and its syntax remain hidden. In this setting, user input is processed and translated into MuPAD language via JavaScript; the computations are carried out in a MuPAD session at the Computing Server. The results are returned to the client and transformed again in order to obtain presentable output.

Two Examples of Web-Based Drills with Instant Feedback

It is crucial for successful learning to give the students the resources to practise certain mathematical methods and to test their performance. In this context, the necessity of constructive feedback has often been emphasized (see Musch 1999). These ideas were taken into account when developing exercises in math-kit. In this section, we present two examples of web-based drills with instant feedback using the Session Applet.

Differentiator

The Differentiator is a tool which allows students to practise differentiation. It offers a variety of functionalities: random selection of exercises or user input of problems, results checking, tips for solving the differentiation problem, detailed outline of the computation, computation of a derivative by the CAS.

An important advantage of the Differentiator is that it accepts many different forms of the same answer with MuPAD checking for mathematical equivalence. This 'intelligence' is an important argument for using a CAS. Furthermore, the list of functions presented in the exercises can easily be modified by the teacher to ensure that the student will practise at an appropriate level. The 'tutorial functions' are also of great use for the student as they help them to understand the algorithm.

Gausstrainer

The Gaussian algorithm is the standard method for solving systems of linear equations, by which a given matrix is transformed to the reduced row echelon form. The Gausstrainer supports the student when practising this transformation: the student has to apply elementary row operations to a given matrix using input forms and buttons. A protocol of the steps and the current status of the matrix are displayed and finally, of course, the student can check their result.

One merit of the Gausstrainer is that the student can concentrate on the algorithm rather than the arithmetic or MuPAD commands. Moreover, the number of attempts is unrestricted, and as only the final result is checked and not the process to the result, the student can build their own strategies as long as the operations are valid. The user can also decide on the size of the matrix and thus on the complexity of the problem.

Conclusion

We have shown that the integration of a CAS like MuPAD offers new promising opportunities for creating web-based learning elements with mathematical content. Not only does it ease the development of web-based drills as all necessary mathematical functionalities are provided by the CAS, but it also allows for constructive feedback. Furthermore, the student can do drills independently of time, location, browser, and platform and without a local installation of a CAS let alone any knowledge of how to use it.

Online Learning and Adult Basic Education: A Review of the Literature

by

G. Andrew Page
University of Georgia
College of Education
Department of Adult Education

Abstract
Technology is playing an increasingly important role in the delivery of adult education. As early as 1984, Bates suggested that new technologies promised "a wider range of teaching functions and a higher quality of learning, lower costs, greater student control, more interaction and feedback for students" (p. 223). This paradigm shift has ramifications in all areas of society from the major metropolitan areas to the rural communities. "Technology has contributed to, if not caused, the shift to an information society, which is creating dramatic changes in the workforce...Adult education both reflects and responds to the forces prevalent in the sociocultural context"(Merriam & Caffarella, 1999, p.23). That shift and the associated complexity is evident in distance learning technology as it is providing some adults with a new and exciting avenue to learn. It is also broadening the gap both educationally and economically between those that have access to computer technology and those that do not. This study looks at the cross disciplinary aspects within fields of instructional technology and adult education. Conceptually, what does current research say about adult learners and their perception to computer mediated communication and distributed learning? Is online learning a means by which systemic problems can be addressed? Does distance learning provide the instructional design, curriculum and support for the rural adult learner? While there has been much research on college students and other populations of learners in metropolitan areas, there is a considerable gap in the literature about the experiences of adults in rural America and their perceptions of online learning.

This study adds to the knowledge base of adult education and instructional technology because it provides conceptual research about the “digital divide” and how that chasm is being addressed. We are currently living in the Age of Information and whether we embrace the diffusion of technology or not it is affecting our lives directly and indirectly. Information is power. This research also helps bridge the gap between our knowledge of how adults learn in new electronic educational setting and the factors that play a crucial role in this domain.

Andy’s Perceived Logical Flow

1. Background of online learning
2. Statistics of online learning
3. Technology Community centers and their problems
4. Digital divide
5. Online learning for everyone? Has the instructional technology advanced to the point that adult basic education learners can be benefited? I think we sometimes forget that Instructional Technology is about the Technology of Instruction, not about media, or computers or delivery systems per se, and that there is
6. Technology and methodology: Research and theory that covers the practical application of the science of instruction and how it is changing to meet the learners need.
7. Systemic Problem with staffing community centers and finding relevant content for adult learners addressed through distance learning. Has the time has arrived?
Comments: I am pondering an analysis of the system dynamics of online learning for low-middle income rural Adults at community centers.

A subset of those dynamics is the emotions, perceptions, and factors contributing to or inhibiting education via online learning. Only the adult learner can tell us if online learning and the interactivity from the technology is effective or not.

Regarding the theoretical framework/perspective, you could say it is post-Critical Theory. We are living in an information age so we'd better learn to adapt to the changes with technology.
ACT: Acting Cartoons for Trainers' Presentations

Abstract: In this paper, we describe the architecture of an authoring tool for creating web-based presentations that embed user interface agents as primary actors. The expressive functions of the medium (UI agents) are not yet revealed and we expect that an architecture that enables the authoring process and empowers people with no advanced technical skills, will unfold new types of mediation experiences that are not still taken under consideration. We discuss the desired authoring conditions and describe ACT's architecture that tries to realize them. ACT is comprised by two primitive modules, a) the Authoring module which includes the Kinaesthetic Space component, the Cognitive Artifact Library, the Stages Model and the Scenario Authoring Line Authoring component, b) the Scenario Processing Engine module which is responsible for the execution of script produced by the Authoring Module.

Introduction

The computer is a different, possibly unique medium, in its ability to store, deliver, and help manipulate a variety of symbol systems. The computer affords the ability to work in a number of languages, visually, acoustically, textualy, numerically. Embodied animated agents are a new kind of metaphor in user interfaces, which assemble a rich unexplored expressive interactive space. Reasons for using user interface agents are (Andre, 1998, Paiva, 2001):

- an animated and personified agent can support the activities of the user in a more active and friendly way,
- an animated character can more easily provide an emotional dimension to the interaction,
- an animated character can take advantage of its body movements and expressions to convey an explanation in a more effective way
- an animated character may help user learn procedural tasks by demonstrating their execution etc.

Moreover, lifelike animated agents offer great promise for learning environments. Because of the immediate and deep affinity that students seem to develop for these agents, the potential pedagogical benefits they provide, may perhaps even be exceeded by their motivational benefits (Lester, 1999). Agent’s multimodal communication channels via gestures, facial expressions and speech synthesizers raise a potential of different roles and goals it can achieve. If agents also can “sense” their world of living and they are enhanced with action capabilities, their presence functions as a better metaphor of human-to-human communication.

However, the question of who is capable to design, develop and integrate user interface agents in computerized learning experiences is not yet answered. The research community is mainly focused in other aspects of design and implementation issues such as automatic dialogue generation, behavior modeling languages, task model based interaction etc. while the involvement with the authoring process of agent’s behavior is restricted in the determination of general variables that affect agent’s automatic behavior. We believe that authoring tools that make feasible the creation of agent presentation acts by teachers with no advanced technical skills must be developed in order to figure out agent’s multiple usage perspectives in everyday learning experiences. In this paper, we will discuss ACT, an agent-based presentation tool for creating web presentations that tries to formalize the authoring process in a way that facilitates teachers’ goals and ensures the consistent behavior of the interface agent and its environmental setting.

Pedagogical Interface agents

In an abstract view, user interface agents have four modules that integrate the metaphor of face-to-face conversation in the human-computer interface (Cassel, 2000). Several authors address the need for models of personality in designing embodied conversational agents (Andre, 1999). Characters with personality make the information easier to remember because the narration is more compelling. Furthermore, embodied
conversational agents that present consistent personality cues are perceived as more useful (Cassel, 2000). Secondly, models of emotions that can inform conversational behaviour, expand the communicative capabilities of the agent (Ball, 2000). With a richer expressive repertoire, the agent can easily advise, encourage and empathize with students. But how humans are communicating a particular message? Performative acts are goal oriented structures of speech acts enhanced with non verbal behaviour. They create the semantics of the communication message (Pogii, 1998). A conversation has also a syntactic framework. This consists of the interactional conversational functions that regulate the flow of the discussion. Any modality may convey several communicative goals.

User interface agents that exploit the totality of these characteristics are already in use in educational environments. “Herman the Bug”, interactively provides contextualized advice to learners as they graphically assemble plants from a library of plant structures in a botanical anatomy and physiology lab (Lester, 1999). STEVE can teach students how to operate and maintain the gas turbine engines aboard naval ships, including both individual and team tasks (Rickel 2000). Students can interact with another agent, named Cosmo, as they learn about network routing mechanisms by navigating through a series of subnets. Helpful, encouraging and with a bit of attitude, Cosmo explains how computers are connected, how routing is performed, etc.

In all previous examples, agents can interact proactively and reactively with the student because they maintain a representation of the task model and incorporate dialogue interaction models and predefined heuristic algorithms for manipulating the different possible perceptual and conceptual states of the student. This kind of interactive circumstances are particularly critical for constructivist learning environments in which learners participate in active problem solving (Lester, 1999). The expressive power of a computerized presentation system should not be misvalued. We should not directly correlate presentation systems with instructionism. Although active participation in learning environments can motivate a comprehensive knowledge construction in students, “displaying acts” may assist them infer coherence and meaning on the basis of the semantic structures of the different scenes. Learning in this occasion is the reconstruct of a coherent semantic world starting from fragments (Mancini, 2000). The main actor can be an interface agent which performs and takes action in a stage which is informed of agent behavior and it can also serve automatically the trainer’s goals.

Authoring and designing

Powerful commercial tools provide an impressive palette of media authoring techniques to designers. But why do designers prefer pencil and paper, to make design specifications, when they create the design of a commercial title? Research has indicated that when the authoring procedure starts with the immediate use of authoring systems, critical design issues are implicitly specified while defining minor perspectives of the development environment. The final products are usually unstructured and problematic. Causes are usually the underestimation of the potential of the design space, the “bounded rationality” of human beings, and the ambiguous activity unit. Innovative authoring tools should include:

- **Conceptual Modelling**: conceptual design is a top-down strategy for the confinement of the design space. Most of hypermedia design methodologies as HDM, OOHDM, contain in their analysis steps, a conceptual modelling procedure that not only constraints the design space but also enhances it with a semantic structure.
- **Cognitive artifacts**: research in the cognitive field has shown that thinking is heavily dependent upon the experiences with physical and intellectual objects. Decreasing the semantic distance between the computational objects and existing everyday working objects, inevitably increases the number of the cognitive schemas in which these object can participate and simultaneously decreases the required cognitive effort.
- **Activity Unit**: The authoring activity is a form of doing directed to an object. The relationship between the subject and the object of activity is mediated by a tool (cognitive artifact) into which the historical development of the relationship is condensed. The cognitive artifact is transformed into an external scaffolding that simplifies our cognitive tasks. Gradually, people form a tightly coupled system with their environment. The determination of the activity unit specifies the efforts for the cognitive artifact transformation that essentially will define the degree of complication of the authoring process.

Agent-based authoring tools usually have a semi-autonomous execution engine which frames general agent characteristics as personality and emotive behaviour into certain categorical options (Andre, 1999) and an authoring tool for adding dynamic utterances (Ball, 2000) and behavioural templates. These conditions narrow the interpolative actions of authors and presuppose discrete and global understanding approaches for the kinaesthetical behaviour spaces of agents. Teachers need to be in control of their products and always want to develop a clear understanding of the underlying assumptions in autonomous behaviours.
ACT's architecture goals

The main goals of our architecture are the following:

- To detect the appropriate cognitive design artifacts and activity units for scenario procedures that facilitate the mediation experience of user interface agents authoring.
- To provide services for creating multiple composite stages on which agents perform.
- To create an architecture that ensures coherent and consistent behaviour sequences during execution time.
- To establish an open architecture that can encapsulate a variety of agent technologies.

We design ACT in such a way that it follows a theatrical metaphor. To prepare a story presentation, authors have to:

- create the "theatrical" stages they want to include in their story
- create and import into the stages artifacts which change their functionality and appearance during the presentation and comprise essentially world update calls
- author reusable agent performatives
- instruct in an abstract level, the agent to perform specific tasks or actions - scenario

The overall architecture can be seen in figure 1. It consists of two modules.
a) the authoring module, which is responsible for providing the necessary facilities in the authoring process,
b) the execution module, which acts as the run-time engine.

![Figure 1: ACT architecture](image)

**Authoring Module**

The authoring module consists of five components:

- the *Kinaesthetic Space Editor*, in which anyone can develop different categories of abstract performatives with an internal structure and declaration,
- the *Kinaesthetic Space Library*, which includes pre-built agent performatives,
- the *Stages Model* component, which serves as the stage constructor tool,
- the *Cognitive Artifacts Library*, which includes pre-built template-based propositional presentation items
- and the *Scenario Authoring Line* which uses the previous four in order to make available to the user a rich repertoire of activity building blocks during the presentation authoring.

**The Kinaesthetic Space Editor - Library.**

This component feeds the *Scenario Authoring Line* component with alternative agent performatives. We use the notion of performatives in order to communicate the composite structure of the agent actions (Poggi, 1998).

The performatives that we use here are based on a model of communication in terms of goals, beliefs and emotions. A communicative act is the minimal unit of communication and it can be performed via linguistic devices or via gestural, bodily, facial devices. The meaning of a communicative act includes performative and propositional content. Different classes of performatives can be distinguished. We offer three categories of performatives:

- *emotive performatives*, that communicate emotions,
informative performatives, which we can classify further as requests (order, command, implore, propose, offer and advise), as questions and as informative acts (inform, warn, announce). The system provides the means to the author to create dynamic utterances by using a library of global variables ($time, $date, $username, etc.), or select external sources of information that the system supports (e.g. services of a news agency) as sources of utterances. This gives the environment a dynamic notion and

believability enhancing performatives (Lester, 1999), that can give the « illusion of life » to our character.

The whole set of performatives constitutes the kinaesthetic space. In the implementation level, the system stores sequences of gestures and utterances that correspond to different discrete performatives. The first two categories of performatives also have their own «distance» axes that specify the difference of intensity for each performative in the related category and the prerequisite familiarity the agent must have with the user. These axes are used later by the scenario processing engine in order to provide emotionally and informatively consistent sequences of performatives in the flow of the presentation (to avoid non-human behaviour). Also its subcategory of informative performatives has its own propositional declaration form which is determined by its literary operation. For example, the performative order has the definition: <order, whom*, what*>. The authors have in their disposal a rich Kinaesthetic Space Library which can be enriched by the Kinesthetic Space Authoring Tool. The Kinaesthetic Space Library can be shared between different users of the web application or someone can request to have his own instance of it.

Figure 2: Kinaesthetic Space Authoring

Figure 3,4: Stage Editor, Scenario Authoring Line

The Stage Model component

In order to facilitate the scene development for the agent acts and give the notion of real environmental settings, we introduce the stage model – figure 3. The stage model consists of different stages. Stages are the various theatrical scenes in which the actor can perform its pedagogical acts. Every stage has two layers:

A) A background layer which can be built by primitive HTML objects like textboxes and images. These objects are not considered as active and they are not taken into account in Scenario Processing Engine sub-components.

B) An active layer which can also have state-based objects (SB). SB objects are constituted initially by two states, a hidden and an empty state. The author can insert any object in the empty state and change its appearance properties, he can insert a new empty state or clone one of the existing. Examples of SB objects are
an URL guide SB object in which all states contain an HTML “iframe” which displays different URLs in
different states and another example is a moving SB object in which all states contain the same object with
different position values. The author can insert as many objects he wishes in each state. Every primitive object
can have event-based states which are selected when the corresponding events are fired.

The Cognitive Artifact library

The Cognitive Artifact library should provide authors with authoring elements that can be easily
integrated into their cognitive schemes. E.g. while commercial presentation programs provide generic
computational objects (e.g. bulleted list), we differentiate our approach by providing conceptual objects like
summary, comparison, multiple perspectives object. We combine the function of editing the conceptual objects
with templates of related agent performatives. So, while in the first place the author should edit the list, insert
the items, select the agent’s performatives and specify the synchronization conditions, in our approach the
author edits a template that includes the structure of the required synergies. For each conceptual object there are
many behavioral templates with characterization attributes similar to the ones in the Kinesthetic space.

The Scenario Authoring Line component

The Scenario Authoring Line component functions as the central unit of the authoring tool. It embeds a
conceptual organizer which makes feasible the hierarchical organization of the scenario blocks. The conceptual
organizer functions also as a navigation tool because of the large number of scenario building blocks that are
usually produced in such environments. The basic scenario blocks can be
a) an agent performative, (informative or emotive)
b) a cognitive artifact (summarization, comparison etc.),
c) a world model updating (change of display state for complex objects).
d) a draw attention function (only items in active layout can be specified)
e) raw actions (very close to the kinaesthetic space authoring)
f) a branching unit.

As in most authoring tools, one of the most important factors for the design complexity manipulation is
the provision of several views (Harada, 1996). Multiple views are provided with a reorganization algorithm
which shows the building blocks by type (emotive performatives, informative performatives, etc.) or by
conceptual section. Anytime, there exists a focus scene for which the properties are shown. Since the meaning
of an action is embedded in the semantic structure of the multiple sequential building blocks, for each scene
being edited, we show the list of adjacent utterances and gestures.

Scenario Processing Engine

The products of the authoring process are stored in the server datastore. In order to be executed, a new
page is spawned containing the Scenario Processing Engine with the scenario data structure to be executed.
The main architecture of the engine can be seen in figure 5. Our Scenario Processing Engine is predictive-
reactive. Before the actual playback commences, it passes the scenario once, and computes statistical
information about the flow of the building blocks. These statistics, along with more general variables that are
calculated at execution time, are stored in the Statistics Datastore.

The Actions Sequence & Branching Management Module is responsible for user input and branch
processing. Generally, the user can provide feedback in a branching situation, can select the conceptual section
that wishes to attend, can change the speed of the execution engine and exit the presentation. More important
role for this module is to analyze each building block and activate the respective Block Management Module
(Attention, Performative, Stage). (1) The Block Management Units query the History Tracing Unit and the
Statistics Datastore (2) in order to scan the previous engine’s choices and apply heuristic rules for selecting (3)
the appropriate instantiation of the building blocks from the corresponding libraries. They operate in a way that
ensures their self-consistency. Each one maintains its own history of actions and has the ability to communicate
with other subsystems in order to exchange required data. As an example, while executing a scenario data
structure, the Performative Management Module accepts two requests for suggestion performatives that are
close in time. In order not to repeat the same performative twice, it searches the informative «distance» axis in
the Kinaesthetic Space Library for an adjacent suggestion performative. The Template Instantiation Module
undertakes the presentation of the selected template (4) and updates the History Tracing Unit (5).
Discovery of Ontologies for Learning Resources Using Word-based Clustering

Abstract
Educational intermediaries are information systems that support the exchange of learning resources among dispersed users. The selection of the appropriate learning resources that cover specific educational needs requires a concise interaction between the user and system. This paper describes a data mining process for the discovery of ontologies from learning resources repositories. Ontologies express the associations between the learning resources metadata and provide a controlled vocabulary of concepts. Ontologies and the derived vocabularies could be used for the development of taxonomies of learning resources and they contribute to the sense disambiguation in seeking interesting and appropriate knowledge.

Introduction
The huge volume of information existing in the World Wide Web, the complexity of its structure, as well as the keyword-based character of retrieval, make the discovery of the required information resources an unfriendly, time consuming and inefficient procedure. A promising approach to tackle the existing difficulties and word sense ambiguities lies in the development of the Semantic Web (Berners-Lee et al., 2001), i.e. the existence of machine-processable and interoperable semantics in Web-based services and applications. The explicit representation of semantics is obtained by the construction and usage of ontologies, which could be considered as "metadata schemas providing a controlled vocabulary of concepts" (Maedche and Staab, 2001).

Educational intermediaries, also referred to educational e-markets (Hämäläinen et al., 1996) or learning media (Guth et al., 2001), host a diversity of learning resources (LR) and provide educational services to their users, who are usually Universities or organizations, which perform educational programs for their personnel. Examples of educational intermediaries are ARIADNE's Knowledge Pool, EDUTELLA, Gateway to Educational Material (GEM), MERLOT and UNIVERSAL. Educational intermediaries store metadata descriptions on each learning resource providing information on its characteristics (title, subject, type, duration, language, required equipment etc.). In order to ensure the concise communications with their users these systems should provide a meaningful catalog of the offered LR. This requirement leads to an automated ontology development for the generation of flexible and dynamic taxonomies of LR and the provision of a vocabulary of concepts capable to express explicitly and formally (i.e. machine understandably) the LR relations.

This paper proposes a methodology for the extraction of ontologies from LR repositories. In particular we use a data mining approach in order to discover the relations of the LR metadata files. Similar LR are grouped into clusters and the cluster processing provides a controlled vocabulary, which contributes to: (i) the efficient and meaningful response to queries and (ii) the dynamic creation of LR taxonomies, without the manual usage of static classification systems (e.g. Dewey, UDC). Our work is motivated by UNIVERSAL (http://www.ist-universal.org/), a European Union funded project (Information Society Technologies Programme), which aims to implement a learning resources brokerage platform for the European Higher Education Institutions (HEI). The platform hosts a variety of LR, covering many scientific domains and different educational needs (Vrabic and Simon, 2001). The following section presents the ontologies concept, while section 3 illustrates the steps we follow for the ontology discovery. Section 4 presents the experimental setting on the UNIVERSAL repository and the
corresponding results. Finally, section 5 summarizes the presented work, introducing future plans.

**Ontologies**

Metadata are definitional data related to other data managed within an application or environment. For example, metadata would document data about data elements or attributes (name, size, data type, etc.), data about records or data structures (length, fields, column, etc) and data about data (where it is located, how it is associated, ownership etc). Metadata may include descriptive information about the context, quality and condition, or characteristics of the data and can be organized in ontologies.

In Artificial Intelligence ontology is defined as "an explicit formal specification of how to represent the objects, concepts and other entities that are assumed to exist in some area of interest and the relationships that hold among them" (dictionary.com). Noy and McGuinness (2001) define an ontology as "a formal explicit description of concepts in a domain of discourse, properties of each concept describing various features and attributes of the concept (slots), and restrictions on slots". The notion of ontology is becoming very useful in fields such as intelligent information integration, cooperative information systems, information retrieval, electronic commerce, and knowledge management.

The vision of the Semantic Web, aiming at the conduct of automated reasoning, requires computers to have access to structured collections of information and sets of inference rules that they can use. As a first step for the development of this technology, called knowledge representation, XML provides a serialized syntax of tree structures. At the same time a mechanism for encoding and transferring metadata, specified by the Resource Description Framework (RDF), is being developed by the W3C as a foundation for processing semantic information. An improved language has appeared recently called OIL (Fensel et al., 2001) describing ontologies and offering ontology editors, annotation tools and tools for reasoning with ontologies. DAML (DARPA Agent Markup Language) (Hendler, 2001) is also being developed with the aim to represent semantic relations that will be compatible with current and future technologies. While SHOE (Simple HTML Ontology Extension) (Heffin and Hendler, 2000) allows web page authors to annotate their web documents with machine-readable knowledge. Another interesting development in this area is a generic ontology for modeling ill-structured knowledge domains within educational systems in F-logic notation (Papaterpos et al., 2001).

Ontology engineering deals with domain-specific knowledge, and tries to develop technology for accumulating knowledge within reasonable size of stratified domains utilizing ontologies (Mizoguchi, 1998). The product of such a study is a catalog of the types of things that are assumed to exist (Sowa, 2000). Ontology discovery (Maedche and Staab, 2001) extends ontology-engineering environments by using semiautomatic ontology-construction tools. The framework encompasses ontology import, extraction, pruning, refinement, and evaluation.

Requirements on the ontology design are manifold. From the user's perspective the number of categories should grow with the number of resources indexed, otherwise users have to browse through either too many empty or overcrowded categories. In the first case, browsing becomes ineffective because too many clicks have to be performed to enter the leaves of the category tree. In the later case, browsing becomes ineffective, as a long list requires lots of scrolling, usually favoring the first listed resources. From the catalog administrator's perspective, the effort for categorizing resources should be the least possible. A growing category system is not desirable as the reclassification of resources is an overcostly process. That is why an adaptive category system in the field of e-learning has not been experienced yet. In this paper an approach for building adaptive ontologies is presented.
Methodology

The problem of ontology discovery could be considered as a data mining task, since the fields of the metadata indicating the title, subject(s) and description of the LR are associated. The stages inducing from the XML/RDF metadata syntax to the desired ontology are the same as those of any other data mining task: data collection and pre-processing, pattern discovery and knowledge post-processing.

Data Collection and pre-processing

During this stage, LR metadata are gathered and the title, subject and description fields of the metadata XML/RDF files are separated. The pre-processing aims to enable them to be used as input to the next stage of pattern discovery. The main objective is the selection of appropriate keywords from the metadata files that allow the discovery of similarities among the LR. For this reason function words such as articles, prepositions and conjunctions are dropped. Then, language engineering tools are used, such as the Wordnet dictionary (Fellbaum, 1998) for extracting word roots (lemmatization) and the Brill tagger algorithm (Brill, 1994) for attaching tags to words according to the part of speech they represent. The outcome of this processing transforms the remaining words into a set of unique nouns in singular number, which represent the keywords set. Finally we prepare the dataset, i.e. a matrix for which each column (feature) corresponds to an LR and each row (objects) corresponds to a keyword. The matrix consists of binary numbers indicating the existence or not of a keyword in an LR.

Pattern discovery

Given the training data in the appropriate form, interesting patterns are extracted with the use of machine learning techniques, such as clustering, classification, association rule discovery etc. The choice of method depends largely on the type of training data that are available. The main distinction in machine learning research is between supervised and unsupervised learning methods. Supervised learning requires the training data to be pre-classified. This usually means that each training object is associated with a unique label, signifying the class in which it belongs. The important feature of this approach is that the class descriptions are built relative to the pre-classification of the objects in the training set. In contrast, unsupervised learning methods do not require pre-classification of the training objects. These methods form clusters of objects, which share common characteristics. When the cohesion of a cluster is high, i.e. the items in it are very similar, it is labeled as a class.

The metadata file structure of the UNIVERSAL project provides a taxonomy field, which could be used for the data pre-classification. However as long as the field is unused we have opted for the use of unsupervised learning. In order to provide a conceptual hierarchy (taxonomy) of the LR, we could use the conceptual clustering approach, which is particularly suitable for summarizing and explaining data (Fisher, 1987). Summarization is achieved through the discovery of appropriate clusters of the data and explanation involves concept characterization, i.e., determining a useful concept description for each class. However, most conceptual clustering algorithms, produce disjoint groups. In our case, this means that the LR groups (concepts) cannot be overlapped, claim which is restrictive in educational practice, where a LR could contribute to several courses.

Due to the mentioned drawback, we have selected the Cluster Mining approach (Perkowitz and Etzioni, 1998; Paliouras et al., 2000), which discovers similar LR forming a graph and looking for all cliques in it. The algorithm starts by constructing a weighted graph G(V,E). The set of vertices V corresponds to the LR. An edge eij connecting nodes vi and vj exists if a keyword is common in LRi and LRj. The eij weight is equal to the number of the common keywords in these two LR. The edge weights are normalized by their division with the maximum weight in the graph. The connectivity of the resulting graph is usually very high. For this reason we make use of a connectivity threshold, aiming the reduction of the number of edges in the graph. The
connectivity threshold represents the minimum weight allowed for the edge existence. After the edge reduction the method accepts all the existing cliques as clusters. Despite the large complexity of the clique-finding problem, the implemented algorithm (Bron and Kerbosch, 1973) is very fast.

**Pattern post-processing and evaluation**

In order to examine the produced clusters descriptiveness, we calculate the following two properties by varying the connectivity threshold:

- **Coverage**: the proportion of LR participating in the clustering, since due to the connectivity threshold not all the LR are members of the generated clusters.
- **Overlap**: the extent of overlap between the clusters. This is measured as the ratio of the number of the common LR and the number of all LR in the resulting clustering.

Moreover in this last stage, we pay substantial attention to the extraction of the keywords that characterize the derived clusters. These representative keywords construct a prototypical model for each cluster and provide a desired vocabulary. The selection of the descriptive keywords is done with the aid of a simple measure, which is based on the idea that a keyword is representative of a cluster if its frequency within the cluster is significantly higher than its frequency in the dataset (Paliouras et al., 2000). Given a keyword with frequency \( f \) in the entire dataset, and frequency \( f_i \) in a cluster \( i \) the difference of the squares of the two frequencies defines the required measure:

\[
FI = f^2 - f_i^2
\]

FI stands for Frequency Increase. Clearly, when FI is negative there is a decrease in frequency and the corresponding keyword is not candidate to the vocabulary. A keyword is representative of a cluster, if \( FI > \alpha \), where \( \alpha \) is a threshold of the frequency increase.

**Experimental results**

In Universal LR metadata is described by using RDF (Brantner et al., 2001), which is serialized in XML. The Universal RDF binding is based on the RDF binding provided by the IMS (http://www.imsproject.org/rdf/), which combines various metadata standardization initiatives such as Dublin Core, IEEE LOM, and vCard.

For our experiments we used 69 LR descriptions stored in the UNIVERSAL repository till September 2001. The LR offered by twenty European Higher Education Institutes covering a variety of scientific domains. The result of the procedure of word separation from the fields indicating the title, subject and description of the XML/RDF metadata files were about 1,400 words. The utilization of the mentioned language engineering tools returned 678 nouns in singular number. Thus the derived dataset was a matrix with 69 columns and 678 rows.

The cluster mining algorithm was applied to the dataset and constructed sets of cliques for various values of the connectivity thresholds. Depending on the value of the connectivity threshold the coverage of the clusters and the overlap varied. Figure 1 presents the results along those two dimensions. As expected, the overlap for small threshold values is large due to the large number of very large cliques. A similar behavior follows the coverage. Around the threshold value 0.3 about half of the LR appear in the cliques (coverage equals to 0.41), while there is little overlap between the cliques (overlap equals to 0.25). This observation suggests the selection of this threshold value for the formation of the desired representative vocabulary. At this connectivity threshold value 14 clusters are generated. One of them includes 6 LR, three include 3 LR and the other ten clusters include 2 LR.

\(^1\) The Universal metadata model is available at:
http://universal.infonova.at/UNIVERSAL/servlet/Universal?pageD=aboutWebRDFmain
The application of the frequency increase measure for each cluster had as result a matrix with 14 columns and 678 rows. Each cell kept the FI value of each keyword for each cluster. These values ranged from -2 up to 3, while the value for most keywords in all clusters was zero. Table 1 presents the derived vocabulary per cluster for a FI level greater than or equal to 2. Overlapping clusters share common keywords and thus are grouped together. In the parentheses the number of LR in each group of clusters is indicated.

Table 1. The derived vocabulary per cluster, connectivity threshold = 0.3, FI ≥ 2

From the results of Table 1 we can conclude into a three-level taxonomy starting from a general level for the whole UNIVERSAL repository. Four main categories have been formulated consisting of Science (cluster 1), Engineering (clusters 3-5), Business Administration (cluster 14) and Computer Science (clusters 6-10 and 11). Furthermore Computer Science category could be decomposed in three subcategories: Databases & Software Engineering (clusters 6, 7, 8 and 11), E-commerce (clusters 9,10) and Web Technologies (cluster 13). Cluster 12 collects LR described in the German language and is therefore not integrated in the taxonomy. The data pre-processing phase failed for that as the language engineering tools can only accept input from the English language.

Conclusions and Outlook

In this paper we described a methodology of ontology engineering for learning resources repositories, based on the data mining approach. The main conclusions are that automated
discovery of adaptive ontologies is essential for the operation of educational intermediaries and constitutes a powerful tool for the improvement of their services.

Critical issues for extending this research comprise the selection, testing and evaluation of appropriate algorithms for the construction of precise and meaningful ontologies. Specifically we intend to experiment using statistical clustering methods allowing the clusters overlapping. An important issue that we intent to explore is how the RDF annotations of the UNIVERSAL metadata descriptions could be used for the creation of improved ontological descriptions (Delteil, et al., 2001).

Abstract: At the beginning of the complex 21st century, education is no longer regarded as a means of teaching or certifying. ... Two vital areas are necessary in order to ensure the improvement and equity of education: first, to know what students actually learn, and second how they learn in the present context. We believe that the concept of Human Education Interactive Network (HEINET) is an instrument that can help answering these questions and improving learning conditions.

Learning versus Constructivist Approach

The complexity of educational environments is one of the main factors to take into consideration in the teaching/learning process nowadays. The stronger the development is, the more complex it becomes to learn to look beyond the immediate to the structures which prevail long enough to be “photographed”, analyzed and modeled by the thing we conventionally call science. In this environment, learning and teaching and teaching and learning are absolutely independent processes, which occur at moments very near in time.

Never as today was mankind so much culture product and producer in a society, which interacts at an increasingly interplanetary level, and in which the concept of a system projects the level of data and information production in an exponential way. Never as today was it so necessary for mankind to focus its limited interaction resources with the data (world), in order to appreciate the underlying structures of such great diversity. Especially today, facing this multi-stimulating environment, it is advisable to make use of some of our sensitive faculties for cognitive acquisition, which up until now were only regarded as mere means of balancing and interacting with the environment. Nowadays it is crucial to find mechanisms that enable the increase of the cognitive performance, by using multi-modal ways of sensitive stimulation, which in turn can activate this process of change. This issue leads us to two fundamental questions: one of ontological nature (in view of knowledge) and another one of methodological nature. The first concerns understanding to which extent and where the limits to the knowledge horizon should be placed in the traditionally established relationship between teacher and learner. The second one concerns understanding the frame, freedom and flexibility that should be attributed to the references, to the conceptual frame and the environmental conditions in the present state of the Society of Information.

It seems to us that the constructivist approach to knowledge is an adequate response to the first question, for it establishes the balance between the components of instruction and construction in the teaching/learning process. The second question, of a more methodological nature, can be dealt with within a perspective of flexible orientation of teaching/learning towards solving real problems, adequately framed by the different contexts in which they occur.

Within the constructivist approach, the teaching/learning processes have to consider measures to promote the development of learners’ performance/cooperation competences. Therefore it will be necessary that learners have the possibility to apply and exercise new knowledge, thus developing their new skills and differences of thinking/acting. For this purpose, the teacher should choose to use different approaches to the lesson plan:
- Creating groups and assigning tasks, hereby promoting the cooperative side of learning, through discussion and confrontation of ideas;
- Supporting contents through the application and determination of real cases;
- Developing simulations, which encourage the active application of new knowledge and skills;

Supporting this kind of approaches, it is up to the teacher to decide for the most adequate learning methodology to use. This decision depends essentially of the contents and of the starting conditions of the learners. Some of the methodologies we consider most interesting are: cooperative learning, learning through “anchorage” and construction/simulation sets.

![Diagram](image)

**Figure 1: Teaching/Learning Methodology**

**Improving Classroom Teaching**

At the beginning of the complex 21st century, education is no longer regarded as a means of teaching or certifying. The bounds of education lie on the attitude of encouraging the acquisition of multidimensional knowledge, as well as on the development of corresponding skills. This results in a set of knowledge, attitudes and behaviors capable of providing a responsible and enterprising citizenship, founded on innovation, renovation and the leveling by the highest pattern of common life. Two vital areas are necessary in order to ensure the improvement and equity of education: first, to know what students actually learn, and second how they learn in the present context. We believe that the concept of Human Education Interactive Network (HEINET) is an instrument that can help answering these questions and improving learning conditions. Learning environments, traditionally called classrooms, are currently facing processes of change, which are the essential outcomes of two great tendencies:

- The velocity of change introduced by the Information Society and by all technical means that operate within it;
- The need to find edification/installation solutions, which in the short term do not acquire characteristics of obsolescence, resulting from the exponential growing of maintenance costs;

The development of HEINET at the School of Health Sciences, in the Viseu Centre of the Portuguese Catholic University, enabled us to fulfill these vectors, as well as to increase the global performance of the system, concerning the following aspects:

- It sends on solid and information about the teaching and learning processes within the new scientific-pedagogical unit;
- The conditions at the learning space provide crucial information for the development of the new pedagogical methodology used at the unit at stake – Flexible Learning – Problem Oriented Learning;
- Evaluation of the pedagogical methodology/learning process and factors to be focused on.

From these three vectors emerges the need for the use of HEINET as a first step towards making pedagogical processes and learning contents more uniform. However the improvement of learning does not happen only by adopting pedagogical standards. The pedagogical team (teaching staff, learners and other learning actors) should as far as possible analyze the processes themselves, in order to attain the optimized use of the different learning spaces. The inherent ideas to the creation and implementation on HEINET reveal a concern for the continuous improvement of the teaching/learning system in its different dimensions: the system, the process, the products and finally the users. HEINET, as a means for optimization, allows us to focus on teaching in the real learning by students, which conveys a new vision/mission to the teaching/learning process.
Every Word a Click: The Hypertext Being Smart

Young Park (yp85@columbia.edu),
Instructional Technology & Media, Teachers College, Columbia University

Abstract: Hypertext, one of representatives of Internet is well known for its unique features for knowledge generating activities. Now, the new types' smart hypertext is appearing to overcome current hypertext's limitations. They seem to be promising since they start developing recognizing the current Internet users' needs. The study's purpose is to investigate the new hypertext's meaningfulness on knowledge activities and to propose hypertext's future direction. And it calls researchers' attentions by asking its interrelationship with cognitive development.

The Problems

The hypertext is well known as a tool to represent rich semantic relationships. A learner builds up her memory structure by adding a new object to existing memory structure. So some factors such as proper visual association, meaningful relationships or appropriate category are very significant to enhance learning. For this reason, hypertext is very suitable to support knowledge activities.

The current hypertext is built up only by links created by a web author. It is incomplete in terms of user-centered information environment with the following reasons. Very often a web page's information can be interpreted as very different anchors from information author's original intention. It could mean that it does not provide the right response or feedback according to users' inquiry. Immediate response is one of very important factors in knowledge activities because otherwise, a user might lose her curiosity or even forget soon what she would look for. Thus, with some kinds of aids, if a user is able to construct her own hypertext-links for herself, presumably, she is able to follow her own curiosity and to facilitate knowledge activities. It could also encourage a user's flexible and creative thinking process. On the basis of such a point, I propose that the current hypertext should be more developed to be more user-centered, context-oriented and learning-focused. On the basis of this perspective, I searched the Internet and found out three new types' hypertext applications, Atomica (www.atomica.com), Flyswat (www.flyswat.com) and Microcosm (www.microcosm.com) reflecting my perspective.

The Example

Among them, Atomica, a free shareware is an exemplary one to demonstrate the above perspective. Its key point is the simple human computer interaction, which is that one just clicks on the word you want defined or explained. When a user clicks a word on where it is available, whether you're using, for example, an e-mail client, a word processor or a spreadsheet as well as Web, Atomica automatically searches its relevant information as well as definition and then opens a small window to show the list.

There is an example for understanding its features. Suppose that a user was reading an article on the Web, or an e-mail and she came across this sentence: "The abstemious people from Woonsocket invested aggressively in companies like Tecumseh Products, hoping to become as rich as their idol, John Kluge." And suppose she had no idea what "abstemious" meant, where Woonsocket was, what Tecumseh Products did, or who Mr. Kluge was. To find them out quickly using the Internet, she needs to look up each term individually, which requires her to leave the document that she was reading and laboriously type in each term for multiple searches, probably at multiple sites. Instead, she could use Atomica that fetches such answers from the Internet, without leaving the text she was reading. Also, Atomica combines the ability to search multiple information sources simultaneously with a natural intelligence that helps to ensure target ed results. Users don't have to memorize Boolean logic or even construct an English language query. For the
kinds of information Atomica is designed to parse—word definitions, language translations and company profiles—it works well.

Finally, one of the most distinguishable elements of Atomica is trying and guessing the entire phrase or context of a word that a user clicks on although it is still very limited. If, for example, a user clicks on either word in the phrase "Supreme Court," the program pops up with an answer about the highest court in the U.S., not a definition of either word on its own. And it pays attention to capitalization. It knows that the word "polish" is something a user does to furniture, but Polish is a language and culture (Wall Street Journal, 2000).

However, the service is still a work in progress. First, it doesn't work with text inside an image. Second, it is not able to search multimedia-based information such as mp3 files or quicktime movie files. Third, while it draws on a host of reference works and Web databases, it doesn't use premiere sources, such as the Encyclopedia Britannica and major newspapers. It tends to rely on almanacs, single-volume encyclopedias and little-known reference sites, though it does use major dictionaries (Wall Street Journal, 2000).

The Suggestions and Discussion

I conducted the small pilot study with five graduate students in Teachers College, Columbia University in order to explore for the new hypertext's future direction. Based on Atomica's functions and the results of the pilot study, I propose the following directions.

First, hypertext is merging with a search engine. With it, hypertext is becoming more effective and is able to reduce users' information seeking efforts considerably.

Second, the future hypertext's success empowered by a search engine depends on, I believe, how much it understands users' intention. Namely, they should be smart enough to understand not only what a user is looking for but also the whole context where a user is. The findings of a pilot study support it. Its subjects merely used very simple search formulations. What they wanted to obtain was simply the quick and effective search results and not-so-complicated human-computer interaction. Hence, the concept of 'agent software' is inevitable one so that it can play a role like a secretary or a task manager reducing human users' cognitive overload to a certain degree that they feel comfortable. At the same time, such agents will restrain information overload by filtering and analyzing information on web pages.

Third, when the smart agent, hypertext provides advice or a hint to users by being modeling and doing scaffolding exactly like a teacher in a classroom, I assume that it could reduce users' unnecessary search behaviors and assist developing their meta-cognitive process. Atomica's 'did you mean?' description or its additional key words' list can be exemplary.

Finally, while more successful information seekers seem to be able to initiate their search behaviors on their own, less successful ones need a structure to help them search and do knowledge activities. Hence, it will be worth to consider if hypertext can provide different levels' gateway or interface design according to information seeker's search capability consisted of novice, intermediate and expert.

Such a new hypertext seems to be worthy for further consideration to influence users' information search behavior. Although I have explored mostly the positive impacts of it but there should be negative impacts such as users' dependence on its smart functions. Thus, it should be pondered critically to what degree and in what ways it would support human beings' Internet search. That is, we should investigate its multi-dimensional aspects carefully. I hope that this study could draw educational researchers' attention to explore its roles and potential to build up the enhanced learning environments.

The Role of a Reusable Assessment Framework in Designing Computer-Based Learning Environments

Young Park (yp85@columbia.edu), Teachers College, Columbia University
Malcolm Bauer (mbauer@ets.org), Educational Testing Service

Abstract: This paper will introduce the concept of a reusable assessment framework (RAF). An RAF contains a library of linked assessment design objects that express a) specific set of proficiencies (i.e. the knowledge, skills, and abilities of students for a given content or skill area), b) the types of evidence that can be used to estimate those proficiencies, and c) features of tasks that will aid in the design of activities (e.g. features that need to be present in order for students to produce the evidence, features that affect task difficulty, etc.). While RAFs can speed the design of many kinds of assessments, in this paper we focus on their use to aid instructional designers in embedding assessments within computer-based learning environments. The RAF concept is based upon the evidence-centered design methodology described in Mislevy, Steinberg, Almond, Haertel, & Penuel (2001).

The Problem

There has been substantial discussion and research concerning the advantages of embedding assessments within instructional activities and learning environments (e.g. Shavelson, 1992; Hopper, 1998; Treagust, Jacobowitz, Gallagher, and Parker, 2000; Van Lehn, 1988). Van Lehn (1988), for example, describes several ways in which embedded assessments can help people learn including a) determining appropriate tasks based upon estimates of students' skill level, b) determining when to provide feedback, and c) adapting explanations to students' level of understanding. However, designing learning environments that embed assessments is a labor-intensive activity. There are several reasons for this. First, creating learning environments is already hard. Given the time and budget constraints that instructional designers face, it is hard to justify the added time effort, time, and expense of incorporating reliable, valid assessments as part of a learning environment. Secondly, designing embedded assessments requires an interdisciplinary approach involving experts in such diverse areas as educational measurement, psychology, instructional design, statistics, and the content area. The opportunity to assemble a team that has the requisite knowledge of both assessment design and instructional design is rare. Consequently, while students could benefit from interacting with learning environments that contain well-designed embedded assessments, not enough are produced.

The primary problems of the current paper-pencil tests

Billions of dollars are spent each year on education, yet there is widespread dissatisfaction with our educational system among educators, parents, policymakers and the business community. Efforts to reform and restructure schools have focused attention on the role of assessment in school improvement. After years of increases in the quantity of formalized testing and the consequences of inappropriate test scores, many educators have begun to doubt the measures used to monitor student performance and evaluate programs. They claim that traditional measures fail to assess significant learning outcomes and thereby undermine curriculum, instruction and policy decisions. The timed nature of the tests and their format of one right answer has led teachers to give students practice in responding to artificially short texts and selecting the best answer rather than inventing their own questions or answers. When teachers teach to traditional tests by providing daily skill instruction in formats that closely resemble tests, their instructional
practices are both ineffective and potentially detrimental due to their reliance on outmoded theories of learning and instruction.

Contrary to past views of learning, cognitive psychology suggests that learning is not linear, but that it proceeds in many directions at once and at an uneven pace. Conceptual learning is not something to be delayed until a particular age or until all the basic facts have been mastered. People of all ages and ability levels constantly use and refine concepts. Furthermore, there is tremendous variety in the modes and speed with which people acquire knowledge, in the attention and memory capabilities they can apply to knowledge acquisition and performance.

According to Dietel et al (1991), Current evidence about the nature of learning makes it apparent that instruction which strongly emphasizes structured drill and practice on discrete, factual knowledge does students a major disservice. Learning isolated facts and skills is more difficult without meaningful ways to organize the information and make it easy to remember. Also, applying those skills later to solve real-world problems becomes a separate and more difficult task. Because some students have had such trouble mastering decontextualized "basics," they are rarely given the opportunity to use and develop higher-order thinking skills.

Recent studies of the integration of learning and motivation also have highlighted the importance of affective and metacognitive skills in learning. For example, poor thinkers and problem solvers differ from good ones not so much in the particular skills they possess as in their failure to use them in certain tasks. Acquisition of knowledge skills is not sufficient to make one into a competent thinker or problem solver. People also need to acquire the disposition to use the skills and strategies, as well as the knowledge of when and how to apply them (Dietel et al, 1991). These are appropriate targets of assessment. Thus, different types' alternative assessments are being considered now.

Alternative Assessment on Computer-Based Learning Environments

Alternative assessment based on cognitive modeling may be a more valid indicator of students' knowledge and abilities because they require students to actively demonstrate what they know. The following were described by Leighton et al (1999) as the characteristics of alternative assessment: (a) assessment should be integrated with instruction; (b) it should be transparent, that is, it should help students learn to monitor, self-evaluate, and reflect on their own performance; (c) assessment tasks should be authentic, extended over time, meaningful and challenging; (d) students should have access to tools, resources and coaching support during assessment of their performance and learning; (e) assessment should be diagnostic, providing information about students' knowledge, cognitive processes, misconceptions and errors during performance of problem-solving tasks; (f) students' knowledge and their ability to apply (transfer) their knowledge to new or novel problems should be assessed; (g) ability to collaborate effectively with others in solving problems should be assessed. These characteristics of alternative assessment address limitations of traditional testing approaches and promote more authentic assessments of knowledge, learning, cognitive processing, and problem-solving skill in complex natural domains and contexts of task-oriented action. And some studies show that the integration of assessment and Intelligent Tutoring System (ITS) could play a role as the alternative assessment framework as a problem-solver to cure the current malfunction ((Dietel et al, 1991). However, because designing and confirming validity of a cognitive assessment is on very early developing stage, needless to say, embedding such one on ITS that is already hard to develop should be double-efforts. Therefore, as I mentioned earlier, many researchers and practitioners for ITS tend to assess learners temporarily only for their specific purpose. Consequently, such assessment methods being used so far are not easy to transfer to another ITS. RAF would help solving such barriers.

Defining of Evidence-Centered Design (ECD) Methodology

The RAF concept is based upon the evidence-centered design methodology described in Mislevy, Steinberg, Almond, Haertel, & Penuel (2001). To grasp RAF's essential mechanism better, it will be necessary to consider what ECD is.
Its essence is focused on reasoning on the basis of evidence. When we reason from masses of data of different kinds, humans interpret complex data through some underlying "story" - a narrative, or an organizing theory. We attempt to weave a sensible and defensible story around the specifics. And it is the story that builds around what we believe to be the generative principles and patterns in the domain. Based on their story and principles, we can use them as building blocks when we tackle some novel problems that pose new questions or presents new kinds of evidence. In this spirit, RAF applies an approach structuring arguments from evidence to inference manage uncertainty (Mislevy et al, 1999). RAF approach is an evidence-centered perspective on assessment design, and object definitions and data structures for assessment elements and their interrelationships on the basis of student model, task model and evidence model.

Student Model:

The student model indicates, "What complex of knowledge, skills or other attributes should be assessed?" The student model variables are the terms in which we want to talk about students - the level at which we build our story, to determine evaluations, make decisions or plan instruction - but we do not get to see the values directly (Mislevy et al, 1999). The student model variables, all proficiencies that learners would acquire would be defined through cognitive task analysis. And then we just see what the students say or do and must use it as evidence about the student model variables. However, we encounter the evidentiary problem of constructing this inference from limited evidence. Hence, The inference drawn from what the learners say or do may be also on the basis of probability rules, which may be able to rule out its uncertainty.

Evidence Model:

The evidence model means, "What behaviors or performances should reveal those constructs and what is the connection?" The evidence model lays out our argument about why and how the observations in a given task situation constitute evidence about student model variables. There are two parts of evidence models, the evaluative submodel and the statistical submodel. The evaluative submodel extracts the salient features of the "work product", that is, whatever the student says, does, or creates in the task situation. The statistical submodel updates the student model in accordance with the values of these features, effectively synthesizing the evidentiary value of performances over tasks. Defining statistical submodel is beyond this study's purpose so I will not mention it any further.

Here, I will illustrate more clearly what work product means since it is a very important element mapping between the concept and data scoring. According to Mislevy et al (1999), it is a unique human production, as simple as a mark on an answer sheet, as complex as the presentation of disconfirming evidence or a series of work product represent "observable variables". It represents what is important in a performance on the basis of our belief. And these mapping between learners work product and doing assessment could be very simple or could be very complicated to require several expert's evaluation of multiple aspects. In the same context, they can be automatic, or they can require human judgment.

Task Model:

Task model means, "What tasks or situations should elicit those behaviors?" A task model provides a framework for constructing and describing the situations in which learners act and includes specifications for the environment in which the learner will say or do, or produce something. The examples could be characteristics of stimulus material, instructions, help, tools, and affordances. It also includes specifications for the work product, the form in which what the learner says, does or produces will be captured. A particular task is produced by assigning specific values to tasks model variables and providing materials that suit the specifications there given, a task thus describes particular circumstances meant to provide learners an opportunity to act in ways that produce information about what he or she knows or can do more generally. Accordingly, the task controls the level of complexity or difficulty of circumstances that learners encounter. The task itself does not describe how we should evaluate what we see. This is specified
in the evidence model. The advanced ITS is a supreme place providing the means for producing theses situations, and capturing, evaluating and communicating what learners do there.

A Solution

One solution to this problem is to develop assessment frameworks that compile the needed assessment design expertise into reusable chunks that instructional designers can instantiate as they design learning environments. In the paper, we will describe the structure of an RAF in terms of an assessment delivery model proposed by Almond, Steinberg, and Mislevy, 2001. The figure below (adapted from Almond, Steinberg, and Mislevy, 2001) provides a conceptual representation of the components of learning and assessment delivery systems.

![Figure 1: The Four-process model of Almond, Steinberg, and Mislevy (2001)](image)

The activity selection process is responsible for determining on which activity a student will next work. This process could be as simple as allowing a student to choose the next activity or as complicated as an automated decision based upon the systems assessment of a student's strengths and weaknesses. The presentation process is responsible for providing all direct interactions with a student including presenting all instructional and activity related material, recording all student interactions, and capturing student work. The evidence identification process scores student work, extracting evidence from the student work products as a set of "observables"—variables that contain evaluations of the student performance along a set of relevant dimensions. The evidence accumulation process uses the observables to update a student model that consists of a set of estimates of students' knowledge, skills, and abilities.

As displayed in figure 2, in an RAF several parts of this framework are defined by assessment designers before instructional designers begin their work.
In the figure, these predefined components are represented in bold text. Specifically, the evidence accumulation process is defined and implemented, and the observables and the work products are defined. In addition, the RAF includes task models as defined by Mislevy, Steinberg, and Almond (1999). The task models consist of collections of task features that include a) features that need to be present so that students will create appropriate work products (i.e. those that contain the needed evidence, b) features that affect task difficulty, and c) features that can be varied to produce task variants. The task models in the RAF define requirements for tasks that instructional designers may create. However, as will be described in the paper, considerable flexibility remains for instructional designers to design many new creative tasks as long as they incorporate selected subsets of features from the task models.

An Example: an RAF for Science Inquiry

In this section, we will describe an example RAF for the area of science inquiry. We will first present the general structure of the RAF including proficiencies, evidence, and task features. We will then provide an example of how an instructional designer might use the predefined RAF to design a computer-based learning environment with embedded assessments for middle school children. The domain of the example will be science inquiry focusing on the physics of hot air balloons. The domain of the knowledge is provided with the form of computer-based simulation program. Whenever learners encounter a challenge task, they solve it; otherwise they are not able to go to the next step. During such an itinerary, their learning progress is captured by systems, their learning outcomes are collected and measured through RAF method.

Educational Importance

An RAF is a way to represent assessment design knowledge in reusable structures. Just as the object-oriented programming movement in computer science allowed a new, deeper level of code reusability for programmers, RAFs offer instructional designers access to reusable assessment design knowledge, and hence, make it easier for them incorporate embedded assessments in their designs, without overly constraining their creativity.

Implementation/Research perspective
A RAF will be used to as a tool to support the research project that examines the correlation between assessment and a learner's information search behavior on intelligent tutoring system (ITS). Through being used in such a project, a RAF's validity and usefulness will be examined and it can point out a RAF's limitation as well as additional usefulness in an actual performance.

Abstract: This paper examines the decision-making associated with the design and production of Hurricane Strike!, a CD-ROM and Web-based instructional multimedia module that teaches about hurricane science and safety for 6th-9th graders. The module design is based on anchored instruction (Cognition and Technology Group at Vanderbilt, 1992) that engages the learner in a variety of activities related to the science of hurricane development, movement, and structure, and to home and personal safety practices for when hurricanes threaten. Our process of defining the problem, iteratively creating solutions, and frequently evaluating those solutions illustrates the general pattern of Analysis, Synthesis, and Evaluation in the instructional design process, but also demonstrates how the process is often unsystematic and how the phases typically overlap.

Overview

New instructional development projects are always approached with a mixture of excitement and uneasiness. It was no exception in our case when the Federal Emergency Management Agency (FEMA) asked the COMET® Program (Cooperative Program for Operational Meteorology, Education & Training, http://www.comet.ucar.edu) to create an instructional multimedia program on hurricane safety for an audience of children. The excitement came from expanding our products beyond the professional meteorologist community we usually serve, and from being able to contribute an educational piece that could save lives. We were uneasy because of several unanswered questions: Could we develop something suitable for kids, making it both appealing and highly educational? What technologies would allow us to make compelling media that could be used in a wide range of schools? How would we share the focus on science education (our specialty) and safety education? What can we do well for a very modest budget? And finally, what processes will be most effective and efficient for completing the project?

This paper examines the decision-making associated with the design and production of Hurricane Strike!, a CD-ROM and Web-based instructional multimedia module (http://meted.ucar.edu/hurricane/strike) that teaches about hurricane science and preparedness for 6th-9th graders who live in regions vulnerable to hurricanes. The module design, modeled on anchored instruction (Cognition and Technology Group at Vanderbilt, 1992), engages the learner in a variety of activities related to the science of hurricane development, movement, and structure, and to home and personal safety practices for when hurricanes threaten. Our process of defining the problem, iteratively creating solutions, and frequently evaluating those solutions will illustrate the general pattern of Analysis, Synthesis, and Evaluation in the instructional design process, but also how the process is often unsystematic and how the phases typically overlap.
Background

The COMET Program is a not-for-profit organization that provides classroom and distance education and training for weather forecasters. COMET also produces materials to improve the use of weather products by users of weather forecasts, such as emergency managers. The program has developed over 180 hours of computer-based training in the past 11 years, including many hours of Web-based training. Hurricane Strike! is the first project we have attempted for a K-12 audience.

This project required contributions from a people with a wide variety of skills, including part-time efforts from a lead instructional designer, two additional, very part-time consulting instructional designers who also handled project coordination (the lead designer lived out-of-state), graphic artists, multimedia authors, a digital audio technician, a multimedia quality assurance professional, two volunteer middle school teachers to review the design and content, volunteer subject matter experts from FEMA, the Red Cross, and the National Oceanic and Atmospheric Administration (NOAA), contributed recording and voice talent from The Weather Channel®, and our own kids as willing subjects for formative evaluation sessions. Additional important resources for this project included support from management to attempt a new type of project, and existing content, data, and graphical images we had already developed for training forecasters and emergency managers on similar topics.

Analysis (Defining the Parameters of the Problem)

Sources of analysis data primarily included discussions with FEMA professionals, email and conference calls with teachers in school systems affected by hurricanes, and reviews of existing content on hurricanes, hurricane hazards, and public safety for hurricane preparedness. While most of the analysis was done at the front end, new analysis information continued to be received after production began. This information was not ignored, and was considered while our work progressed.

The need for this product was based on the fact that increasing populations are living in hurricane-prone areas in the U.S, both on the coast and inland. Their vulnerability requires that the public become more hurricane-aware. We believe that such awareness can be promoted effectively by educating students about why/when/where and how hurricanes form, the difficulties in predicting their strength and movement, the hazards associated with them, and the protective measures people can take. Students in middle school and above are an ideal audience for this effort because they can influence their parents to take appropriate preparedness measures and because they will eventually become decision-making adults.

As suggested above, the project had two, sometimes complementary, sometimes competing, goals. It should contribute to science education and support the National Science Standards. At the same time, it should achieve the very important goal of teaching hurricane safety and preparedness, a goal that could have a direct impact on saving lives and reducing property losses during hurricanes. Yet these distinct goals should not be allowed to make the final product seem un-integrated.

These goals helped us derive many objectives regarding knowledge of safety measures and hurricane science. However, we quickly worked to establish priorities, knowing that the effort, unless it received further funding, would have to be relatively narrow. In consultation with FEMA, we were able to establish the safety and preparedness goal as primary. This goal was most in line with FEMA's organizational mission and would have the most direct impact on saving lives and property. However, the secondary goal of enhancing hurricane science education contributed to the first by providing learners the rationale for the safety measures. Because additional funding was considered a possibility, we created a priority table instead of simply dropping objectives. Many of the objectives that were considered lower priority were ones that treated the science in more depth. Others regarded understanding the jobs of hurricane forecasters and emergency managers. We also reluctantly dropped the priority of an objective to have learners understand the experience of surviving a direct hit of a forceful hurricane. While this would have been engaging, it presented uncertainties to production because it required travel to interview hurricane survivors.
Our FEMA representative desired a “whiz-bang” treatment to grab students’ attention. The product needed to stand up to commercial products in terms of a sophisticated look and highly interactive nature. But of course, this desire had to face serious constraints:

- Available funding for the project was much lower than is typical for a highly interactive multimedia project. We needed to find ways to leverage off existing products and available staff time.
- The project could not interfere with our core project efforts in any way.
- The product needed to be relatively easy for teachers to use, while pushing the technology to a comfortable limit.

Other constraints also affected our eventual design decisions:

- The product needed to be flexible for use in multiple contexts, such as assigned or independent self-paced instruction, guided group instruction within a classroom setting, or kiosk-based delivery in a traveling exhibit.
- It needed to be designed in sections short enough to hold a student’s attention and to fit within classroom lesson times.
- It was meant for wide and inexpensive distribution, so it needed to be Web-based, but also available on CD-ROM for those with limited bandwidth Internet connections.
- The product needed to be fun, not didactic, but suitable for a rigorous science curriculum.
- The teacher reviewers on the team wanted it to be relatively self-contained for easy use, so it needed to include evaluation tools.
- As mentioned above, it had to link to National Science Standards and also to the newly released Red Cross “Masters of Disaster” Curriculum.
- Since the initial budget was low, but the aims high, it needed a modular design that was expandable in case new funding should become available.

Synthesis (Creating a solution)

Early on, when only a limited analysis of the needs and goals of the project had been done, we had already begun considering solutions. Because we had to decide whether we even wanted to pursue the project, early consideration was necessary about how we might approach it and remain within the given budget. We thought that the safest approach was to take an existing module, “Community Hurricane Preparedness,” which we had designed for emergency managers, and simply adapt the content for teenaged students. Instead of the complex decision-making simulation it contained, we would substitute several game-like exercises to maintain an equal level of engagement. Had we carried it out this design, the product would have been more like a textbook with multimedia elements to help maintain interest. Clearly, this was the safest route to ensure the project could be done within budget.

However, while we felt the more textbook-like portions of the adult module were fine for the professionally motivated users of “Community Hurricane Preparedness,” we worried that we would quickly lose our younger audience without a higher degree of interaction. Besides, our representative from FEMA who funded the project expressed an enthusiastic desire to push the technological envelope and create something that would wow students (and decision-makers who might fund additional projects). We felt this expectation was a bit high given the limited funding, not to mention the high standards of today’s teenagers when it comes to technology. But we listened and pondered our options.

Still early on, and before our first extensive meeting with FEMA, we agreed that a good approach would be to create a learning scenario that would involve students in decision-making related to hurricane safety and preparedness, while also supplying motivating experiences with science content through games and simulation. The exact story for the scenario was still vague, but the main character would be a teenager who experiences the events around an approaching, and then landfalling, hurricane. As this treatment evolved, we realized that the science content could be delivered in the guise of information provided to the main character to help her understand the potential impacts of the hurricane and to understand the limited predictability that we face when making decisions about preparedness and safety. We considered the use of
stories to be an effective instructional strategy for involving and engaging learners, as well as providing an effective structure for encoding and recalling information (Schank, 1990). The story would allow us to model good safety and preparedness behavior, rather than simply providing information about good behavior. In addition, the scenario structure allowed for relatively easy future content additions. If budget allowed, we would simply add supporting activities to the design. We were sold on the idea and the FEMA representative liked it as well, but could we create a learning scenario and stay within budget?

We thought we could, but only if we borrowed as much content from existing sources as possible, reducing the content gathering activity that is typically required. We already had expertise in hurricane science and safety, had contacts who would be willing to supply the expertise we did not have, and possessed many visual and verbal source materials from the "adult" module. Another cost-saving attribute of the project was that the sponsor was not asking for a set schedule for completion. We would have the luxury of fitting the project into the small lulls within our more schedule-sensitive core projects. We decided to hire an instructional designer from outside the organization, but one who was a former employee, highly aware of our sponsors, the content area, and our development processes. His consultant status allowed the project to be non-disruptive to our core projects.

In addition, we saved on development costs by "paying it forward." Macromedia Flash was a Web tool that was relatively new to us, but we knew it was about to become an important tool for us because of the interactive and visually compelling Web applications that could be built with it. We would use this project to stimulate an R&D effort for developing Flash skills and techniques that would be useful in the near future. Instead of risking schedule slippage on core projects, our prototyping with Flash would happen on a project that did not present any schedule risk.

Before fleshing out the scenario any further, the lead instructional designer developed a design matrix that depicted how and where each of the primary learning objectives would be treated in the scenario. We would have students:

- **Identify the main ingredients that support or prevent hurricane formation.** This is done within a discovery learning game where students experiment by changing the values of necessary ingredients to create the optimal conditions for hurricane formation.

- **Understand the key characteristics, life cycles, climatology, and classification schemes of tropical storms and hurricanes.** This is presented more as information, but treated in a visually compelling way, with embedded interactions included. Students use worksheets to encourage engagement with the material. Because we had an existing 3D digital model of a hurricane developed for a previous project, we include an activity to explore this model via "virtual reality" software. Discarded methods of treatment included video footage of a flight through a hurricane. It was decided that the bandwidth required for adequate video quality was prohibitive.

- **Identify factors that can contribute to uncertainty in hurricane forecasts.** This is necessary to help the public understand why evacuation can sometimes be necessary even though the hurricane never becomes a local threat. This is treated both with information content and with a simulation/game that allows learners to change the positions of high- and low-pressure systems and see the resulting hurricane path. This exercise was developed using actual numerical model simulations performed by a NOAA researcher at Colorado State University, although the game is not a fully functioning simulator itself. The interface for this simulation is reproduced below.

- **Identify hazards associated with landfalling hurricanes.** Again, this content is treated with information presented with engaging media qualities and supported with embedded interactions and worksheet questions. Discarded treatments included presenting interviews with survivors of hurricanes and others. We decided that this would likely require travel and would increase uncertainty in the schedule.

- **Choose appropriate safety and preparedness measures for hurricane events.** It was this content that would primarily drive the scenario. This is discussed more fully below.

The scenario itself involves the learner making a visit to Camille Castillo and her parents in the coastal Florida community of Ft. Walton Beach, site of the actual Hurricane Erin strike in 1995. The scenario unfolds over 7 days as Hurricane Erin develops, approaches, and then makes landfall at Ft. Walton Beach. Each day as the hurricane nears and then finally arrives, the learner participates with the family as they prepare their home for the threat and prepare themselves and Aunt Betsy for the potential of
Evacuation. Safety activities include choosing what to pack in the evacuation duffle bag, going over emergency plans, shopping for appropriate emergency supplies, preparing the house for high winds, and advising Aunt Betsy what to do as she evacuates her mobile home and then returns to a potentially damaged home after the storm passes.

Each day the learner has access to an informative TV weather update (courtesy of The Weather Channel) and instructional applications stored on the family's laptop computer. The laptop computer applications primarily treat science topics, but some relate to the hazards and safety of hurricanes as well. The primary interface for Hurricane Strike!, the Castillo Home, is displayed below. Learners receive a task list each day to remind them of things they need to do, but they can also just explore the rooms of the house and click on the active items that lead to the various instructional activities. For example, Hugo the dog presents a new task each day by way of the various items he carries in his mouth—clicking on Hugo when he carries the purse instigates a shopping trip for emergency supplies.

**Evaluation (Fine-tuning the Solution)**

Evaluation activities for the project began almost immediately. After our initial planning meetings and further reflection, the instructional designer for the project created a Project Plan that included our analysis assumptions and a detailed list of proposed objectives. In addition, he also created a Planning Matrix that described the potential ways we would treat each objective. FEMA representatives and two middle-school teachers reviewed these documents to validate our conclusions. This helped us clarify our priorities, but fortunately, they did not observe any major misconceptions on our part.

As the scripts for various sections were written, they were shared with the middle school teachers and content experts from the Red Cross, FEMA, and COMET. This helped us correct misleading or incorrect pieces of content and also helped us confirm the material was written at the correct level. As the pieces were developed, we performed formative evaluation by trying them out ourselves, but also observing how our own middle school-aged children used them (we had purposely chosen a modular design so that we could develop and test incrementally).

The scenario structure offered tremendous opportunities for learning activities, but it was a bit daunting to think through all the usability issues in advance. As we recorded audio content and prototyped several days of the scenario, the difficulties became apparent. For example, since many computer games are designed to be exploratory and open-ended, we had speculated that this approach would be engaging to students. But since we also had specific learning objectives we wanted learners to achieve, we weren’t willing to allow them to bypass or miss out on activities (which some of our testers did). Worksheets were designed as a solution to provide the structure necessary to ensure that learners used all the parts of the module. Similar to that way a list in a scavenger hunt works, learners would have to explore each element of the module in order to complete the worksheets. But this is also where the comparison with a home computer game broke down. Completing the worksheets could be perceived as a typical school assignment as opposed to part of a game. Therefore, some of us felt it necessary to provide more guidance within the module so that the task of completing worksheets was less stressful. There were a few heated debates within the team about the amount of guidance necessary. In the end, we erred on the side of clarity by providing task lists for each day and making the items learners needed to click more obvious.

Another design decision that generated lots of debate centered around the simulation/game that allows learners to move high- and low-pressure systems to see their effects on hurricane paths. This was originally proposed as a type of bowling game, including pins to knock down and a scoring system. Kids would probably have loved this, but some of us were concerned with the ethical dimensions because hurricane strikes (and spares) obviously can take lives and cause serious destruction. Also, we had to remind ourselves that the most important learning objective was not knowing what forces move hurricanes, but that hurricane movements are difficult to predict. In the end, the “game” became more of a scientific simulation that drives this point home. Some kids who tested this application ended up making their own game out of the exercise anyway when they tried to make the hurricane strike certain cities. At least they are learning about the causes of atmospheric flow patterns and why hurricane paths are hard to predict, we told ourselves.

Usability was the most frequent issue we encountered during formative evaluations. For example, nearly all the instructions and interfaces for the various exercises needed some tweaking. However, as the members of the team reviewed each other’s work, many aesthetic concerns were raised as well. These are
by nature subjective and sometimes difficult to resolve with group consensus. We did the best we could, giving and taking to keep the project moving. Subject matter experts raised a few content issues during their final reviews, but early reviews of the scripts meant such issues were few and did not require any major revisions.

Summary

As this paper has demonstrated, the instructional design process is often non-linear. We may conveniently think of the process as sequential Analysis, Design, Development, Implementation and Evaluation phases, but such linearity in reality would be stifling. Many authors have recently developed models that describe a process of iterative refinement of the problem definition and solutions (Willis & Wright, 2000) or depict a dynamic system of interacting authoring activities that lead to one of many possible solutions (Tennyson, 1997). In our experience, such models of the instructional design process more accurately describe how good ID is done.

Like all projects, this one began with substantial analysis activities, but we also began almost immediately mentally trying out solutions, even when only a limited amount of analysis data had been gathered. These initial trial solutions were necessary to consider fully our production needs and implementation constraints, and to determine how best to use the available budget. The early potential solutions essentially became additional analysis data to allow us to consider project needs. We did not allow early synthesis of potential solutions to box us in, however. Only a few isolated components of the product saw early development activity; the bulk of the development work was done only after thorough analysis and design review. Evaluation was an essential part of the project and occurred throughout. Designated reviewers and fellow team members reviewed documents and prototypes at all phases, including the initial analysis. Such formative evaluation, performed by a range of staff and user representatives with a variety of skills and perspectives, saved many hours of wasted work. Some team members may become frustrated with this “committee” approach to project decision-making, but, if done within reason, more highly participatory design and evaluation can lead to important improvements and reduced effort by identifying more numerous and diverse design options and issues early in the process.

Acknowledgments

No instructional development project of this scope and complexity is performed without the contributions of many talented individuals. Special recognition is required for paper co-author Dwight Owens, the lead instructional designer on Hurricane Strike! and the person primarily responsible for its creative approach, for Steve Deyo, the talented illustrator and Flash programmer responsible for so much of the module, and for Carl Whitehurst, our senior Flash programmer and also the person who provided technical oversight for the entire project. Other COMET Program contributors included Kay Levesque, Mike Smith, Heidi Godsi, and many others. We also need to thank the COMET Program senior management, Joe Lamos and Tim Spangler, for their support. Finally, we must acknowledge and thank Bill Massey of FEMA, who spearheaded the project and entrusted it to us.
Abstract: Though schools report an increase in the quantity and quality of use of technology in education, many still question of the merit of use of technology in K-12. Technology simply used as information distribution deserves such scrutiny and criticism. Using technology in educational projects in a variety of ways increases novelty and student interest and can also approach higher critical thinking levels. Government has recognized a challenge of preparing children for a lifelong commitment and involvement in the court and identifies the schools in playing a key role in meeting this challenge. This project calls for direct involvement of the Court in a variety of programs in partnership with the schools, integrating education on the court into the curriculum in K-12. This project between the courts and schools demonstrates how partnership between public agencies enhanced by technology has the tremendous potential to multiply the impact of civic education for students.

Introduction

There is a distinct point in the diffusion of innovations that I have come to call the point of no return, not to be seen as detrimental, but to indicate that a society cannot function without that innovation and would indeed be deemed primeval with its absence. Surely, communication technology has reached that point. One indicator of this placement is that the product is seen as essential across living category dimensions such as education, religion, entertainment and consumerism. Another indicator in reaching this pinnacle is that the use of the innovation cuts across age lines. Despite the increase in the quantity and quality of use of technology in education, there is still the persistent questioning of the merit of the technology in K-12 education (Panel on Educational Technology, 1997). Technology simply used as information distribution deserves such scrutiny and criticism. The research in technology use in education points to four distinct ways that technology can be used as media (Bruce and Levin (1997). Media as inquiry emphasizes the use of the Internet and other databases for data gathering for research or other problem-centered, fact-finding activities, media for communication underscores functions such as email and word-processing, media for construction looks at computer-aided design and media for expression represents more interactive outcomes of technology projects. Using technology in educational projects in a variety of ways, thus a variety of levels, not only increases novelty and student interest, but as the activity moves to higher levels of interactivity it also approaches higher critical thinking levels.

At the same time education is assessing its use of technology in the classroom, government is evaluating its role in the community, how it is perceived in the community and how the court can partner with the education community to educate K-12 students on the Court's role in the community and on their future role and responsibilities in the administration of justice. We realize that the court and the schools face the very real challenge of preparing children for a lifelong commitment and involvement in the Court and have identified the schools in playing a key role in meeting this challenge.

The overarching project plan calls for direct involvement of the Court in a variety of programs in partnership with the County A Superintendent of Schools integrating education on the court into the curriculum in K-12. This project infuses educational objectives with the goals of the Court, increases involvement and interest on the part of our educators, and places the learning of the courts into a familiar and credible context for the students - the educational context. This model reflects the ideas of the Goals 2000 legislation in using authentic tasks in teaching with technology http://www.ed.gov/pubs/EdReformStudies/EdTech/overview.html#authentic.
The Project

This prototype project between the courts and schools in County A demonstrates how partnership between public agencies enhanced by technology has the tremendous potential to multiply the impact of civic education for young students. Schools and students who participate in this project will develop knowledge about and appreciation for the justice system and its important contribution to a free society. In State A's schools the courts are first studied in third and fourth grade. Very little material is available to make this study concrete and meaningful for young students. Most teaching is done from generic national textbooks with little relationship to the students' own community. Television reinforces a concept of law and justice based on heroic individualism rather than Constitutionally protected procedure and thoughtful, reflective deliberation. This is reinforced by the problem that teachers have little direct experience with the justice system beyond jury summons or a traffic issue.

The Internet offers the opportunity for many classrooms to learn about and participate virtually in the justice system. Structured creatively and at the proper level of difficulty, the online experience can be interactive and memorable. In addition, classroom support materials can be made available to a wide audience at very little cost.

Recognizing the enormity of such a project, the Court and County A Superintendent of Schools have decided that the first step in enabling this collaboration is to initiate the project focusing on the elementary school grades in the social science and history curriculum. Initial meetings have determined that the curriculum has to be innovative and exciting for students, must blend educational and Court goals, and meet the Judicial Counsel's long-range goals for community outreach and education.

Specifically, the project includes 1) Multimedia Curriculum. This package includes web-based lessons and non-web-based activities that will be scheduled throughout the year that promote the court in the community, including school assemblies that feature court-related speakers, a formal integration of law day into the schools throughout the school year, while still identifying May 1 as the "official" Law Day as recognized by Congress. Appreciating the research that indicates that online materials are more attractive to teachers when included in a "curriculum package" we will link these activities with corresponding web-based curriculum that will be designed for student preparation or post study to tie the activity to further education of the court, 2) Virtual Courthouse. The historic courthouse of County A houses a wealth of information, stories, and legends that can only add to a student's understanding and appreciation of the role of the court and law in the community and county. Our plan for the County A Virtual Courthouse is to use actual diagrams and pictures of the County A Courthouse, not cartoon or clip art as is typically used. The courthouse will be interactive and hyperlinked, using pop-up figures that will respond to questions that a student may ask from a set of pre-preprogrammed questions. Various paths will be available for a teacher to choose to focus on in a lesson (with corresponding online curriculum material) that teachers help in designing, and 3) Virtual Fieldtrips. County A Courts and Superintendent of Schools propose to develop a virtual fieldtrip to the courts for 3rd and 4th grade students. The discussion so far is that this online project will utilize the hyper-linking capability of the Internet by allowing the user to follow multiple pathways through the site. For example, a user might follow the day of a person who is serving on a jury; a typical day in court of an attorney; or a day in the life of a judge. These "day in the life of" Virtual Field Trips will each be supported by classroom materials. The materials will be developed by outstanding teachers in the region and be specifically designed to meet the needs of County A's diverse student population but with an eye to the curriculum of schools throughout State A. As part of this Virtual Tour, various times will be scheduled for students to interact with a court official via email in a type of "Ask and Expert" experience. These may be part of a response to video interviews of a judge, a bailiff, an attorney, a court reporter, etc. posted on the site.

Designing for a moving target

Designing an effective learning experience on a PDA in a wireless environment has forced a reexamination of the instructional design principles normally associated with the content development process, a team of instructional designers in Canada has concluded. The typical project management model that has been applied to face-to-face and elearning projects can't be relied on for the emerging mlearning environment. Instructional design strategies have to be modified for a mobile learning environment that seems to be changing monthly.

Several significant issues are affecting the instructional designers responsibilities in the new mlearning world. Constantly changing PDA devices means that the potential of the technology platform is largely unknown and enormously difficult to design for. Uncertainties surrounding the type(s) of content that may or may not work on the market-ready PDAs impact on the choices available to the subject matter experts. While many of the learner and faculty support issues are similar, the complexities of these resources are increasing. And, of course, for many pilot exercises, the costs for mlearning production activities seem to be larger than for their elearning counterparts.

At the end of the day, how can the instructional design principles developed over the past few years be applied to a moving target? Moreover, how can student and faculty expectations for a satisfying and, ultimately, successful learning experience be met? These questions—along with the increasing importance of the development project team that involves content providers, SMEs and instructional designers—will be explored against the backdrop of a pioneering mlearning educational experience at two leading Canadian colleges.
Assessing Student Programming Knowledge with Web-based Dynamic Parameterized Quizzes

Sharad Pathak and Peter Brusilovsky
School of Information Sciences
University of Pittsburgh
Pittsburgh PA 15260
peterb@mail.sis.pitt.edu

Abstract: Web-based knowledge assessment with on-line quizzes is one of the oldest and most popular ways of using the Web in education. Almost all major Web courseware management systems support authoring and delivery of on-line quizzes made from static questions. Our work attempts to address several known shortcomings of static questions. We suggest an approach and a system to author and deliver Web-based dynamic parameterized quizzes for programming-related subjects. The system has been used in a practical class for two semesters with both desktop and mobile computers and in both assessment and self-assessment modes. This paper briefly describes the system and summarizes the results of its formal classroom evaluation.

Introduction

Objective tests and quizzes are among the most widely used and well-developed tools in higher education. Web-based knowledge assessment with on-line quizzes was the first to be implemented and currently the most well developed and most popular interactive component in Web-based education [Brusilovsky & Miller 1999; Brusilovsky & Miller 2001]. All major Web courseware management systems support authoring and delivery of on-line quizzes made from static questions. A lot of efforts have been put by the vendors of these systems to support a larger variety of question types, make question authoring easier for a teacher, and provide support in managing quizzes and pools of questions. Yet, with all these powerful authoring tools can't solve a few inherent problems of this traditional assessment tool - quizzes made of static questions.

All these problems come from an obvious fact: when author creates one static question, one and only one question is created. Modern authoring tools made creating of Web quizzes much easier then it's used to be, however, creating every question is still a large investment of time because, if questions are taken seriously, creating the content takes much more time than entering this content into a system. Thus, every question is an expensive component of teaching material and the number of questions that can be created for a particular course is relatively small. In this context, it is quite natural, that in both assessment and self-assessment contexts all students in the class are using the same set of static questions. It creates at least two well-known problems:

• In an assessment context, the use of the same set of questions for the whole class provokes cheating. Cheating is quite an issue even for the classroom quizzes. For take-home and Web-based quizzes cheating become a major problem that actually prevents the teacher to rely on results of this kind of quizzes. Cheating is an issue not only within the class, but also between classes. In the places where the same questions are being used in several classes (during the same term or during different terms) the students are known to accumulate and pass each other the correct answers.

• In the self-assessment context, where the cheating is not a problem, the students usually suffer from the lack of material: There are usually too few questions to work with and one question can be answered only once.

1 A number of my colleagues who were creating quizzes with the top-of-the-line Blackboard 5.1 system have claimed that the old "paper and pencil" way is still much easier for them. Creating quizzes in an editor such as Microsoft Word is still faster (especially taking into account slow Web-based authoring tools). What can really save time is automatic grading (at least for large classes). However, in many cases, quizzes are graded by Teaching Assistants and thus this saving does not affect the professors themselves.

2 A more progressive approach where every student is getting a subset of a pool of questions developed for a quiz is used very rarely exactly because questions are expensive to develop.
A known remedy for this approach is the use of parameterized questions. With this approach, an author creates a pattern of a question. At the presentation time, the pattern can be instantiated with parameters taken from a particular set. This, every question pattern is able to produce a large or even unlimited number of different questions. Parameterized questions are currently a focus of one of the promising research directions in the field of Web-based education (WBE). A number of pioneer systems such as CAPA [Kashy et al. 1997], WebAssign [Titus, 1998 #1386], EEAP282 [Merat & Chung 1997], or Mallard [Graham, Swafford & Brown 1997] have has explored the use of parameterized questions in different settings. The early results are very encouraging. For example, the authors of the CAPA systems have carefully monitored the use of their system and reported that the use of parameterized questions can practically eliminate cheating [Kashy et al. 1997].

Our own work capitalizes on the experience of early systems with parameterized questions and is aimed at extending their application area to a non-traditional and challenging subject of programming languages. We have developed an approach and a system to author and deliver Web-based dynamic parameterized quizzes for programming-related subjects. The system has been used in a practical class for two semesters with both desktop and mobile computers and in both assessment and self-assessment modes. This paper briefly describes the system and summarizes the results of its formal classroom evaluation.

Parameterized Questions for Programming-related Subjects

Traditionally parameterized questions are used in math-based courses such as physics and various math subjects. In these application areas, a correct answer to a parameterized question can be specified by a formula that includes one or more question parameters. In this context, creating parameterized questions and checking the correctness of student answers is relatively easy: the question author provides the interval for the possible values of a randomized parameter (or parameters) and specifies the formula to calculate the correct answer. The quiz system generates a question and stores its parameters along with the content of the question. To check the student answer, the correct answer for the given set of parameters is calculated using the provided formula and compared with the given answer. The formula-based approach is simple and powerful. It even enables the system to recognize most typical misconceptions if an author can provide a "wrong" formula that corresponds to a misconception.

Unfortunately, the formula-based approach can't be used in programming except for very simple cases of calculating numerical expressions. Our challenge was to design a different approach that can work for a large variety of questions in programming courses. While analyzing several large pools of questions created for courses based on such languages as Lisp, C, and Java, we have found that a large portion of questions in these pools are code evaluation questions. In a code evaluation question, the user is provided with some fragment of a program and is asked to predict the value of a particular variable or a string to be printed at the end of execution of this fragment. This kind of questions is very important - it enables the teacher to check the student's understanding of the semantics of programming language constructs. Semantics of a programming language is an important body of knowledge on itself and also a prerequisite to a higher level programming skills.

In traditional Web-based courses, where code evaluation questions are very popular. They are authored much like other kind questions in the form of multiple choice or blank-filling using provided tools for developing of static questions. They are evaluated by comparing the answer given by a student with the answer pre-specified by a teacher. However, it is known that code evaluation questions allow a different approach to checking the correctness of student answers. Using a language interpreter or compiler the system can ran the given fragment of code and calculate the correct answer for a code evaluation questions without the need for a teacher to provide it. It can then compare the calculated answer with student answer. We have used this approach is several earlier systems such as ITEM/IP [Brusilovsky 1992], ILEARN [Brusilovsky 1994], and ELM-ART [Weber & Brusilovsky 2001] to save some sizeable amount of question development time and to avoid authoring errors.

When developing our system QuizPACK (Quizzes for Parameterized Assessment of C Knowledge) we have attempted to combine our earlier work on code evaluation questions with the ideas of parameterized questions. Our motivation was to create a system that would allow a teacher to create parameterized code evaluation questions and quizzes easier than creating static questions with existing authoring tools. The idea of QuizPACK is very simple. A teacher provides the core content of the question: a parameterized fragment of code to be evaluated and an expression that have to be evaluated by the student at the end of the fragment execution. The system does the rest: randomly generates a question parameter, creates a presentation of the parameterized question in a Web-based quiz, gets the student's input, compares the student answer with the result of running the parameterized code "behind the stage", and records the results into a server-side database.

The current version of QuizPACK can support a whole programming-related course based on C or C++ programming language. It supports simple questions based on a few lines of code as well as very advanced questions with the code that includes multiple functions and header files. QuizPACK allows the teacher to prepare full quizzes of different length in the form of static sequence of parameterized questions. It also allows a teacher to display various kinds of reports about the student performance on quizzes. The following sections of the paper presents the student's
and the teacher's side of QuizPACK and reports some result of its evaluation in a Data Structure course based on C language.

Students Interface of QuizPACK

The students are accessing the quizzes using our KnowledgeTree learning portal. The KnowledgeTree portal allows a teacher to create a course support Web site that can use course materials distributed among different servers. With knowledgeTree, a teacher is able to specify the objectives, readings, and other critical information for every lecture and to specify relevant learning activities of different kinds. In particular, a teacher can specify a set of quizzes to support a lecture. When a student selects a quiz in KnowledgeTree, the portal request the selected quiz from the quiz server and passes the student parameters to the server. The server immediately loads the first question of the quiz in a separate window.

The parameterized question is presented to the student just like a normal static fill-in question. First, the program fragment to be evaluated is presented then the expression to be evaluated, then form box to write down the answer (Figure 2, left). One or more constants that the student can see in the body of the question are, actually, instantiated parameters. They may be different for different students taking the quiz as well as for the same student attempting the question several times. In a properly designed question, the value of the expression to be evaluated depends on the instantiated parameters and thus will also be different for different students. Every student is supposed to mentally execute the program, evaluate the specified expression, enter its value into the box, and hit "submit" button. After that the system generates an evaluation screen for the student. The evaluation screen repeats the content of the question, evaluates the correctness of the student's answer, provides the correct answer if the student's answer was incorrect, and generate a link to the next question (Figure 2, right). This screen lets the student to re-think the question and the answer. In particular, the student may want to attempt the same question again by using the Back button and reloading the question screen. The student can attempt the same question many times, though in evaluation context only the results of the first attempt is recorded (Figure 2, right). Students may finish working with the quiz anytime simply by closing the quiz window and returning to the KnowledgeTree portal. Note that the student interface does not sport elaborated graphics and uses the minimal required space to present the question and the feedback. It was done to enable working with questions on multiple handheld wireless devices. As a result, the QuizPACK perfectly works on small Windows CE computers like HP Jornada and even on Palm-based organizers.
We welcome the readers to try QuizPACK system by logging in to KnowledgeTree system at http://dbpc.sis.pitt.edu/sharad/kt/login.html. The system allows self-registration. We suggest to use your e-mail address for your login name to avoid name conflicts.

QuizPACK from the Teachers Point of View

Teachers use QuizPACK to publish online parameterized quizzes for the students. There are three major steps a teacher has to complete in preparing a quiz.

- First, the teacher has to provide the programs to be evaluated. The code of each program has to reside in a separate file. The place of a randomized parameter in the code of the questions is denoted by a pseudo-variable Z. At the question generation phase QuizPACK every occurrence of Z variable will be substituted by an integer randomized within some interval. In effect, a teacher defines a pattern of a question. A pattern is a simple way for a teacher to give different questions of the same difficulty level to all the students without being biased with the choice of questions for different students.

- Second, the teacher has to specify a quiz in a special quiz index file. Each line in this file corresponds to one question. For each question the teacher has to specify the name of the file with question code, the lower and the upper limits for randomized variable, an expression to be evaluated by the students, and a type of this expression (i.e., int or float). With this approach, the code of the question in QuizPACK is separated from the pedagogic information such as randomization limits and expression. It allows the author to use the same question code in different quizzes with possibly different parameters.

- The last step is to compile a quiz. QuizPACK system is developed to can work on any Unix system with a variety of Web servers. The system itself is a collection of several prototype data files and several commands (in Unix sense). The commands are all written in C++ and can be recompiled on any Unix platform. The authoring interface for compiling a quiz consists of just two commands. The newquiz command generates a folder (catalog) for a new quiz with all required prototype files. The name of this folder is also the name of the quiz. This is the folder where teacher have to place the question files and the quiz index file for the quiz. Naturally, these files can be simply created inside the quiz folder using any editor, moved from other folders or transported by FTP from another computer (including Macs and PCs). After all files are added to the quiz folder, the author has to execute compile command that generates and compiles a set of CGI programs for the quiz. More exactly, two CGI programs are generated for each
question - one to present the question and one to evaluate the answers. The code of the original question is included into both of these programs. Thus, the same code provided by the teacher is used for both - presenting the question and evaluating the answer. If the author will decide to changed or update the quiz, the `compile` command should be used to re-generate the quiz.

QuizPACK authoring aproach allows the authors to create and compile quizzes remotely using Telnet and FTP tools. Note that the authoring side of QuizPACK does not use traditional Web form-based authoring approach, but relies on generic text editing and communication tools. For teachers of programming subjects it's a benefit, not a shortcoming. A full-featured randomized quiz can be produced very fast, with the use of familiar tools on their preferred platform and with minimal authoring efforts over creating the code for questions. Teachers can publish the questions from their homes and then can just e-mail the students to take the quiz. They don't need to come to the class and distribute the papers to the students to take the quiz.

Figure 3: The structure of a database table with the quiz results.

QuizPACK use a specific http-based protocol to communicate the results of the student work with every question to a server specified by a teacher. We have successfully used this http-based approach to support communication between distributed components of educational software in our previous work [Brusilovsky, Ritter & Schwarz 1997]. With this approach any http server can be used to log or store the results of the student's work. For the needs of our own course we have implemented a simple storage server using Microsoft Internet Server and Microsoft Access database. The database stores results of the student's work in a very simple format (Figure 3). This is a convenient solution since allows to produce easily a variety Active Server Pages (ASP) scripts for creating student progress reports. With these reports, teachers can evaluate the performance of the a class or a particular student on a quiz or question level by calling the URL for one of the ASP scripts.

Evaluation of the System

During the Fall semester of 2002 we have performed a formative evaluation of QuizPACK in a real university course "Data Structures and Programming Techniques" at the University of Pittsburgh. The course was based on C programming language. During the first part of the course, we have use QuizPACK in in-class assessment mode using wireless handheld computers. During the second part of the course we have used the system in out-of-class self-assessment mode using regular desktop computers. The analysis of the in-class use of the system is beyond the scope of this paper since the results were significantly influenced by the use of wireless computers. Below we discuss some results of the evaluation of QuizPACK in the self-assessment mode.

QuizPACK was used to serve self-assessment quizzes of 5 to 10 questions each for almost every lecture of the second part of the course. The questions were prepared to let the student practice the knowledge of programming constructs and data structured introduced at the corresponding lecture. In addition to self-assessment computer quizzes we have also used regular paper-and-pencil assessment quizzes at the beginning of every lecture. A few weeks before the end of the course we have prepared a short 9-question assessment tool to collect the students feedback about QuizPACK. The students were informed about the questionnaire and were encouraged to fill it in. The participation in the study was voluntary. All participants were rewarded by thee extra credit points. In total, 27 students of 40 choose to participate. It's important to note that all students participated in the study have taken at least three self-assessment quizzes over the duration of the course.
Overall, the students have got a very positive feeling about the self-assessment questions. 48% of respondents thought that it "can significantly help", 37% though that it "can help", 15% thought that it "can sometimes be of help" and none found them useless. The ability to take a parameterized quiz several times was also highly evaluated. 56% found this feature "very useful", 26% found it useful, 19% found it "sometimes useful" and none "useless".

The last of the questions in the questionnaire allowed the students to provide an unstructured feedback. We have specially welcomed critical feedback and suggestions. While we have not asked about praise, many students has provided a very encouraging feedback from unspecified: "The self-assessment quizzes were of great help" to very specific: "The quizzes helped me to figure out link list implementation". The students also appreciated the parameterized nature of the quizzes: "You can also take the self-quizzes over and over again unlike the [paper-and-pencil] in class quizzes. You learn more for taking different quizzes over and you don't have to stress yourself over getting the answer right the first time". The students have also pointed out several problems and generated a number of suggestions. One of the most often mentioned suggestion was to provide self-assessment quizzes for every single course lecture, not just for a subset of them: "There were a few areas, I had trouble with, but there were no quizzes to go along with them". Many students also wished the tool not only reported the write answer, but also provide a detailed explanation of how this was obtained. We think that such an explanation can be generated by an explanatory visualization tool are planning to explore this direction. Finally, a number of students commented that they prefer a quiz format where all questions are shown on one page (as in paper-in-pencil quizzes). This format allows them to see the whole set of questions, take them in arbitrary order, and re-consider the answers before submitting the whole set.

Summary

We have reported an approach and a tool QuizPACK that enable teachers to produce easily parameterized quizzes for programming subjects. Parameterized quizzes greatly increase the productivity of a teacher enabling them to produce a range of questions where regular tool allows producing only one question. Parameterized quizzes prevent cheating in an assessment mode and allow the students to take the same question over and over in the process of mastering the subject. The tool was used in an undergraduate programming course and was very positively evaluated by the students. We are planning to continue the work in this direction taking into account students suggestions generated during the first formative evaluation.

EQUAL: A Universal Design Framework and Implementation of Novice Programming Language and Computing Environment for Native Users

Basawaraj Patil*, Klaus Maetzel and Erich. J. Neuhold
Fraunhofer Institute for Integrated Publication and Information Systems
Dolivostrasse 15, 64293, Darmstadt, Germany
{patil, maetzel, neuhold}@ipsi.fraunhofer.de

Abstract: In the evolving Information Society (IS), programming and computing skills are becoming important in educational, professional and personal endeavors and constitute an integral part of computer science education. In the current programming languages, programming constructs, semantic concepts, and syntactic elements, are based on English and implemented using ASCII character sets, seriously limiting the universal access to programming and computing skills. Especially, native users (e.g., non-English speaking students, adults, linguistic minorities etc), encounter enormous difficulties in understanding and translating their programming plans into the syntax and semantics of a programming language. Authors have designed and implemented a universal design methodology and experimental programming language - EQUAL and its compiler/interpreter and an integrated programming environment, in which, native users can write and execute programs in their native "customized" programming languages. EQUAL provides a unique opportunity to native users for learning programming and may be used as a scaffolding tool for teaching basic concepts of programming and computing.

Introduction
In the evolving Information Society (IS), programming and computing skills are becoming important in educational, professional and personal endeavors and constitute an integral part of computer science education. With globalization and rapid developments in Information Technologies (IT), the majority of Internet users do not use English, native users' issues may become serious because the vast majority of the world's population who do not, and will not in the foreseeable future speak English will be excluded from the Information Society. Students and people lacking programming and computing skills may become a serious individual and social problem [Dyson, 1997] and in the worst case, may lead to - Internet Apartheid [Shneiderman, 2000]. Native users referred to here include non-English based educational background students (e.g., primary and high schools, colleges and universities), adults, indigenous societies, people with special needs, linguistic minorities from developing and underdeveloped countries from Asian, the Middle East, Eastern European, African and South American countries or geographical regions. For these native users, it is unrealistic and impractical to learn and adapt to English based paradigm of HCI interactions and communications. In particular, millions of native students, for some reasons (e.g., political, social, etc.) are compelled to learn in native medium, have no alternative solutions to learn the IT skills and programming expertise.

Policymakers, educators and government administrators from these countries have realized the potential of IT and their impact on the emerging information societies. Even with special initiatives, free hardware or subsidized access to Web, Universal Access (UA) to appropriate linguistic and cultural content, textual information structures and programming languages has been a serious impediment to the development of IT skills and effective E-applications (e.g., E-democracy, E-Governance, E-Learning etc). Unfortunately, simple textual information structures (e.g., email addresses, domain names, operating system components), novice programming languages (e.g., LOGO, BASIC etc.) and textual languages (e.g., command, query, programming etc.) are not available and useful to the native users.

In general, from a technical point of view, there is a critical need of Enabling, Scaffolding, and Assistive mechanisms to cater to the diverse requirements of native users. Enabling mechanisms are mainly concerned to the enabling the native users to interact in native languages and socio-cultural environments with the computers. Scaffolding mechanisms are necessary to help and assist the native users to join the

* A doctoral candidate at Fraunhofer-IPSI, Darmstadt, Germany.
main stream of English based paradigm of HCI interactions and programming. Special assistive mechanisms are necessary to the native users with special needs. We consider universalization textual information structures and textual languages as fundamental strategy to support enabling, scaffolding and assistive technologies for the diverse needs, preferences and requirements of native users. With a long, term goal of IT Empowerment and Life Long Learning, we take the proactive approach of universalization of textual information structures and textual languages, and as a step towards a Inclusive Society, we recommend that, the "digital divide" has to be minimized by developing sustainable, enabling and scaffolding technologies by adopting universal design perspectives towards the design and implementation of textual information structures, programming languages and computing environments.

With respect to computer science education, in particular, teaching and learning of programming languages and computing skill with English as "programming paradigm" will seriously limit the universal access to IT technologies and programming skill. Because of historical reasons the majority of programming languages and programming paradigms (e.g., declarative, procedural, functional, object oriented etc) are mainly based on English semantics and syntax and implemented using ASCII character sets. Especially, the native users such as students and adult users, whose medium of education and instruction is in their native, natural languages and socio-cultural environments, encounter enormous difficulties in understanding and translating their programming plans into the English-based semantics and syntax of a programming language. In the new technology adaptation for Educational Computing and Learning, in particular, with respect to programming languages, non-availability and non-accessibility of programming languages and computing environments (e.g., integrated editors, debuggers etc) and language processors (e.g., interpreters, compilers, translators etc) constitute a major stumbling block to native users [Rogers, 2000]. Other factors, such as lack of native user interfaces and interactions, linguistic barriers, complex social and cultural factors will continue to hinder the effective learning of programming and computing skills. We also believe that user interfaces to systems for programming and computing environment can critically influence the development of programming skills. Hence, a wide range of native user programming languages and computing issues must be included in the universal design and universal access to programming languages, language processors and computing environments.

In this paper, we mainly focus on on-going work research work related to the universal usability issues of programming languages, language processors and computing environments from native users' perspectives with more emphasis on semantics and syntax i.e., notational aspects of programming languages and programming constructs. We also discuss a universal, inclusive design methodology of programming languages, language processors and computing environments. Furthermore, it will contribute to the better understanding of native user requirements, universal design of programming languages and computing environments, and implications to scaffolding and teaching tools.

Native Users: A Profile

The research studies on needs and requirements of native users are scarce and poorly understood. Within the scope of our research work concerned with universal design methodologies and universal access to textual languages (e.g., command, query, programming etc) with a long term research goal of "Information Technology for All (IT4ALL)", we define and focus our studies to a diverse, global, end-user populations called "native users". In-house studies on usability and universal accessibility of textual languages and novice programming issues were conducted with the help of researchers, HCI experts, native users and students with diverse multilingual and multicultural backgrounds. From these preliminary studies, in general, native users may be defined as end-users, including users with special needs with one or more characteristics such as: (a). They prefer or use their native, natural language-like constructs for human-computer interactions and programming. (b). They have minimal or no English knowledge. (c). Their medium of education and instruction is in their native, natural languages and socio-cultural environments. (d). They are novices or possess minimal computing skills. (e). Native student communities would like to acquire not only information manipulation skills but also skills of programming. (f). Native users may also include people with special needs, (e.g., visually challenged users prefer to use native Braille).

Native User HCI Model and Programming Language Issues

In general, programming is the task of mapping the mental plans and program compositions into language constructs, i.e., semantics and syntax of a computer language to achieve a particular computing task. For historical reasons, the majority of programming languages and paradigms are derived from English semantics and syntax and implemented using ASCII character sets. A native user HCI model of interaction
and communication between the native user and the computer for programming tasks can occur at conceptual, semantic, syntactic, and lexical levels. At conceptual level the "meaning" of the task model should match the native user's world model, and here reside the concepts of programming, programming language features, relationships, and operations. At the conceptual level, the technology, programming paradigms, metaphors are new and unfamiliar to the majority of native users. At the semantic level, the ideas from the conceptual level are represented by means of a programming language placed in the context of a computing task. The abstract operations from the conceptual level are fully defined in terms of objects, functions and programming constructs of a programming language. At the semantic level, the semantics of programming do not match well with the natural semantics of native users' languages. At the syntactic level, the "grammar" of the programming language is defined, including the arrangement of valid programming elements and program construction. At the lexical level, the primitive elements such as tokens and literals of a programming language are used to write a program to achieve a computing task. The "grammar" at the syntactic level is highly inflexible to the requirements of the native users and the ASCII-based lexical tokens at the lexical level do not cover the majority of native user languages and cultural conventions.

In other words, the majority of programming languages "do not speak the language" of the native users and seriously hamper understandability, memorability, learnability and ease of use of programming languages. The native users are compelled to use semantic and syntax concepts that are not compatible and comprehensible to the majority of native users. Hence, current programming languages does not provide flexible approaches and alternative opportunities to native users to learn programming. In general, programming is difficult, but native users encounter additional difficulties at conceptual, cognitive, semantic and syntactic levels in translating the programming plans into the formal syntax of a programming language. Thus, we need not only syntactic but also semantic and cognitive adaptations in programming languages and computing environments.

In general, from the native users' perspective as well as from the preliminary usability studies, the major issues are:

- **Lack of Computing Resources:** The native user computing resources are scare and poorly understood. The computing resources include programming languages, language processors, computing environments, teaching and learning resources and materials. There is a critical need of production, publication and dissemination of computing resources for the native users. Other serious issues are complex computing concepts, unfamiliar metaphors, unnatural programming paradigms, lack of integration of pedagogical concerns, and poor training and teaching resources.

- **Syntactic Inflexibility:** The majority of syntactic elements or vocabularies, punctuation, programming conventions and cues of programming languages is based on English syntax, and conventions and implemented using ASCII character sets. Using ASCII character set, seriously hampers the universal access to programming at syntactic and lexical levels for non-Roman based scripts and complex native language diacritics.

- **Semantic Mismatch:** The semantics of programming constructs do not match well with the concepts and semantics of native user natural languages. For example, many programming semantics of input/output statements (e.g., READ, WRITE, INPUT, OUTPUT, PUT, GET, PRINT etc) have a generic form `<VERB> <objects>`. Many native users' languages (e.g., Asian, Arabic, Indian etc) have the generic form `<objects> <VERB>` and sometimes freely mixes both the formats in general communication. Similarly, the IF-THEN conditional statement and its variants have a generic structure IF `<condition>` THEN `<statements>`, but these programming constructs have diverse native interpretations. In novice programming studies, it is observed in [Bonar and Soloway 1985, Ebrahimi, 1994] that, the majority of semantic errors arise due to the semantic mismatch and novice users relaying on preconceived knowledge and translating the programming plans using their natural language semantics.

The visual programming systems, programming by demonstration and form-based programming may be used to address some of the native users programming issues by providing native "customized" GUI components. Visual languages for programming may help and highlight only a few aspects of programming and manipulation of information structures. But, it is observed in [Gilmore and Green 1984, Green and Petre 1992] that the textual languages are more useful in learning the skills of programming such as comprehension, creation, documentation, modification and debugging and learning programming.
EQUAL Design Principles and Rationale

EQUAL (Easy, Quick, Universal, Accessible Language) is a universal, human-centric, inclusive design methodology for the design, implementation and evaluation of textual languages for command, query, programming tasks and computing applications for native users, including native users with special needs [Patil et al., 2001a, Patil et al., 2001b].

Since, native users are novices, the research studies and empirical results in the fields of Psychology of Programming [Hoc and Nguyen, 1990, Dyck and Mayer, 1985, Rogalski and Samurcay, 1994] and Novice Programming [Mayer, 1981, Bayman and Mayer, 1983, Bonar and Soloway 1985, Boulay 1989] provide valuable insights and may be extended and integrated into the universal design of novice programming languages and computing environments.

It is observed that natural language-like constructs and commands are effective in the design of user interactions with the computer systems [Ledgard et al., 1980, Landauer et al., 1983, Biermann & Ballard, 1983]. Even the recent studies [Pane et al., 2001] demonstrate the concept of “natural programming”. Natural programming does not mean that the native users should use their natural languages, but the languages of programming and interactions should be as "natural" as possible and able to "mentalize" the interactions, learn quickly and use effectively - support of high degree of naturalness.

Cognitive processes and structures, program constructs play a vital role in problem solving, programming and comprehension [Hoc and Nguyen, 1990, Rogalski and Samurcay 1994]. Such an understanding would lead to better programming languages whose syntactic structure more closely reflects internal semantic structures thereby easing the process of programming - support closeness of mapping.

The process of translating a programming plan into one that is compatible with the computer is a highly cognitive activity. The programming language should minimize the difficulty of this translation by providing high level primitives that match the operators in the programming plan and composition - exploit cognitive dimensions of notations and information structures.

The characteristics of the language and notational aspects play a vital role in acquiring the skills of programming. Avoid unnecessary and confusing operators, cryptic programming constructs, complex data structures and control statements - keep it simple and effective. From the basic guidelines and principles of usability engineering, the programming languages and computing resources should satisfy the needs, preferences and requirements of native users - speak native users' languages.

Salient Features of EQUAL Language

EQUAL is a simple, experimental, novice programming language mainly designed by taking into consideration the special needs and requirements of the native end-users, including visually impaired users. The design and rationale of the EQUAL language is discussed more detail in [Patil et al., 2001a]. Here we highlight the salient features:

- EQUAL language features are deliberately kept simple but have important features of programming to teach novice programming. Syntax is simple, readable, understandable and consistent with native user's knowledge. EQUAL supports simple data types, commands and statements and control constructs.
- The language “vocabularies” and programming paradigms are highly customizable to the universal needs and preferences.
- The computing environment is “internationalized” and supports divers time, date, currency, calendar, numeral standards and formats.
- The visually impaired native users can program using native Braille codes using suitable transcription mechanisms. The programming constructs and interactions (e.g., messages, errors, results etc) may be extended and enhanced with digitized speech and text-to-speech technologies in users' native languages.

EQUAL Programming Constructs

Variable Names, Values and Operators

The empirical studies in [Carroll 1978, Teasley 1994] have demonstrated that meaningful variable names and numerical values improved program comprehension and facilitate learning. For example, in a simple statement Area_of_Circle: = 2 * PI * Radius; may represented in EQUAL for Chinese user (Refer Fig 1d). In Arabic (Refer Fig 1b), programs are written and displayed in bi-directional format and prefer 'five pointed star' or 'X' for multiplication operator. The assignment operator '=' may be represented by '. The general interpretation of statement termination symbols ';' varies considerably (e.g., ';' is used for question mark in Greek). The enclosing the string constants, also vary considerably (e.g., «string constant» in French,
"string constant" in German, etc.). The relational and logical operators are quite confusing and native users misinterpret their meaning and it is mainly due to lack of knowledge of Boolean algebra. EQUAL universal design framework supports these notational flexibility and adaptations, and EQUAL helps in easy comprehension and facilitates effective learning. These simple adaptations will reduce cognitive loads, avoid unnecessary frustrations and motivate native students to learn programming skills.

**Command Names and Simple Statements**

Both formal and informal observational analyses repeatedly identified names, naming and structural contexts as an important practical problem [Landauer et al., 1983]. The majority of assignment statements, input/output statements are simple imperative statements or commands and often take the form of VERB <objects> or <objects> VERB or mixed format. EQUAL supports the above formats and exploits the natural "patterns" of commands, programming constructs and information structures that are consistent with native languages and general communication conventions.

![Image of EQUAL programs in various languages](image)

**Control Statements**

Control strategies and looping constructs are very difficult concepts and demand high cognitive loads [Soloway et al., 1983]. It may be observed that, just by providing equivalent control and looping constructs in native programming language constructs may be insufficient and inadequate, some time quite misleading and confusing from the preconceived knowledge [Bonar & Soloway, 1985]. In IF-THEN statement or its variants, it is observed that [Pane et al., 2001] end-users use THEN for "sequencing" which contradicts the meaning of "consequently" in the formal languages. In REPEAT or WHILE control constructs, native users fail to understand the terminating or exit conditions. One effective design strategy is to "map closely" the natural semantics of native users' languages and concepts onto the formal semantics of programming. In the present state of research, explicit training is the best way to circumvent these difficulties.

**EQUAL Implementation and Computing Environment**

The basic design principle of the EQUAL language design and development environment is to separate the formal grammar, semantic concepts, syntactic and lexical components and represent them in a language independent, user defined profiles and culture neutral representations. From these design constrains and specifications, EQUAL design and development environment provides an integrated platform to generate automatically or semi-automatically language components, scanners, parsers and compilers/interpreters [Patil...
et al, 2001b]. Special morphological and linguistic knowledge is necessary to process complex languages. EQUAL uses Unicode, Java, XML and Compiler technologies and functional components may be deployed as standalone application or client-server architecture.

The EQUAL computing environment consists of Code Window, Input Window, Output Window, Error Window and Help Window. The native users can write EQUAL programs using Unicode compatible text editors and submit them for the compilation. The syntactic and semantic errors are displayed in the Error Window with necessary information to facilitate easy correction. In case of an error-free EQUAL program, the interpreter/compiler will execute the program on Java Virtual Machine (JVM). The Input Window expects the inputs to the program and generates the outputs in the Output Window. On-line help information and documentation is available in the Help Window. The error messages, dialogues, help information, training and learning resources are hand-coded and stored in separate files in native user preferred languages. EQUAL is flexible enough to incorporate pedagogical and learning modules.

Conclusions and Future Work
In this paper, we discussed the universal accessibility and usability issues of textual information structures, programming languages and computing environments from native users' perspective and developed a universal design framework and methodology for the design, implementation and evaluation of programming languages for computing tasks and applications. We highlighted universalization of textual languages as a basic strategy for the enabling, scaffolding and assistive technologies with necessary conceptual, semantic, syntactic and lexical adaptations in computer languages and computing environments. We also discussed the salient features of the EQUAL language in a few representative native user languages such as Arabic, Chinese, Zimbabwean and German. The EQUAL design methodology and computing environment is also flexible to incorporate native users' versions of Braille codes, digitized and text-speech technologies. We believe that, the EQUAL language and EQUAL computing environment provide a unique opportunity to the native users to learn programming and computing skills. We highlighted the general principles, guidelines and design methodology of EQUAL, but they are also applicable in different textual languages, programming paradigms, and textual applications. The experimental work is in progress and the implementation of complex data types, control constructs, usability studies and critical evaluations are planned in the future work.

Abstract: This paper describes the pilot portal project, involving development of public installations in two distant locations, which will act as portals into each other. The current state of the world is calling for new means of world-wide communication and understanding. The Portal Project is a work in progress. Its objectives are to connect people and places, and to encourage broad cultural and environmental observation and reflection. Portals will be supported by a network of cameras streaming live video which is received and projected by plasma screens in other locations and collectively displayed at a website. The video installations will promote awareness and communication among participating foreigners.

Introduction

The Portal Project will bring together people and places in a way that has become possible only through the advent of modern communication technologies, via live video web streams. Unlike more traditional art projects that usually happen at a specific place and time, for those particular observers who choose to participate, the Portal Project installation creates a framework of experience to facilitate cross-cultural interaction at the most basic, passive, everyday level.

Imagine this: While taking a break from work at 11:20 in New York, right next to the fed ex truck, you will be able to look into Vienna, where idle Austrians enjoy an afternoon stroll. You may even make a friend and arrange to meet on sixty-first and Lexington in New York and Stephansplatz in Vienna.

Rationale

Cities are complex environments, comprised of people, social interactions, communities, architecture, invention, history, etc, offering rich learning opportunities. However, our everyday lives make the meanings of the city and the dilemmas coexisting in it remain unseen. We become accustomed to them as part of our visual environment and they no longer provoke our reflection (Greene, 1978). Art, and urban installations, have the potential to make these resources more evident for us.
The installation inserts itself in the city landscape intercepting people in their daily existence. It calls for being seen and, in the same process, makes the city itself visible by its inhabitants. It provides an opportunity to bring the background to the stage. By including the mediational device, the images of a spot in a city get the status and attention of a spectacle. This project, inspired by Kit Galloway and Sherrie Rubinowitz's 1974 installation "Hole in Space," allows for taking a look at the lives, faces, spaces, and reactions of the others; people from another city and culture. This is a chance for seeing but also a chance for awareness of being seen. And being seen in a way that we don't know ourselves - by other eyes, by other culture, as others.

New York and Vienna are dissimilar and alike. Almost the same neutral space of the central touristy area exists in every city, an equivalent functional place, crossed by city people with similar concerns, walking on avenues and squares. Big cities' spaces are common to all big cities around the world in globalization, where people are always in transit with their bodies and sensibilities.

Our present time highlights the need for cultures to find new ways of communicating and of seeing each other and themselves. American people and all cultures are subject to stereotyped perceptions of the others, of us, and of conflict - in which the media plays a mayor role. The Portal Project intends to provide a different, less censored and less edited insight opportunity for understanding. It intends to provoke questioning, confusion, reflection, awareness. And in this process of identification and differentiation, it intends to mobilize citizens of distinct cultures in active explorations of the complex world community within which we are all connected. If we are successful with this pilot connection, we will expand to other connections between locations of similar and dissimilar environments and cultures.

Design and Technology

Much like backlit print advertisements at bus stops, the Portal Project uses a metallic frame to become integral part of the city landscape and our daily visual experience as inhabitants of our cities. Instead of print, however, this metallic structure contains a 50" plasma television screen. The moving images are a live video feed, streamed over the Internet, from an identical box located in Vienna. Both boxes, hidden on top of the structure, contain a network video camera connected to the Internet via a high-speed connection. These boxes, therefore, become windows into a different city and culture. Like a window, they provide a view into a different environment, as well as becoming part of the familiar one.

Complementary WWW Site

The website will include the live images of the two locations one next to the other on the screen. The two sites and the reactions of people looking at the screens may be seen by any website visitor. The site will include a discussion forum and chat room for the observers to discuss these views. Links to useful resources, such as online translation dictionaries and cultural historical references, will be provided. An archive of selected video clips and discussions will create a record of the participation of the users and viewers in the installation. This archive, as well as the experiences of comparing the two screens and/or of being in the location of one city will be the basis for educational activities designed for school and museum groups.

Future Directions

The project is in its early stages. Our near future goals are to establish corporate, government, school and museum partnerships. We are seeking partnerships with organizations wishing to promote their products by donating their use. We are looking for the provision of space in the ideal locations, balancing public access and security, in each city. We are also seeking partnerships with schools and museums to collaborate in the development of supplementary educational materials provided on the web site. This methodology can be exported and expanded by altering the locations and connections in the network. For example, other projects may be intended to remind city folk of non-human aspects of nature, involving live-video feeds from cameras in remote outdoor locales to projections in cities, or they might support/build/highlight the connection between people of similar ethnic origin living across the world.

Reusuable Models of Pedagogical Concepts -
a Framework for Pedagogical and Content Design

Jan M. Pawlowski

Information Systems for Production and Operations Management
University of Essen, Germany
jan.pawlowski@wi-inf.uni-essen.de

Abstract: Standardization initiatives in the field of learning technologies have produced standards for the interoperability of learning environments and learning management systems. Learning resources based on these standards can be reused, recombined, and adapted to the user. However, these standards follow a content-oriented approach. The process of applying pedagogical concepts is not covered by these standards. In the last years, several approaches for pedagogical and didactical concepts have emerged, but their use within a framework of standards is not yet consistently solved. Therefore, a model is presented which combines pedagogical and content-oriented design. The model, based on the Essen Learning Model, is a basis for the reuse and recombination of pedagogical expertise.

Introduction
Development processes of learning environments have changed significantly in the last years. The enormous cost for multimedia production led to the consequence that a high amount of end-users are necessary to be efficient. Learning resources have to be adapted and updated in shorter periods of time. Furthermore, learning environments must be individually tailored to the users' needs and preferences in order to optimize the learner's performance.

Standardization is a means to ensure interoperability between systems. Both, learning management systems and learning environments have been subject of standardization initiatives. These initiatives, such as IEEE Learning Technology Standards Committee (LTSC), Instructional Management Systems (IMS)-Project, or the Advanced Distributed Learning Network (ADLNET) have developed a broad range of standards, from high-level specifications for architectures to bindings for certain components. However, most of these approaches focus on the reuse of content. These specifications do not provide adequate concepts for modeling pedagogical concepts. As a consequence, several approaches of pedagogical models, such as Educational Modeling Language (EML) or Tutorial Modeling Language (TML) are being developed. These models cannot be seen as a substitute for content-oriented standards. Moreover, a framework for the combination of content-oriented standards and pedagogical approaches is needed to model a complex learning environments.

In this paper, an approach is presented providing a framework for the description of pedagogical and didactical concepts. The approach is based on the Essen Learning Model (ELM). ELM is a development model for the development of learning environments. It provides support for developers, designers, content providers, teachers, and learners on various levels. Processes and activities in project management, quality assurance, curriculum development, course design, and implementation are supported. Furthermore, the specification of learning technology standards is integrated in this model.

First of all, related standards are presented. It is shown how these standards provide a framework for the interoperability of learning environments. Secondly, related approaches for pedagogical concepts are presented. Furthermore, an introduction to relevant aspects of the Essen Learning
Model is given. We focus on the aspects of modeling pedagogical concepts. As a conclusion, further research activities are suggested.

**Learning Technology Standards**

Learning Technology Standards are being developed by several initiatives. In this section, the relevant standards for learning environments are presented. Currently, two standards have reached a high level of maturity (Pawlowski, Adelsberger 2001a, Pawlowski 2001): Learning Object Metadata (LOM) and the Sharable Content Object Reference Model (SCORM).

**Learning Object Metadata (LOM)** is a standard by the IEEE Learning Technology Standards Committee (LTSC) for the description of learning resources (LTSC 2001). LOM are used to describe learning resources, such as learning environments. For this purpose, nine categories are included: General, Lifecycle, Meta-Metadata, Technical, Educational, Rights, Relation, Annotation, and Classification. This standard is useful to describe general characteristics of learning environments to facilitate search, retrieval, and reuse of learning resources. However, the description of educational aspects is limited to a generalized summary (e.g., interactivity type, learning resource type, interactivity level). This classification cannot be used to represent detailed information on pedagogical and didactical concepts used in a learning environment.

The **Sharable Content Object Reference Model (SCORM)** (Dodds 2001a, Dodds 2001b) by the Advanced Distributed Learning Network (ADLNET) is a standard to ensure interoperability between Learning Management Systems (LMS) and learning environments. SCORM integrates LOM and the content aggregation model which is a standard to represent the structure of a learning environment and relations of learning units. The run-time environment in SCORM is the interface between LMS and learning environments. It controls the sequence of a learning environment by integrating the Computer Managed Instruction (CMI) standard (LTSC 2000). This standard can be used to represent courses and learning environments. However, the focus of this standard is to combine and control learning environments. The main aspect is to model content and its structure. Although the structure can implicitly contain a pedagogical approach, no pedagogical concept is used to determine the structure, navigation, or other adaptations. Both standards serve as a base for interoperable description and reuse of learning environments and learning resources. However, these standards need individual extensions in order to apply pedagogical concepts.

**Pedagogical Models**

The current representation of metadata such as LOM does not provide an adequate representation of pedagogical concepts (Koper 2001, Pawlowski 2001). Additionally, there is no adequate mapping of content-oriented representation to a pedagogy-oriented representation. A variety of models have been developed in order to close this gap.

The **Tutorial Markup Language (TML)** (Netquest 2000) is a markup language for the development of tutorial systems. Questing and problem-solving scenarios can be specified through questions, answers, rules, and help functions. It is possible to develop simple tutorial systems. However, only certain didactical approaches can be realized using TML.

The **Instructional Material Description Language (IMDL)** (Gaede 2000) represents structure, content, assessments, metadata, and a learner profile. The approach strictly follows an instructional design approach. Therefore, it restricts the pedagogical design. It is not flexible enough to model any given pedagogical approach.

A promising approach for the representation of pedagogical concepts is the Educational Modeling Language (EML) (Koper 2001) which is based on a meta-model for pedagogical modeling. It focuses on the embedding of learning resources in a pedagogical context. The metamodel consists of four components:
• Theories of learning and instruction describe theories, principles, and models of learning and teaching. The model distinguishes between empiricist, rationalist, pragmatist-sociohistoric, and eclectic theories.
• The Learning Model describes the interactions of learners in specific learning situations.
• The Domain Model represents the domain in which a learning environment is used.
• The Unit of Study Model describes the design of learning units depending on learning theories, learner models and domain models. The following categories are included in this model: Unit-of-study, Metadata, Roles, Learning-objectives, Prerequisites, Content, Activity, Environment, Method.

EML provides a promising representation of content and pedagogical concepts. Currently, there is no mapping to other standards such as SCORM. In order to use both standards, a common framework must be specified.

Essen Learning Model (ELM)

ELM Development Model

The Essen Learning Model is a modular system (Fig. 1) supporting development processes as well as the system's use on different levels: the support of curriculum design (C-level), the development of learning sequences (D-level), and the development of learning units (E-level) (Adelsberger, Bick, Pawlowski 2000, Pawlowski, 2000, Pawlowski, 2001). Three abstraction levels can be distinguished: The generic development model provides knowledge for a variety of contexts. This generic model is customized depending on the users' needs and preferences, and transformed into a specific process model for each development project. The process model is implemented using the Architecture of Integrated Information Systems (ARIS) and provides a framework for educational technology projects. ARIS is a frame concept for a global description (modeling) of computer supported information systems, covering the whole life-cycle range - from business process design to information technology deployment (Scheer, 1998). The third level is the result of the development process in the form of certain implementations for each module.

Figure 2 represents the main processes of the Essen Learning Model. The result of ELM-C is a detailed network of learning objectives and goals, determining structure and relations of learning sequences (e.g. courses). Based on these results, learning sequences are developed in ELM-D. The focus of this phase is to find an adequate didactical method together with the right technology depending on learning objectives and user groups. Finally, single learning units are designed and implemented in ELM-E, using the Extensible Markup Language (XML).
Modeling Pedagogical Concepts in ELM

Modeling pedagogical concepts mainly consists of three processes in ELM:

**Context Modeling:** Learning cannot be separated from the context. The context includes the environment of the learner (e.g., institution, organization, company) and the learner's experiences and knowledge. The context is analyzed on two levels: A description of the learner's characteristics and preferences and the organization the learner is involved in.

**Content Modeling:** The content of a learning environment is described on three levels: learning sequences, composite learning units, and learning units. These levels correspond to the structure of SCORM (Content, Block, Sharable Content Object).

**Didactical Modeling:** Didactical concepts are directly related to the learner (actor), learning objectives, learning setting, and the description of a method (see Fig. 3). The description of a method consists of phases (activities) which can be grouped to phase blocks. Furthermore, experiences and the usability of a method for certain content, settings, or learning objectives is described (see Bick, Pawlowski, Veith 2001). By this description, a knowledge base for didactical methods is created. Designing a learning environment means that the context, content, and didactical method must be related. As an example, the method "simulation game" consists of the phases introduction, motivation, activity/interaction, reflection, abstraction, and analysis/feedback. These phases are mapped to learning units. The mapping of learning units to phases provides the connection between the pedagogical model and the content model (e.g., SCORM).

Fig. 3: The Essen Learning Model Overview

Fig. 4: The Essen Learning Model: Methods

The model of a pedagogical concept consists of the three main components (context, content, and method). In Table 1 the information model for methods is described.

Conclusion

In this paper, the weaknesses of current standards have been identified. Learning technology standards such as LOM and SCORM focus on content-oriented models of learning. The representation of pedagogical concepts is neglected in these models. It has been shown that most existing pedagogical models do not provide a generic representation for pedagogic expertise. The Educational Modeling Language (EML) is a step towards a generic representation. However, pedagogical specifications and other existing standards need to be mapped into a common framework. The Essen Learning Model provides this framework by integrating existing standard with a generic pedagogical model. This model serves as a base for a high-quality design of learning environments from a pedagogical and content perspective.

Essential Elements in the Design and Development of Inclusive Online Courses

Dr E J Pearson
Special Needs Computing Research Unit
University of Teesside
United Kingdom
e.pearson@tees.ac.uk

Associate Professor Tony Koppi
Educational Development and Technology Centre
University of New South Wales
Australia
t.koppi@unsw.edu.au

Abstract

This paper discusses the issues that we consider central to accessible online education. A recent research project investigated the accessibility of online courses for students with disabilities by evaluating existing courses, developed by academics at the University of New South Wales (UNSW). The evaluation revealed evidence that some aspects of the courses were inaccessible, but that with careful design guidance and awareness of the needs of students with disabilities, those courses could be made more accessible. As a result a set of Guidelines for Accessible Online Courses was produced (Pearson & Koppi 2001) specifically to aid academic developers of online courses with limited technical ability.

However, these guidelines assume that the academic developer understands and accepts the issues related to inclusive design and development. We decided therefore to take a step back and use our experience and the knowledge gained through researching the guidelines to identify the specific issues that one needs to consider, and the required skills to understand inclusion and accessible design. The issues were encapsulated into five major themes: legal or quality assurance requirements; awareness of and the ability to use the available guidelines and protocols; some understanding of the assistive technologies used by students with disabilities; awareness of designing for inclusion; and understand and apply the checking tools and mechanisms that are available.

These themes have been incorporated into a series of face-to-face workshops and an online course offered in flexible mode, aimed at assisting the academic in understanding both the broader issues of accessibility, and in developing the skills and knowledge for accessible course design.

Background
Our own research (Pearson, 2001) and others (Grimaldi and Goette, 1999) have noted the liberating effect for students with disabilities being able to access learning materials and resources on the web. However, the same research concludes that students may have particular needs which need to be addressed in the design of online course and learning materials and which can in fact present further barriers to inclusion. Some examples include:

- students with vision impairments may use screen magnifiers or screen readers
- those with hearing impairment may need captioning or commentary for video and other multimedia
- students with learning disabilities such as dyslexia might use speech recognition software for data input
- people with other disabilities including aphasia or colour blindness need clear access to structure, careful use of colour, and consistent organization of learning materials
- students with physical disabilities may use alternative input mechanisms and need easy navigation

All of these requirements have an impact on the way the student interacts with a learning environment. Furthermore, some students might not be fluent in the language of study or there could be other technical barriers e.g., a slow modem or they might be using a text-only browser – all of these things can present further barriers to access. While many of the adjustments, which make sites accessible for use with screen readers, also provide effective access for others with disabilities; that is not always enough. Careful design – particularly in the context of online learning – can mean more effective access for all students and provide a better experience for all.

Partners

This work is a collaborative project between University of New South Wales (UNSW), and University of Teesside (UoT). UoT provide the research expertise in special needs and accessibility, while UNSW contribute the technical expertise and resources. The courses have been developed for staff development purposes at UNSW and for a Masters level module for Multimedia students at UoT.

Introduction

As a result of a research project (supported by the Leverhulme Trust, UK) which set out to investigate the accessibility of online courses (in this case courses developed in WebCT), we produced a set of guidelines for accessible online courses (Pearson & Koppi, 2001). The guidelines were based on those produced by the Web Accessibility Initiative (http://www.w3.org/WAI/) but have been designed specifically to aid academic developers of online courses with limited technical ability. The guidelines constitute a handbook and guide for academic developers for the design and implementation of online courses. They provide advice, practical examples, references and links for the designer. The guidelines are available to staff at UNSW, but also to anyone requesting them both in print and online (in an accessible format).
Following on from this research and the resultant guidelines, we set out to explore the extent to which the guidelines can be used as a basis for staff development and to encourage prospective online course designers to develop courses which are accessible and inclusive for all students. We used the Guidelines first as a basis for the development of a face-to-face workshop concerned with accessibility. The workshop was used not only to train Teaching Fellows in accessible design, but also as a pilot for the creation of an online course in accessible design. Our experience of the face-to-face workshop provided us with the opportunity to reflect on the process, the content and the tasks and consider how they could be translated to a flexible mode (Koppi and Pearson, 2002).

Five major themes were identified which we considered desirable for the academic to understand, appreciate or develop skills in for accessible design. These five themes encompass:

- legal or quality assurance requirements;
- awareness of and the ability to use the available guidelines and protocols;
- some understanding of the assistive technologies used by students with disabilities;
- awareness of designing for inclusion; and
- understand and apply the checking tools and mechanisms that are available.

The workshops and online course were developed to cover these five areas. The remainder of this paper discusses each of these areas and how they relate to the development of accessible online courses and the designer’s role in meeting the requirements of students with disabilities.

**Legal and Quality Assurance Considerations**

The rights and needs of students with disabilities are now recognised in the Special Educational Needs and Disability Act 2001 and through changes to the Disability Discrimination Act 1995 in the UK, the Disability Standards for Education under the Disability Discrimination Act 1992 in Australia, and the section 508 of the Americans with Disabilities Act in the USA. Those developing courseware need at least to be aware of the acts and take this into consideration in the provision of online resources.

However, it is perhaps more relevant for academics to consider accessibility in terms of quality assurance and the Quality Assurance Agency’s (QAA) (in the UK) expectations of Higher Education Institutions in complying with legal obligations. The QAA set out 24 precepts or standards that institutions are expected to meet, including treating students with disabilities as part of the academic community. Possible action includes:

- accessible Web and Intranet sites, and alternative formats for programme details and other information;
- adaptation of course material (including electronic material) and course delivery to ensure access; and
training staff to use relevant technology and to produce accessible electronic
courseware, (JISC, 2001).

Guidelines and Protocols
Web designers and course developers need to be aware of and be able to use the
guidelines to ensure that their websites and courses are compliant with the W3C
thereby meeting basic accessibility requirements.

The W3C guidelines for accessible web design are, at present, quite technical in
nature and lack examples. Although the WAI are working on developing a more user
friendly set of guidelines, the Pearson and Koppi (2001) Guidelines for Accessible
Online Courses, are designed to assist the average non-technical academic designer
who is developing online learning materials and resources. They consist of a set of
tips, techniques, examples, references and links to other sources of information to
help the developer to produce accessible courses. There are also other guidelines,
most of which are based on those developed by the WAI at W3C, relating to the
design of web sites in general.

Assistive Technologies
Assistive or enabling technologies are devices, hardware or software, which enable
people with disabilities to use the computer. Examples of assistive technology include
screen readers (such as JAWS), screen magnifiers, alternative keyboards or input
devices, voice recognition software and text-only browsers. Some experience in the
use of these devices is beneficial for the courseware developer. It helps to understand
the way that students interact with the online environment and the overheads that the
use of such technology can involve, including difficulty in navigation and the extra
time that may be required. Experience in interacting with the learning environment
using assistive technologies can also highlight their limitations when used with certain
features e.g., chat rooms. Some assistive technologies (e.g., screen magnifiers, high
contrast screen settings) can also be used for simple accessibility checks.

Designing for Inclusion
Design is central to the whole issue of accessibility and in this context we are really
referring to learner-centred design (Pearson & Green 1999), which means
understanding and considering who the user is, what their needs are, what you want
them to learn, how they are going to learn it, and how you are going to support them
in achieving their learning objectives (McLoughlin and Marshall, 2000; and Winnips,
2001). In addition, we need to consider structural, navigational and interface design,
and we also need to think about designing accessible resources and documents.

Accessible document design requires some forethought and skill to be accessible to
those using assistive technologies. The academic designer needs to consider the
structure and appropriateness of their documents as well as the format in which they
are presented. PDF documents, for instance, can be a particular problem. With the
correct tools and skills, however, many PDF and other documents can be made
accessible.
Checking tools and mechanisms

Checking tools can be used for either checking documents for accessibility before they are published or to check an existing web site online. There is a number of tools, or mechanisms, available.

BOBBY (CAST 2001) can be used to check single pages online, or can be downloaded to check entire web sites on payment of a license fee. It provides checks on the accessibility of web pages in accordance with the W3C guidelines and the requirements of ADA section 508. The checks are, however, largely functional and many design elements require a manual check.

A-Prompt (Accessibility Prompt 2001) evaluates web pages for accessibility barriers and making repairs to correct those problems. A-Prompt is also based on the W3C guidelines and is made available free of charge through the University of Toronto and the University of Wisconsin.

Authoring tools such as Macromedia Dreamweaver include a number of plug-ins or extensions that enable accessibility checks of web pages as they are developed. These extensions include the ability to evaluate and fix some accessibility problems to meet the requirements of the W3C guidelines and the ADA 508 requirements.

There are tools available within Internet Explorer or as Windows utilities that might be used by people with disabilities and that are available to any PC user at no additional cost. So that, for instance, you can use the screen magnifier or switch off graphics to check what the site would look like to someone who either doesn’t use graphics or can’t see them.

Conclusion and Further Developments

Taking all of these themes into consideration, the legal and quality assurance obligations; the guidelines that are available for us to follow; awareness of and an ability to use some of the assistive technologies that people with disabilities use; particular attention to the design of learning environments; and being able to use the checking tools that are available, we have created a course which will give students of multimedia and staff developing online courses the opportunity to investigate and develop skills in each of these areas. At the end of the course the participants will be well equipped to both understand and undertake the development of accessible online courses. It is important that course designers both understand the need for accessible courses but also that they are equipped with the skills and resources necessary to be able to do that.

Further developments will include adapting the course to cater for the needs of the more technical web developer to encompass techniques in the development of accessible multimedia, such as video streaming; and understanding of the accessibility features, claims and limitations of software products such as Adobe and Macromedia.

The next stage of the process is to evaluate and compare the face-to-face workshops and the online course in practice to determine its effectiveness and requirements for enhancement.

Guidance for a Learner Using an Aided Learning-to-Read Software

Chrysta Pelissier
Laboratoire de Recherche sur le Langage
Maison de la recherche - 4 rue Ledru - Clermont-Ferrand
France
pelissier@lrl.univ-bpclermont.fr

Abstract: The design of resource software intended for learning raises various problems. In this paper we shall deal with one problem in particular — the guidance for the learner. To illustrate our ideas we shall use as an example the Lexical Research Module, or LRM, of the AMICAL project.

In the first section of this paper, we shall introduce the AMICAL PROJECT. Then we shall describe the various functions of the LRM, as well as the various problems that it raises. Finally, in the third section, we shall look in more detail at the problems of such guidance, concentrating more specifically on the different uses this guidance can have.

1. The AMICAL Project

AMICAL[1] (Chambreuil, & al., 2001) is a theoretical research project, and one of its objectives is to think about the design of computer environments for helping learning in one particular area — reading.

In the computer environment of the AMICAL project, currently intended for five-year-old children beginning to learn to read, belong several types of software, which we call 'modules'. These modules are knowledge-based systems and correspond to specific types of learning situations and interactions with the student. We can separate these actions into three groups: "tutorial", "explanation" and "resource" modules.

Modules in the tutorial group, also called tutorial modules, lead, in a controlled manner, to the pupil gaining knowledge. Their aim is to propose to the learner training courses in reading. These courses are the result of didactic activities. They are created dynamically by the system and adapted to a given learner at a particular stage of his/her training.

Modules in the 'explanation' group are interactive-learning environments in which a collection of components are put at the learners disposal. The pupil can thus combine them in order to make his own, more complex components. The system is interactive in the sense that it is capable of communicating, of reacting in real time to various actions carried out by the learner. The components are complex in the sense that they correspond to a combination of simpler elements — those provided by the system.

Modules in the "resource" group are environments which can be compared to resource-documents (CNDP, 1992) such as dictionaries or encyclopaedias which are already traditionally present in classrooms. Resource modules, in the environment of the AMICAL project, have — in comparison to resource-documents — the ability to provide specific information for the initial learning of reading, and offer guidance to the learner.

More specifically, we are interested in a particular module of the resource type— the LRM.

2. The LRM and its Problems

The goal of the LRM is to present, for each lexical element present in the system, information relevant to learning to read from scratch.

At the beginning, the system provides the learner, through various access methods, the possibility of selecting a lexical element, which we shall subsequently call a 'word'. Among these possibilities we distinguish between the access modes by text, by theme, and by a list of the words of the module in

---

1 AMICAL: Architecture Multi-agents Interactive Compagnon pour l'Apprentissage de la Lecture (interactive learning-to-read environment with a multi-agent architecture)
alphabetical order. The access mode by text allows the learner to select a word in the module, taken from a
text that s/he has already seen in class. The system proposes, firstly, that the learner chooses the title of the
text he wants. Then, to allow him/her to choose a particular word of the text, the system displays on the
screen the entire text, and the name(s) of the author(s). The access mode by theme allows the learner to first
of all select a theme such as ‘animals’, ‘places’, or even ‘fruits’, and then a word belonging to this theme
such as ‘cat’, ‘dog’, or even ‘hen’, given that the learner chose the theme animals. Finally, the access mode
by the list of words in alphabetical order allows the student to choose a word by initially selecting its first
letter.

Afterwards, having selected a word, the learner can visit the various interfaces carrying

information related to this word. These interfaces have the feature of being able to make use of knowledge

linked to the field of learning (Pelissier, 2001).

A piece of knowledge linked to the learning domain with regard to reading is, for example, ‘a word
is a structure of letters’. This knowledge consists of making the child aware that a word can be broken up
into letters, re-formed from these letters, and that these letters have a particular order in the word. For the
learner to acquire this knowledge, many interfaces carrying information can be envisaged. We can quote,
for example, the animation: ‘The presentation of the splitting up of a word into letters using flashing
letters’. In this animation, the word chosen by the learner initially appears on the screen [Screen 1]. Then,
the letters making up this word flash in turn, one by one from left to right [Screen 2].
We should note that the term “knot”, which will be used subsequently, indicates a collection of
selection interfaces which allow a student, using the LRM, to select a word and the interfaces carrying
information associated with this word.
To allow the learner to move, within the module, from one knot to another – i.e. to select a word
and see the collection of interfaces carrying information linked to the word – a navigation and guidance
specific to the learner are put into action.
Finally, in order to respect the various given functions of this type of module, a specific
computational architecture ought to be envisaged.
Therefore, the design of a module of the ‘resource’ type, such as the LRM, raises the following
problems:
• the identification of knowledge in the area
• the design of the interfaces carrying information
• the access modes
• the navigation
• the guidance
• the computational architecture of the system
Of these six problems, we shall focus more particularly on the guidance.

3. The Guidance

3.1 The Problem

According to Tom Murray (Murray, & al., 2000), the disorientation of the learner is one of the
basic problems which seem to arise when designing a computer environment. This disorientation is, for
Aude Dufresne (Dufresne, 1991), linked to the incapacity of the user, “who confuses one interface with
another, unable to remember where he came from or what he wanted to do”; to be disoriented is also not
to know where you are, not to know how to get somewhere you think you know exists (Conklin, 1987), to
not know if there remain pertinent documents in the system which you would have forgotten to visit, to
forget selections which you have previously taken or finally to be incapable of giving an overview or a
summary of what you have just seen.
To prevent the user from being disorientated, guidance would seem to be necessary, even
indispensable. It seems to facilitate learning at the same time as using a computer system (Bastien & Scapin
1993).
Bastien & Scapin define guidance in a technical report of the INRIA as being “the collection of the
methods used to advise, orientate, inform, and guide the user when s/he is using the computer
(messages/alarms/labels ......)
Two problems linked to the guidance can therefore be distinguished:
• The functions of the guidance
• The methods implemented by the system to make use of these functions.
Of these two problems, we choose to present more particularly the problems with the various
functions.

3.2 The various functions

Within the framework of designing a computer environment to help learning, we can cite three
main functions that the guidance can have: the function to inform, the function to advise, and the function
to position. These three functions pose three main types of problems, namely, the elements or types of
elements affected by the function, the timing of their being presented and their ways of being presented to
the learner.
Peter Brusilovsky (Brusilovsky 2001) points out two main items on which the guidance operates:
• The informational content of the knot
• The navigation links
We shall subsequently see that, depending on the functions, these two items can be regarded in a different way, and that other items, not presented by this author, can also be the subject of a guidance.

According to Kobsa (Kobsa & al., 2001), three groups of data are taken into account when writing a guidance:

- the data related to the user's characteristics
- the data related to the interaction between the user and the machine
- the data of the environment which brings together all the aspects not related to the user.

We shall see, more specifically, how the first two groups of data can be used in the guidance. We shall also present other information, not listed by the author, which can be usefully used.

**The Function to Inform**

By this function, the system gives the learner a range of information linked to the knot that he is trying to visualise.

This function firstly raises the problem of the different types of information which the system can provide for the learner. These types of information can be different according to the knot. However, we can cite at least three types of elements about which the system can inform the learner:

- the type of knot involved
- the components of the knot

The system can provide the learner with information which permits him to identify the type of knot he is visualising, i.e., if the learner is before a selection interface or an interface presenting information. Information can also be carried by the components of the knot — which can be, in the case of the LRM, words, texts, images, graphics etc, on the different navigation links shown on the screen, as well as events such as transfers, colour changes, flashing etc — which can be associated with the information.

Among the various navigation links, we can distinguish between those belonging to intra-knot navigation and those belonging to inter-knot navigation (Pélassier 2002). Intra-knot navigation occurs within the same knot. In the selection interface for a theme, intra-knot navigation allows the learner to obtain the reading of each theme present on the screen. Inter-knot navigation refers to the movement from one knot to another. The student, from the selection interface for a title of a text, can reach the selection interface for a word within a text.

The system to glide the learner can inform him/her of the existence of these two types of navigation and their consequences. When selecting a link related to intra-knot navigation, the knot on the screen stays the same, whereas if the learner uses an inter-knot navigation link, the knot on the screen disappears and a new knot appears.

This function then poses the problem of the nature of the information presented. The system can inform the learner exclusively of the existence and/or position of the components on the screen. For example, in the LRM, the system can tell the learner that a reading button for the title of a text is at his disposal by specifying, or not, its position on the screen (at the top / at the bottom, on the right / on the left).

Thirdly, there is the problem of choosing the information and the timing of its presentation. In effect, all the information cannot be presented at the same time for fear of overloading the learner. The guidance should be able to provide information at an opportune moment during the session. It is therefore necessary to select the information to be presented for a given knot, and to choose the precise moment of its presentation.

The choice of information to provide can be made according to the type of knot, of its components, but also, as for the selection of the timing, partly from diverse hypotheses made about the learner — such as hypotheses regarding his level of knowledge, his behaviour, his habits, his motivation — and partly from a history made from different knots seen by the learner during the current session and/or during previous sessions. For example, if we draw the hypothesis that a learner has acquired one or several particular pieces of knowledge related to an area, we can chose whether or not to let the computer system present a navigation link allowing the user to access a knot, making use of his knowledge. Similarly, if the learner visits for the $n$th time the same knot, the system can, for example, avoid presenting the different components, such as the various navigational possibilities available, when the learner opens this knot.

**The function to Advise**
To advise is to encourage the learner to do one thing rather than another, a particular choice from a range of possibilities available to him/her.

First of all, this function poses the problem of the elements on which it operates. For example, the system can advise a learner, confronted with a selection interface for the title of a text, to choose one particular title such as the last title he has seen in class. The system can also advise him/her to use an intra-knot navigation link like a loud-speaker button, which allows the title to be read out loud.

Then there is the problem regarding the choice and timing of the presentation of different types of elements for a given knot during a session. For example, the system can advise the learner at one particular moment to choose an interface carrying specific information, and then, afterwards, recommend the same learner to choose another information-carrying interface in the same knot.

This choice of different elements and the timing of the advice can be made, as with the function to inform, according to hypotheses about the pupil and the history of the different knots already seen. For example, according to the history, if the learner is regularly confronted with one word in particular, the system can advise the learner to visualise one or several other word(s) of the module.

Advice can also be given according to pedagogical hypotheses. For example, the interfaces carrying information are characterised by the different areas of knowledge they utilise. Such knowledge can sustain a particular line of succession in relation to learning. In this case, rules can allow the system to encourage the learner to use one particular information-carrying interface before another.

The Function to Position

To position the learner in a computer environment is to allow him to have an overview of the items which he has already encountered in relation to the set of items left at his disposal.

This function can work, for example, on the level of:
- knots
- navigation links

The system can position the learner in relation to the various knots he has encountered. It can, for example, sum up the information-carrying interfaces associated with a specific word, seen by the learner during the course of one or several sessions, in relation to the collection of knots it is possible to access. The system can also show the student, for a particular knot, the set of links he has used in relation to the set of links available to him.

This function of positioning poses, firstly, problems such as that of the identification of knots which could be the subject of a positioning. For example, in the LRM, we can position the learner solely on the level of selection interfaces and/or interfaces presenting information.

Then, there is the problem of the determination of the positioning. For example, the system can take into account, in the positioning, the different knots that the learner has encountered since his entry into the environment, or since his first session.

Finally, there is the problem of choosing the elements of the knot from which the learner can be positioned. For example, the learner can be positioned in the selection interface of a title of text, in relation to the titles he has chosen and/or in relation to the navigation links used. The selection of these elements can be done in accordance with various theoretical and experimental hypotheses (Dufresne, 1991), but also in accordance with hypotheses formed about the learner. From the interactions between the learner and the machine, the computer system can determine the elements and the moment where a positioning seems necessary. For example, if the learner takes no action whatsoever, no longer clicks anywhere, the system can inform the user of the collection of interfaces he has seen since the beginning of the session, carrying information associated with the word, in relation to the collection of information-carrying interfaces it is possible to see.

Conclusions

We have just presented the different functions associated with a guidance in a resource module intended for learning, such as the LRM, the function to inform, to advise, and the function to position.
These different functions can be used in the system in one or more ways. That is the second problem linked to a guidance. We can distinguish several sorts of ways. Firstly, the visual methods such as the changing of colours and the flashing on the screen of the components of the interface. These methods can have, for example, the function of informing the learner of their presence. Next, we have audible methods such as commentaries which, for example, are able to advise the learner when making his/her choice. Finally, we have guidance knots which are specific interfaces, for example, that show the learner, on the screen, the collection of interfaces carrying information associated with a particular word; among this collection the interfaces seen by the learner are presented in a specific way.

Abstract: During the academic year 2001-2002 the Oral Pathology web-based course ran its 3rd edition. The site is the result of the collaboration between the Ctu - Centre of Technologies for Learning of the University of Milan and the University Unit of Oral Pathology. The aim of the site is to support traditional in-class teaching, to offer students an environment that enables them to communicate with teachers and other students, to give access to a wealth of teaching materials, to carry out self-evaluation of their learning and to favour the acquisition of a methodological approach to solve clinical problems. This paper describes the three-year development of the web-site, its conception and the basic rationale of the course: from a focus on the definition of the site itself to its smooth integration with face-to-face lessons.

Introduction

During the last three years problems in regulating student intake numbers in the Degree program in Dentistry at the University of Milan have led to an average of 250 students in every first year class with students' age ranging from between 20 to 50 years. With such a "scenario" some teaching difficulties have also emerged: life histories, attitudes, interest in the subject and demands vary widely within the class; difficulties in establishing a student-teacher relationship have increased; the "lecture" format tends to be preferred; clinical instruction has become more or less impossible.

In an attempt to solve problems due to student numbers and support the face-to-face classroom, in 1999 a collaboration between the Centre of Technologies for Learning of the University of Milan (CTU) and the University's Unit of Oral Pathology\(^1\) was set up: it led to the development of an online environment which could support teaching activity and give students the possibility to develop new skills in the use of technologies for their learning too. The project team considered it very important that students face their future professional activity with basic competence in the use of those tools that would allow them to benefit from a continuing self updating (internet search, database consultation, evidence based approach to learning), as well as from communication with colleagues and access to patient records. Moreover, multimedia and Information Technology now offer plenty of opportunities to support medical education effectively, especially for image

---

\(^1\) The traditional course of Oral Pathology starts in October and ends in May and consists of: a two-hour traditional face to face lesson once a week; weekly professor and tutor counselling; first official exam sessions (May - June - July).

\(^2\) The Ctu is Milan University's centre devoted to educational technologies (www.ctu.unimi.it). In the joint project it was responsible for designing the software and the site, for methodological support to the teachers during the course, for technical help and the final evaluation of the online environment. The teaching team from the Unit of Oral Pathology, consisting of 1 professor and 6 assistants, was responsible for the site contents and the activities carried out in the site itself.
intensive subjects such as Anatomy, Histology and Pathology (Dowker et al. 1997), (Lehmann et al. 1999), (Grimes 2001), (Hallgren et al. 2002), (Greenhalgh 2001).

Do students get this opportunity? Does the learning change with the introduction of a blended course? Some criticism has been reported about the methods that have been and are used to evaluate new computer-aided and web-based learning instruments, comparing their teaching efficacy with the so defined “traditional” methods (Keane et al. 1991), and it is not an easy task to separate and evaluate the parts that play in an educational intervention (Hutchinson 1999).

Most of the studies that have been conducted to evaluate the effects of computer-aided packages or web-based courses collate information regarding the subjective rate of acceptance of the programs, of their usefulness and of the skills gained after their use, as well as give an overview of the informatic background of the users.

When more objective evaluations are conducted, many studies comparing online versus traditional in-class learning report no significant difference in terms of students’ evaluation of performances and support the argument that the development of reasoning and positive attitudes toward the subjects being studied can take place in both online and classroom environments and that online instruction can be designed to be as effective as traditional face-to-face instruction (http://teleeducation.nb.ca/)

In our case, the website was designed to support and not replace the in-class learning activity. Moreover, it offered a wide range of web tools to complement the traditional learning.

Therefore, for the first two years of experience, we chose to base the evaluation of the quality and efficacy of the Oral Pathology web course, on the four criteria on which, according to the Cerfad classification (Cerfad 2001), quality can be measured:

1) What did the students learn?
2) Were the educational demands for which the site was planned satisfactorily met?
3) The learning route: who takes part, how, when and what sort is it?
4) How does the system work?

Data were recorded through two kinds of questionnaires. The first, distributed at the beginning of the academic year, aimed to trace students' computer literacy and the availability of computer/Internet facilities, the second focused on the attention of student opinions about the web support, and was distributed to students in the middle as well as at the end of the course. Interviews with both a couple of randomly selected students and teacher of the course were recorded each year. Moreover, the tracking system of the web site allowed the monitoring of files most downloaded, total number of accesses (per user) and number of messages sent per user.

In addition, during the still on-going third edition of the course, a pilot study with an experimental design has been set up in order to include more objective information on the subjective data already existing.

The study aims to assess if the opportunities and learning aids offered by the web-course make any difference in the learning gain of students who have access to the web-support. Students were randomly divided into two groups. During a one month period the test group had access to the web site, while the control group did not. The web site offered material to integrate lessons: images and short videos, link suggestions and, most of all, exercises to stimulate students to search the web and try to develop a method to observe images and describe them. Pre and post tests were recorded as well as questionnaires about computer skills, attitudes and web course usage opinion (just for the test group). Moreover, an external observer (pedagogist) attended lectures “randomly” in order to record the teacher’s behaviour during in-class teaching activities. Data analysis is currently study.

Structure

First and Second Editions (99-00; 00-01)

The site was organized into four main sections (classroom, resources, secretarial area, R & D) and 15 subsections. Classroom was composed of: lessons (text, graphs, tables, images); case studies (exercises based on “problem solving” or “role playing” methodology); syllabus; material archive; web-boards (one dedicated to counselling, the others to case study discussion); self assessment3; professor and students (details of the teaching team and a list of students registered with the site). Resources consisted of: bibliography and links.

3 The test – generator system, named “Mirror”, is a property of Ctu software (http://mirror.ctu.unimi.it), it creates tests containing questions selected at random from question banks. Tracking is available for each student. Each question can be linked to a forum, to positive or negative feedback, and to teaching material to help answer the question.
In the Secretarial Area you could find: notice board; the explanation of the exams; help online (technical aid web-board); personal profile; e-mail. The R & D area, a part from the questionnaires, was visible only by the project team (statistics and project team web-board).

Third Edition 2001-2002

In the third edition of the course the site structure has been modified, reducing the number of sections from 15 to 6 by merging some aspects and eliminating those that in the previous versions had been indicated as not useful. According to the results of the previous courses, it is necessary to maintain a site structure that foresees not only a sequential usage supporting the logical progress of the learning route but also a free usage encouraging critical independence in the analysis and selection of sources. The web site includes: the home page of the course (latest announcements, important deadlines, the latest messages in the forums); syllabus; table of contents; study area; self assessment and web-boards.

Evaluation Results

What did the students learn? Only 65 students out of 151 sat the final examination in the summer session, 25 failed and 40 passed with an average mark of 27/30. Considering the answers to interviews and questionnaires to the question “Has the site made your learning more efficient?”: 63% replied YES, 11% replied NO and 26% did not reply. Comments given to these replies were: teaching material was abundant, precise, corresponding to the lectures and easy to consult, allows a better organisation of the studying; forum allows doubts to be cleared up, as well as an exchange with professors and fellow students; self-assessment provides practice; the wealth of images and case studies bring the clinical aspect of the subject closer. Even if clearly of a subjective nature, these latter data show appreciation for the learning experience yielding a more positive stance towards the experience itself and thus an active and fertile attitude towards learning (Ananda 2001).

Were the educational demands for which the site was planned satisfactorily met? Students found it difficult to set up a correct diagnostic procedure; they frequently faced clinical problems in a disorganised manner. The section of the site dedicated to this skill was that regarding case studies. Only a few students participated in it. Most of the students focused on the self-assessment part (9000 tests done!) and on studying the lectures (the parts in which the examination consisted of).

The learning route: who takes part, how, when and what sort is it? Although few students actually took part in the forums, to the question “Did the online course allow for more direct contact with the teacher?” 3% replied not at all, 26% not much, 36% a fair amount, 24% a lot (11% did not reply). To the question “Did the online course allow for more dialogue with fellow students?” 24% replied not at all, 33% not much, 24% a fair amount, 8% a lot (11% did not reply). From the messages it is possible to see that the communication within the forum took place mostly between teacher and students and came in the “question and answer” category rather than being an open debate. A clear increase in the use of the site was registered during the pre-examination period.

How does the system work? Some of the students had insufficient computer skills to allow for adequate use of the site activities; the answers to the question “How much experience do you have of using a PC?” were: 15% none, 55% little, 23% quite a lot, 4% a lot (2% did not give an answer). Not all students had Internet access at home (only 31%) and the university did not have laboratories for individual use of the Internet for learning; the system was often slow in loading pages and downloading material.

The table of contents is sequentially organised, displaying together all the lessons in chronological order; specific materials for further study and practice exercises are linked to each lesson. The organization according to units of content was adopted in order to provide students with preparatory information, both for the understanding of the lesson itself and for doing the exercises. In the study area the student can access and use the materials according to his/her own interests or requirements, it contains content organized by type.
Consideration and discussion

The results of this first version of the course were quite satisfactory. The objectives established were not fully achieved, but, both students and teachers proved to be enthusiastic about the online environment. This aspect has also been found in other previous, similar studies (Pilcher 2001, Wegner et al. 2002).

Emphasis should be placed on the commitment and expertise demonstrated by the teaching team in creating appropriate teaching materials. Overall, students reported that the communication tool increased student-teacher contact more than student-student interaction. This is quite reasonable considering that students could meet every day in class. It could also be a characteristic of the blended modality of the course since lack of instructor’s contact can also be perceived by students in completely on-line courses (Wegner et al. 2002, Gagne M. and Shepherd M. 2001).

On conclusion of this first version of the course, we faced a dual challenge:

1) solving problems relating to the system and the use of the course: speed of the system, computer laboratories, teaching students basic computer literacy;
2) involving the students more actively: the site should be seen not as a sort of “super textbook” to get ready for the examination but as a proper learning place to acquire a methodological approach to diagnosis.

What Did the Students Learn? Only 28 out of 190 students sat the examination at the summer session: 21 passed, 7 failed with an average mark of 26.7/30. Considering the answers to interviews and questionnaires to the question “Did the site help your learning efficiency?”: nobody replied not at all, 5% very little, 9% quite a lot in and 54% a lot (31% did not answer the question). To the question: “Do you think it is useful to have both lectures and website?”: 60% said YES, nobody NO whilst 37% did not answer the question.

Were the Educational Demands for which the Site was Planned Satisfactorily Met? Students in the second edition stressed the value of the whole project from a methodological point of view (e.g. clinical cases, consultation with teacher or tutors, range of sources).

The Learning Route: Who Takes Part, How, When and What Sort Is It? Fewer messages than in the previous year were exchanged through the forum (104 instead of 120), but the quality of the content remained high (88 content messages out of 104): the same results were obtained for the case studies section. Sections most widely used were the lectures (files downloaded 4643 times) and the self-assessment (13082 tests done), while the teaching archive was little used (files downloaded 1351 times).

How Does the System Work? The difficulties and demands encountered by the students in the second version of the course were mainly of a didactic-organizational nature: too many demanding courses had to be followed. The majority of the students did not take part to the web-course activity probably because working on the site was left to the student’s desire to go in depth with the material and not mandatory for the final examination; in addition, it seems there was an unreadiness of third-year students to approach the on-line exercises independently and critically: this was the first clinical course they had face and, despite having studied, the student had not yet fully grasped all the knowledge required to take part in discussion on case studies.

Consideration and discussion

In the second version of the course an attempt was made to meet the challenges raised by the first one: four computer laboratories were opened for the students; a seminar in basic computer skills for the whole class was organised; students’ critical-analytical skills and their ability to establish correct diagnostic procedure was promoted.

Whilst during its first experience the didactic group was enthusiastic about educational technologies, after the first two months of the second edition of the course, a somewhat “cooler” attitude of the teaching team seemed to be recognizable. A decrease in enthusiasm and participation of the teachers was observed, probably because the “novelty effect” (Clark 1992), which could have lasted the whole of the first year, had worn off. Face-to-face lectures seemed to be unrelated to the site and there was a lack of participation in online activities.
As reported in other studies (McNulty et al. 2000) peak in the access of web learning resources have been recorded during the pre-examination period. The site was mostly used as a teaching text and guide to the learning route.

From this second experience, reflections arose on the nature, usefulness and function of a web based-course supporting classroom lectures. Both students and teachers should be taught to reach beyond the concept of the site exclusively as a collection of teaching materials and the lecture room as the place where the real teaching takes place: the site has to be considered an environment for learning/teaching relations and activities that are complementary to the classroom course. We became aware that in it is far more difficult to “educate” students and teachers in the use of online teaching/learning methodology in a blended course than in fully online courses. In fact, as opposed to the latter, the classroom lectures provide a weekly contact during lessons, where students can exchange opinions and compare notes directly and where the professor teaches according to his own experience and customary approach. Thus, often the site is relegated to the status of a mere extra activity.

Third Edition 2001 -2002

The course in its third edition is only at an initial stage and it is not yet possible to give an overall assessment. However, on the basis of the first month’s work, some considerations are emerging.

In this edition both the role and demands of the students and of the teachers have become the object of attention. Participation in the activities offered by the site has remained voluntary but this version foresees the skills acquired online being evaluated during the examination.

To accommodate any difficulties or hesitation relating to the use of the Internet on the part of the students, the tutors collect the considerations of the online debate at the end of each month and discuss the methodological organization of individual contributions in the classroom, leading students towards a correct approach to diagnostic procedure. Another new feature is that it is not only is the course online evaluated, but also the teacher’s behaviour and the teaching activity since an external observer attends lectures “randomly” in order to record data.

Considerations and Discussion

Teaching in a web environment requires preparation of material in advance, attention to students’ questions, facilitation of interaction among students and a continuous guiding of learners who value the input of the teachers (Binshan and Chang-tseh H. 2001). However, an initial analysis of the data about web usage of the third edition shows that teachers have still not yet grasped the concept of an integrated “classroom-website” system and concentrate all their teaching activity in the classroom, without linking classroom activity with the other side of the system.

Furthermore, since teaching activities offered by the site, such as the discussion of case studies and exercises, aiming to encourage and educate students to participate more actively in their learning, are not emphasised by the teachers who do not mention the web-site in the classroom, students mainly access the site to download lessons. One of the values of web-base support most reported by students still remains access to material and lectures. Handouts have been reported to be the most helpful features also in other similar studies conducted with dental students (Filcher 2001), with only a small portion of them which take part in the case studies discussion.

Conclusions and Future Prospects

Much work remains to be done in working out the correct organization for a blended course in order to make it effective and efficient. The opportunity of access to computer laboratories and to a course in computer literacy, the efficiency of the system, technical aid, etc. are necessary but are not sufficient conditions for the success and effectiveness of a course. To reach success in running a blended web-course, the preparation of both teachers and students for this new type of educational interaction online is needed. In fact, this kind of environment requires a shift from "lecture-style" to "teacher-mentor" teaching, which guides and motivates students. It is a shift from passive students who mainly engage in listening to active students who ask questions, make suggestions, and write their observation and comments.

Our experience shows that, in a context of a correct and active learning relationship between teachers and students and amongst students themselves, the following factors are essential: careful and holistic planning of the
curricula for classroom-website interaction and the training and education of both students and teachers in the use of educational technologies.

Future work will focus on training teachers to use educational technologies. The following projects are foreseen:
1) a survey regarding computer literacy and present knowledge and use of educational technologies;
2) a seminar to explain the educational technologies available at the Ctu at present;
3) a workshop on educational technologies for those teachers who prove to be particularly interested in the subject.

Better Living Through Faculty Development? How Teachers Can Develop Better Practices by Using Multimedia to Document and Share Their Work

Désirée H. Pointer, Ph.D., The Carnegie Foundation for the Advancement of Teaching
pointer@carnegiefoundation.org

Abstract: When teachers document their practice of teaching using technology, and share what they've learned with others by making their work public, they can effect important changes in faculty development, student learning, and pedagogical innovation. In particular, multimedia technologies allow teachers to document interactions and processes that don't easily lend themselves to text-only representations; they provide opportunities for faculty to relatively easily share one another’s materials, assignments, and students’ work in order to build on one another’s research and reflections; faculty may critique each others’ work to provide a peer review process akin to other academic disciplines. The production of more and more sites that document teaching will also make it possible to look across the experiences of many different faculty members working in many different disciplines and contexts, and to generalize from those experiences.

The Knowledge Media Lab at the Carnegie Foundation has been collaborating with K-12 and Higher Education faculty members to document and represent inquiry into their practice of teaching using multimedia and online technologies. Over the past three years, these faculty have participated in various cohorts of a 2-year program (CASTL) to share what they know (and do) about teaching. Their final products have constituted a diverse array of representations, ranging from dramatic presentations to more traditional academic genres such as books and journal articles. The diversity of the representations demonstrates the importance of using existing disciplinary genres and methods to invent new ones. The use of technology enables faculty to deepen their individual knowledge about previously unrevealed aspects of their pedagogy and curriculum; develop collective understandings of the practice of teaching and learning through sharing what they’ve observed with colleagues; and to enable others to build upon what they’ve learned by making their inquiry into teaching and learning public.

Deepening Knowledge about One’s Practice

Once documentation is complete, the effort that goes into creating an engaging and compelling, and succinct website can lead faculty to deepen their knowledge about the representation of their practice and the central questions of their inquiry. Roberto Corrada, a professor of law at University of Denver, wanted to document his active learning course on Labor Law, one in which students may elect a union and negotiate a collective bargaining agreement with Corrada, their “employer.” Working in collaboration with the Carnegie KML, Corrada has created an interactive timeline to illustrate the spread of union activity in his class, and has begun documenting his class to enrich the timeline with clips from his course, student work samples, and email communications from his student “union activists.” This documentation process has transformed his perspective on his teaching; he commented, “Just thinking about how to represent the scholarship on the web has made me think differently about how I teach the class, how I present the class, and most importantly, how I document what I do in the class.”

By choosing to represent his scholarship online, Corrada transformed his perspective on the unfolding of his course from one in which the course was largely unpredictable to one in which he was attuned to look for and document the “explosive moments,” and in so doing, be able to tell the story of the “infestation” in his class by student-led union activity. By documenting his work through multimedia, he begins to be able to make his work public and, therefore, be able to share it with others.

Developing Collective Understandings

Some scholars have found that sharing what they’ve learned about their teaching leads them to develop deeper collective understandings of their practice, transforming artifacts of teaching into objects of knowledge that can be discussed and debated. Heidi Lyne, a teacher at the Mission Hill School in Boston, wanted to represent her school’s portfolio graduation process through documentary film. She followed several students over the course of the year as they prepared their portfolios, all of which were expected to reflect the school’s “Habits of Mind,” and
collected student work samples, notes from faculty meetings, her own reflections, and school assessment rubrics to support and extend the video.

As she began to select clips and share them with her colleagues at Mission Hill, Lyne commented that their conversations began to transform: "An interesting thing happened when I or other people, other staff members started watching [the videos]... the information was gathered in one place, whereas otherwise it would have been discrete people doing discrete pieces, and it would have taken years... to get to the point of knowledge about what we were doing, that we got to very quickly."

Lyne, her students, and her colleagues were all able to benefit from examining their collective practice—once the portfolio preparation process was transformed from ethereal, moment to moment interactions, to a set of documents and data that could be examined, debated, and reflected upon. Before she even got to the point of analysis (Lyne 2001), Lyne’s multimedia documentation had already had an impact upon the school’s plans to transform the portfolio graduation process for the coming year, when Lyne again plans to document their collective work through video.

**Influencing Others**

Particularly for novice and student teachers, professional developers, mentor teachers and teacher educators, having models and examples to look at may enable them to talk more deeply about and build more richly from their teaching experiences. For example, Deborah Smith, an Assistant Professor of Education at Michigan State University, has created a website to document a large course on the teaching of science for pre-service elementary teachers. While Smith hopes to use her site (Smith 2001) to discuss her inquiry-based approach with other faculty in her field, she also plans to use the site as a key means of support for the many teaching assistants who lead sections of the course. In her work with a local school district, she also planned to share her experiences with documenting her practice using multimedia with novice teachers, encouraging them to examine their own pedagogy, curriculum, and classroom documents, as well as sharing them with others: “I think the power of [multimedia representations of teaching] is a way to help pre-service and other practicing teachers get underneath and inside a teacher’s practice and feel like it’s accessible—and that, I think, is very heartening for people who want to learn to teach or change their practice.”

Smith is able to use her website not only to show her own investigations into her practice, but to inspire others to do the same. These sites also create learning opportunities for the students themselves. Students taking Smith’s course can see examples from previous years of students’ work, and they can read the instructors’ feedback to determine, before they begin work on their own projects, the kinds of questions and problems they may encounter.

**Implications**

The value of scholarship is determined in its use—in discussions, in critiques, replication efforts, responses, applications, deviations and adaptations. Thus, the evolution of scholarship online will go hand in hand with the development of the means for reviewing and exchanging scholarly work and the growth of the communities in which it is discussed and debated. Faculty who develop web galleries of “best practices,” or interactive portfolios of teacher and student learning, can contribute to an advancement of the profession as a whole, particularly in the development of new teachers. However, websites that collect teaching materials and document teaching practice cannot advance the field without the language, criteria and forums for informal and formal assessment needed to examine them. In short, we know that we can put scholarship online, but it remains to be seen how online representations can be more effective in capturing the many aspects of teaching and learning that are often too ephemeral, too subjective and too fleeting to represent productively in print. We believe that the collective effort to produce, examine and use websites and other means of representing teaching will facilitate both the development of the scholarship of teaching and the growing professional and public understanding that can serve to advance the field.

Student Roles in Online Learning Communities: Navigating Threaded Discussions

Linda Polhemus & Karen Swan
University at Albany

Abstract

This paper discusses navigation strategies affecting the interactivity of a graduate level course's asynchronous online discussion with a focus on the development of a learning community and knowledge building. This qualitative analysis reports on an exploratory investigation of student interviews and observations while interacting with the online discussion board. The data was collected from students taking different online courses from the State University of New York Learning Network (SLN) in the 2001-02 academic year. Observations revealed that students are interacting with the content vicariously where the integration of multiple perspectives facilitate the construction of knowledge. Routines for reading and responding to discussion board messages also suggest that first students negotiate through the threads created, then based on personal criteria interact directly or vicariously with the content of messages.

Purpose

Quantitative researches provide valuable information for online teaching and learning however, the emphasis on grade/test score improvement does not really explore what is really going on in an online learning environment. How can we identify factors that increase participation and the quality of an online discussion? How can we evaluate the navigation patterns and their influence on the dynamics of the online community only assumed in an online discussion? This study presents the development and implementation of a research and evaluation protocol that analyzes online course participation for community building indicators and perceptions of learning.

Literature

Many believe that the defining characteristic of the computing medium is its interactivity (Bolter, 1991; Landow, 1992; Murray, 1997; Turkle, 1997). Recent research has focused on the general topic of student interaction within four defined categories: (a) learner-content, (b) learner-instructor, (c) learner-learner, (d) learner-interface (Hillman, Willis, and Gunawardena, 1994; Moore, 1989). And it has been more recently reported that a fifth interaction is that of (e) 'vicarious' interaction (Sutton, 2001), whereby students do not interact directly at all, but observe and process both sides of direct interaction between two other students or between another student and the instructor (Sutton, 2001).

The online discussion board of an asynchronous course requires students to navigate and interact with the discussion board thereby manipulating its structure. This research project examines these interactions, however, further investigates the interaction a learner has with the interface of the discussion board, as well as the instructor, course-mates, and content. The online discussion board is one tool students use to communicate with each other, where they are working together to reach course goals while providing feedback to one another. Working together produces the externalization of the thought processes, the comparison of alternative perspectives, social facilitation, better learning, high self-esteem and more positive attitudes toward the learning experience (Salomon & Globerson, 1989).

Methodology

This qualitative analysis involved interviews and observations. Students who were enrolled in online graduate courses volunteered to take part in this research. This exploratory study included a heterogeneous mix of eight students enrolled in online courses in education at a large research university in the Northeast. Their participation included an interview and an observation. Interviews included questions about their feelings, attitudes and beliefs about using the discussion board to build knowledge and community online. Observations were made using a camcorder and picture in picture monitor, where the student's image and computer screen were recorded onto videotape. The students were video taped to have a record of their interaction and their thoughts when participating in the discussion board. During this time, students were asked to ‘think aloud.’ The think aloud method was used to elicit any emotions, feeling or perceptions of the messages posted to the discussion board, from the perspective of the user.

Results

In the interviews, students responded that they felt a part of a learning community and described their routines for navigating the online discussion board. Examples for each are given:
Learning community

“I feel a part of the online community of all people who’ve taken online courses and also a part of the smaller community that is my online course I’m taking now.”

Knowledge building

“I am excited that the information in this module correlates with an ETAP course I took last summer! I have the opportunity to draw on prior knowledge.”

Routines for Navigation

“First I check to see if anyone has responded to any postings I have made. Then I check out new postings. I respond to several postings, sometimes I do this randomly as to not respond to the same person all the time.”

In the observations, student interactions with the structure of the discussion board, the content, their peers and instructor were a result of the learning community’s dynamics. As a result, an online discussion provides students with the opportunity to experience the interactions of others based on their own personal interests and goals. Observations and interviews indicated that students were more motivated to read and respond to a message with which they identified culturally, professionally, or personally; to meet course requirements; to make others feel a part of the course; to anyone who responded to them; to those messages that integrated multiple perspectives.

Similar to Salomon & Globerson (1989), students reported that learning took place in the comparison of alternative perspectives. Also, as indicated by Gunawardena & Zittle (1997) and others, students were aware of other student’s social presence based on immediacy behaviors. During observations, students made mention of other’s negotiation patterns (such as how where, when and to whom they posted), experiences and cultural backgrounds. In addition, students used the discussion board to ‘prime’ their thought processes when composing messages to others, where vicarious interactions were observed.

Conclusion

Bangert-Drowns & Pyke (1997) defined learning engagement as the strategic mobilization of cognitive, volition and affective processes to foster personal meaning making. For the context of an online learning environment, we will continue to conduct more interviews and observations to investigate the possibilities of cognitive processes in terms of the message content, volition (decision-making) as the student’s rationale for reading and responding (or not), and affect as the integration of social presence. We will also examine strategies for facilitating a discussion that promotes the integration of multiple perspectives, as well as, learning engagement where community and knowledge are built.

Abstract: Multimedia Technology is an excellent technology for training students with disabilities. Because multimedia is interactive and synthesizes sound, images, and text, it supports new methods of communication in the learning environment. Multimedia Technology, applied to education, typically involves the use of computer-assisted instruction (CAI) in conjunction with other media and is very helpful when incorporated in technology-based training (TBT). Although a computer cannot replace a teacher in the classroom, when used as supplement, multimedia use in the classroom provides undeniable benefits for both teachers and students. The purpose of this research is to examine the degree of effectiveness of multimedia technology in training, in comparison to traditional print-based training methods. The course content is the same in the print-based training methods as in the multimedia program; it is the method of delivery that is different. Another concern of this research is to measure the qualitative nature of learning using multimedia.

INTRODUCTION

This study will discuss knowledge engineering in multimedia design for training purposes. The specific training context for testing is the training of finger spelling in eighth grade high school student at the School for the Deaf, in Bangkok, Thailand. Finger spelling is different from sign language; sign language is a complex visual-spatial language that is used by the deaf in which meaning is conveyed by a system of articulated hand gestures and their placement relative to the upper body whereas finger spelling means a communication by signs made with the fingers (Merriam 2001).

A knowledge engineer is one who participates in building expert systems (Poulter, Morris, and Dow 1994). Knowledge engineers are specialists in eliciting knowledge from experts rather than necessarily being experts in the domain itself. A new professional specialty has emerged from the development of expert systems. The term knowledge engineers (Heinich 1999) has been coined to describe the people who work with experts in a field to assemble and organize a body of knowledge and then design the software package that makes it possible to train someone to become skilled in the area or to enable anyone to call upon the skills of experts to solve the problem. The work of a knowledge engineering is similar to that done by instructional designers in task analysis and module design.
The objectives addressed in this study are: (1) to examine the effectiveness of multimedia technology in the training of hearing impaired students. In particular, is multimedia technology effective in training those who wish to learn finger spelling? (2) to measure the qualitative nature of learning using multimedia technology.

EXPERIMENTS

To test the effectiveness of multimedia technology compared to traditional training methods, the testing involved two comparison groups of learners from eighth grade high school students from the School for the Deaf in Bangkok, Thailand. Group one (the first group), used the multimedia training program in CD-ROM format. The program called Life in Saskatchewan. Group two (the second group), learned from print material representing traditional methods. There were nine hearing-impaired students from the eighth grade who participated in this program. Four hearing impaired students were in the first comparison group and five students in the other group. All students in both groups were required to finger spell specific 30 English words.

ANALYSIS & RESULTS

- The results of the test have shown that most students improved their learning in both methods.
- The two methods of teaching and learning (multimedia training and print-based methods) impacted students about the same since the average scores of both groups of students were not much different.
- Most students (eighth grade high school students at the School for the Deaf) enjoyed learning from CD-ROM.
- Even though the result has shown that 67% of the students preferred computer, there were 22% felt more comfortable to learn from the instructor.
- In learning English Finger Spelling, the students preferred computer rather than instructor whereas 22% preferred both.

CONCLUSIONS

In this study we have been trying to examine the degree of effectiveness and potential benefits of multimedia technology and to measure the qualitative nature of learning using multimedia. The result of this study has shown that there were similar results in learning between multimedia technology and print-based methods. However, students enjoy learning from multimedia training more than from traditional methods. We found that the impact of multimedia was much more effective than print-based methods in motivating the students to want to learn and practice the lessons. The results have shown that almost 70% of the students accepted that learning with computer is excited and fun. In addition we would like to add that multimedia technology can be used as a motivational tool and as a valuable supplement in the training.

Pre-service Teacher Education Students Teach Their Teachers Technology!

Teaching to Learn: A Consultant/Client Model to Enhance Classroom Integration of Technology
1999 PT3 Implementation Grant Project

Anne E. Porter, Ph.D. Project Director
Associate Professor, Instructional Systems Technology
Oakland University, U.S.A.
porter@oakland.edu

Abstract

In its third year, this PT3 project places established professional educators and pre-service teacher education students with technology skills in a mutually supportive, collaborative, technology enhanced environment to enhance the modeling of classroom technology integration. Hear about lessons learned and how project activities will continue after the end of the grant period.

Description of Project

A recent national survey on the preparation of new teachers to use information technology (Moursund, 1999) reports that most college and university faculty do not model the use of information technology skills and most student teachers do not routinely use technology during field experiences. This integration factor, composed of items that addressed graduates’ classroom skills and the actual use of information technology during college training was the best predictor of other scores on the survey. The “Teaching to Learn Project” offers a model, which provides a long-term solution to the “lack of modeling and use of technology in pre-service teacher education” problem in university classrooms and in field placements. The project’s consultant/client model places pre-service teacher education students with technology skills and established educators (university faculty and K-12 teachers) in a mutually supportive, collaborative environment which itself is enhanced through information technology.

The central focus of our project is a 4 semester hour elective course entitled “Consultation: Technology Applications in Education” which is open to pre-service teacher education students who have successfully completed a required hands-on Educational Applications in Technology course. During the Consultation course the students are taught consulting skills in a real world, project-based learning situation. A required component of the course is an 80-100 hour commitment to serve as a technology consultant to a K-12 classroom teacher (client) in an urban or suburban district which serves as a field placement site for our education program, or to a university professor (client) in any discipline which might serve teacher education students. This consultant experience provides “behind the scenes” experience with the actual problems classroom teachers face when they try to integrate technology into their daily classroom activities.

The primary goal of each student consultant is to help the client (experienced educator) enhance the modeling of technology integration in his or her classroom. The secondary goal is to learn “classroom wisdom” from the experienced educator. After establishing and piloting the course in the first year of our PT3 grant, during the second year we refined the course, determined more specifically what support the student consultants need to successfully carry out their charge, developed enhanced support mechanisms and materials in the form of:

- major additions to the project website (http://pt3.oakland.edu)
- major additions to print and software resources available in our Educational Resource Laboratory
- improvements in identified areas in the recruitment, selection and preparation of the clients (experienced educators)

We have also begun the process of identifying and developing alternative systems for carrying on various components of the project after the end of the grant.

Major findings

Persistence pays off. As we enter the third and final year of our grant period we are very much aware of one of our original goals, which was to develop a strong following for the consultant course, the cornerstone of our project. Because it is an elective for our undergraduate teacher education students and is very demanding, if the course is not considered “worth the effort” students will not continue to enroll in the course. We have now offered the course 5 times, including the pilot, and it appears that the word is out among the students that the course is definitely one of the highlights of the undergraduate program. We have averaged approximately 13 students in each class after the pilot offering, and already have students on the waiting list for the Fall 2002 course after the end of the grant. We have received permission and have begun to develop a major and a minor
in Instructional Systems Technology for which the Consultant course will be the capstone experience. This program begin going through the approval process in Fall of 2002.

Quotes from Project Evaluators Report

Qualitative types of information are being collected during the evaluation process. A summative evaluation has been conducted at the end of each semester beginning with the pilot semester and will continue in the years after the project has ended in order to assess the project's outcomes and long-term impact. Using both individual interviews with the consultants (students) and the clients (faculty members, K-12 teachers), observations, and surveys, the impact of the project will be measured.

Client: All clients highlighted the benefits of having a consultant who can cater (one-to-one) to their needs and can accommodate their own personal pace of learning. Some of them have already participated in technology related training and described how difficult it was to keep pace with all the other participants and after the training to find the time to practice what was learned. The client-consultant relationship allowed them not only to learn at their own pace, but also to practice under the guidance of their consultant. One of the clients described her experience in the following way:

It is a wonderful program. To me it was a tremendous support, because you see, I love the one-to-one thing, and the fact that the consultant is a student, because then you don't feel intimidated. Every time, I tried taking classes, but most of the people who go there, some of them are really good, and I was always three steps behind, and I would feel completely stupid, because I didn't know what they were doing, and I did it a couple of times, and it didn't work for me, because it was too far, or I got lost, and I was embarrassed to ask questions. This way is great, because the student comes and if you have any questions, she goes and asks and the next time she has the answer, so it's perfect. I think it is a perfect situation. I love it. To me it was great. Whoever invented this had a great, great idea and I think the people are doing a wonderful job. And I commend them, and I'm very thankful that I learned about this [PT3 program] because I could never have done this by myself. So to me it was very, very helpful.

Consultant: The primary reason for participation in the project by the pre-service teacher consultants was to increase their knowledge of how to integrate technology into their classroom teaching. A majority of the consultants did not consider themselves to be highly skilled in technology as they began the Consultant course. For this reason, a majority of consultants felt discomfort and apprehension at the beginning of the project. The principal source of this apprehension was a perception of not being an expert in technology. However, as the project proceeded, eighty percent of the consultants indicated that they had crossed a confidence threshold or competency threshold with regard to the use of technology. One of the consultants described her experience in the following way:

I think of all the things that I learned, the most valuable is just get out there and play around and just give it a try, rather than be scared. I used to always want somebody over my shoulder when I did it. Now, I am willing to get out there and try it and fail a little bit. But I just keep pushing away at that and I don't think I had that before. Because that's, to me, that's a lot more important because I can try every program now and I can get my way through it.

Understanding Participation in Online Courses: A Triangulated Study of Perceptions of Interaction

Abstract

This presentation reports the results of a study that explored instructor and learner perceptions and attitudes toward interaction in online courses. Participants included faculty and learners involved with an online course as well as other faculty and learners who have expressed reluctance toward participating in online courses. Analysis of data revealed that although perceptions regarding interaction varied among all interviewed, upon reflection all course participants agreed that the interactivity was at least adequate in learning.

Purpose

The purpose of this study is two-fold. First, our goal was to gain a deeper understanding of the perceptions shared by learners and faculty that are reluctant to enroll in online courses or those who withdraw early in the experience. Second, we wanted to explore instructors' and learners' attitudes and perceptions of interaction after they had experienced an online course.

Research Questions

1. How do learners and faculty (both participants and non-participants of the course) perceive the value of interaction in online courses?
2. What is the nature of the relationship between learner-learner and learner-instructor in the online class?
3. What strategies did the instructional team design to promote interaction?
4. In what ways did the instructional team address learner-interface interactions, and how did the learners perceive this form of interaction?
5. What pattern of interaction developed?

Methods

This study was based on data gathered from interviews, online course documents, and computer transcripts. Participants included 3 faculty (1 course instructor and 2 non-course participants) and 15 learners (11 learners who were enrolled in Engaging with Technology (EWT) and 4 who either chose not to enroll or withdrew after the first session).

The online course documents included an analysis of the course syllabus, a participant's guide and other materials that supported each of the learning activities. Transcripts of online communications captured threaded and chat discussion among learners and the instructor.

The analysis of the transcripts used a 5-step discussion analysis technique devised by Henri (1992).
Analysis and Preliminary Results

The interviews revealed the following about the four types of interactions: Interaction between the learner and the course content—most of the learners found that the course content was appropriate for the stated objectives of the course and was presented in a clear and concise manner.

Interaction between the learner and the instructor—most of the learners found their online interactions with the instructor (through the chat room and discussion board) to be very helpful.

Interaction between the learner and other learners—most of the learners thought that interactions with their fellow learners were very helpful in doing assignments, and clearing up questions and doubts.

Interaction between the learners and the interface—most of the respondents said that they were for the most part satisfied with the interface of the online course.

Computer Transcripts Analysis

We analyzed the average length of a student's post. For example, in Week 2, the learners replied to the instructor's messages and posted on average 55 words or about 5 sentences. For later weeks, learners seemed to post more than the average of the first week because they were looking for help in terms of course projects, and computer and technology-related problems. Also, some of them needed help in order to implement technology in their teaching in their school districts.

We found that most of the messages that were posted involved the course content, computer and technology skills, and the course projects. Not only did the learners share knowledge, but content analysis indicated that the learners were posting messages at a very high cognitive level. Furthermore, after reviewing the messages each week the researchers were able to distinguish some of the learners' characteristics in both the discussion board and the real-time chat room. For instance, many learners who are sociable in nature posted more messages and demonstrated high cognitive skills. Moreover, they added the comparison of the messages between themselves and the other classmates. Some learners, however, posted quite short messages.

Summary

Analysis of data revealed that although perceptions regarding interaction varied among all interviewed, upon reflection all course participants agreed that the interactivity was at least adequate. Detailed discussion analysis substantiated these perceptions, showing that deep levels of processing and interactivity were achieved.

Internet Work Strategies and their Influence on Learning Outcome

Burkhard Priemer, Lutz-Helmut Schön
Physics Education Department
Humboldt-University Berlin
Germany
priemer@physik.hu-berlin.de, schoen@physik.hu-berlin.de

Abstract: This paper is a report on the findings of an exploratory study investigating students' use of the WWW and the corresponding learning outcome in a school related setting. 45 students aged around 17 were asked to perform research on a topic in physics in order to write an essay. The only help provided was access to the Internet and a word processing program. A pre-post-test design captured learning outcome, and log files were used to follow user activities.

First results show that we are able to describe and distinguish different strategies of students using the Internet. Beside other factors like prior domain specific knowledge, computer literacy, and writing skills navigation strategies do have a significant impact on students' posttest scores: there are favorable and unsuitable Internet-Work-Strategies.

The identification and description of effective strategies and their influencing factors will lead to a better understanding of students' work with the WWW and hence can improve their Internet performance for the purpose of learning.

Introduction

The Internet plays an important role in schools nowadays and is seen as an essential tool to support teaching and learning. Much credit is given to this new medium pointing out that the WWW opens a set of new options which teachers haven't had before the times of the Internet. In the past, much euphoria about the Internet itself concealed the basic idea of any media, to provide a tool to support learning. We like to draw the attention on aspects of learning by identifying and evaluating Web-Work-Strategies of students. By analyzing both these strategies of students' work with the Internet and the gained knowledge, we investigate the dependence between these two aspects (see Priemer & Schön 2001).

The Study

The main objectives of the investigation are:
1. an identification of Web-Work-Strategies and factors influencing and describing these strategies,
2. the assessment and analysis of domain specific knowledge gained by students working with the WWW, and
3. an approach in detecting dependences and correlations between strategies and gained knowledge.

In December 2001 and January 2002 we asked 45 students of German high schools to participate in a laboratory pre-post-test investigation. The students had to write an essay on a topic in physics: the description of the generation of tides. For the corresponding research and text editing the students were allowed to use computers only, which provided Internet access and word processing programs. The students were selected in a way that they had sufficient prior knowledge in general physics and the mechanical laws behind the complex phenomenon of tides. About tides in particular the students had almost no knowledge at all. In the pre-evaluation this proved to be ideal to connect the Internet work with students' learning outcome. A data mining program collected all activities of the users: webpages visited, time on webpages, words typed, local actions also.

Findings

On a five level rating-scale students specified in a self-assessment how much their work strategy matches with the navigation strategies defined by Canter et al. (1985).
In addition, the posttest contained questions about tides to assess learning outcome.

<table>
<thead>
<tr>
<th>Navigation Strategy</th>

</tr>
<tr>
<td>Searching: users are motivated to find a particular target.</td>
<td>0.357*</td>
</tr>
<tr>
<td>Exploring: users are seeking the extent and nature of the field.</td>
<td>0.504**</td>
</tr>
<tr>
<td>Browsing: users amble along and inevitably revisit nodes in an unstructured journey.</td>
<td>-0.424**</td>
</tr>
</tbody>
</table>

Tab. 1: Navigation strategies (Canter et al. 1985) and their relation to posttest scores

The left column of table 1 summarizes the strategies. Students' strategies do not necessarily exclude each other, e.g. a person can see himself as an "Explorer" and as a "Searcher". In addition, strategies do not have to be stable attributes of students but may depend on the task they are working on. Table 1 shows the correlations between navigation strategies and posttest scores. We can conclude on one hand that "Searching" and "Exploring" seem to be favorable strategies since they correlate significantly with the posttest. On the other hand "Browsing" and "Wandering" seem to hinder learning with the WWW. Between the self-assessment of working as a "Scanner" and the posttest scores no significant correlations were found.

Log file data is used to verify these results by objective measurements and the help of a mathematical model (a first approach is outlined in Zajonc & Priemer 2001) that differs between three categories (see as well Choo, Detlor & Turnbull 2000): moves (visits of single webpages), patterns (clusters of moves that are directly connected to each other), and strategies (clusters of patterns that sequentially performed describe a complete Internet-session). This will allow us to collect and process user data in order to describe and evaluate Internet-Work activities without having to rely on subjective assessments.

Conclusions and Outlook

Our investigation shows that indeed Internet work strategies do have a veritably influence on learning outcome. "Searching" and "Exploring" can be seen as helpful strategies while "Browsing" and "Wandering" hinders learning with the WWW at least as far as a specific given learning objective is concerned. The identification and description of effective Web-Work-Strategies (or combinations) enables teachers to support students' work with the WWW. An objective and automated collection of user data with log files can identify and evaluate Web-Work-Strategies (in addition to those described by Canter at al. 1985). In a long run we aim to set the base for an adaptive help tool that reads, analyses, and evaluates log files of students' who work with the Internet, detects weaknesses and gives suggestions to improve the working style.

Daskom On-Line: Implementation Distance Learning
On Basic of Computer Course

Anak Agung Putri Ratna, Astha Ekadiyanto, Djoko Hartanto, Seinosuke Narita*
Multimedia Application and Networking Research Group
Jurusan Elektro Universitas Indonesia
Kampus Baru UI Depok 16412 – Indonesia

* Department of Electrical, Electronics and Computer Eng., Waseda University, 3-4-1 Okubo, Shinjuku-ku, Tokyo, Japan

ABSTRACT

Recent developments in the WWW have brought major changes in distance learning practices. With the connectivity advantage, distance learning through the web can now be conducted on-line to support both instructional aspects and technical aspects. The Department of Electrical Engineering, University of Indonesia has started the implementation of such distance learning mechanism called The “Daskom On-line”. One of the supporting functions the the Daskom On-line is the Online Test System.

This paper will discuss the implementation of the computer-based testing in the way the Daskom On-line been developed with. The type of computer-based testing adopted in the system is a linear testing method. The system used for computer-based testing is called “Kuis Dasar Komputer On-Line” (“Daskom On-Line Quiz System”). By implementing the software, lecturers can better manage evaluations on student’s performance, thus resulting more objective scores.

Keyword: Daskom On-Line, Quiz On-Line, Web Based Learning, Distance Learning.

1. INTRODUCTION

The Internet with all its infrastructures spread all over the world has proven to be a very effective and efficient tool to provide any requirements and services. Its revolution of information transfer capacity attracts many people to immediately participate in its utilization [1]. Internet is the superhighway of information network also known as the Web Based System (WWW) [2]. Among many fields utilizing the internet, the education is one of the most that has been taking advantage of the internet community in the form called web-based learning or distance learning. Some systems developed for such distance learning environment were EDLIN [3] and PASSENGER [4].

Whenever there is a learning process, there will also be an assessment process to evaluate the level of student’s understanding and capability. In a distance learning environment, computer based testing or online testing is an environment where students participating in distance learning can take their exam or quizzes through out their own computers technically without making the use of papers or any other writing tools.

This paper will discuss some aspects found in the implementation of distance learning project developed in the Electrical Engineering Department, University of Indonesia which is called the Daskom Online. The focus of this paper will be on the learning evaluation process.

2. THE DASKOM-ONLINE [2]

The Daskom On-Line is using a strategy called collaborative learning strategy. Collaborative learning has proven to be a unique and important strategy in online learning. Collaborative learning is the learning strategy that relies strongly on the concept of interactivity between teacher and the class [5]. In this research, interactivity can be implemented through all media in the Internet.

Another consideration of using collaborative learning strategy is that it provides greater chance of achieving best result rather than other strategies [6]. The concept of distance learning and Daskom On-Line incorporates the collaborative learning strategy in this research through the utilization of computer network media to access the material.

The course’s material is developed for the web based learning implementation based on materials provided by the teacher of basic computer course. Material was developed using HTML and was placed in a web server that is connected to the campus wide network. This type of material distribution has several advantages such as easy to update, can be access from almost every places through Internet connection and can be provided with interactive basis. Links from the syllabus to a web page for each class session or each chapter can be added to this kind of material.

Daskom On-Line use several types of media to communicate, which are e-mail, mailing list, bulletin board, and discussion board. The students can use these communication media to solve problems or to communicate with the teacher or assistant.

Daskom On-Line Quiz System is a computer-based testing implemented to support the Daskom On-Line Distance Learning environment. It support the multiple choice questions on the topics related to the Daskom materials (Introduction to Computers). Students participating in the Daskom On-Line can take quizzes as part of the evaluation process required for them to pass the course. The participation in this system also benefits the analysis of the computer-based testing implementation that being developed.

The Daskom Online Quiz Process

The Daskom On-Line Quiz System performs several steps from the beginning of the quiz until the end. All the processes are sequential processes that required to be executed exactly the same way. To ensure that the system will work in the exact sequential manner, pages delivered to the student’s browser is managed by a scripting language. This scripting language will also enables some overrides in the system whenever needed.

4. SYSTEM’S IMPLEMENTATION AND TESTING

Entering Questions and Answer Options
The Question’s type currently supported is the multiple choice questions. A radio button is used to provide answer selection among options. This will prevent duplicate answers.
Quiz Result's Analysis
After a quiz has ended, the results in forms of score cards of all the participants can be analyzed. There are two analysis modes provided in the system:

- Simple Mode
  Using this mode, a lecturer can easily observe the scores each students got in their quiz. All the results are shown in pages.

- Expert Mode
  This mode supports advanced filtering techniques and detailed views of the quiz results. It is intended to provide in-depth analysis of the quiz performance and the quality of questions.

Question's Analysis
The purpose of question's analysis is to determine whether the question is correctly stated and whether the students can answer it correctly. Questions are displayed with their hit scores. The hit scores are the number of right answers the students choose on that specific question. This tool is very useful in detecting faulty questions and in the long run can detect the depth of overall students' achievement that may require improvements in specific parts of the course material. The tool can also rank the level of difficulty of topics being examined. Figure 1 shows the screen capture of Question's Analysis interface.

Advantages and Weaknesses of the Daskom On-Line Quiz System
The Daskom On-Line Quiz System has several advantages and weaknesses. The Advantages are:

- Provide isolated environment
  The scrambling technique can minimize cheating especially since no student gets the same presentation of questions.

The Weaknesses are:

- The radio button prevents students from canceling their answers. Any selection will indicate that an answer has been performed and the user can only change the answer but cannot cancel the process.

- Since the answers cannot be cancelled, the only grading mechanism supported is the correct answers calculation mechanism. Implementing negative scores in wrong answers will not be fair since the students are forced to choose any options presented whenever they have committed the answer.

- The current database design can only support a one-time quiz session. Any re-examination will result in overwriting the existing data.

Analysis on the Online Quiz Execution
Through a field observation in an environment where the quiz takers are performing their exams, there are several problems identified.

The problems are closely related to the behavior changes in exam environment. Some of the students felt inconvenient taking exams from the web using a very limited screen size. This problem leads to impatience that induces them to become careless when answering the questions.
Generally, the Daskom On Line Quiz system satisfied the requirements. Comparing the results of the online Quiz with the conventional ones (in this case these same questions have been implemented in different environment), it shows no significant difference between the two. Most of the students acquired similar scores and statistically the results are identical.

6. CONCLUSION
- The Daskom On-line Quiz System has proven to satisfy the standards of exam requirement and worked well under the circumstances in the department of Electrical Engineering, Faculty of Engineering, University of Indonesia.
- The evaluation results show that the Online Quiz has similar results when compared to the conventional exam environment.
- There are some weaknesses in the system, but most of the problem can be overcome when the students got enough practice with the new learning environment of distance learning through the web and its multimedia network.

7. ACKNOWLEDGMENT

Using Computer-Based Learning Environments to Offer Collaborative Opportunities to Engage Students: One Case Study Using the Program “Alien Rescue”

Ondrea Quiros
Department of Instructional Technology
The University of Texas at Austin
United States
quiros@cox-internet.com

Abstract: A project was initiated to study computer-based learning environments as they relate to collaboration and engagement. In a sixth-grade classroom, five pairs of students were observed while they worked through a computer-based program called “Alien Rescue”. The main research questions were: 1) what aspects of the program “Alien Rescue” in a classroom environment support collaborative efforts to engage students? and 2) what behaviors are exhibited by the students that could indicate engagement? It was observed that time pressures and complexity of the problem were two factors that supported full engagement of collaborative efforts.

Theoretical Perspective

The CD-ROM based program, “Alien Rescue”, developed and designed under the supervision of Dr. Min Liu at the University of Texas at Austin, is designed to offer a meaningful learning experience by combining a realistic, authentic environment with problem-based learning meant to incorporate collaborative activities. Students must learn about several alien species as well as the planets and moons in our universe in order to find suitable homes for each alien species. To obtain the information, the students have access to several databases, as well as a simulated base from which a student can retrieve information from probes.

For students to be successful in completing the program in the time allotted, the students must consistently collaborate with each other and stay engaged in the task of finding the aliens homes. Yet, what does it mean to be engaged? One way to look at engagement is to break it down into a combination of two ideas: user involvement and user participation (Hwang & Thorn, 1999). Csikszentmihalyi (1997) looks at user involvement in his theory of “flow.” One becomes so mentally involved that “the sense of time is distorted, hours seems to pass by in minutes” (p.29). It is this complete psychological immergence within the experience that characterizes a state of flow (Foshay, 1991). Metros (1999) feels that such involvement depends upon the user’s perception of the information, or the “value” as Metros says it, that keeps a user engaged. One could speculate that a problem-based learning activity, in which students found value of information-gathering activities, combined with interesting interactive tools and a collaborative format, would lead to a high level of user participation. Furthermore, the instructional design of the activity would need to incorporate a high level of concentration as well as collaboration to lead to an engaging experience. Therefore, the questions this study hoped to answer included: 1) what aspects of the program “Alien Rescue” support collaborative efforts to engage students? and 2) what behaviors exhibited by the students could indicate engagement?

Method

This study was done in one sixth-grade classroom in a middle school in the Greater Austin, Texas area. Students were tasked to work in pairs to decide, based on evidence they collected through the computer program “Alien Rescue”, where each of six species of aliens should be placed in our solar system. Each pair of students had one computer to use for 45 minutes a day for a total of three weeks. The researcher observed five sets of students, four from one table and one from a separate table for approximately two weeks. The pairs of students were chosen based on preliminary observations of the class as a whole, and the decision to choose both students who seemed to collaborate well together and students who did not. The pairs of students were labeled A, B, C, D and E. Pairs A through D were at one table, and pair E was at a separate table. Data was taken in the form of observations of the class as a whole and the five pairs of students, questions asked of the students, and the place each pair stood when the teacher checked the databases.
Results

At first, the students read and took notes about the fictitious aliens, a relatively simple task. During this time, the students seemed relaxed, and sometimes made jokes among them that were not topic-related. Of the five pairs chosen for study, only four of the groups seemed to work well together. As the days went by, students became more aware that they would soon need to be finished with the program. At the same time, most groups progressed to the point of creating probes to find out information about the Solar System. Creating a probe incorporated complex thought processes that included matching data needed to appropriate instruments to probe mechanics. Groups A, B and C frequently asked questions of each other concerning probe design. However, group D did not participate in the table discussion. Group E continued a pattern of not discussing the program with each other and often not exhibiting behaviors consistent with being engaged in the assigned task.

Four days before the end of the project was due, the teacher looked at each pair's database to assess where each pair was in relation to finishing the program. Groups A, B, and C were allowed to continue, while Groups D and E were told to stop. During the last four days, pairs A, B and C worked together more and more often, to the point of delegating responsibilities among themselves with the idea of sharing what each had found with the others. Furthermore, in these last four days, the students of pairs A, B and C rarely made jokes or talked of anything besides the topics at hand. They seemed to lose track of the time in class, and they commented on how fast the classes seemed to go by. These comments support the idea that these pairs of students became engaged to the point of “flow” (Csikszentmihalyi, 1997; Foshay, 1991).

Discussion

If Metros (1999) is correct about how perception is related to engagement, then the activities held more value as the deadline neared (a point of extrinsic motivation) and the complexity of the tasks increased (a point of intrinsic motivation). Furthermore, the more successful each group was in collaboration within the group and with other groups, the farther the group progressed in the program. It would seem that the collaborative aspect of the activities created a more engaging environment, as such an environment led to the shared value of the activities.

However, this study has several limitations. The scope of the study was very small, and it may not be possible to reproduce the results. Furthermore, as this is a newly-initiated project, more observations need to be done to better determine the relevance of the data collected during this study. Factors that may have contributed include student perception and self-efficacy as they related to the task, and the depth of teacher facilitation. Further studies regarding teacher facilitation and motivational factors, such as time-limitations and complexity of technology-enhanced tasks, need to be implemented so as to better understand how a constructivist paradigm fits into a technology-enhanced instructional design. However, it is hoped that this study can begin investigations to lead instructional designers of multimedia programs, as well as those who use such programs, to consider factors relating to the collaborative engagement of their intended users.

CD-ROM Drives & Their Working:

CD-ROM is the abbreviation for Compact Disk – Read Only Memory. A CD-ROM is actually a thin piece of aluminum oxide with a little added gold or silver. This disk is covered both on the top and bottom by a transparent piece of plastic. Data is stored on to these disks by "burning" holes on the disk. These holes are called "pits". Depending on how deep they are, the data is read in as a '1' or a '0'. To store data on these disks, we need a CDR drive. There are also disks called CD-RW where data may be burned on to the disk, erased and re-burnt later on with new data. These disks are however, costly and are beyond the scope of our discussion.

To read from a CD-ROM, the LASER hits the area to be read, and reflects of the disk to a miniature scanner, which translates it to the machine language. The difference that actually occurs in the reflected light is that, the intensity is lower due to diffraction when the LASER falls on a deeper pit.

Tape Drives and their Working:

Tape drives are very much similar in working when compared to that we use on our music systems. Both have a thin plastic strips with a magnetic coating. This magnetic coating is what is responsible for the data storage. Data is stored by actually magnetizing a few parts of the tape to indicate the 'on' state or the '1' in machine language.

As you can see that the winding up increases the access time. This is what is the greatest disadvantage of the tape drives. These drives are still existent in a few companies. Despite a lot of advantages, the tape drives are in the verge of extinction due to their speeds.

Our Model:

As discussed earlier, our model uses the same mechanism of the CD-ROM drives and the Tape drives. Each of those technologies contributes a significant part in our device.

DESCRIPTION:

The device contains a similar casing as that of the tapes with a small modification. The casing is transparent on the top and the bottom near the middle. A small shutter, like the ones in the floppy drive, covers these places. They can be opened and closed at will inside the tape drive. The rolling mechanism is the same as the magnetic tapes. The tape that holds the data is a thin strip of plastic in which another strip of aluminum oxide is sandwiched. This tape is rolled up and placed inside the casing. Data is burned into our tape by the use of a LASER as in CD-ROM drives. This data is stored in the tapes one after another in the data strips, as we shall call them. These strips are the thin layers of aluminum oxide. The data access time may be a little better that that of the tape drives as the reading of our device use a LASER rather that an magnetic head which takes considerable time to position itself. The fine LASER should be capable of
emitting light at multiple frequencies and should be able to focus at various distances. This shall enable us to store data on both sides of the tape thus increasing the amount of storage space available. As in a CD-ROM, a deeper pit is read in as the 'off' state and the less deep pit is read in as the 'on' state.

WORKING:

The tape moves along the LASER beam and the scanner at the other end reads the data. This data is then decoded to machine language. The data may be stored on the tape in the same way as given below. The ASCII value of the codes are converted to their respective 8 bits or 16-bit binary code and stored in a sequence. Say we want to read the data on a particular strip at a particular position; the tape drive mechanism moves the tape first to the position and then seeks the strip on that position. This is similar to the floppy and hard disk mechanism where the data is retrieved by first moving to the sector from where the data is to be retrieved and then to the track from which to retrieve. The codes that may be used for storage, is given in the next page. The shutter of the casing opens automatically due to the use of some mechanical device like the ones on the floppy drive. The Laser is focused on the tape drive directly and also by making it reflecting over a mirror place inside the casing. This allows the LASER to scan both sides of the tape. This adds to more data storage. The LASER should be capable of multiple frequencies for the sake of security purposes. The default frequency as in the CD-ROM disks is used to store the code which resembles the frequency at which to read the rest of the drive if the data to be stored is to kept universal or available to all else the code for the frequency has to be entered by the user in order to read from the tape as the data is stored at that frequency and reading it using other wavelength of light will return meaningless data called Junk in computer jargon.

ADVANTAGES:

Most of the advantages of this disk have been discussed earlier. But for the sake of summing things up, here is what it has to offer

➢ No loss of data due to scratches
➢ No problem of absolute data loss due to breakages
➢ Larger storage space than other storage media
➢ Better access time than tapes though inferior to CD-ROM's in that aspect
➢ Better security for the data
➢ No contact between the head and the tape as in tape drives thus no problem of the tape getting rolled up
➢ Can be used to store data, video or sound as in the case of other storage media.

Abstract: In an effort to fill the need for lab-like experiences for distance learners, we have developed the 'BiologyOne' CD-ROM series. The CD series provides students with a series of open ended computer simulations that mimic the laboratory investigations commonly encountered in a traditional course. Assessments of the effectiveness of these simulations have shown student comprehension comparable to students in traditional courses.

Offering a general biology course in a distance learning format has presented instructors with the problem of providing the students a laboratory experience. To include this experience, instructors have often relied on compromising the course's outreach by having students attend an on site lab periodically, by investing in materials to be sent individually to students or by relying on the numerous computer based tools which generally offer a 'interactive' narrative of the text material but fall well short of investigative lab experiences. In an effort to fill the need for lab-like experiences for distance learners, we have developed the 'BiologyOne' CD-ROM series.

Material in the BiologyOne CD is organized into four primary sections. There are a Tutorial section, a Glossary section, a Laboratory section, and a Testing section. In addition, to aid and or speed up a user's navigation through the CD, a 'Site Map' of the material is also available.

Within the BiologyOne CD, Tutorial Units have been developed which provide the student with dynamic visual and descriptive introductions to concepts and processes commonly covered in an introductory biology course. Visual resources include illustrations, animations, photos, and video. If the student is enrolled in a traditional course, these resources provide a means of reviewing material seen in lecture or lab. For the distance learning student, these units allow the student to view the material in a format that resembles the experience they would have in the actual laboratory.
For many of the topics covered in a general biology course, the BiologyOne CD provides an investigative laboratory simulation. The goal of these laboratories is to provide the student with an experience that mimics the laboratory experience they might have in a traditional course. For many of these simulations, the student has control of multiple variables that offers the opportunity for greater experimentation than is typically available in an introductory biology laboratory. Additionally, as we have developed these simulations, we have tried to expose the student to some of the equipment they might encounter in a 'live' course but at the same time have tried to keep the interface with the computer straight forward.

In addition to these sections, the BiologyOne CD also provides the student a glossary and a selftesting section. The glossary currently contains approximately 2,000 terms that the student may encounter during a general biology course. The student may access this glossary from any point within the program to review or clarify the meaning of a term. The Testing Section is designed as for the student to use to self assess their mastery of the material. Questions within the Testing Units include crossword puzzles, multiple choice and matching formats.

Accompanying the CDs are web based resources that provide the student a 'laboratory manual' as well as a short introductory biology textbook. The laboratory manual provides the students with directed activities to complete using the simulations and a location to record their observations.

Feedback from students that had used the BiologyOne CD in a distance learning course has been quite positive. Comments include: "The lab simulations were fun and educational. I was wondering how well the labs would be for this online class, and I was pleasantly surprised."; "I was very impressed with how real some of the lab simulations seemed. I learned a little more than I thought would be possible."; "I think the lab simulations are a really neat way to get the point and experience across conveniently. I wondered before I took the course how the lab was going to be done. I think it is great."; "The labs were my favorite part of the course."

Of primary importance is the effectiveness of the BiologyOne CD in allowing the students to learn the course material. An assessment of the effectiveness of these simulations was performed through comparisons with students in tradition courses. Student groups were either not exposed to the BiologyOne CD, used the BiologyOne CD in addition to their traditional course work, or used the BiologyOne CD as an alternative to their traditional course work. When students used the BiologyOne CD only, their comprehension of the course material was found to be comparable to those students in the traditional course. When students received both the computer simulations as well as the traditional laboratory, comprehension appears to increase with test scores increasing between two to ten percentage points.
“Citizen Jane”: Rethinking Design Principles for Closing the Gender Gap in Computing

Chad Raphael
Santa Clara University
United States
craphael@scu.edu

Abstract: This paper identifies three rationales for closing the gender gap in computing—economic, cultural and political—in the relevant literature. Each rationale implies a different set of indicators of present inequalities, disparate goals for creating equality, and distinct principles for software and web site design that aims to help girls overcome the gap by increasing their interest and knowledge about computing. It is argued that designers should pay greater attention to the political rationale for equity, conceiving software and web sites that cultivate girls' civic uses of computers, so that women can exercise equal control over the architecture and policy of the information age.

In the recent literature on the gender gap in computing, arguments for pursuing greater equity among males and females may be urged for economic, for cultural, or for political reasons. Each rationale is significant, and often they are entwined in practice, but they are worth disentangling because each suggests different goals for achieving equity, distinct measures of current inequalities, and disparate design principles for media that aim to help girls overcome the gap. Focusing exclusively on one rationale is likely to obscure designers’ understanding of the gender gap and how to address it. This paper compares each strand of thinking, and considers their implications for designing educational and recreational multimedia and hypermedia aimed at attracting girls to computing. Although many reasons have been offered for the gender gap, the lack of suitable software and web sites for girls is often cited as a cause (American Association of University Women 2000; Cottrell 1992; Furger 1998; Schofield 1995). Finally, it is argued here that the political rationale for equity has been neglected and that designers should devote greater attention to fostering the civic uses of computers by girls.

Economic Rationales

Traditional liberal feminist concerns about gender equity in schooling and the workplace underlie economic arguments for ameliorating inequalities of access to, uses of, and attitudes about computers (Fig. 1). Indeed, there is continuing cause for concern about girls’ preparation for technical careers, according to the measures employed in this approach. Compared to boys, girls still report less experience with computers (Schumacher & Morahan-Martin 2001), less confidence in their computing abilities (Young 2000), and less interest in the technology (American Association of University Women 1999). In higher education, women’s share of bachelor's degrees in computer science declined from a high of 37 percent in 1983 to 28 percent in 1996 (Camp, Miller & Davies 2000) and women earned just 17 percent of the doctorates in the field in 1998 (U.S. Bureau of the Census 2000). In 2000, UCLA’s annual survey of first year college students nationwide found that 1.8 percent of women, compared to 9.3 percent of men, said they planned to pursue a career in computer programming, the biggest gender difference since the survey first posed the question in 1971 (Higher Education Research Institute 2001). In the workforce, women hold an estimated 20 percent of information technology (IT) jobs, and are especially underrepresented in systems analysis, software design, programming, and technological entrepreneurship (American Association of University Women 2000).

Arguments for educational and economic equity often lead to calls for software and web sites that feature women role models in the technical professions (e.g., Furger 1998), such as Cascade Pass’s You Can Be A Woman Engineer CD-ROM or web sites for girls about careers in the field (e.g., www.backyard.org). It is hoped that this strategy will counteract many girls’ image of technical work as masculine, dull, sedentary and anti-social (Garnett Foundation 1997), sucking more females into the educational “pipeline” toward higher

degrees and jobs in computer science and engineering. However, sole pursuit of the economic rationale can narrow designers’ vision in ways that may be counterproductive, even for girls’ economic interests. Too often, the range of role models provided is limited to professional and managerial roles in corporate IT settings, where employment is notoriously unstable. Moreover, as computer skills become central to many fields, from medicine and law to auto mechanics, these fields should exert more influence over technology design and uses (American Association of University Women 2000). Even if gender parity in IT jobs were achieved tomorrow, the vast majority of girls (and boys) would not work in this sector. Thus, girls would be better served by media that demonstrate the relevance of computing skills to a broader range of work than systems analysis or programming, which are not the only paths to molding technology and may be rejected by many girls.

The larger problem with the economic argument is that it tends to reduce the goal of technological fluency, indeed of education and play, to vocational training. The rhetoric of “keeping up” or “achieving equality” with males in technical careers rarely encourages girls to question the norms of the high technology workplace or the purposes of technology design. Nor does this approach ask girls to consider how women could transform those norms in ways that might benefit everyone, such as by making high tech careers more compatible with family life. Focus group research suggests girls are not necessarily fearful of computers but disenchanted with a masculine computer culture that they associate with obsessive work, materialistic motives, trivial and unethical uses of technology, and a false sense of control over the world (American Association of University Women 2000). For these girls, appeals to join such a culture that do not acknowledge how it might be changed and why it would be worth making the effort are likely to fall on deaf ears.

Cultural Rationales

Cultural arguments for equity focus on increasing females’ opportunities to use and adapt technology to explore and express their identities, create and communicate, and maintain relationships. Here, the gender gap appears to be closing in some ways, according to the indicators used or implied by this approach. Men and women entering college now report that they use computers frequently in almost equal numbers (Higher Education Research Institute 2001) and women have gained parity with men in using the Internet, with teenagers accounting for the fastest growing segment of female users (Hamilton 2000). Women take greater advantage of email to maintain relationships with friends and kin across distance than do men (Boneva, Kraut & Frohlich 2001). In accordance with females’ tendency to view the computer as a tool to accomplish tasks rather than an object of interest to be explored in its own right, females are more likely to use computer applications for word processing, graphic design and communication instead of play, programming or systems
design (American Association of University Women 2000). There are more multimedia games designed by women-led companies for girls, although girls still buy only 12 percent of games (Gorriz & Medina 2000).

Cultural arguments emerged in discourse about the gender gap in the 1990s, especially in the debate over how to design multimedia games for girls (see Cassell & Jenkins 1998). One camp appealed to girls’ traditional interests in cooperation, collaboration, glamour, bright colors, multiple paths through stories and environments, and so on. This “game girls” strategy suggests that the most effective way to increase girls’ interest in computers is to show how the technology can be used to explore conventionally “feminine” activities, endorsing traditional aspects of girls’ culture. It is indebted to cultural feminism, which posits a separate women’s culture of nurturing and knowing (e.g., Gilligan 1982). This approach extends to web sites for girls that primarily feature information on dating, friendships, shopping and communication.

A second strategy urges girls to become more comfortable playing aggressive games designed for boys, in hopes of fostering girls’ assertiveness. The “game girls,” as these teens and young women call themselves, appropriate the formerly male domain of computer games, embracing its images of feminine warriors and potent female sexuality as self-empowering (Wakeford 2000). Game girls reject constricting images of females as passive victims or supportive helpmates, which they accuse girl games, boy games and prior feminist thinking of perpetuating. From this standpoint, the optimal way to boost girls’ interest in computers is not to pursue a separatist design strategy, but to demonstrate the relevance of nontraditional gender interests to girls’ lives, appropriate them as legitimately feminine, and beat boys at their own games. The game girls share “third wave” or postfeminist rejections of earlier feminisms, seen by girls as “constricting (politically correct), guilt inducing, essentialist, anti-technology, anti-sex, and not relevant to women’s circumstances in the new technologies” (Wilding n.d.) The game girl strategy extends to the web on sites that offer discussion forums and articles on games, sex, and culture.

A third approach calls for creating gender-neutral content based on non-violent interests common to boys and girls. This software may include mystery games (such as Myst) and puzzle games (such as Tetris) that do not feature recognizably gendered protagonists and villains, or that employ characters (including animals) of indeterminate sex. Justine Cassell (1998), one of the foremost advocates of this strategy, has designed software that appeals to boys’ and girls’ shared interests in self-expression and self-construction by embedding computers in familiar objects such as blankets and stuffed animals that children can use to record and share their own stories. Her games and toys apply feminist pedagogy’s call for sharing power more equitably between teacher and student to the relationship of designer and user, and an emphasis on validating and learning from children’s own subjective experience. Under this approach, the best way to interest girls in computers is to show their relevance to all children’s interests in acting as detective or storyteller, with no intervening protagonists and overt gender preferences with which to identify.

One danger of the cultural approach is its exclusive thinking about how to address girls’ identities and gender socialization. Thus far, the debate over game design for girls seems to have been won in the marketplace by gender-traditional advocates, as evidenced by the commercial dominance of Barbie Fashion Designer and other “pink software” (Gorriz & Medina 2000), and in academic and policy circles by gender-neutral proponents (see American Association of University Women 2000). However, recent experimental research suggests designers can increase girls’ interest in computers, even in programming techniques, by demonstrating their relevance both to girls’ non-traditional and traditional interests (Lynn, Raphael, Olefsky & Bachen forthcoming). Approaches that offer a single way of constructing girls’ identities, including those that reflect only the interests they share with boys, are bound to feel limiting for some girls.

In addition, cultural rationales require a great leap of faith that girls’ use of current multimedia games, regardless of how they construe users’ identities, can serve as a gateway to technical skills and careers. Almost none of the current multimedia games foster an understanding of programming, systems or network design, where the gender gap is widest. Rather, they treat computers as a means to design clothes, disembowel aliens, or disclose stories. If we want to introduce girls to what is compelling about working with computers, none of these design strategies reveals much that is compelling about how computers work. If we want girls to have equal opportunity to shape the hardware and software of the future, multimedia design needs to encourage girls more overtly to explore how they might design or adapt the technology and to what ends.

**Political Rationales**

Political arguments for equity stress the need for women to be fully informed and enfranchised citizens of the information age. This approach suggests that girls and women need to know how technology works to
participate in democratic processes of designing, implementing and regulating what Lawrence Lessig (1999) has called “code.” By “code” Lessig means both the design of computer architecture (software, hardware and systems) but also relevant codes of law, policy and ethics. Girls need hands-on experience writing both kinds of code according to this rationale, which surfaces occasionally in policy discussions about technology in education (e.g., Committee on Information Technology Literacy 1999; Alliance for Childhood 2000), but almost never in the literature on gender equity and computing.

Is there a gender gap in the civic aspects of computing? We know far less about this gap than the economic or cultural ones, largely because we have not developed indicators that would allow us to measure its dimensions. Doing so requires thinking about who shapes technology design and regulation within corporations, government, academia and civil society. We could begin by assessing the amount and quality of women’s participation in making decisions about code as corporate managers, directors, market researchers and designers; as members of relevant congressional committees and executive branch agencies that control research and development funding, marketing subsidies, military procurement, and the like; as managers of government IT projects; as members of the judiciary that frequently hear high tech law cases; as academic researchers and publishers on technology issues (not only in computer science and engineering, but in law, medicine and other disciplines); as program officers, presidents and trustees of foundations and nonprofit organizations involved in technology policy and research; as organizers of technology-related ballot initiatives; and so on.

From the civic standpoint, girls need to know how computers work, both their capabilities and limits, primarily to develop personal and public codes of technology ethics, law, and policy. Girls need confidence in their own ability to effect change in computerized settings, democratize technology design, reflect on their own choices about computers and get feedback on their social impacts. They need to develop critical thinking and ethical reasoning skills both with computers and about them. A single piece of educational software might allow them to do both, for example, by simulating the impact of different methods of computer donation, recycling or disposal on a town’s schools, environment and economy. A game might be built around the challenges of keeping and communicating secrets in a school where web and email monitoring software is deployed, spurring exploration of how such programs work and their legal and ethical dimensions.

**Figure 2: Some Engaging Design Features for Girls and Contemporary Issues of “Code”**

Media designers concerned with boosting female participation in writing the larger code of the information age would be well-served by design principles common to constructivist (Papert 1993) and feminist pedagogy (Cassell 1998). Designers would foster users’ active construction of games and web sites rather than laying down fixed rules and rigid structures. Designers could develop content from the start in consultation with girls about meaningful problems of interest to them, showing girls how computing is relevant to the sources, solutions and arenas for exploring these problems. Media could encourage users’ autonomous experimentation and discovery with the computer itself rather than leading them down narrow paths toward predetermined conclusions or lessons. Design might foster greater cooperation and interactivity among users. This kind of approach aims to inspire ongoing, reflexive consideration of girls’ own experience with computer
technology, "incorporating and coordinating considerations of self, others, and society" (Kahn, Jr. & Friedman 1998, p. 165). It asks girls to write not only programming code, but regulatory code.

Fig. 2 presents some design features that research has found are specifically compelling for girls (Beato 1997; Kafai 1996), and for girls and boys (American Association of University Women 2000), as well as some of today's most widely debated issues of code in technology law, policy and ethics. To serve girls' needs and rights as citizens, we can start drawing more lines between the columns, employing design features that work for girls to encourage them to explore questions of code and discover how they might shape the politics and architecture of computing.

Conclusion

This review of the literature suggests three distinct rationales for closing the gender gap in computing, indeed three different gaps: economic, cultural and political. It argues that scholars and policymakers have neglected the political gap and urges software and web designers to devote greater attention to addressing it. There are a number of good reasons for doing so. First, the cultural divide in computing already appears to be narrowing, as women go online in equal numbers and use the internet for communication. Second, by pursuing the approach suggested here, designers would more overtly foster girls' understanding of computing architecture, contributing to closing the economic gap as well by helping to familiarize girls with how the technology works as well as the social choices encoded in the hardware and software we use. Finally, and perhaps most important, this kind of design strategy would develop the kind of skills that all girls, and boys, need for effective citizenship in the information age: critical thinking with and about computing's impacts on our lives, and an appreciation of the relevance of information technology ethics and policy to gender-traditional and nontraditional interests.

Abstract: Heuristic evaluation is a methodology for investigating the usability of software originally developed by Jakob Nielsen (1993, 2000). Nielsen’s protocol was modified and refined for evaluating e-learning programs by participants in a doctoral seminar held at The University of Georgia in 2001. The modifications primarily involved expanding Nielsen’s original ten heuristics (developed for evaluating software in general) to fifteen heuristics (developed to be more closely focused on e-learning programs). The application of this evaluation protocol to a commercial e-learning program supported enhancements in the usability of the program.

Introduction

Heuristic evaluation is a methodology for investigating the usability of software originally developed by Jakob Nielsen (1993, 2000), a widely acknowledged usability expert. According to Nielsen (1994), heuristic evaluation “involves having a small set of evaluators examine the interface and judge its compliance with recognized usability principles (the “heuristics”).” Nielsen’s original protocol for heuristic evaluation can be found on the Web at: http://www.useit.com/papers/heuristic/.

For this study, Nielsen’s protocol was modified and refined for evaluating e-learning programs by the participants in a doctoral seminar held at The University of Georgia between August and December 2001. The modifications primarily involved expanding Nielsen’s original ten heuristics (developed for evaluating software in general) to fifteen heuristics (developed for evaluations of e-learning programs). This paper describes the set of fifteen e-learning heuristics as well as the protocol that guided the evaluation process. In addition, the results of the application of this heuristic evaluation protocol to a commercial e-learning training program are illustrated.

Method

Figure 1 presents the protocol we developed for the heuristic evaluation of e-learning programs. Figure 2 presents a set of fifteen usability and instructional design heuristics which should be viewed as a work in progress. Further refinements are likely to be made based upon the application of the heuristics to various e-learning products as well as the feedback we receive from others who use this tool for their own heuristic evaluations.

Seven instructional technology doctoral students and two faculty members (one from cognitive psychology and one from instructional technology) were involved in the development and initial application of these heuristics and the accompanying protocol. There were twenty heuristics in our initial set. These were generated through a critical analysis of Nielsen’s (1994) heuristics as well as several small and whole group “brainstorming” sessions aimed at identifying additional heuristics for the usability evaluation of e-learning programs.

The initial twenty heuristics and the protocol were first applied to a commercial e-learning program called “GMP Basics” designed for the American Red Cross by LearnWright, an award-winning company located in Rockville, Maryland, USA (http://www.learnwright.com). LearnWright specializes in the development of e-learning programs for regulated industries such as pharmaceuticals. Training for these industries is mandated by the U.S. Food and Drug Administration (FDA). From the perspective of the FDA, the collection of blood and plasma products is a regulated activity. While not everyone at the Red Cross is involved in collecting, processing, or distributing blood or plasma products (e.g., some workers are involved exclusively in disaster relief), all workers in blood services must learn the
principles encompassed in the FDA's regulations for Good Manufacturing Practices (GMP) The courseware we evaluated was presented on a CD-ROM, although it will eventually be accessible via a Web-based intranet.

Protocol for E-Learning Heuristic Evaluation

This instrument and protocol are intended for use by instructional designers and other experts engaged in heuristic evaluations of e-learning programs. The instrument itself lists fifteen heuristics for e-learning programs, some of which are based upon Jakob Nielsen's widely used protocol for heuristic evaluation of any type of software (http://useit.com/papers/heuristic/), and the rest of which are based upon factors related to instructional design. Although we have tried to be comprehensive, experts may decide to add new heuristics deemed relevant to the types of e-learning programs being evaluated or to the expert's specific expertise.

Steps:
1. An expert should review the heuristics and accompanying "Sample questions to ask yourself" in the instrument before reviewing an e-learning product. The expert should modify the instrument if needed, by adding, deleting, or changing heuristics.
2. It is important that the expert spend substantial time exploring the e-learning program before beginning the actual heuristic evaluation. Ideally, the expert will assume the role of typical learner who would use this e-learning program. Before beginning the review, the expert should be given (or try to discover) background information related to the e-learning program such as:
   a. Target audience and learner characteristics: A thorough description of the intended audience and their learner characteristics (e.g., education level, motivation, incentive, and computer expertise) will enable the expert to judge the appropriateness of the user interface and other aspects of the program's usability in an informed manner.
   b. Instructional goals and objectives: The expert should know as much as possible about the needs that the e-learning program is intended to address, ideally in terms of clear goals and objectives.
   c. Typical context for using this program: Realistic scenarios for when, where, and how the e-learning program will be used should be known by the expert.
   d. Instructional design strategies used in the program: If possible, a description of the design specifications used in developing the e-learning program should be provided to the expert so that the expert's judgment of the appropriateness of the instructional design strategies are informed with respect to the instructional designer's intentions.
   e. The status of the program's development and possibilities for change: The expert should be informed as to where the program is in the development cycle (e.g., an early prototype, beta version, or older version under consideration for redesign).
3. After spending enough time to become familiar with the program, the expert should go through it from beginning to end to conduct the actual heuristic evaluation. (With lengthy programs, the expert may only review a representative sample of the program.)
4. The expert should make note of every usability problem found. For each problem, the expert should identify the heuristic it violates, and then give it a severity rating using the severity scale below. If the problem cannot be attributed to a violation of a specific heuristic, the expert should make a note of this. (If a number of problems are found that cannot be associated with specific heuristics, this may suggest the need for the development of new heuristics.)
   Severity Scale
   1. cosmetic problem only; need not be fixed unless extra time is available
   2. minor usability problem; fixing this should be given low priority
   3. major usability problem; important to fix; so should be given a high priority
   4. usability catastrophe; imperative to fix before this product is released
5. After all the usability problems are found, the expert should go back though them and give each one an extensiveness rating using the extensiveness scale below.
   Extensiveness Scale
   1. this is a single case
   2. problem occurs in several places in the program
   3. this problem is widespread throughout the program
6. Most heuristic evaluations involve 4 to 5 experts. Once all experts have completed their evaluations, they may be brought together for a debriefing led by a moderator. The discussion of the usability problems may be videotaped for further analysis. If major differences appear in the problems found or the ratings given, the moderator may try to get the experts to resolve their differences and reach consensus. The experts may also be asked to suggest strategies for resolving the major usability problems found.
7. A heuristic evaluation report should then be compiled. Bar charts, tables, and other illustrations should be used to display the results. If feasible, screen captures should also be incorporated into the report to illustrate major problems as well as suggested enhancements.

8. The most important component of the heuristic report is a set of recommendations for improving the usability of the e-learning program. These should be as specific as possible to provide the designers with the information they need to eliminate the problems and improve the e-learning program.

**Figure 1. Protocol for heuristic evaluation of e-learning programs.**

1. **Visibility of system status:** The e-learning program keeps the learner informed about what is happening, through appropriate feedback within reasonable time.
   
   Sample questions to ask yourself:
   a. When modules and other components of the e-learning (e.g., streaming video) are downloading, is the status of the download communicated clearly?
   b. Is the user provided with information that indicates that the e-learning program is operating correctly?

2. **Match between system and the real world:** The e-learning program’s interface employs words, phrases and concepts familiar to the learner or appropriate to the content, as opposed to system-oriented terms. Wherever possible, the e-learning program utilizes real-world conventions that make information appear in a natural and logical order.
   
   Sample questions to ask yourself:
   a. Does the e-learning program’s interactive design utilize metaphors that are familiar to the learner or related to the specific content of the program?
   b. Is the interface “user friendly,” given the content of the program and its target audience?

3. **Error recovery and exiting:** The e-learning program allows the learner to recover from input mistakes and provides a clearly marked “exit” to leave the program without requiring the user to go through an extended dialogue.
   
   Sample questions to ask yourself:
   a. Does the e-learning program distinguish between input errors and cognitive errors, allowing easy recovery from the former always, and from the latter when it is pedagogically appropriate?
   b. Does the program allow the learner to leave whenever desired, but easily return to the closest logical point in the program?

4. **Consistency and standards:** When appropriate to the content and target audience, the e-learning program adheres to general software conventions and is consistent in its use of different words, situations, or actions.
   
   Sample questions to ask yourself:
   a. If appropriate to the content and target audience, does the e-learning product adhere to widely recognized standards for software interactions (e.g., going back in a Web browser)?
   b. If the e-learning program does not utilize common software conventions for interactions, are the novel interactions appropriate for the content and target audience?
   c. Does the program maintain an appropriate level of consistency in its design from one part of the program to another?

5. **Error prevention:** The e-learning program is designed to prevent common problems from occurring in the first place.
   
   Sample questions to ask yourself:
   a. Is the program designed so that the learner recognizes when he/she has made a mistake related to input rather than content?
   b. Is the e-learning program designed to provide a second chance when unexpected input is received (e.g., “You typed “bat” in response to the question. Did you mean “tab?”)?

6. **Navigation support:** The e-learning program makes objects, actions, and options visible so that the user does not have to remember information when navigating from one part of the program to another. Instructions for use of the program are always visible or easily retrievable.
   
   Sample questions to ask yourself:
   a. Does the interface of the e-learning program speak for itself so that extensive consultation of a manual or other documentation does not interfere with learning?
   b. Does the e-learning program provide user-friendly hints and/or clear directions when the learner requests assistance?
   c. Does the e-learning program include a map or table of contents that allows the learner to see what has been seen and not seen?
7. **Aesthetics**: Screen displays do not contain information that is irrelevant, and “bells and whistles” are not gratuitously added to the e-learning program.

Sample questions to ask yourself:
- Are the font choices, colors, and sizes consistent with good screen design recommendations for e-learning programs?
- Does the e-learning program utilize white space and other screen design conventions appropriately?

8. **Help and Documentation**: The e-learning program provides help and documentation that is readily accessible to the user when necessary. The help provides specific concrete steps for the user to follow. All documentation is written clearly and succinctly.

Sample questions to ask yourself:
- Is help provided that is screen or context specific?
- Is help or documentation available from any logical part of the e-learning program?
- Is help or documentation written clearly?

Figure 2. Usability and instructional design heuristics for evaluation of e-learning programs.

9. **Interactivity**: The e-learning program provides content-related interactions and tasks that support meaningful learning.

Sample questions to ask yourself:
- Does the e-learning program provide meaningful interactions for the user, rather than simply presenting long sections of text?
- Does the e-learning program engage the learner in content-specific tasks to complete and problems to solve that take advantage of the state-of-the-art of e-learning capabilities?

10. **Message Design**: The e-learning program presents information in accord with sound information-processing principles.

Sample questions to ask yourself:
- Is the most important information on the screen placed in the areas most likely to attract attention?
- Does the e-learning program follow good information presentation guidelines for organization and layout?

11. **Learning Design**: The interactions in the e-learning program have been designed in accord with sound principles of learning theory.

Sample questions to ask yourself:
- Does the e-learning program follow an appropriate learning design to achieve its stated objectives?
- Does the e-learning program engage learners in tasks that are closely aligned with the learning goals and objectives?

12. **Media Integration**: The inclusion of media in the e-learning program serves clear pedagogical and/or motivational purposes.

Sample questions to ask yourself:
- Is media included that is obviously superfluous, i.e., lacking a strong connection to the objectives and design of the program?
- Is the most appropriate media selected to match message design guidelines or to support instructional design principles?
- If appropriate to the content, are various forms media included for remediation and/or enrichment?

13. **Instructional Assessment**: The e-learning program provides assessment opportunities that are aligned with the program objectives and content.

Sample questions to ask yourself:
- If appropriate to the content, does the e-learning program provide opportunities for self-assessments that advance learner achievement?
- If appropriate to the content, do assessments provide sufficient feedback to the learner to provide remedial directions?
- Wherever appropriate, are higher order assessments (e.g., analysis, synthesis, and evaluation) provided rather than lower order assessments (e.g., recall and recognition)?

14. **Resources**: The e-learning program provides access to all the resources necessary to support effective learning.

Sample questions to ask yourself:
- Does the e-learning program provide access to a range of resources (e.g., examples or real data archives) appropriate to the learning context?
b. If the e-learning program includes links to external World Wide Web or Intranet resources, are the links kept up-to-date?
c. Are resources provided in a manner that replicates as closely as possible their availability and use in the real world?

15. Feedback: The e-learning program provides feedback that is contextual and relevant to the problem or task in which the learner is engaged.

Sample questions to ask yourself:

a. Is the feedback given at any specific time tailored to the content being studied, problem being solved, or task being completed by the learner?
b. Does feedback provide the learner with information concerning his/her current level of achievement within the program?
c. Does the e-learning program provide learners with opportunities to access extended feedback from instructors, experts, peers, or others through e-mail or other Internet communications?

Figure 2. Usability and instructional design heuristics for evaluation of e-learning programs (continued).

All seven doctoral students and the cognitive psychology faculty member served as the experts for this heuristic evaluation and followed the protocol during a one-week period in October 2001. After an initial group review of the findings, another week was allowed to refine the individual reports that each expert compiled. Next, the instructional technology (IT) professor led a debriefing session during which copies of all the reports were made available to all experts. During this session, an acceptable level of consensus was reached concerning the major usability and instructional design problems, their severity, and their extensiveness. After the discussion, the IT professor synthesized the findings of the individual heuristic evaluations into a succinct report that was provided to the client.

Findings

The results of the heuristic evaluation of the GMP Basics courseware identified a number of important, but resolvable, problems with the e-learning program. For example, one of the heuristics violated in the initial version of the GMP program was Number 3, Error Recover and Exiting. In Figure 3, the screen capture on the left is from a timeline game within the GMP Basics course that did not allow the learner to exit easily, short of quitting the program altogether. The screen capture on the right illustrates the same game in the new version of the e-learning program after being redesigned based upon the results of the heuristic evaluation described in this paper as well as the findings of a field evaluation conducted by the first author in December 2001. In the revised version of the program, the learner can easily go back to the previous screen or exit this part of the program.

Figure 3. GMP Basics timeline game screen captures before (left) and after (right) evaluation.

Another heuristic violated in the early version of GMP Basics was Number 7, Aesthetics. In Figure 4, the screen capture on the left is from a quiz show game within first version of the GMP Basics course. The screen capture on the right illustrates the same game in the revised program. The aesthetics as well as the professional look-and-feel of the e-learning program have been enhanced in the new version.
Figure 4. GMP Basics quiz show game screen captures before (left) and after (right) evaluation.

As a final illustration of the results of this heuristic evaluation, the Message Design (Heuristic Number 10) of the e-learning program was enhanced. In Figure 5, the screen capture on the left is from a typical instructional segment within the GMP Basics course that some learners found difficult to read because of the extensive use of light text on darker backgrounds. The screen capture on the right illustrates the same screen with the primary text appearing in a dark font on a lighter background. The screen on the right also illustrates improvements in the Navigation Support (Heuristic Number 6) that were made after this evaluation.

Figure 5. GMP Basics instructional screen captures before (left) and after (right) evaluation.

Interestingly, both the heuristic evaluation and the field evaluation revealed relatively few instructional design problems of the kind that would be represented by Heuristics Numbers 9 – 15. In other words, the original GMP program represented sound principles of instructional design, but the usability of that version of the program needed to be strengthened. Of course, usability is critical to a learner’s experience with an e-learning program, and the effectiveness of even the most instructionally sound programs will be decreased if the learner’s experience suffers from problems related to navigation, orientation, visual appeal, and other usability criteria (Reeves & Carter, 2001).

Discussion

There are limitations to this study that must be clarified. This heuristic evaluation took place over more than two weeks whereas most heuristic evaluations generally last only one or two days. There were eight experts involved instead of the usual four or five recommended by Nielsen (1994). In addition, changes made in the GMP Basics program were informed by a field evaluation conducted by the first author at a pharmaceutical manufacturing plant with real
workers, not by the heuristic evaluation alone. It is impossible to attribute exactly which enhancements were based upon which of the two evaluations. Nonetheless, LearnWright expressed great satisfaction with the results of the heuristic evaluation protocol and has requested that the protocol be applied to other programs being developed.

Although heuristic evaluation is fast, convenient, and economical, it is not sufficient for evaluating e-learning programs, and usability testing is advised (Nielsen, 2000). Heuristic evaluation and usability testing usually detect different types of usability problems (Nielsen, 1994). Heuristic evaluation is often conducted as a supplement to usability testing or when usability testing is not feasible. Through this study, we found that Nielsen’s original ten usability heuristics were insufficient for e-learning programs, and we developed and refined the fifteen heuristics presented in Figure 2. We encourage others to adapt our e-learning heuristics to their own evaluation needs. We only request that, if possible, the results of subsequent evaluations be shared so that we can further refine this tool.

The Role of the Facilitator in Active Learner Support

Franz Reichl, Ursula E. Vierlinger
University Extension Centre, Vienna University of Technology

Background

The SOCRATES/ODL project FACILE (FACIlitated open distance Learning for continuing Engineering education, 1998-2000) was a starting point for universities' centres for continuing engineering education to complement continuing education by e-Learning provisions with active learner support. The experiences made during the project are currently applied for e-Learning in university continuing education and in training for companies.

e-Learning for Practitioners and Professionals

In continuing education, learners acquire knowledge for a variety of different reasons. Practitioners and professionals come to a course as learners with already a high level of expertise. Motivation to learn is generally high, but does not regard "formal" completion of the course. Instead, participation in such a course generally is driven by the need to solve a specific problem at the work place. This specific need varies widely among individual learners, as does the familiarity with the subject and the level of mastery of the skills necessary [Payr/Reichl/Csanyi/Vierlinger 2001].

The learner's motivation and needs or demands to learn determines the contents and type of learning. Following Bloom's taxonomy [Bloom 1954], Sparkes distinguishes four different types of learning:

- learning factual knowledge;
- learning mental or physical skills;
- learning understanding or comprehension;
- learning attitudes and values [Sparkes 1985, pp.4-10; Rowntree 1992, p.46].

Sabine Payr complements these learning and knowledge types with "mastery", i.e. transfer of knowledge and skills to personal practice [Payr/Reichl/Csanyi/Vierlinger 2001; Baumgartner/Payr 1999; Payr 1999].

Learner Support by Facilitation

Individual learners in continuing education learn for different reasons, want to achieve different objectives, have different previous knowledge, have developed different strategies to acquire knowledge, etc. It is neither appropriate nor economically feasible to deliver completely different learning packages to meet all these different learning needs. Thus, an appropriate educational method and delivery system has to provide the flexibility necessary to apply general learning material in heterogeneous learning situations.

Reflection, group learning, consultation and guidance, as well as interaction are of utmost importance for the success of any learning activity. Especially in such a heterogeneous learning situation, the effectiveness of learning significantly profits from interaction between individual learners who may gain different viewpoints from discussing the subject with their colleagues. Learner support services thus constitute an indispensable complement to packaged distance learning materials to ensure interactivity and feedback.

Especially in continuing education, self-directed learning is most effective. Significant learning is much improved if learners can be given the opportunity to discover laws, concepts and theories – they should not be taught but can be coached [Sparkes 1985, p.9; Schön 1987, p.17, quoting Dewey 1974, p.151]. A facilitator should be willing and interested in helping the learners; facilitators should not repeat the contents or immediately answer the learners' questions; they shall help the group of learners to discover the answers by themselves [Gibbons 1977, pp.18-19; Rowntree 1992, pp.79-80].

Experiences with Tutored Video Instruction [Gibbons/Kincheloe/Down 1977] and with facilitated e-Learning show that people do not learn directly from learning material – the learning material rather acts as an "organiser" of the learning process. For the success of the learning process, the best results occur when the participants can bring problems, examples and experience from their own work into the learning process. Thus, it is important to integrate real life experience and problems into the process [Reichl 1996].

Experiments with different Models for Facilitation

Typically, "facilitation" in ODL (Open&Distance Learning) is understood as the support of learner activities at a remote learning site [Sherry 1996]. The facilitator is the one and often only person involved in a course with whom the learners are in face-to-face contact. The role of a facilitator is to ensure communication between faculty and
students, to ensure smooth running of technical equipment, to respond to students' questions concerning course administration, learning facilities, but rarely on the subject itself [Payr/Reichl/Csanyi/Vierlinger 2001].

In the FACILE project, on-site facilitation was replaced by distance facilitation. While in most ODL courses the role of support, tutoring, coordination and contact at a distance is taken over by the teacher/trainer him/herself, this model did not work out satisfactorily for this new type of networked ODL. The first approach taken in the project was to make the author of each module responsible for its delivery. Different content areas would be facilitated by different persons. Learners experienced problems with this approach, for several reasons:

- Each author brought his/her own concepts and methods of ODL to the undertaking.
- Learners did not know any of the authors personally and did not have time to get to know (and to adapt to) their differing methods and pedagogic backgrounds.
- The individual authors of the modules were "bound" to the specific contents they wanted to deliver, so that no continuous course activities could develop.

For the following attempts, the project partners thus separated the role of the facilitator from the role of the content providers and experts and to assign one single person as the facilitator. During the pilot run of the FACILE course, the role of the facilitator was a "passive" one, being available for questions and problems when needed, but the facilitator did not intervene actively in their learning process. The drop out rate of this pilot run was around 80%.

Experiences showed that learners need to be guided actively through the course. In consequence, the project partnership developed a didactical and pedagogical concept to provide effective online facilitation. The (tele-)presence of a single facilitator in the FACILE course as delivered in its final form turned out to be a substantial factor in providing stability and continuity in this networked ODL environment.

The facilitator did not only co-ordinate learners' activities, but also became a mediator between the learners and the different authors and experts in the field. While the modules still were authored by different people, learner activities were designed and monitored centrally and over the whole duration of the course. This active facilitation has turned out to be the key to success in the FACILE courses. The drop out rate of the second course run was only 15% [Reichl/Payr/Csanyi/Vierlinger 2001].

Roles and Tasks in Facilitated ODL

In our approach for learner support through active facilitation, it is important to clearly distinguish between the different roles of actors involved, the most important being:

- Learners;
- content providers or authors of learning material;
- experts in the subject area;
- facilitators.

It is not necessary that these different roles be "played" by different persons – the roles of expert and content provider can be played by one and the same person, as can be the roles of expert and facilitator, and as in peer tutoring even one of the learners could take over the facilitator's role – but for the success of our approach to e-Learning, it is important to have these different roles represented.

The central and most important role in our approach is the one of the facilitator. The facilitator's role could best be compared to a "spider in the web", tying together the most diverse persons, interests and activities. The most important task of a facilitator is to take "motivating" action, not by re-enforcing extrinsic motivation (e.g. by sanctions), but by building a learning group that develops its own social dynamics and commitments:

- the facilitator is the primary contact person for all the participants and contacts authors and experts;
- the facilitator has to take the initiative e.g. in soliciting questions, contributions or personal information from participants; (s)he elicits questions from participants and acts as moderator between the learning group and the authors/experts;
- the facilitator keeps track of and monitors each participants' activities, e.g. by reminding them of their tasks;
- the facilitator creates a social learning environment within a virtual learning group, using the available technology.

In short, the facilitator has to react timely to every input by a participant, triggers self help and group support instead of answers by facilitator or expert, and keeps the team learning going by setting tasks and deadlines, by ensuring information flow among participants, by being supportive and communicative [Payr 2000].

While a content provider or expert has to be qualified in his/her subject area, the facilitator – unless (s)he is the same person – does not have to be overly qualified in the subject area (but should have enough insight into the content to decide whether a question from a learner can be solved within the learning group or needs the advice
of an expert); the facilitator has to be technically and socially competent in communication technologies and communication processes. If this role is played by one of the experts, this person also has to hold this necessary qualification.

Conclusions

Since the most important type of learning (as described above) that can take place in an ODL course for practitioners is learning mental or physical skills, intensive assistance for the learners by active facilitation from a socially competent person has turned out to be the key to success in e-Learning courses.

Designing online quiz questions to assess a range of cognitive skills

Nick Reid
University of New England, Australia
nreid@metz.une.edu.au

Catherine McLoughlin
Australian Catholic University, Australia
c.mcloughlin@signadou.acu.edu.au

Abstract: This paper discusses the design and pedagogy underpinning the use of online quiz items in which students are presented with a range of questions designed to enhance understanding of complex linguistic constructions. It explores the design of different types of quiz question from the perspective of pedagogy and cognitive demand. The particular types of questions presented in this online learning setting demonstrate a formative approach to assessment, closely integrated with learning processes. A matrix of questions is presented using Bloom's taxonomy showing the type of question, pedagogical underpinnings and cognitive skills required. The implication of the paper is that automated quiz type questions do not necessarily imply a narrow focus on recall, but can be designed to assess a range of learning processes.

Theoretical background: CAA

Educators can be in no doubt of the demands of society for lifelong capable learners who are able to perform cognitive, metacognitive and metacognitive tasks and demonstrate competencies such as problem solving, critical thinking, questioning, searching for information, making judgments and evaluating information (Reeves, 2000; Oliver & McLoughlin, 2001). Figure 1 represents the changing nature of assessment, showing a transition from a focus on testing to a focus on learning and transfer of understanding. The traditional approach to assessment was largely a form of objective testing which valued students' capacity to memorize facts and then recall them during a test situation. Testing was concerned with measuring a range of cognitive skills, though many of these tests relied on quantifiable approaches rather than qualitative displays of skills and knowledge. Magone et al (1994) called this the one right answer mentality.

Figure 1: Continuum of assessment

The next form of assessment depicted in the continuum is the measurement of competencies, or what we call 'sequestered problem solving' (Schwartz et al, 2000). In these contexts students are asked to solve problems in isolation and without the resources that are typically available in the real world such as texts, Web-resources and peers. Often these tests of aptitude are single shot, and summative rather than formative. In contrast, assessment that supports learning and knowledge transfer provides the basis for future learning, and continuing motivation to learn (far right of the continuum in Figure 2). This approach is sometimes called the alternative assessment movement, as it is concerned with authentic performance (Cumming & Maxwell, 1999). Both testing and measuring competence as forms of assessment have been critiqued as being controlling, limiting and contrary to student centered teaching and learning. Morgan and O'Reilly (1999) add the following criticisms of traditional assessment practices:

• a lack of variety and autonomy and student choice;
• lack of applied work-based and project based learning;
overuse of summative forms of assessment;
limited use of peer and self-assessment strategies.

Other indicators of the need to rethink online assessment have come from Bull & McKenna (2000) who argue that "the development and integration of computer-aided assessment has been done in an ad hoc manner". In a similar vein, Angelo (1999) maintains that we need a more compelling vision of assessment, research-based guidelines for learner-centered assessment, and a new mental model of assessment.

**Online assessment: Are multiple choice items appropriate?**

Computer-based assessment using a range of question types has been shown to have positive effects on student learning, as students appreciate the speed of marking and the feedback provided (Thelwall, 2000). Multiple choice items can be designed to assess a range of competencies relating to student performance rather than concentrate on 'objective' questions that text recall of discrete facts (Brown et al, 1999).

Multiple choice items can be used for both formative and summative assessment, and thus to broaden the range of skills that is assessed. This paper describes the use of a system of computerized assessment utilising a variety of question types to assess higher order skills. Despite the skepticism surrounding the use of multiple choice items as a means to assess the skills of analysis, synthesis and evaluation, carefully crafted questions can overcome this limitation (Haladyna, 1997).

**Context: Extending the use of multiple choice items**

The context of the study was a 2nd/3rd year level university course of study in Linguistics delivered online. In this unit students are required to develop and apply skills in analyzing the grammar of a language which they have not encountered before. Intended learning outcomes are analytical skills, the capacity to synthesize conceptual knowledge and

It was decided to use the quiz feature of WebCT and to create a database driven item bank of questions to assess student learning and provide feedback. The learning objective was for students to develop skills in linguistic analysis and synthesis. Students are given a database of 84 sentences in language X, beginning with simple sentences (like 'The woman is going home'), and increasing in complexity until they involve quite complex sentences involving constructions like relatives and passives (as in 'The woman who cooked the meat is sitting down.') Students are supplied with English translations for each sentence, but they do not receive any indication of which words mean what, and which of the meaningful subparts of words (morphemes) are represented. Using prior knowledge of linguistics, students have to make inferences about words parts and combine these in order to interpret the language. Students were required to satisfy assessment requirements by completing two separate activities; the construction of a dictionary of this language and the completion of a grammatical description of this language. This required higher order thinking skills and the capacity to analyze and synthesize language elements.

Bloom's taxonomy was used to categorise questions according to cognitive skills required. See Table 1 for the matrix summarizing question types.

*Table 1: Matrix showing question type and cognitive skill required*
Design of the quiz questions

The quiz items were constructed with three different question styles, designed to assess a range of learning outcomes.

**Multiple Choice Questions** were used to test skills in the cognitive domain, focusing on comprehension and analysis of the grammatical patterns evident in the data. For example in the sample question below, students are asked to select variables true of a word class type.

**Question 5 (3 points)**
Which of the following characteristics are true of the class of nouns in this language? [You need to select all the characteristics which are true to score full marks, and there may be more than a single correct answer]

Nouns can occur;
1. as a bare stem (unaffixed root)
2. with the prefix ‘ma?-’
3. with the possessive suffixes
4. with the definite suffix ‘-e’
5. with the suffix-ka?

Multiple choice items were extended in several ways;
- multiple variables could be true
- all true variables had to be selected for full marks
- all untrue variables were negatively weighted, so that selection of all variables gave 0%.

**Matching Questions** were also used to test the skills, focusing on comprehension and analysis of the grammatical patterns evident in the data. For example in the sample question below, students are required to demonstrate their understanding of word class characteristics by matching each word class type with a sample sentence which only that wordclass could fill. Note that the sample sentences are not necessarily in the database, and are untranslated. In WebCT Quiz mode, students see all four matching variables randomly listed for each subpart of the question.

**Question 2**
Match each word class category listed on the left below with the Lg X structural frame that could only be filled by a word of that class.

| noun: | u-ita-i ____-e |
| verb: | ____-i tau-e |
| adjective: | tau ____-e pole-i |
| proposition: | lao-ka? ____ marege |

**Short Answer Questions** were used to test students’ ability to synthesise and apply concepts. Application and synthesis, as cognitive objectives, are demonstrated by students’ ability to apply general grammatical rules they have learned to the creation of new sentences. In other words, students were required to go beyond the database given to them, and make up new sentences in *Language X* which were fully grammatical in terms of the grammatical rules they had already worked out.

The Short Answer style of question allows students to translate a language item and to enter a response, as in this sample question.

**Question 36**
How would you say the following sentence in Language X?
[Use lower case only, use no punctuation, leave only a single space between words, leave no spaces between morphemes within a word].

The woman who cooked the meat is hit by her father.

**Answer:**
The marking of questions of this type is also automatic using the Regular Expression syntax feature built into WebCT's Short Answer shell. This compares students' responses against a specified string, but unlike the Equals and Contains functions, Regular Expression allows predictable variables (is the first letter capitalized or not?, has the students put a double space between two words?) to be catered for. It additionally allows, still in automated mode, for a range of less than perfect responses to be awarded partial marks, for example:

100% = [Mm]akunrai/s+tunungengngi/s+jukkue/s+ri/s+ambo?na
50% = [Mm]akunrai/s+tunungengngi/s+jukkue/s+peddiriwi/s+ri/s+ambo?na
50% = [Mm]akunrai/s+tunungengngi/s+jukkue/s+peddiri/s+ri/s+ambo?na
40% = [Mm]akunrai/s+tunungi/s+jukkue/s+ripeddiriwi/s+ri/s+ambo?na
20% = [Mlm] akunrai/s+tunungi/s+jukkue/s+ripeddiri/s+ri/s+ambo?na

Task 1: Building the dictionary

Firstly students had to work out the meanings of each of the words and word parts in the data provided to them on language X. This was achieved as a collaborative task whereby students contributed their analyses of word meanings to an online dictionary available on the unit homepage. This dictionary begins as an empty shell with 4 fields of information for each entry. Students are free to add any text to the 'headword' and 'meaning' fields. The 'word class' field offers a fixed menu of choices. The 'name of contributor' field is generated automatically. The dictionary required the development of a specialized tool which does not come as a standard feature of WebCT. This tool enables an online class of students to contribute entries to a database, and those entries are viewed on screen as though they were a single document. An extract of the dictionary looks like Table 2:

<table>
<thead>
<tr>
<th>Word</th>
<th>Class</th>
<th>Definition</th>
<th>Person</th>
</tr>
</thead>
<tbody>
<tr>
<td>buaja</td>
<td>Noun</td>
<td>crocodile</td>
<td>Janice L [edit delete]</td>
</tr>
<tr>
<td>@omme</td>
<td>Verb (tr)</td>
<td>wash</td>
<td>Sharon E [edit delete]</td>
</tr>
<tr>
<td>de?</td>
<td>Particle</td>
<td>negative</td>
<td>Sharon E [edit delete]</td>
</tr>
<tr>
<td>galung</td>
<td>Noun</td>
<td>field</td>
<td>Ruth D [edit delete]</td>
</tr>
</tbody>
</table>

Table 2: Dictionary extract

The unit co-ordinator has the capacity to edit and delete any entry, while each student has the capacity to edit and delete only the entries that they themselves have contributed. The class as a whole is responsible for the accuracy of all entries, so students must negotiate changes to other students' contributions through discussion on the Bulletin Board. This form of collaborative negotiated learning is highly conducive to co-construction of meaning and self-directed learning (Coomey & Stephenson, 2001).

During the semester there were hundreds of postings to the Bulletin Board renegotiating such changes. A sample exchange is included below;

> Hi Joanne et all! I have been mulling over all the 'ng's that are placed in differing amounts on various words! When earlier, I had analysed the verb 'drink', I had thought of it as 'menung' rather than 'menungng'. This is because, from the available data, both verbs and nouns that end in 'ng' seem to only have it as a single sound. Where further instances of 'ng' appear on a word they seem to be added as suffixes (e.g., 'tedong' - 'tedongng'). However, I may be entirely wrong! What do you all think?
> cheers, Sally.

> Sally, I think the verb is definitely menung, but all words ending in -ng reduplicate this cluster before certain suffixes, for instance the suffix -i and the suffix -e. (Anna)
Dear Sally, Anna, Joanne & all,
I agree with Anna about the verb menung. The 'ng' is reduplication before a suffix. (Eileen)

Hi guys,
Yes I can see now that you're right. I'll change this straight away in the lexicon. (Joanne)

The construction of the dictionary was not formally assessed. Each student was asked to contribute, and a cap of 5 entries per student was specified to encourage involvement by all students. Students were highly motivated to assemble the dictionary as soon as they could, in order to facilitate their capacity to tackle the higher level grammatical analysis. All words were entered within the first 3 weeks of the semester, with subsequent tinkering, as negotiated on the Bulletin Board, over several more weeks. The lexicon was essentially completed by week 6 of the semester.

Task 2: Completing the grammar

After analyzing the grammatical structure of this language, students were required to demonstrate their understanding of it by completing an online Quiz consisting of 39 questions. Students had the option of submitting their Quiz twice. On the first submission, they received back only a grade, but no indication of which answers were right or wrong. This mechanism had several advantages;
- it was reassuring to those students who were apprehensive about the technology, and who felt uncomfortable with opening a new tool and submitting a Quiz in a single go. These students took comfort from a practice run.
- it gave students some means to check that they were on the right track, but without explicitly highlighting their weak spots. Most students reported that they found this spurred them on to do better. So that on learning that they scored 72% on their first submission, they were motivated to do for some further study before the second submission in order to better their score.

Results

Analysis showed that the short answer items were the most demanding as it was these questions that required students to transfer their knowledge of the lexicon into more abstract forms of understanding. The items also required students to synthesise and apply knowledge to create new lexical items, and there was a greater range of responses and grades than for the other items. Without a doubt, students who successfully completed task 2, (creating the dictionary) demonstrated the desired learning outcomes of analysis and synthesis. In all three types of questions, the automated quiz tool and feedback mechanisms provided learning support. The pedagogic rationale for the use of these forms of assessment was to align learning objectives with assessment tasks, while providing feedback and performance data to learners. The quiz questions provided individual and group feedback, allowed students to check their responses and enter an alternative answer, and compare their scores with others. In addition, it fostered self-regulated learning as learners would access the tests at a time and place convenient to them.

Conclusions and further research

Computer-based assessment may suffer an 'image problem' as some assume it is capable only of summative testing using multiple choice tests derived from item-banks. Increasingly, computer-based assessment is enabling innovative approaches to formative assessment that close the gap between actual and desired levels of performance. A number of factors can be cited concerning the potential value of online learning environments and computer-based assessment. Among these are its potential to cater for individual needs, foster self-regulation, increase motivation for learning by giving student more control over when and how often they test their own knowledge. Current software development and the interactive capabilities of the Web enable the creation of procedural, conceptual, cognitive and collaborative assessment tasks and can tap students' prior knowledge, and assess learning in personally meaningful ways that are flexible and learner-centered.

Using computers to evaluate teachers' understanding of physics concepts

Ali. R. Rezaei
California State University; Long Beach
Hans Laue
University of Calgary, Canada

Introduction

The video "A Private Universe", a production of Harvard-Smithsonian Center for Astrophysics, Science Education Department, Science Media Group, was considered an important eye opener in the history of Science Education. The interviews with Harvard graduates revealed students' misconceptions in science among the best students of the country. According to Mazur (1997) another eye opener was the release of the Force Concept Inventory (FCI) developed by Hestenes, Wells, & Swackhamer (1992). It was called an eye opener because he realized that students' misconceptions could not be diagnosed through the conventional standard or teacher-made tests or even problem solving strategies that he used to use for many years of his teaching at Harvard University. Research in the area of science education has repeatedly shown that only certain types of questions can evaluate the ability of students to resolve concepts from one another and to apply them to real situations. However, successful construction of such conceptual tests is hardly ever reported in the literature. So far FCI and a few other conceptual tests have been used exclusively to evaluate students' misconceptions rather than teachers' misconceptions.

Misconceptions are not limited to students. They are also very common among teachers (Mestre, 1994). For example, after a comprehensive study on 159 science teachers’ misconceptions, Kruger, Palacio, and Summers (1992, p. 344) concluded that “virtually none of the primary school teachers had a correct (in the Newtonian sense) view of the instances involving forces and motion with which they were presented”. According to Mestre (1994) some significant changes in teacher education programs are necessary. He suggests that the science content knowledge of elementary and middle school teachers has to be upgraded, but this does not mean that in-service and pre-service teachers need to take an inordinate number of science courses. Therefore, there is an urgent need to investigate teachers' misconceptions in science targeting the concepts that they are supposed to teach in the future. The authors believe that the best way to evaluate teachers' misconception is to develop more conceptual tests similar to FCI. However, there are many scientific conceptions that could not easily be evaluated with paper-pencil tests such as FCI. In an attempt to make a more sophisticated evaluation and instructional tool the authors have developed an instructional model (Inventive Model) and a physics CD and an on-line physics course based on the model. Using such multimedia and/or Internet tool with sophisticated interactive simulations to investigate teachers' misconceptions is considered to be very important and ultimately could be a third eye opener in the area of science education.

Goals and objectives

In this paper the authors introduce two educational software that have been used in conceptual physics instruction. First, a multimedia CD targeting common misconceptions in physics based on a new instructional model (Inventive Model) developed by the authors. Second, an ongoing collaborative
project among several universities in Canada using the Inventive Model. The project is called Modular Approach to Physics (MAP). The goal of this paper is to propose a project in which the physics CD and the on-line physics course will be used to investigate teachers' misconceptions in physics. Although this investigation will deal specifically with examples from physics, the authors believe that our model and conclusions would have enough validity to be used in other areas of science and perhaps beyond. The focus will be on concepts that teachers are supposed to teach in their future teaching career.

Cognitive learning theories such as discovery learning or constructivism have focused on students' learning and students' cognitive processes. Generally in student-centered science education the focus is on student rather than teachers (Roblyer, & Edwards, 2000). In these approaches the teachers play a role as facilitator rather than instructor or lecturer. However, the authors believe constructivist teachers should have a much deeper understanding of scientific concepts than traditional teachers. Therefore, evaluation of teachers' misconceptions could have significant implications for the quality of science teacher training programs.

Theoretical Background

The quality of current educational software

The quality of educational software particularly for the purpose of conceptual learning has been the subject of so many studies since early 1980s. Komoski (1989) estimated that 1500-2400 new packages are published in the United States each year and that the proportion of good quality software is something between 5 to 10 per cent. Even today U.S. Department of education reports that a significant proportion of computer software in schools is obsolete by today's standards. Results of a survey of educational software shows that regarding the criteria they use to guide software development 67 percent have no formal guidelines (Roth & Petty, 1988). According to the literature, low quality of educational software has many reasons including lack of a theoretical model for the instructional design. After reviewing hundreds of research papers in the area of instructional design, and dozens of educational software, the author developed the "Inventive Model" as a theoretical framework for science instruction and particularly for software development in science education. (Rezaei & Katz, 1998) The Inventive Model is developed to pave the way from edutainment or infotainment toward high quality educational software.

Even if teachers find good quality software, the problem is they often find it difficult to integrate it into their lesson plan. In other words some parts of the software does not match with the goals and objectives of the course. The Modular Approach to Physics has been developed to overcome this difficulty. This approach provides customized instruction for teachers. Teachers usually prefer to make their own instruction rather than fitting themselves into somebody else's design. This on-line navigation and arrangement tool provides modules instead of units of instruction. Therefore, teachers can easily select the modules that they want to use and arrange the modules in their own way. All modules are designed based on the "Inventive Model" (i.e., each single module is designed based on research findings on students' difficulties in understanding scientific concepts). Lack of interest and perhaps lack of a good background in science, has caused a great decline in North American students' enrollment in science related fields at the undergraduate and especially graduate levels (Halpern, 1992). With the integration of technology, however, it is possible to make it easier for teachers to teach and for students to learn. (Katz, Rezaei, 1999)
Previous research on the Inventive Model

The Inventive Model has been developed as a theoretical model for educational software development and also as a conceptual change model to improve conceptual learning. Research findings consistently show that students' misconceptions are deeply seated and likely to remain after instruction, or even to resurface some weeks after students have displayed some initial understanding immediately following instruction (Halloun & Hestenes, 1985; Mazur, 1997; Mestre, 1994). Research also shows that instructional approaches that facilitate conceptual change are more effective than other approaches that disregard students' cognitive structure (Mazur, 1997). However, teachers and educational software developers rarely build their instruction on a valid measure of students' misconceptions. The instructional design used in the Inventive Model is based mainly on such a longitudinal and systematic evaluation of students' misconceptions.

Theoretically, the inventive model has four phases. The first phase starts with a systematic analysis of students' preconceptions. Although students' conceptions are unique and private, most of their concepts are similar and public. Therefore, in the instructional design of the inventive model both kinds of misconceptions are addressed. The simulations and the videotaped experiments are developed based on literature on students' common misconceptions. However, the feedback offered by the teacher or the software is based on the individual student's answers to the conceptual questions. It should be noted here that the piece of software based on this model could be used either by the teacher in the class as an instructional tool or by students after class individually or collaboratively.

In the second phase, advance organizers or other cognitive strategies such as, concept maps and/or analogies, are used to activate the students' prior knowledge and bridge it to the new concepts to be learned. How these cognitive strategies are integrated into the inventive model is explained in an earlier paper. (Rezaei, Katz 1998) Both in this second phase and in the last phase, students' acceptable concepts are refined and reinforced in a guided discovery manner. This means that, if the majority of students have a deep misconception, the teacher will move to the third phase processes to rectify the misconception. However, if the answers are close enough to the scientific conceptions, the teachers will move directly to the forth phase were they refine students' conceptions.

The third phase includes different activities, such as having students:

a. test their preconceptions through hands-on activities or computer-based simulations.
b. compare their preconceptions with natural phenomena and related scientific theories and identify any conflicts between their misconceptions and the scientific theories.
c. become dissatisfied with their misconceptions through a multi-perspective demonstration and problem-solving situation and feel the need for a new concept; or, explore plausible alternatives by themselves or as suggested by their classmates or the teacher, and choose the more convincing one.

In the fourth phase, the teacher explains the correct answer and demonstrates the advantages of the conceptions currently accepted by the science community through a multi-perspective demonstration. The teacher may also help students to summarize what they have learned.
The basic rationale of the Inventive Model is the belief that conceptual change does not occur simply because students see a conflict between their preconceptions and the scientific realities; rather, students, after testing their preconceptions, will gradually realize the advantages of scientific explanations. This will happen only if the teacher and technology supply the required cognitive tools, and provide a clear contrast between the student's conceptions and scientific conceptions through a variety of demonstrations.

The key factor in the Inventive Model is the multi-perspective presentation. The author believes that generalizations based on a single experimental design might be misleading. However, considerable time is required to probe students' conceptions and to present new concepts from different perspectives via a variety of demonstrations. An effective way of dealing with the time limitations in formal science classrooms and many inquiry approaches is to empower the instruction and the inquiry processes by using computers. Rezaei (1999) developed the multimedia physics CD based on the Inventive Model as a practical way to achieve this goal. Videotaped or simulated science experiments were designed, developed, and presented based on the best scripts of teachers' probes in longitudinal studies. Dozens of science experiments, animations, sound clips, simulations, pictures, graphs, tables, concept maps, analogies, metaphors, and advance organizers were saved in a multimedia program, available on a single CD-ROM.

Modular Approach to Physics

The Modular Approach to Physics (MAP) project is a multi-institution venture funded by the Province of Alberta in Canada under the Learning Enhancement Envelope (LEE). The project is currently in its 3rd year of funding and coordinates the efforts of groups at 6 college and universities in Alberta, Canada. There is a need for being able to efficiently and easily collect and organize Web-based content into a package such that others can easily find in the package what they are looking for. A program with this capability has been developed at the University of Calgary. CANU (Content Arranging and Navigating Utility) is a Web-based Java program with which one can arrange and deliver structured content. The program has been designed at the University of Calgary as part of a LEE-funded MAP project. Although currently CANU is being used to arrange and deliver physics content, it could just as easily be used to arrange and deliver many other kinds of content, e.g., materials for other courses or descriptions of the programs of a faculty or an entire university. Minor changes only would be required, e.g., a change to a new title page. The principle investigator of MAP, Dr. Hans Laue, has a strong interest in conceptual difficulties in learning physics and has been involved since 1987 in the creation of tutorial software at the introductory physics level aimed at helping overcome such difficulties. Hicks, R. B., & Laue, H. (1992) have developed an extensive computer tutorial system to support some first and second year university level courses. Their Computer Assisted Learning in Physics (CALiPH) provides 40 tutorial modules. Dr. Laue, together with Dr. B. Martin, the present author, and several other Alberta physicists, are currently involved in the evaluation process of MAP.

Finally, as mentioned before, in the MAP project, two versions of the software have been developed both based on the Inventive Model. One version is the customized version and the other one is the sequential version. Although both versions are based on the Inventive Model and both focus on conceptual learning they are not quite similar. One purpose of the ongoing project is to compare the effectiveness of these two versions. The results of such a comparison could be very important for the future of on-line course development. The Modular Approach is currently under its evaluation process.
and the results will be published later. Two versions of the course are provided. One is pre-organized or sequential and the other is the customized version. Teachers and/or students could choose if they want to follow up the sequential version or they want to customize their own units. The online courses based on this model are available at
http://www.ucalgary.ca/MAP/
http://ugl-gw.phys.ualberta.ca/~alphy/meltp/

The proposed project

The Inventive Method was used in a two-year experimental research by the first author. One hundred and forty three "grade 10-12" high school students from three high schools were randomly assigned to three groups. The Inventive Model was compared with a radical constructivist approach and the conventional physics instruction. The results showed that the Inventive Model group scored significantly higher than the Radical Constructive group on the conceptual posttest. It was also concluded that only the Inventive Model led to conceptual change in the students' understanding of Newton's laws of motion. Finally it was observed that 3 hours of working on the Inventive Model CD was as effective as 16 hours of conventional physics instruction. The qualitative analysis indicated that most students actively interacted with the software during the whole program. In terms of rectifying students' misconceptions it was found that the model was effective for about more than 50% of the students. This should be noted that successful report of conceptual change is very rare in the literature.

The author surprisingly observed some misconceptions among teachers while they were previewing the CD and while they were teaching their students. Therefore, it was decided to perform a new research to investigate teachers' misconceptions in physics. A detailed analysis of teachers' interactions with the computer (e.g., keeping log files of which items are chosen, which buttons are clicked, the amount of time spent on a question) could be an invaluable source of information on teachers' cognitive processes.

To start the research the authors will contact American Association of Physics to locate and call high school physics teachers in Los Angeles, California. Only volunteer physics teachers will be called to participate in this project. Either the physics CD or the On-Line physics course will be used to evaluate teachers' misconceptions. The CD version is limited to Newton's laws of motion and will be used by teachers who do not have access to Internet. The On-line course is a comprehensive advance physics course for high school teachers. Although both software have been developed for conceptual physics instruction the investigators plan to use them as a means to evaluate teachers' misconceptions. As an incentive to encourage teachers to participate in the project they will be paid to evaluate free educational software (i.e., the physics CD or the on-line physics course). The plan is to ask teachers to preview the software to see if they would like to use it in their teaching. However, teachers' interaction with software will be saved in a log-file that later will be used by the investigators to evaluate teachers' misconception. The teachers will be informed that their interaction with the software will be saved. They will also be asked not to input their real name or other kinds of identifying information. Therefore, the anonymity of the participants will be guaranteed.

Assessing out-of-the-box thinkers: Professional development for IT support staff

**Background**
Since its inception in 1996, the Center for Instructional Technologies (CIT) has offered leadership and assistance to educators in integrating technology into instruction throughout the UT Austin campus and beyond. It serves as a training, consulting, and resource center, and an incubator for projects using promising new technologies—all aimed at enriching the teaching and learning experience.

**Internal knowledge and skills gap analysis**
The CIT has traditionally focused on technology implementation and consultation. Recently, The CIT has been engaged in activities designed to move the center from a production shop toward a systems-approach to support. As a necessary first step, an internal team of three, supplemented with feedback from the rest of the CIT staff, developed a tool to help staff members self-assess their knowledge and skills in teaching, learning, and technology. When the team analyzed the results, they found a large section of technically cross-trained staff members throughout each unit. However, only three staff members out of 18 believed themselves to be expert in instructional design and only two assessed themselves as experts in learning theory. After the results of the self assessment were presented, the CIT challenged itself to increase its staff’s comfort and use of instructional design and learning theory with minimal financial cost and without sacrificing needed staff production time.

**Training goals**
Based on findings from the skills gap analysis, Joe Sanchez and Suzanne Rhodes developed a curriculum based on engaged constructivist learning principles to meet the following goals:
- Provide ongoing training to increase internal staff awareness and comfort level regarding use of instructional design techniques and strategies to improve faculty support
- Increased faculty client satisfaction with CIT support services
- Motivate staff to create new workshops with creative and solid engaged-learning principles at the foundation.

**Training strategy**
We are employing a blended approach of classroom computer lab-based instruction and online resources and collaborative tools. The training curriculum components include:

- Classroom-based presentation and collaborative activities
  The concepts were first presented, using multimedia where appropriate as well as examples of best practices. Questions and whole-group discussion are integrated with the presentation. Second, using a problem-based learning-by-doing approach, participants work in small groups with
facilitation from the two trainers. The groups select a real-life scenario and develop solutions by answering guiding questions about instructional goals and approach and the best application of a variety of technologies. The small groups then present their solutions to the whole group, leading to whole-group discussion targeted around current faculty consultation opportunities. This format varies depending on the content and the current needs of the participants, but always employs a hands-on approach to learning that is personal and relevant to the participants. Topics have varied from Bloom's Taxonomy to John Keller's ARCS Model. Each of the classroom-based presentations not only exposed the users to instructional design principles, they also served as a demonstration of different teaching techniques and styles. Gaming, simulation, discussion, group activity, experiential learning, and the Socratic method were all teaching styles used as examples of effective teaching. Each session included a debriefing explaining the reasons for selecting a particular teaching style followed by a discussion of the planning process.

- Online resources
  Using Blackboard courseware, we created an online course site to provide digital versions of the presentations and handouts, additional links and resources related to the training for extending learning, and a message board to extend the session discussions. In addition, online surveys allowed participants to provide feedback for each session.

**Project plan and timeline**
Month 1-begin curriculum and content development for training sessions
Month 2- conduct and evaluate in-house training
Month 4-modify and expand training to include UT faculty and TAs
Month 6-CIT staff to participate in skills gap analysis #2

**Assessment approach**
This project is ongoing and currently under deployment with short-term goals completed in November 2001. We plan to use CIT internal training as a pilot that, with modifications, will expand to reach other audiences such as other IT staff, teaching assistants, UT professors, and possibly even students. Another goal of the project is for CIT members to use the instructional design models they have learned to create new or improved workshops. The workshops have also served as a testing ground for new technologies such as Horizon Live, a synchronous streaming video presentation tool, and the department's new smart board.

This project employs an iterative design, development, and assessment process. Data will be collected before and after each training session and by online means through tracking, observation, and surveys. Past training activities will be revised and presented to new audiences as well as converted to become completely online for those interested in learning the material on a self-paced, just-in-time basis. New activities will be designed and developed each month as needed.
We hope that the materials and strategies used for internal CIT training in instructional technology will result in the following outcomes:

- **Increased comfort-level and awareness of instructional design techniques**
  Staff members, while unable to draw directly from instructional design theory, have been using systematic design process with each project they develop. The workshops will identify the processes and provide a broader range of design principles to draw from.

- **Increased use of instructional design principles during faculty consultations**
  CIT staff members will be able to quickly identify the needs of faculty members during consultations and place their needs in an instructional design framework.

- **New innovative workshops created by staff with sound ID principles**
  Using working knowledge of instructional design principles will allow for creation of hands-on, user-centric based workshops for faculty clients. Previous workshops maybe re-evaluated for instructional soundness.

- **Enhanced student learning and engagement**
  Application of sound instructional design principles will lead to hands-on, interactive workshops that will enhance student learning.

Conference attendees interested in the following concepts would find this demonstration to be of interest:

- **Training strategies for constructivist learning with technology**
- **Building community within an organization**
- **Integrating new or existing IT support organizations**
- **Assessment and evaluation techniques**
- **Skills gap analysis techniques**
- **Moving IT support to a systems approach**
Flexible Learning: Latest International Research Discoveries as a Part of High School Curriculum

Riitta Rinta-Filppula
Helsinki Institute of Physics / CERN Education and Technology Transfer Division
Geneva, Switzerland
Riitta.rinta-filppula@cern.ch

Abstract: Many high school science teachers will retire in the ten years and unfortunately so many new ones will not become graduated science teachers in Finland. In addition, the amount of high school and university students who are interested in physics has decreased dramatically during the last decades but now, this is turning slowly to the better direction. Anyway, the situation can lead to serious lack of physics researchers, physics teachers. Web University, an international research pilot of the Open Learning Environment project in Finland, has created a new model how the research discoveries of the European Organisation for Nuclear Research, CERN, can be integrated into high school curriculum in Finland. The activities are targeted for both the students and the teachers of Finnish high schools. A great part of the activities is based on exploiting the capabilities of information and communications technology and the Internet. We apply, for example, web-based learning for high school students and we have created an Internet community for the network of high school teachers. In addition, we organise intensive physics training for high school students and in-service training for high school teachers. Both of these activities take place at CERN, where the visitors are guided and instructed by particle physics researchers. The long-term goal is to permanently raise the status of physics studies and physics-related occupation in the society.

The European Organisation for Nuclear Research, CERN [8], situated in Geneva, Switzerland, is one of the largest particle physics research organisations in the world. CERN tries to find out what happened in the big bang when the universe was born by studying the origin and the structure of the matter and antimatter. As a physics research organisation, CERN supports initiatives of the member states that are aiming at improving the level of knowledge in natural sciences.

Web University [9] was launched already in 1995. In the beginning, Web University co-operated with Finnish universities and promoted CERN and physics studies by enabling remote audiences to participate in lectures and seminars held at CERN [1], [2]. Only recently, the activities of Web University have been extent to cover also the high schools [3], [4], [5], [6], [7].

Inspired by positive experiences of the first visits of Finnish high school student groups at CERN in autumn 2000, Web University has initiated a model aiming to integrate the research discoveries of CERN into the high school physics curriculum. The objective is to increase the amount of talented high school students who are interested in physics. The flexible learning consists learning periods both in the own school in Finland and at CERN in Switzerland.

Learning in the own high school

Learning takes place in modern physics period in the physics curriculum. Students must have completed their modern physics course or, at least, they are on the course in parallel with the intensive training period at CERN. It is recommendable that the students have familiarised themselves with the CERN research topics already before coming to CERN. There are several options how to prepare before travelling to CERN. The students can, for example, study CERN-related digital material on the web produced by Web University or they can attend an introductory lecture on CERN activities given
by a local university professor. The students can also given preparative research tasks or project works, which they prepare beforehand and continue at CERN. However, the science teachers, who are responsible for the class, carry also the responsibility of the students’ preparation for the training period at CERN. Web University provides them with electronic material and instructions how it is recommended to prepare. In addition, Web University has created an Internet community for science teachers to help them when they are teaching the students about CERN research topics.

After training at CERN, the students publish their personal research work, for example, on the net or in newspapers. Some high schools have organised events, where students can present the results to journalists, school board, parents and other students.

Intensive physics training period at CERN

The intensive three-day physics training has been planned in collaboration with Finnish physics researchers. The researchers give lectures, guide trips to physics experiments and discuss their research topics with the students. At the same time, the researchers can share their enthusiasm and knowledge with the students.

The objective of the first day is to give a general outlook of CERN and its most important experiments and research goals of the future. On the second day, the students get familiar with the structure of the matter and nuclear physics. On the last day, they get acquainted with particle physics and antimatter research. The researchers guide the students at different experiment sites. Before each site visit, the students are informed about the theoretical background of the experiment. At the end of the training, the students give feedback about their visit CERN. The results are used for refining the intensive physics training for the next group.

Conclusions

Altogether, five training periods for Finnish high school students were organised during the school year 2000-2001. The school year 2001-2002, eight student groups of about 20 students will visit CERN.

Both the parents and the teachers of the students, who have visited CERN, have given us positive comments on the influence of the flexible physics training on the students. However, because our activities are relatively recent, we cannot yet report how they have affected the status of physics studies among the high school students or the amount of candidates for physics studies in universities.

At the same time, the teachers have been able to improve their knowledge on modern particle physics. This should have a positive impact on the education. The teachers have also networked with other teachers and university professors in order to get more information how their school classes can prepare for the training period at CERN. For this reason, during the school year 2001-2002, it has been started the in-service training for high school physics teachers at CERN. Furthermore, we are developing net-based applications and tools to advance communication and networking between those who are interested in developing physics education in high schools.

Supporting the Claims of Campus Transformation Through Assessment of Southeast Missouri State University's "Technology Serving Learning Institutes"

Michael Rodgers, PhD
Associate Professor of Chemistry
Southeast Missouri State University
Cape Girardeau, MO 63701
mrodgers@semo.edu

David Starrett, PhD
Director, Center for Scholarship in Teaching and Learning
Southeast Missouri State University
Cape Girardeau, MO 63701
starrett@cstl.semo.edu

Abstract: The Technology Serving Learning Institutes have provided instructional technology training to 73% of Southeast Missouri State University faculty since 1997. The Institutes were perceived to be at the center of a major transformation of campus culture, in which both faculty and students embraced technology in teaching and learning. In an effort to assess the role of the Institutes in this transformation, and to validate the transformation itself, we defined "transformation" and developed instruments to probe the role of technology in teaching and learning on campus. We will briefly outline our assessment effort, describe our instruments, and show how the results support our claim that the Institutes have contributed to campus transformation. We conclude by summarizing ways to use assessment to guide future faculty development efforts and to influence campus policies.

The instructional technology revolution has attracted attention and funding for several years. Many programs, products, and experiences have been generated to facilitate both teaching and learning. But educators, administrators, and funding bodies are not sustained forever by excitement; calls for objective assessment of the effectiveness of technology efforts have increased. On the campus of Southeast Missouri State University, assessment of our faculty development program for instructional technology began in earnest when we applied for a Hesburgh award for excellent faculty development programs. Our application focused on evidence of campus transformation resulting from our “Technology Serving Learning” (TSL) faculty development Institutes.

The TSL Institutes have been offered to faculty at Southeast Missouri State University since Summer, 1997. In that time, 73% of faculty have attended at least one Institute session. The Institutes were developed in response to the University’s 1995 Strategic Plan, which placed strong emphasis on implementation of information technology in teaching and learning. Prior to 1997, the University considered itself to be at the trailing edge of technology adoption, with no online courses, incomplete infrastructure, and a faculty quite deficient in the skills and understanding necessary to successfully implement technology in courses. The Institutes provided needed technology training in a context of sound pedagogy, targeted primarily to faculty who were technology novices.

Faculty used the training to develop 80 online courses in only three years, and in so doing, began to address a critical need for enhanced student access to University courses in our large, rural service area. Faculty use of instructional servers greatly increased, so that today 275 faculty maintain an instructional server account, and 500 courses have a Web presence. Faculty interest in technology also increased, as
indicated by faculty attendance at technology conferences and greater willingness to take part in campuswide technology planning.

The rapid embracing of technology by the faculty led us to believe that we had achieved a fundamental transformation of the campus culture. We set about to define "transformation", as it would be understood by faculty, administrators, students, and the public. We then investigated the drive for assessment on our campus: Who is interested in knowing if transformation has occurred, and what difference does it make if it has occurred? We then developed survey instruments for both students and faculty to collect data from both groups on the role of technology in teaching and learning. We designed questions to probe the effectiveness of online instruction, especially as compared with face-to-face courses. The survey results became an integral part of the award application, but they have also found application in other venues on- and off-campus.

In this session, we present our definition of "transformation" as we briefly outline the history of our assessment effort. We then describe the instruments that we developed, and show results for our campus. A total of 1250 students enrolled in Southeast Online courses over the past two academic years were asked to complete the student instrument; 265 students (21.2%) responded. A total of 52 faculty who taught online in the same time period were asked to complete the faculty instrument; 35 faculty (67.3%) responded. Results from both instruments indicated widespread acceptance of online courses, and a perception that online courses were effective vehicles for teaching and learning. For example, we found that 75% of student respondents felt that the online instructor was knowledgeable, encouraged participation, provided helpful feedback, and was responsive to student concerns. Sixty-five percent of these students rated the instructor's overall performance as high or very high as compared to on-campus courses, and 70% would recommend the instructor to other students. Clear course objectives, well-organized materials, and effective communication were seen by 70-80% of students. Sixty percent of students said that interest in the course subject had been increased, 85% rated their level of learning as medium to very high, 70% felt the academic quality was on par with traditional courses, 70% agreed that they have learned as much as in a face-to-face course, and 80% said that the online course was as good as or better than a face-to-face course. Ninety-three percent of surveyed students in face-to-face courses felt that course Web pages improved their learning experience in the course. In the faculty survey, 80% felt that the TSL Institutes prepared them well to develop an online course, with 70% saying the Institutes prepared them well to teach online. Also, 90% felt that online instruction increases student access, 65% thought that students find online courses as good as or better than face-to-face courses, and 90% would teach online again.

We will show how the results support the claim that our Institutes, offered since 1997, have indeed made a major, measurable contribution to campus instructional technology transformation. We will conclude with a summary of some of ways that the assessment information has been and might be used to guide future faculty development efforts, and to influence policy on campus.
Learner-Centric Online Teaching for Non-Computer Science Students

Guido Rößling, Jana Trnková, Uwe Langendorf, Karin Tillack, Max Mühlhäuser
Department of Computer Science, FG Telecooperation
Darmstadt University of Technology
Alexanderstr. 6
D-64283 Darmstadt, Germany
{guido, jana, uwe, tillack, max}@ik.informatik.tu-darmstadt.de

Abstract: This paper reports on two key elements of successful online teaching: learner-centric design and harmonization of content and facilities. We show how these two crucial requirements could be fulfilled with great success in a project that involves a non-computing related subject matter (civil engineering) and thirty-one educators from five European countries. We explain the context of the project, called WiBA-Net, and introduce the L³ system chosen for providing content access and navigation. We also outline key decisions in designing and building WiBA-Net, emphasizing the two crucial aspects mentioned above. This outline can serve as a guideline for projects in other subject matters and context, and is thus regarded as valuable for a general audience.

Introduction

Many online learning materials suffer from two common drawbacks: the lack of learner-centric design and display disparities in content by different authors. The first drawback especially touches the offered learning path which often comes in either of two extremes: statically fixed or nearly absent. Fixed learning paths are encountered for example in lecture slides which are placed in a certain order and may be restricted to forward and backward navigation. Mostly unstructured HTML documents with cross-references, on the other hand, do not provide any clear path by giving too much leeway to the user.

Neither approach is helpful for the student. As has been shown in various research projects, not all learners are the same! Providing a single type of access for all students is therefore unlikely to result in optimum learning and retention. Learner-centric navigation requires guiding the learner to a learning path tailored to his or her individual preferences and learning style. However, the learning path should not be enforced. Thus, both extremes are ill suited for learner-centric teaching.

Within our ongoing research project, we are looking for a middle way solution. To be usable outside computer science, the system must not place high expectation of computing familiarity on users or authors. Finally, standard content as commonly found on Web pages should be embeddable, for example QuickTime or MPEG movies that illustrate special subtopics.

Our research is part of the WiBA-Net project funded by the German Ministry of Education and Research. The project shall provide a common platform for online teaching. Our current topic focus is on civil engineering. The finished system shall be embedded into the teaching at the various participating universities, to the benefit of both learners and educators.

In this paper, we present the chosen approach for supporting learner-centric online teaching. The paper is organized as follows. We first provide a short overview of related online teaching systems, focusing on their support for individual students. We then give a short overview of the L³ system used for content modeling, followed by the technical implementation. Finally we summarize the paper and outline areas of future research.

Related Work

Although e-learning has become very popular lately, there is still no “ideal environment” which attracts masses of learners and fulfills all their needs. Many “traditional” educators are therefore skeptic about massive use of the Internet as a medium for learning processes. Virtual School or University is still more “vision” than reality. However, most universities are trying to implement an online form for at least some courses. At the moment
probably the best individual access is given in WebCT (WebCT 2002), which allows the tutor to distribute the learning materials and assessments to each student separately— we could say “manual individualization of study”. Element K KnowledgeHub™ (Element K 2002) also offers this feature. Macromedia Authorware 6.0 (Macromedia 2002) can be considered as the most flexible environment in which a high level of interactivity can be reached. For course and test building, it provides an iconographical language with decision step elements so the author can in fact “program” some individualization for the students. However, this is relatively difficult for authors without programming experience.

Teachers are of course aware that really effective learning requires more than the individualization in the above-mentioned meaning. It is only logical that we recently observe a boom of many different projects, mainly at universities, focused on building learning environments, which would provide epistemological pluralism and hence a better transfer to the learner. Following the learner way of thinking has been shown to increase the efficiency of education (training) and retention. In these environments intelligent tutoring and adaptability to learner needs are present at different levels and are also interpreted differently. A brief overview with a short characteristic of the most important projects follows.

*TANGOW* (Carro et al. 2001) (*Task-based Adaptive Learner Guidance on the WWW*) lets students choose their learning strategy, for example placing theory before exercises. Suggestions for changing the current strategy can be made by the system if the student does not obtain good results with a given strategy.

*ELM-ART II* (ELM-Art 2002) is an intelligent interactive textbook for programming in LISP. Adaptability is implemented by selecting the next best step in the curriculum on demand. Links are annotated according to a traffic lights metaphor, indicating if a section is ready to be learned, ready but not recommended or not ready yet. The annotation is updated after a learning unit is finished, reviewing all prerequisite concepts to the current unit (Carro et al. 2001). *ELM-ART II* enables direct interactivity by providing live examples and intelligent diagnoses of problem solutions. All function call examples can be evaluated. When the learner clicks on a live example link, an evaluator window shows the evaluation of the function call. Users can type solutions to a programming problem into an editable window and then send them to the server (Weber et al. 2002).

*SKILLS* (Neumann et al. 2002) (scalable Internet-based teaching and learning system) organizes the course material according to its prerequisites. Adaptability is implemented by taking the student’s previous knowledge of the subject into account (Carro et al. 2001). The teacher prepares a default configuration for every course. Concepts addressed by the system are marked in the user’s profile. If the user is familiar with some concepts from external sources, control questions are given from the tutoring component. If these questions are answered, the known concepts are removed (hidden) from the course. If the student does not want to answer the control questions, the concepts to be removed are marked until the student solves the exercises at a later time (Neumann et al. 2002). Annotations, notes and additional files can be stored or published to other students.

*WINDS* (*Web-based Intelligent Design and Tutoring System*) (WINDS 2002) produces individualized courseware for the students according to their current state of knowledge, their preferences and learning styles. Each learning element has a didactical goal. Authors can create new content using a set of predefined paragraph templates. Examples paragraphs are *Cover Story Simple Explanation* or *Picture Compare*. Complex Paragraphs combine several elements (“content blocks”) with different pedagogical functions to fulfill a pedagogical goal, for example *introduction, definition or example*. Each such chunk of information has a predefined order, pedagogical role and other metadata. Based on the user model and the metadata, the system can adapt the content sequence according to the chosen learning strategy. For instance, a concrete example can precede or complement an abstract statement if needed. To prevent or at least reduce cognitive overload, the pedagogical roles of the learning elements as well as those of the content blocks can also be expressed graphically, for example by different background colors (Specht et al. 2001).

The L³ Learning Environment

L³ (Leidig 2001) (“life-long learning”) is a learning environment by SAP CEC at Karlsruhe, Germany. L³ structures course materials into four different types of containers. *Learning networks* (LN) are the topmost element of the hierarchy and may contain a set of LN, learning objects (LO) and instructional elements (IE). The actual content is represented by *instructional elements* (IE), each covering roughly one page of paper. The different types of IE include example, action, introductions or resource links. Learning objects combine a set of IEs addressing a common topic. Additionally, the relation between given elements can have different types, specified by the classification of the edge connecting the elements, as shown in (Fig. 1).
Each element has a title, an author and a set of metadata. This metadata includes the knowledge and media type, approximate time required for finishing the unit, the types of competencies that can be achieved by working on the unit and a classification of the content according to an underlying taxonomy.

The learning path is generated based on the relations between the elements and the content type of IEs. The user can choose a learning strategy on two different levels. The macro-strategy covers the order of the higher-level elements such as LNs and LOs. The following macro-strategies are offered: table of contents, deductive and inductive, as well as one linear version each of these strategies. The ordering of the IEs within a given learning object is controlled by a micro-strategy. Currently available are orientation only, orientation first, explanation oriented, action oriented and example oriented microstrategies. The learning material can also encode temporal or causal dependencies between IEs as prerequisites, if they cannot be avoided.

The learner may submit offered tests at any time. Failed tests may influence the course process, for example by asking the learner to review parts of the course. Any SCORM-compatible test (SCORM 2002) can be used, for example generated using Authorware (Macromedia 2002). Additional techniques that may be integrated into page content are beyond the scope of this paper. Basically, all content types acceptable in HTML 4.0 can be integrated easily, for example Flash, MPEG, RealMedia or QuickTime media.

L³ courses are executed on a standard Apache Web server with an Enhydra Application Server (Enhydra 2002). Enhydra performs the rendering of the L³ content. The end-user requires only a current web browser. Additional plug-ins may be required for special embedded content, such as MPEG or QuickTime video material.

The WiBA-Net Approach

WiBA-Net is a course network that contains learning units for civil engineers and architects. The content is a central part of civil engineering studies. We have to address the following user groups, each with its own unique interest in the system:

- Undergraduate students use the network to prepare for the mandatory exam at the end of the course,
- Graduate students use WiBA-Net to access the basics of their study and additional courses,
- Professionals in related fields use the network for research and learning more about covered materials,
- High school students can experiment with WiBA-Net to gain or increase their interest in the topic area and possibly induce a desire for studying in this field.
The target audience also contains the educators who can use the WiBA-Net for publishing content for lectures and sharing it with other educators. Currently, 31 educators have agreed on a content memorandum for WiBA-Net, coming from universities in Germany, Austria, Switzerland, Denmark and Hungary.

We have to consider not only different needs of user but also a different (moreover non-computer science) backgrounds of the authors. Therefore, our system has to respect the learner's individual needs and be easy to use. At the same time, it must also be comfortable for authors who want to share their materials and combine them in different way to course contents. We have decided to adopt L² as the tool for managing and displaying the content for WiBA-Net due to the features offered. Key aspects in the decision were the following:

1. learner-centric approach - for example, the "orientation only" micro-strategy fits high school students,
2. a user-friendly interface which can be used intuitively,
3. metadata support should allow authors to provide essential information about materials for efficient sharing of resources, even among different universities,
4. online courses require high interactivity and lots of multimedia materials. Therefore, we need good support for tests and multimedia files.

As shown in (Fig. 2), the course elements on the learning path are marked with different colors according to their degree of recommendation, including not recommended, recommended and visited elements, as well as the current element and test entities. The elements in the right row from top to bottom contain the current element, two recommended elements followed by two tests and two elements which are not yet recommended. The second element in the middle row is a finished learning object.

The educator specifying the course contents does not directly define the learning path. Rather, the path is assembled dynamically from the learner's chosen strategy. Thus, WiBA-Net offers a very good compromise between cognitive and constructive learning, both for educators and students. The learner can also pursue a different path than the offered learning path by clicking on the element in the navigation structure at any time.

An example content provided by WiBA-Net is shown in (Fig. 3). The left frame contains elements for customizing the environment, selecting a course, and entering communication via mail, forums or direct contact. The actual content of the page is shown in the center of the window. The standard navigation elements for
leaving the current course or accessing the index, as well as stepping forward and backwards, are placed below the content area. The bottom of the page shows the current learning path.

Similar to the common navigational elements provided by L², the course contents are formatted using a common underlying style sheet, providing a corporate identity for the whole set of courses. By assuming the same underlying layout, we achieve a harmonization of both the content and the facilities, making the finished product "smoother" to both look at and use.

A key concern within the project is that learners shall not be restricted by the tight focus of the single course they currently are in. For this end, our project partners have coined the concept of knowledge clusters. A cluster contains a set of pages addressing a common topic in a well-structured manner. They can be referenced from any course as "related topics", offering a more in-depth treatment for the selected topic than would be possible within a given course. The page order of clusters may also adapt dynamically based on the strategies.

Since the project shall create a platform for online learning at the field of civil engineering for the whole German academic community, metadata are one of the key points. The metadata must provide sufficient reusability of the learning materials, as well as a basis for an effective searching function for the authors and for the students. L² itself supports the definition of various LOM-based metadata (LOM 2002), as illustrated in (Fig. 4). For the reasons mentioned above we have decided to adapt this model as follows:

- all the metadata are fully SCORM compatible (SCORM 2002),
- those optional data in SCORM model which are relevant to the project; most of them will actually be mandatory for the authors within the project,
- as much as possible is generated automatically by the system (e.g. metadata scheme, size of the file,...),
- many categories have already predefined content but authors are allowed to change it anytime (e.g. intended end user role, copyrights,...).

![Figure 4: Example screen shot of the LOM-based Metadata editor](image)

We are working on realizing automatic links to the appropriate knowledge clusters for the current content. This requires both a thorough classification of the content with metadata and a clever server component that can automatically deduce "related" entities. Additionally, a precise taxonomy is needed for building a meaningful set of terms for classifying the contents.

**Conclusions and Further Research**

Effective Web-based learning requires two key features: learner-centric design and a harmonization of both content and facilities. The former point mainly touches upon the degree of guidance given to learners for navigating the content.

The WiBA-Net project builds a prototypical system for learner-centric online teaching that incorporates the SCORM (SCORM 2002) standard. WiBA-Net has to address different target user groups and accommodate a
large set of educators from different countries. The main focus of our prototype system thus lies in learner-centric navigation support and the harmonization of both content and facilities. The content is presented within the L² environment. L² accepts standard HTML-conformant input for its components and thus supports many different input types. We employ a default style sheets that provides a common look and feel that is not restricted to a single course. The large amounts of participating parties that provide content necessitate such measures to keep the system's harmonious look.

The project presents several challenging aspects for all project partners, including different views of software solutions and slight but important differences in the usage of key terms. More seriously, some key definitions needed for the software solution are currently lacking. This is especially the case for the support of related elements to be linked to the currently displayed content, termed “knowledge clusters” within the project.

Deploying an Infrastructure for Technologically Enhanced Learning

Sami Rollins and Kevin Almeroth
Department of Computer Science
University of California
Santa Barbara, CA, USA 93106-5110
{srollins, almeroth}@cs.ucsb.edu

Abstract: A number of university campuses have undertaken the development of digital classrooms that enable presentation of digital media and digital lecture recording. Deploying the infrastructure for a digital classroom is difficult at best even for a technically savvy person. As people from many disciplines become interested in building similar digital classroom spaces, there is a need to produce a useful set of design and implementation guidelines to reduce the project risk and steepness of the deployment curve. The goal of this paper is to report on the experiences we have had in deploying the UCSB digital classroom. The two main contributions of this paper are: (1) a phased deployment model; and (2) a discussion of how the proposed technology enables new educational models and techniques.

Introduction

Advances in technology coupled with increased familiarity with technical tools have paved the way for new paradigms in teaching and learning. Instructors are now using media such as PowerPoint slides and digital video in their lectures. Students can take digital notes on laptop computers or Personal Digital Assistants (PDAs). These types of technologies allow students and instructors to communicate digitally across time and space. However, while these tools are readily available, using them in a coherent manner is still a challenge. A number of university campuses have undertaken the goal of developing digital classrooms that enable presentation of information using cutting edge multimedia tools as well the capability to digitally record an account of the classroom activity. The account can be used in realtime to enable distance learning or realtime collaboration, or can be archived and reviewed at a later time.

A number of universities have deployed digital classrooms for both teaching and research on new learning methodologies and tools. One of the earliest experiments with this kind of technology was the AT&T Learning/Teaching Theater at the University of Maryland (Schneiderman et al. 95). More recent examples include 405 Soda at UC Berkeley (Wu, Swan, & Rowe 99) and Georgia Tech's eClass (Abowd 99). While the research that has come out of these projects has focused largely on user-level issues, the piece of the puzzle that has yet to be solved is the question of what functionality these classroom spaces should support, and more importantly, how that can be achieved. Without a useful model to draw from, there is an enormous learning curve involved in determining first, what functionality a classroom should support, and second, what technology exists to realize the design. A huge number of tradeoffs need to be considered. It is difficult at best for a technically savvy person to undertake the challenge of deploying a classroom. As people from across disciplines become interested in building similar digital classroom spaces, there is a need to produce a useful set of design and implementation guidelines for ease of deployment.

The goal of this paper is to report on the experiences we have had deploying a digital classroom. By drawing from our experiences, future classroom architects can reduce project risk as well as the steepness of the deployment curve. We identify four classroom functions, and suggest that a classroom should be deployed in four phases corresponding to those functions. In June of 2000 we took on the challenge of deploying a digital classroom at UC Santa Barbara. To date, we have spent approximately $70,000 on our classroom setup broken down as roughly $14,000 for phase 1, $42,000 for phase 2, and $12,000 for phase 3. To date, our phase 4 deployment has leveraged technology purchased in the prior phases. It is difficult if not impossible to deploy a fully functional digital classroom infrastructure before testing or using it. Therefore, it is imperative to support incremental development, deployment, use, evaluation, and modification.
Presentation Facilities

The first phase of classroom infrastructure deployment focuses on providing technology to allow an instructor to give a multimedia presentation in a digital classroom. It is impossible to develop an infrastructure that will accommodate every lecturer or class ever held in a digital classroom. Some professors will use PowerPoint slides while others prefer to use transparencies while still others stick to the standard chalkboard method. In addition, instructors using digital presentation media may require a variety of software. Managing a few pieces of software is tractable, however a system to manage lots of software is not. Fortunately, a large percentage of cases can be accommodated with a standard collection of hardware and software. Minimally, a classroom should include a data projector to show PowerPoint slides or other computer video in addition to providing an Internet connection for a presentation laptop or desktop machine.

Selecting a presentation computer and data projector for purchase requires some thought about the specific classroom and the complete functionality that will eventually be supported by the classroom. We identify three main concerns that need to be addressed when selecting equipment. The first is compatibility. A major concern is whether or not each piece of equipment will be compatible with the remaining infrastructure. For example, if the classroom will eventually have a room control system to control various components (e.g., power on/off, input device switching, etc), does the data projector support that type of control? An additional concern is how to install the data projector. One option is to simply purchase a media cart where a projector can be stored. However, a media cart is not a scalable or permanent solution. The preferred solution is to mount the data projectors into the ceiling. This requires the purchase of a ceiling-mount kit for each projector. Additional concerns include providing a power source as well as ensuring that the ceiling is high enough to mount the projectors out of the way of sight for students and other equipment. Once a data projector and presentation computer have been selected, the next concern is connecting them together. The standard solution is to run a VGA cable from the computer to the projector. However, in a digital classroom the distance might be too great thus the quality of the video signal degrades. The solution is to purchase a signal interface -- a device to boost a computer video signal such that it can travel greater distances.

The UCSB digital classroom shown in Figure 1 has three ceiling mounted data projectors that project on standard projection screens, two presentation laptop computers with signal interfaces at the front of the room, and one presentation desktop with signal interface at the back of the room. In addition, we provide a VCR for showing standard VHS videotapes. Each computer has a DVD player and an Internet connection and can be used for showing DVDs, presenting PowerPoint slides, and/or web browsing. In addition, speakers may bring their own laptop computers with specialized hardware and/or software and use the data projectors we provide. Finally, students may connect to the Internet using their own laptops or PDAs though a 10Mbps wireless network.

We are currently in the process of identifying other extensions to the infrastructure. Short-term extensions include integrating existing technology such as a document camera. Longer-term extensions include upgrading the display technology to be more sophisticated. Instead of three separate screens we could have a single wall-sized display (Fox et al. 00).
A Webcasting Studio

Once the basic infrastructure is in place to support lectures in a classroom, the next step is expanding the infrastructure to include support for webcasting. A webcasting environment captures audio and video feeds generated in the classroom and sends them, potentially accompanied by other materials such as slides, over the Internet to a remote location. There are two pieces involved in making this happen. The first is to provide support for capturing video and audio of the presentation. The remote audience should be able to see and hear the instructor. Second, multimedia material (e.g., slides) presented to the local audience should also be presented to the remote audience.

The minimal requirements for a webcasting environment are one camera, a microphone for the instructor, and an encoding computer. However, producing a reasonable quality webcast requires a great deal more effort. First, a single camera can be limiting if you hope to capture all of the activity that occurs in a classroom. To capture all of the classroom activity including instructor and student movement, multiple cameras must be mounted in various locations in the room. In addition, capturing slides or a web page can be done simply by focusing a camera on the projection screen. However, capturing the computer video feed straight from the computer can produce a higher quality image. Determining which streams are encoded and webcast at any given time adds a non-trivial bit of complexity to the system. Generally, a producer must be available to manually select the stream for webcast. A producer is generally a student or staff member who produces the webcast by controlling the encoding tools and selecting the appropriate video and audio streams.

Managing multiple streams simultaneously introduces a host of complexities. First, devices such as cameras have an associated control interface and may be controlled (e.g., zoomed) from a remote control or computer interface. However, when numerous, heterogeneous devices are installed in a room, it becomes difficult to control all of the individual elements. Rather than having multiple interfaces such as computers and remote controls, it is desirable to support a single, integrated interface that supports control of many or all of the devices in the room (Yu et al. 01). Also, it is unlikely that any hardware configuration would support encoding of all possible streams simultaneously. The general protocol is to select a subset of all available streams for encoding. In order to accomplish this, the infrastructure must include a video matrix switch. A video matrix switch is a device that takes as input a set of video signals and allows routing of the video signals to one or more of the switch output channels. By routing all video through a video switch, the architecture becomes much more modular. Audio signal capture poses many of the same problems encountered by video stream capture. If an infrastructure supports only a single microphone used by the instructor, the signal can be directly connected to a sound card. However, this model begins to break down relatively quickly. Capturing other audio sources such as audience discussion or the audio track from a VHS video is imperative. The ultimate solution is to install a professional quality audio system that is capable of mixing audio signals from the instructor, microphones placed to capture ubiquitous audience discussion, audio streams from remote sites, and other sources such as video. Finally, video format compatibility is a concern. Video capture hardware generally expects a composite video signal. Therefore, the computer video signal sent from a presentation computer cannot be directly encoded as part of a video stream. The solution is to use a scan converter to convert the high-quality computer video signal to a composite video signal.

Developing an infrastructure to manage and select multiple media streams in various formats is extremely complex and requires much thought. However, once the architecture to capture a selected stream is in place, the next step is to determine how to encode the audio and video streams into a format that can be easily distributed and viewed by remote participants. There are two primary concerns that need to be addressed. The first is expense. Hardware-based encoding solutions provide efficient, high-quality encoding. However, while cheaper solutions are on the way (e.g., NCast - www.ncast.com and VBrick - www.vbrick.com), current solutions can be very expensive. Software-based encoding solutions can also be expensive, but a range of lower-cost solutions exist as well. While encoding formats such as MPEG-4 may seem to be the highest quality solution, the chosen encoding format should have a widely available, cross-platform decoder/viewer. Ideally, students would have the viewing tools already installed on their desktop thus avoiding having to download or purchase them. The most common tools currently on the market are RealPlayer and Windows Media Player both of which have freely available and easy-to-install viewers and encoders.

The UCSB digital classroom infrastructure supports webcast of a single video stream selected from a set of cameras or other video input. In addition, we have implemented the audio setup suggested by the Access Grid specification (www.accessgrid.org) which includes a number of microphones to pick up ambient sound
and a high quality sound mixer\(^1\). The heart of the UCSB classroom infrastructure is a 12 input, 8 output video matrix switch. The switch supports both composite and computer video. The first two switch inputs (see Figure 2) are the composite video signals generated from the classroom cameras mounted to capture both instructor and audience views. In addition, composite video from the VCR is also routed through the switch. All computer video sources from the presentation machines, as well as remote sources, are also inputs to the switch. However, in order to capture and encode any of these feeds, the feed must be routed through a scan converter and converted from computer video to composite video. The resulting stream is then fed back into the switch and may be selected for encoding. The streams selected for encoding are fed into a video capture card installed on a standard PC. In addition, the mixed audio stream is fed into the sound card of the PC. The audio and video streams are then encoded using either RealMedia format or Windows Media format and webcast to a remote audience.

Remote Collaboration

The one-way distance learning scenario supported by a webcasting studio does not capture the true learning experience. For distance learning to truly be effective, we have to enable remote students to ask questions, participate in discussion, and otherwise appear to be at the local site. This requires two pieces. First, the remote site must have facilities similar to that of the local site. Second, the technology to communicate in realtime between the two sites must be in place.

Ideally, a remote site would be an exact replica of the primary site. In reality though, the infrastructure of a remote site is generally a subset of the infrastructure deployed at a primary site. Minimally, a remote site must include a camera, a microphone, an encoding machine, and a decoding machine. This could take the form of a standard webcam and microphone connected to a student's home PC where the PC is both the encoding and decoding machine. However, if a remote site is designed to support multiple students (e.g., an extension campus) a more complex infrastructure is necessary. For example, displaying video of the instructor on a PC screen is probably not sufficient. In addition, the camera should be able to capture an audience larger than a single person. Fortunately, the problems encountered when developing the remote site infrastructure are the same problems encountered when deploying the primary classroom and thus we can apply the same solutions.

While deploying the remote site infrastructure itself is relatively straightforward and follows directly from the experiences we have already described, deploying a communication layer on top of the infrastructure is more difficult. There are two main topics to be addressed. The first is realtime encoding. Our first inclination was to use the same software encoding solutions for realtime communication that we used for one-way webcasting. However, off-the-shelf encoding software such as RealMedia and Windows Media introduce intolerable delays from 7 to 15 seconds one-way due to buffering requirements. As with many of the problems we have encountered, extremely expensive encoding solutions exist. But, deploying these solutions without knowing whether or not they are going to work is a risky venture. The alternate solution is to use encoding software designed for video conferencing such as vic or Microsoft NetMeeting. While off-the-shelf video conferencing software is generally easy to use, quality is sacrificed to meet realtime requirements. Also, in addition to watching video generated at a primary site, students at a remote should be able to ask questions (Malpani & Rowe 97) and access shared components such as whiteboards. Additionally, as the number of remote sites grows, it becomes necessary to manage the sites so that only one remote site is asking a question or sourcing video at a given time. Some of these problems may be solved with standard videoconferencing software. However, the requirements are different for any given infrastructure and differences require specialized solutions.

We have deployed a test remote site we call a kiosk. The kiosk has one camera, a single microphone (to be passed from participant to participant), a single encoding machine, and two decoding laptop computers connected to data projectors for display (see Figure 3). We use Microsoft NetMeeting to communicate between the sites. The primary classroom sends slides (using the NetMeeting screen sharing facility), a video feed of the speaker, and an audio stream from the speaker microphone to the kiosk. The kiosk sends a single video stream and a single audio stream back to the primary classroom where it is displayed on a side mounted projection screen. Figure 4 shows the flow of streams between sites. In building the kiosk, we have made a number of simplifying assumptions. First, to avoid the problems of floor control and remote stream selection, we assume

\(^1\) The Access Grid is an initiative to enable research labs and universities to conduct large scale, distributed meetings over the Internet through an always on infrastructure.
that there are only two sites participating at any given time. Second, we assume that the only audio stream for either site is generated from the single microphone available at that site thus we do not have to mix the audio signal. Extensions to our infrastructure would include enabling multiple sites to participate at any given time.

Figure 3: Remote site infrastructure.  
Figure 4: Classroom and remote site communication.

Lecture Replay

One of the primary advantages of recording a lecture or course is that it may be reviewed after the fact. Students may review material at the end of a course or before an examination. In addition, lectures given by guest speakers or experts in their field may be archived and watched by students for years to come (Tschiritzis 99). There are a number of issues involved with recording lectures for replay. However, most of the difficulty lies in providing more functionality over straightforward, sequential playback. The goal of the infrastructure is simply to provide a content base that may be accessed and used to research new methods of access. The challenge is to record and encode the content such that it may be accessed later in different ways using a variety of tools. Support of VCR-style interactivity as well as integration of multiple media types provides a more effective replay experience.

There are two main issues in the deployment of an infrastructure for lecture replay. The first is the deployment of a media server. An hour of lecture can be 500Mbytes or more depending on the encoding scheme. Therefore, the first concern is to deploy a media server with enough disk space to hold the recorded lectures. The second issue is to determine which encoding standard to use. The simplest solution is to simultaneously save the stream already being encoded for webcast. However, it may be desirable to support postprocessing of the stream such as including synchronization between video and slides (Mukopadhyay 99).

The UCSB digital classroom primarily focuses on replay of the webcast stream. During webcast, the encoded Real or Windows Media stream is saved to a file and may be streamed from the server later. We are still in the early stages of generating a content base and thus have not yet deployed a server to support large amounts of data. We have also built a tool to support synchronization between notes written by participants and the video of the lecture.

Potential Impact on Education

Multimedia in the classroom presents a number of opportunities for students and educators alike. First, using technology, learning can become a more interactive process. Teachers can use a variety of media to teach students in new and different ways while students can use technology such as laptop computers or PDAs to share information and communicate with one another. Moreover, using webcasting and remote collaboration facilities, we can remove the physical barrier imposed by a classroom environment. Enrolled students can "web commute" rather than miss lectures, and students who may have otherwise been unable to take a class at all have more flexibility to choose to attend lecture from their home. Additionally, the number of people who can fit in a room or be physically present no longer limits audience size. For example, if an expert speaker visits a university, the number of people interested in attending her lecture may exceed the capacity of the largest
lecture hall on campus. Finally, as webcasting enables a limitless number of people to watch a lecture given by an expert, lecture archival and replay can make the same lecture persistent. Students for years to come can watch and learn from experts in their field.

**Conclusion**

Deploying the infrastructure for a digital classroom is a long and often tedious process. In theory, it involves technical staff, facilities staff, as well as researchers. In the past year, we have brought the UCSB digital classroom online to support the four functions defined by our model to varying degrees of completion. While the process has been slower than we originally anticipated, delays in deployment can be attributed to lack of staff as well as to factors such as back-ordered equipment and equipment incompatibility. However, we are pleased with the resulting infrastructure and its use so far.

To date, we have used the classroom for three different types of events: (1) we have hosted and recorded a standard graduate course; (2) we have conducted a graduate student seminar with participants distributed between the classroom and our remote kiosk; and (3) we webcasted a talk given by a Nobel laureate to an elementary school classroom located in a nearby town. The Nobel laureate's talk was also viewed from other locations in the US, as well as in the UK. Overall, our experiences have been successful. While we are working toward automating the process of set up and configuration as well as lecture production, our infrastructure supports nearly all of the intended functionality.

Throughout the process of designing and implementing our classroom model, we have identified a number of considerations that may not be immediately obvious to the designer or implementer. These considerations range from high-level decisions such as supported functionality to low level choices such as required equipment. We would like to acknowledge many helpful discussions with Larry Rowe and other classroom architects that have helped us to determine the common properties of most digital classrooms. We believe that most digital classroom implementations support similar functionality. Thus, it is unnecessary for each design team to start from ground zero. As campuses around the world begin to embrace technology in their curriculums, it is essential to be able to quickly and easily deploy technologically enhanced meeting spaces.

Abstract: Team collaboration is an important part of working in business today. We produced an experiment in which students were given the opportunity to use many different collaborative tools. We used a pre-test survey and post-test survey to evaluate the student's willingness to use collaborative tools. The paper describes the test, findings and ramifications.

Introduction:

Team collaboration is an important part of working in business today. Because teams are used often in business settings, universities require prospective business candidates to become exposed to collaboration through team projects. One type of collaboration that can be used in team settings is electronic. The purpose of this study is to show that electronic collaboration can impact students' frequency of technology usage as well as their acceptance to using collaborative technologies. Our first goal was to verify that students will use technology more often over time in project team settings after they have been exposed to both the technology and the actual team collaboration. Our second goal is to verify that students will find the technologies useful, thus increasing their acceptance of it, with certain features for group projects. Therefore, the student acceptance of using technology in team settings will increase as they become more acquainted with the tool and its features.

Several new tools have been designed to make teamwork and collaboration more efficient. These groupware programs can allow users to exchange files, draw collaborative sketches, and use auditory voicing along with providing many other features. These features are attractive to users who are highly involved in teams and collaboration. Furthermore, electronic collaboration is becoming more important in both academic and business settings. The benefits these technologies can offer to users will hopefully solve problems of distance, communication, sharing information, and costs.

This study in electronic collaboration usage and implications which extends what has already been done in groupware and group collaboration systems. Electronic collaboration holds promise for future studies in a variety of settings as technology continues to grow and becomes an even more integral part of culture throughout the world. The structure of this paper is presented in the following format: I. Introduction, II. Literature Review, III. Hypothesis Development, IV. Methodology, V. Data Analysis, VI. Research Results, and VII. Recommendations, and VIII. Further Studies.

Literature Review:

Information technology has had a revolutionary impact on society within the last several years. The recent growth of networks, cellular communications, and fiber optic cables have spawned the Internet boom and have provided opportunities for convergence with existing media such as television (Halal, 1992). This shows the trend of technology being converged into current social norms. Other examples include the Internet and teleconferencing as means to improving communication in office, school, and home settings (Halal, 1992). These instances further show the fact that technology is changing the way we live and work.
The result of these trends shows that technology is a catalyst for defining our social domain. Consequently, the term “virtual community” formed to reflect how culture acts toward technology; a virtual community is one where the people are able to communicate and interact in an online environment (Halal, 1992). Because of the heavy reliance on technology in our global society, people have a strong need for communication. Collaboration is one aspect which technology can advance in order to bring citizens in virtual communities closer together.

Collaboration is a term for actively communicating with other people. The benefits of effective collaboration can be highly favorable in work, academic, and personal settings (Chandra, 1996). This current term for communicating with the aid of technology is called electronic collaboration. There is a tremendous synergy that exists in an effective e-collaboration environment. The benefits from these virtual teams can solve many problems such as distance and schedule conflicts.

With the enhancements of team communication in business and academic environments, electronic collaboration can revolutionize the way people exchange information. For example, many businesses have integrated collaborative designs and opted toward a paperless environment. In addition to e-collaboration being an advantage, there are several types of electronic tools that offer unique features.

Electronic collaboration tools, also known as groupware contains a certain outline of functionality, which includes messaging, scheduling, and audio communication. There are also special capabilities of e-mail, including beeper triggering, which can be useful to individuals who carry pagers. Another type of e-collaboration is instant messaging. Three popular services, which provide instant messaging, are Yahoo, AOL, and MSN (Agnew, 2000). Instant messaging is a forum for real-time communication that can include text chat and audio transmission over the Internet. This real-time synergy allows individuals to communicate instantaneously with other users, unlike e-mail, which stores a record. Furthermore, text chat simulates person-to-person chatting while e-mail represents letter writing.

Additionally, there are other groupware products on the market that incorporate several features into one package. Among these tools are Blackboard, Stuffincommon, Centranow, Webex, Placeware, Blink, Backflip, Groove, and Lotus Notes. These e-collaboration tools each have their own unique features. One feature is known as an electronic calendar (Agnew, 2000). This can allow one to schedule and plan activities online. Other important features of e-collaboration tools include notification of users online and file download capabilities. These abilities can let someone know when a team member is online. Furthermore, the ability to download and upload files is a tremendous advantage to exchanging information.

Several popular groupware packages, such as Groove, Lotus Notes, and E-Room, allow users to utilize one program for many features (Fontana, 2001). Some of these features include threaded discussion and file sharing across the Internet. Furthermore, bookmarks, post-it notes, and white boards also allow users to post and store information online. Bookmarks are useful for saving links to other websites while post-its can act as reminders for information. Also, whiteboards are a popular feature that allows users to interact real-time and draw (Fontana, 2001). Though e-collaboration features are very important for user-specific tasks, the benefits from those features are far more significant. Another important benefit is the improved flow of communication between users (McDougall, 2000). This peer-to-peer advantage can increase the effectiveness of online collaboration by minimizing interruptions and system lock-downs.

Flexibility, navigation, and control are very important when using software packages (Borck, 2000). These benefits allow the system to adapt to the user and promote usability. Other advantages of using groupware include convenience, accessibility and user-friendly interfaces. If a collaboration tool is fast, easy to use, easy to learn, and visually appealing, individuals will more likely be willing to use the program. Also, timing and costs are important considerations (Darrow, 1997). Collaboration tools that save users time, allow them to work over distant geographic boundaries, and save costs, can be tremendous benefits to users in work as well as academic settings for team projects.

Another important aspect of electronic collaboration is its usage by individuals in team settings. The term usage refers to the frequency of an e-collaboration tool or how often it was used. The frequency of use indicates the number of times a user employs or activates an
electronic collaboration tool or one of its features. If a user increases his frequency of usage, he is
more likely to become more dependent on the collaboration tool.

In addition to frequency, usage can also be referred to by effectiveness. For instance, if a
user sees a purpose in using an e-collaboration tool, he is more likely to use it. This shows that the
tool has been effective in providing a feature to the user for intended use. The variables that mainly
affect this acceptance in use include level of experience using the product, level of tool exposure,
and ease of use (Agarwal, 2000). If a user has had more experience using a product or has had a
significant level of exposure to it, he may be more willing to use it, thus, increasing his acceptance
of the product. Acceptance refers to the opposite of resistance, as it is used in an organizational or
institutional setting (Ishii, 1999). For example, many users resist change from an old product to a
new one. If a user sees a purpose for using an e-collaboration tool or feature, he may increase his
level of usage.

Hypothesis Development:

Within this study, all subject matter is written in terms of class or group project teams. With
this in mind, we will proceed to the hypothesis development. There are several variables in this
study that require hypothesis testing in order to generate conclusions.

In this study, an analysis of the electronic collaboration affects on students in work teams
and their implications was provided. The first objective was to measure how often students use a
particular technology over time in the context of a team setting. The variables measured for this
objective include the number of occurrences or times using a particular technology as well as the
average time spent using a technology in one session. The arguments presented above form the
following hypothesis:

H1: The frequency of technology usage by experienced students after two weeks
using the tool in a team setting will increase

The second objective in this study was to measure student preferences on collaboration
tool features as well as the benefits that can be derived from them. The variables measured for this
objective include the level of importance of a particular technology feature as well as the level of
usage while working on team projects over a two-week time frame. These arguments present the
following hypothesis:

H2: The usefulness and acceptance of technologies by experienced students after
two weeks using the tool in a team setting will increase

Methodology:

The methodology of this study is a progressive test experiment that compares sets of data
over a period of time. The design of the experiment began with a pilot test consisting of a survey
targeting college students. The pilot was given to approximately 10 candidates who were upper
level information systems students.

The next step of the study was to survey a set of students. The set consisted of two
classes; these were upper level and graduate students. Although there were 75 original subjects,
only 38 subjects were usable. There were actually three separate surveys given to each student
throughout the semester. The first survey obtained general background information on each
subject and was given in the middle of the semester. The second and third surveys were given two
weeks apart toward the end of the semester.

Throughout the experiment, the students were given the opportunity to use several e-
collaboration tools including email, instant messaging, and peer-to-peer tools including Blackboard
and Groove; they were encouraged to use these tools for their team projects throughout the
semester. The surveys were posted online through a university server. This allowed the users to
complete the surveys at convenient times.

Data Analysis:
After the data was collected, we performed data analysis to determine if there was a statistical significance in the responses sent via electronic surveys.

For this survey there were several variables analyzed primarily to describe background data about the subjects. This included the variables gender, age, year in school, and location of address.

The first hypothesis to measure frequency of technology usage was tested using several variables for different collaboration types: email, instant messaging, Blackboard, and peer-to-peer groupware. These variables were compared from survey two to survey three after two weeks of student interaction in teams. For each of these five variables, the amount of times used in the past two weeks was also included.

Finally, the second hypothesis to measure the usefulness and increase in importance or acceptance for online collaboration was tested. Comparing survey two and survey three in terms of the features and benefits did this. There were a total of 11 feature variables and 14 benefit variables measured in this study.

Research Results:

After the data was analyzed, the results of the research project were reported in order to deduce outcomes and generate conclusions. In terms of experience in team environments, all users stated they had opportunities to work in those settings. The average amount of team projects students have had in the last year was between five and seven. Also, teams mostly met at the campus library on evenings in person. The majority of subjects claimed to exchange information online through email, as opposed to instant messaging and other more complex groupware packages. Instead of meeting online for team project collaboration, they normally shared information electronically.

H1: The frequency of technology usage by experienced students after two weeks using the tool in a team setting will increase

The usage of instant messaging slightly declined over two weeks. This could be a result of students meeting physically in their teams more often than electronically.

There is no significant difference in the amount of time spent per session using e-mail as opposed to instant messaging. Hypothesis 1 is not supported due to the decline in the means. The decline in email usage over the two-week period could be a result of team members exchanging more files in one setting. Also, only a few members of each team may have been responsible for updating the other members and sending files through email.

Third, results for the groupware, Blackboard, demonstrated a decline in frequency of usage. The means for this variable are distinct; Hypothesis 1 is not supported due to the decline in the means. This shows that there was actually a decrease in the frequency of technology usage for Blackboard. This decrease is mostly a result of a disruption in class meeting times from Thanksgiving break (see Further Study). Also, the number of class assignments requiring students to access Blackboard had decreased before the Thanksgiving break.

Finally, students were tested on their usage of their two most preferred groupware programs. However, the majority of students did not have a preference for using a groupware collaboration tool, nor did they spend time using them during their group activities. This was the case before the study as well as after the two-week test.

H2: The usefulness and acceptance of technologies by experienced students after two weeks using the tool in a team setting will increase

First, the variable for the collaboration feature real-time voice was tested. Initially, students believed that real-time voice was an average concern. It was rated 3 on a scale of 1 to 7, where 7 is the highest rating. However, after the experiment, preference for voice changed to a rating of two. This shows that students did not see much of a purpose for using real-time voice with in their teams. In addition to voice, real-time text messaging had also slightly decreased in level of importance. Initially, students rated real-time messaging as highly important at level six. However, after the study, students rated real-time text chat at level 5.6. Although this change represents a slight decline for text chat, students generally use this feature and find it important. Students' initial perceptions of these features were slightly higher than their actual level of use during the two-week
experiment. The drop in voice usage could have been a result of restrictions requiring students to keep a low voice volume when working in the computer labs.

The next set of features that represented a significant decline in preference, were file download capabilities and Internet file sharing. Initially, file download capabilities and file sharing were rated at 6.5 and 5.7 respectively. However, after two weeks, the two features were rated at 5 and 4.6 respectively. This shows that within the two-week experiment, most users did not use these capabilities as much as they initially did.

Another less commonly used feature was the online calendar. This variable was initially given a rating of 5.1 out of 7. However, after two weeks, users decreased their level of importance rating to 2.4. This shows that students did not have a need for collaboration tool calendars throughout the span of their project.

Also, one last feature was the ability to notify others online. Before the experiment, students had a preference of 5.8 out of 7 for this feature. After the two-week time period, students rated online notification at the range of 5.5. This shows that there was no significant change in this variable. Therefore, online notification is still considered moderately important to students.

In addition to feature ratings, students were also tested on whether they saw a benefit from using electronic collaboration tools. Initially, students rated the importance of control, access, and convenience in the range of 6.4. After two weeks of working with collaboration tools, their preferences for these three benefits changed to a range of 6.2 out of 7. Though there was a slight drop in the means between the beginning and end of the experiment, the ratings were very high at both times, which supports Hypothesis 2. Because users rated these benefits above 6 both before and after the study, they believed the benefits were useful, thus increasing their acceptance of the tools.

The next set of benefits that had a slightly higher decline in preferences included flexibility, information flow, navigation, and security. Originally, students rated these benefits in the range of 6.2 out of 7. After two weeks, these students changed their preferences to approximately 5.8. Although there was a slight drop, users generally find these benefits important. However, they may not be as important as they were before the study.

The next two benefits with similar initial preferences were the speed and the user-friendly interface of the collaboration tool, which were initially rated at 6.3. After the short two-week time period ended, students rated these features at approximately 6.1. This shows that students still find system speed and ease of use to be very important despite the fact that preferences dropped slightly. The student rankings were above 6 on the 7-point scale both before and after the experiment. This supports Hypothesis 2, because students believed the benefits from fast and easy usage were useful, which increased their acceptance of the tools.

In terms of features available, users do not have much of a preference for the number of options that one groupware package can offer. This was shown by the decline in the means from 5.2 to 4.7 for the importance of feature quantity in e-collaboration tools.

One final set of benefits that users rated included the ability to save time, travel, and costs. Despite a slight decline, students believe that the benefit from time savings when using e-collaboration tools are very high, which supports Hypothesis 2; the benefit was found useful for students and has increased their awareness and acceptance of the technologies.

In summary, students generally rate certain features of collaboration tools more important than others. For example, real text messaging, online notification, and file download capabilities were the most used over the span of two weeks within their team projects. This shows that students see a purpose or importance to using electronic collaboration tools, such as e-mail and instant messaging, which contain these features. Users ranked the importance for convenience, easy access, control, user-friendly environment, speed, and time and distance-savings as the most important. Although the importance of these benefits has not significantly changed over the two-week time period, students have continued to rank their usefulness high. This supports Hypothesis 2, because receiving a benefit from technology is considered very important to students; therefore, their acceptance of the technologies has increased as a result of them using the tools to collaborate.

Recommendation:
After analyzing the results of this study, we have proposed a few recommendations. Hypothesis 1 was not supported; it is suggested that facilitators increase the level of e-tool exposure and requirements for their students in order for them to gain experience using a multitude of electronic collaboration features. By making it a requirement for students to study and learn the wide variety of collaboration features available, students would then be more educated and informed about using an e-collaboration tool.

In contrast to the first hypothesis, Hypothesis 2 was supported; students found several electronic collaboration features necessary for communicating in virtual environments. Thus, they saw a purpose for using e-collaboration tools and should be willing to use these tools for projects in the future. I suggest that students should have many teachers promote electronic collaboration environments for classroom use in order to positively reinforce the benefits from these tools.

Further Study:

In addition to this project, there are several possible extensions for consideration when doing further research. For example, time was a very important factor in the completion of this experiment. If more time can be allocated between survey instruments, then the accuracy of the comparisons would improve. Also, the time restriction in this study brought several constraints to the subjects of the experiment who actually used technology. In addition to timing, another consideration for further research was related to the actual subjects. For instance, in this study, many of the student subjects were majoring in academic curriculums that focused on technology, such as information systems. By expanding the subjects by area of expertise and experience, the external validity of this research could proxy for a wider distribution of student academic curriculums.

Web-Notes: an tool for supporting contextual asynchronous discussion on an e-learning platform.

Abstract
We present an HTTP-based discussion tool that allows in-context asynchronous interaction. Our prototypal system can be integrated in any HTTP-based e-learning platform. It allows to annotate web pages, and to share the notes with the teacher, with (a selected group) of other students, or to keep them as personal notes.

Introduction
E-learning platforms aim non only at providing content to the student: in order to be effective they must support the learning process. For this reason virtually every e-learning suite provides at least some tool for asynchronous collaboration, like bulletin boards etc. Very often these tool offer a poor degree of integration with the content of the e-courses. In many cases discussion among the “actors” (students and teachers) is carried on a forum: the forum though is a different tool, so it is separated from the presentation material. While sometimes this is perfectly acceptable, in many cases it is rather inconvenient since the discussion happens out of context, and many external references are necessary, making the whole process rather cumbersome.

Our system allows to discuss in a context: the (e.g.) lecture content can be annotated by (e.g.) students for their exclusive use, or they can share the notes with their classmates or with the teacher. Readers can respond to the notes in place, for instance clarifying the original content of the page. The system allows to annotate web pages, since most platforms today use HTML as a lingua franca for content delivery.

WebNotes use
In order to use WebNotes, existing HTML pages need to be preprocessed to conform to the standard expected by it. An automatic tool allows to perform the preprocessing of the page. During the conversion process the granularity of the markable context that can be annotated is chosen: it can be each word, each phrase or each paragraph. The process is necessary in order to guarantee that the resulting pages are XHTML compliant, and that the contexts are suitably defined. The resulting page is still normal HTML, although it conforms the more restrictive rules that make it XML compliant.

The pages requested by the user are filtered through a servlet enabled Web server, that maintains a set of notes and their properties (like ownership, visibility etc). Notes are shown in the text as tiny icons embedded in the page. Public notes are visible to everybody. After the user identifies him/herself through a login process, s/he can see all notes allowed by her/his privileges.

The user can toggle between two modes: browsing and editing. While browsing, when s/he moves the mouse pointer over an icon that shows the presence of a note, the note pops up on place. When moving the mouse away the note disappears, unless it was stuck by the reader, in which case it disappears only when explicitly closed.

In order to edit the page (adding or modifying a note) the user enables editing mode and simply clicks on the location where s/he wants to add the note. A popup window appears, and the user can edit/modify the note. In the basic version the note contains only text, without any formatting. In an enhanced version of WebNotes, the window contains an applet that allows writing HTML in a simple “What-You-See-Is-What-You-Get” fashion. We kept the applet separated in order to minimize the requirements we make on the browser, and in order to avoid delays related to its downloading.

The system is currently in the final stages of development, and already underwent some extensive testing with different browsers.

Although WebNotes can be used in various contexts, it was explicitly designed for deployment in an e-learning environment. We envision its use for performing some of the discussions that presently happen on electronic forums. In particular, we target at those (many) cases where the emphasis is on clarifying a point in a lecture. For instance, we had many cases of students discussing programming
code presented in an electronic lecture: in those circumstances, continuous references to "line X of code Y on page Z" make the writing and reading of the notes an exhausting task. Our system allows simplifying these discussions, and by diminishing the needed effort to start or join to a discussion thread it will increase the student participation rate. The increased interaction should give a better learning process that is the final goal of every e-learning environment.

At the moment of writing, we plan to use its preliminary version on the field in some e-courses at the University of Trento during the last bimester. By the time of the conference we expect to have gathered statistics on its use and feedback by the users.

**WebNotes requirements**

WebNotes is made by a series of Java Servlets, and can therefore be deployed on any Servlet-enhanced Web Server (nowadays virtually every serious Web Server can has a servlet-compliant engine). We do not assume any special requirement on the client side, the only request being the support of (the standard subset of) JavaScript (that is available on all recent browsers). We tested our annotated pages with all the major players (i.e. Opera, Mozilla, Netscape, Internet Explorer) on several platforms without encountering problems. The notes are simple text, so their writing and the editing is performed in a normal web page. Also the administration of the system (e.g. group creation and maintenance) occurs in a web page. An enriched version of our tool also includes a Java Applet that is a HTML composer: this allows formatting the notes in a reach way, using the full power of HTML. Since the Applet adds functionality but is not needed to make the system usable, WebNotes can be configured according to the preference of the deployer. Thanks to these choices WebNotes can be integrated in most e-learning platforms, enriching them with a new functionality.

**Related Work**

Although much emphasis has been given to the support of collaboration via web since the early WWW years [COL], a convincing technology has not yet emerged. Interesting approaches run from an almost uncontrolled interactive editing of web pages (wiki's [CUN]) to more controlled annotations. In particular, adding notes to a Web page is not a new idea per se. Tools comparable to what we present have been proposed in the past, but in most cases their architecture was dissimilar from the one we've chosen. The main architectural choices were either based on browserspecific tools, or on external mediator servers. A comparison of some available tools can be found in [GAR].

Browser specific tools (e.g. [COM]) require the use of a customized browser, which is certainly an inconvenient choice.

In the proxy-based approach, the annotation process is taken care of by an intermediate server, that collects the notes, gets the original page and present to the user a page decorated it with the annotations. This allows taking control of the annotation process, and in some cases is offered by commercial enterprises [ANN] [THI]. A non-commercial instance of this class of tools is CritLink [CRI].

Our tool is rather based on an automatic pre-processing of an HTML page to include the fields that (with the chosen granularity) define the markable locations, and rely then on a basic browser and on a rather standard web-server architecture to deliver the content. This promises to be a winning point, since it allows an easier integration with existing e-learning platforms.

The Good, The Bad, & The Ugly: lessons learned from electronic portfolio implementation

At the AACE Conferences during 2001, we were inspired by the work being done with electronic portfolios. Returning to campus, we knew that this was something we wanted to do. It fit so nicely with what we had heard about the new NCATE guidelines. So, during the past year, West Liberty State College, a small 4-year state institution in northern West Virginia, undertook the challenge to move to performance-based assessment and electronic portfolios within the Professional Education Department. As a result, over 900 of the institution's 2500 students are now creating electronic portfolios for student and program assessments.

This decision was not made quickly or lightly and reflects our commitment to remain aligned with the new NCATE guidelines and the NETStandards. Through the development and implementation of our plans, we learned many lessons that should be valuable to any other institution considering a similar program. Our faculty required education on portfolios and performance-based assessment before we could begin discussing portfolios, electronic portfolios, or artifacts and structures. This led to an enlightenment that perhaps some very tried, if not true, teaching methods might need to change. We conducted workshops and in-services in addition to one-to-one mentoring sessions. In addition to motivation for the common good of our students, we are approaching an NCATE review next year.

Once a commitment to portfolios was formalized, albeit some reluctance, a committee was formed to make a proposal. The format was determined to be electronic with a meshing of our NCATE Conceptual Framework and the INTASC Standards. Students would be required to select two artifacts to support each standard and provide a written reflection offering (1) a description of the artifact, (2) a statement relating how the artifact demonstrates work related to that standard, and (3) a personal reflection of future growth goals in this area. Additionally, each portfolio would include a personal statement/resume, a philosophy of education, and any additional information the student wished to include. Finally, it was decided that the portfolio would be conceptually introduced in the first education course, Introduction to Education and the technological mechanics would be addressed in the first technology course.

The second hurdle was the decision of how to “use” the portfolios. The department agreed that this should be an assessment portfolio demonstrating breadth, depth, and growth on the part of student. A comprehensive rubric was developed and a decision made to assess the student reflections rather than the specific content of each artifact. As a result, we back peddled and decided that each and every EDUC, READ or SPED course would include multiple assignments that would be designated as “potential” portfolio items. Each assignment should be performance-based and assessed within the course where it was assigned. The instructor of each course would be required to assess the assignment and give a course grade. From this collection of “potential” portfolio assignments, the student then selected the items for reflection and inclusion within the portfolio. The initial evaluation of the portfolio would be at the time of formal
application to the Education Program. This usually occurs after approximately 60 credit hours. A committee of two faculty members would review each portfolio in conjunction with other admittance criteria.

The second assessment would occur midway through the professional/student teaching semester. At this time, the portfolio would be assessed to determine how the student demonstrated mastery of each of the standards. Again, a rubric was developed to guide a committee of three faculty members. Scores for each standard were noted and used to determine weaknesses in our program and courses. Students received an unacceptable, developing, acceptable, or exemplary rating. Feedback from this assessment is used for program modifications and department decisions.

One of the most challenging decisions was to use an electronic format. Several faculty were not comfortable with this idea. Unfortunately, these people are not comfortable with much of the technology available today and reflect many of the skills still found in our local schools. For this purpose, it became necessary to select a platform that was advanced enough to provide a comprehensive picture of the candidate's knowledge, skill, and attitude yet still be consistent with what might be useful for future purposes (i.e. interviewing). We chose to build web-based portfolios with electronic documents, scanned documents and images, digital photos, video clips, and audio clips. Students were encouraged to link PowerPoint presentations, Web Quests and other projects as artifacts.

We have worked on this for one year and now know what we did right and what we did wrong. Our first set of portfolios has helped us to see what we should have considered. The largest problems we are facing are reluctant students and overworked faculty members. The students don't see the value/need for these. They are very comfortable with the tried and true lecture to me and then give me two tests model. Many are kicking and screaming about a shift to performance-based assessment. Yes, it is more work for them; and for us, the faculty, too. The faculty found more work than expected in designing, developing and grading these portfolio assignments. Faculty had the additional burden of assessing the portfolios. Let's see... 90 student teachers with 3 evaluators each means 270 assessments divided among 12 faculty members who don't all do share. Sound familiar? This was the ugly part!

The actual portfolio results have been both good and bad. Some are disappointing. Others made it all worthwhile. The elementary students have more motivation but sometimes lacked the depth of reflection or technical skills. Some of the secondary students really showed their expertise and have portfolios on CDs that will certainly open many job doors. Some others, often by major, are less satisfactory. For us, we will continue and hope that we can grow from our lessons learned. Perhaps, our lessons learned will help you too.
Teacher roles in synchronous chat classes

Abstract

Synchronous classes are mushrooming in post-graduate education and new roles have been heralded as necessary for effective class instruction. This case study looks into transcripts of chat classes from Newport Asia Pacific University Master Program and analyses its discourse analysis to see how true is this assertion of paradigmatic role change. A coding scheme was developed for this purpose and data were then compared against the result of online interviews with tutors and students. Results point to caution in assigning dramatic changes in online instruction because of new technology.

This work will be a case study of online classes belonging to Newport Asia Pacific University and it will look specifically into roles played by tutors in the classrooms, whether they are radically different from face to face classrooms and what patterns of class organization may appear as distinctive.

Newport Asia Pacific University (NAPU) (www.napu.edu) is an Internet university dedicated to providing post graduate courses in TESOL (Teaching English to Speakers of Other Languages) through its Master of Science program. Students from around the world participate in real-time online classes with world renowned professors on a weekly basis. All subject content is provided via a Web site and all communication, including assignment submission, takes place via the Internet. Faculty and tutors are Dr. David Nunan, Dr. Rod Ellis and Dr. Ruth Wynryb. These professionals moderate classes and discussion lists and hold their classes through chat rooms in a synchronous mode.

In order to analyze these classes a coding scheme was developed for discourse analysis and qualitative interviews with both tutors and students of the courses delivered were implemented.

The criteria used to select sample lessons were:
1. classes with a beginning/ending difference with 2/3 students only.
2. classes with one student only.
3. classes with 4+ students
4. classes with same tutor, same content and number of students, from beginning stages of the program and in the last few months.

The coding scheme used

The Online Instruction/Moderator/Facilitator's roles have been categorized by Berge (1995) into the following four categories: pedagogical, social, managerial, and technical.

Following coding into Berge’s four role categories, I developed a coding scheme to capture the essence of the instructor’s actions within each category focusing on abstracting what the instructor actually did in each posting and categorizing these pedagogic acts. This coding scheme was drawn following Speech Act Theory which identifies both locutory (literal meaning of words) and illocutory (motivating intention of utterance) acts as “markers” encoded in the language of the postings. (Searle, 1976)
Berge's categories were further categorized as:

A. Pedagogical: Encompasses all attempts to reach a particular learning objective relevant to the course. Includes:
   1. Feedback
   2. Setting instructions
   3. Giving information
   4. Advice/suggestions/opinions
   5. Framing questions
   6. Summarizing comments
   7. Referring to other sources

B. Social: Encompasses attempts to make students comfortable and/or promote feelings of participation.
   1. Empathy
   2. Personal communication
   3. Meta-communication
   4. Humour

C. Managerial: Encompasses attempts to coordinate course activities and maintain a sense of coherence and structure in the course. Instructor acts include:
   1. Coordinating assignments
   2. Coordinating Discussion
   3. Coordinating course and program information

D. Technical: Includes assistance to students in mastering and troubleshooting course delivery software.
   1. User
   2. System issues
   3. Problem not easily detected

Twenty-five classes by the three different tutors of the program were analyzed in all. The analysis of raw discourse used the participant-defined paragraph since it provided a practical answer to the need to get a code that reflected both the essence and context of tutor contributions to the online class.

Conclusion

What the data clearly show is that the majority of interventions have been the tutor's while students' interventions have been secondary. The tutor's most important role has been management of the online class while pedagogic roles ran second.

The analysis of these classes also point out to highly structured classes, where agendas are set out at start. In general no classes present evidence of cooperative work among students, reflection among students and group production, or class objectives suggested by student input or questions. Role shifting (the teacher-as-learner, the learner-as-teacher) did not show up in any of the samples. They
typically show a teacher-centered classroom delivery where the "sage teacher as expert" role is predominant. On the contrary, the I-R-F (Initiation-Response-Feedback) scheme of discourse characteristic of teacher-led classrooms is recurrent in most classes. (Sinclair & Coulthard, 1975; Sinclair & Brazil, 1982)

Whatever the reason why chat lessons are so characterized, what they certainly point to is the need to provide a pedagogic scenario that can complement, supplement, and also offer the possibility to carry out all the cooperative work and social network necessary to make learning a wholesome experience. In the case of NAPU, this is already set up by an ongoing discussion list and a face-to-face residential. These two elements provide the rest of the architecture that supports the feeling of online presence acknowledged by all the actors.

Online Mastery
A Certification Curriculum for Faculty

ABSTRACT

Faculty certification increases the chances that online instruction in higher education will successfully meet the needs of students. This paper introduces a new approach to designing a program of faculty certification for online instruction. The paper also proposes that the national and state departments of education as well as accreditation institutions establish certification standards that reflect the quality of preparation defined in the proposed program of certification or a comparable program.

Introduction

Status of the Work: Beginning

Partners Involved: The Academy for Teaching Excellence, the School of Letters, Arts, and Sciences, and the Division of Information Technology at Metropolitan State College of Denver.

Major Goals: The project described in this paper/presentation has two goals. First, the system goal involves the introduction of a competency model of certified training of faculty that will demonstrate how faculty should be educated to develop and instruct online courses. Second, the outcomes goal involves training faculty for certification of quality online instruction.

Basic Approach: With the participation of the Director of the Academy for Teaching Excellence, the Director of Training for the Division of Information Technology, and key faculty and staff from the School of Letters, Arts, and Sciences, develop and validate a sequenced and articulate curriculum of mastery certification in online instruction.

The Educational Problem: What sort of faculty preparation does it take to equip an institution of higher education for success in online education? The authors believe that certification of faculty is essential yet very rare in the traditional colleges and universities. Few offer a sequenced, articulated program that leads to officially sanctioned certification for all faculty members who would teach online (POD Network, 2001). Barring such certification, online instruction may be devoid of any institutional standards of quality (Willis, 1994; Ridley & Husband, 1998; and Palloff & Pratt, 1999). The lack of standards rapidly translates into highly uneven quality as seen by students and hence into lost enrollment, particularly given the competition for student tuition dollars that now prevails in the domain of post-secondary online education (Berge, 1997 and Dominguez & Ridley, 1999). Therefore, for the sake of student learning and institutional success, the authors propose a new approach for preparing faculty for the online educational enterprise. Institutions should require certification of faculty for online educational instruction.

Background: The increase in online instruction in the past five years and its projected acceleration in the next twenty leave no doubt about the need for faculty professional development in online instruction both in terms of technology and pedagogical competencies (Ridley, 1996).

In the U.S. very few faculty development programs exist that train faculty in higher education to enhance their online instructional efforts (Schrum, 1995). Those that do
exist consist of fragmented workshop programs or one-shot conferences on technology (Williams & Peters, 1997).

**Description:** A specific concept of a mastery certification curriculum has been developed. This curriculum includes preparation in the core competencies as well as in enabling and sustaining competencies. See below for a full description of the concept.

**Validation:** Two actions will assist the researchers in validating the certification model for this faculty online development training prior to the date of the Ed-Media Conference. First, the researchers will validate the concept of faculty certification training for online instruction in a conference of peers entitled “Teaching Online in Higher Education Online Conference” on November 12, 2001 in which the model for faculty development training will be discussed and assessed by an online set of peer reviewers at the conference. Second, a survey of the top ten institutions with the largest enrollments where the majority of the program majors and minors are taught online will be instituted on current faculty development programs and the data reported in the presentation at the Ed-Media Conference. In addition to these two actions, a pilot test of the model will be initiated during the summer months at Metropolitan State College of Denver through a U.S. Department of Education, Title III, Activity Two grant, the funding of which the college received for the professional development of its faculty at the institution.

**Future Work and Implications for Others:** The paper/presentation proposes that national and state departments of education as well as accreditation institutions establish certification standards that reflect the quality of preparation defined in the proposed program of certification or a comparable program.

### Core Competencies

A program of certification in online education operates on the basis of six functions that Duchastel (1997) describes as: 1) specifying the goals to be pursued; 2) accepting diversity of outcomes; 3) requesting production of knowledge; 4) evaluating at the task level; 5) building learning teams; and 6) encouraging global communities. These functions influence the development of five core competencies learned by online instructors:

- **Selecting:** Selecting materials, activities and courses that are suited for online delivery
- **Preparing:** Preparing content for online delivery
- **Delivering:** Delivering instruction online
- **Managing:** Managing the online course
- **Assessing:** Assessing student learning in the online environment, providing praise, encouragement, and corrective feedback as needed.

### Enabling Competencies

Many faculty members who are excellent instructors and who wish to teach online do not have the computer skills that constitute the essential threshold to online education. For these educators, the certification curriculum should offer instruction in fundamental enabling competencies including:
Selecting a computer system and or essential components
Setting up a computer system and its components
Creating a healthy workspace
Acquiring ergonomically sound work habits
Using input devices
Using the operating system
Mastering advanced features of the operating system
Developing word processing and spread sheet competencies
Using voice input
Selecting and using ADA input and output options
Operating the electronic communication system in the college/university

Sustaining Competencies

To ensure that a program of online education does not fall victim to the entropy of complacency, the certification curriculum must include instruction in the competencies that are essential for creating and perpetuating excellence. These include:

- Evaluating: Evaluating the effectiveness of the online course
- Revising: Altering the online course when and where appropriate

A Closer Examination of Core Competencies

The five core competencies constitute the heart of the curriculum because they are what faculty do:

- From a vast body of domain-specific knowledge, faculty select the concepts, information, and skills to include in their courses.
- They prepare this material for instruction.
- They deliver it in such a way that learners can make it their own.
- They manage the learning experience, taking into account the mix of personality and ability among their students as well as the technology and logistics of the instructional environment.
- Throughout the course, they assess the learning of their students, providing praise, encouragement, and corrective feedback as needed.

Competency in these five steps is essential for success in moving from purely on-site instruction to instruction that is either partially or totally online. The following sections expand on the concept of each core competency.
1. **Selecting What to Put Online**
Faculty will inventory the courses they teach and identify materials, activities and possibly entire courses that could work well online. This component of the curriculum will provide faculty with specific guidelines for accomplishing this inventory. Faculty will be encouraged to work closely with their department chairs for validation of their selection of materials for online delivery.

2. **Preparing the Learning Experience**
With specific instructional content in mind, faculty will explore the options for preparing instruction for online delivery. They will learn pedagogical principles and techniques for making the materials they put online more effective for their students. They will learn to make accurate estimates of how long it will take to implement their plans for preparing their materials for online delivery. They will learn how to use the tools of technology to actually prepare course materials for online delivery. They also will learn how to work with specialists in multimedia development to produce advanced media components or even entire online courses.

3. **Delivering the Learning Experience**
Studies of what makes for successful classroom teaching indicate that personal dynamism, energy, and the ability to make contact with learners are major components of success. Dynamism, energy, and ability to make contact are also major factors in the success of online delivery, but the effective application of these traits requires a set of very different skills compared to classroom instruction. Workshops in this section of the curriculum will present methods of online instruction and help faculty identify those methods that are most appropriate for their teaching style and various types of course content.

4. **Managing the Online Class**
One of the most frequent comments from faculty new to online teaching is that they find it extremely time consuming. Can one avoid being overwhelmed and still provide a quality learning experience for students? What about decorum in the online environment? How does the online teacher keep the tone of the entire experience on high plane? And what does one do if students start "flaming" one another or the instructor? This component of the curriculum will present methods of managing the online class and suggest techniques for success.

5. **Assessing Student Performance**
The online learning environment puts in question many of the standard practices of on-site assessment of student performance. What kinds of tests can one offer online? Is there any way to guard against cheating? Are proctored tests a good solution? Can one assess students in other ways than just testing? Can one require graded group activities in an online course? Classes in this section of the workshop curriculum will help answer these questions by presenting options for assessing student performance in online courses with an emphasis on alternatives to the proctored written exam.
A Closer Look at Enabling Competencies

For faculty members, equipping for the online endeavor means expanding their store of knowledge and skill to include use and ultimately mastery of the essential tools of technology. It means acquiring and installing the essential computer system components. It means learning how to use those components. Finally, it means creating an ergonomically appropriate workspace and adopting healthy computer work practices. All these factors become particularly important when the faculty member plans to handle online courses from home.

Most programs of faculty preparation overlook these foundational considerations. The negative results of such omission affect the full spectrum of faculty, from computer novices to long-time veterans of computing. Some novices drop out because they never grasp the basics essential for being at ease in using computers. Others survive but fossilize in inefficient uses of their computer systems. Finally, many expert users find themselves out of action or hindered in their work due to unhealthy computing practices or poor ergonomics.

A Closer Look at Sustaining Competencies

The two sustaining competencies—evaluate and revise—are essential to ensure that flaws and weaknesses are identified and eliminated as soon as possible. This is a particularly problematic area of endeavor. Some extensive online education enterprises that have been in operation for a number of years still have not determined how to realize peer evaluation of online instruction. As to student evaluation of online instruction, it may be simple to implement but quite difficult to validate. Students come to the online learning experience with widely varying expectations and levels of competency in the computer essentials. Under such conditions, students may be incapable of differentiating between peripheral frustrations and the quality of instruction as they evaluate a specific online course and instructor. Finally, where institutional evaluation exists, it may be purely summative and generalized, serving as a poor tool for identifying what specific changes should be made to improve instruction in specific course offerings. Thus, instruction in the sustaining competencies will provide instructors the tools for formative evaluation and revision of their own courses as they are teaching them.

Summary

This curriculum will offer learning experiences that lead to certification in each of the core, enabling, and sustaining competencies. These learning experiences may be of various sorts, e.g. peer tutoring/coaching, team teaching with certified faculty, computer or Web-based instruction, workshops, classes, and seminars. Faculty who accumulate certification or validation in all competencies will earn “Online Master” certification.

Abstract. This article presents the Helsinki-Lappi project (HelLa) co-run by two Finnish universities: the University of Helsinki, and the University of Lapland. The general aim of the project is to study, develop, and assess how different training programs relate to educational use of information and communication technologies (ICT). The project is expected to contribute substantively to the national Virtual University Project of the Faculties of Education (KasVi). The specific aims of the project are to analyze (i) how the pedagogical models of network-based education (NBE) can be seen in educational use of ICT programs; (ii) what kind of design, quality, and assessment principles can be elaborated in NBE (iii) how a didactic network environment and NBE support media skills and the development of the individual and the community; and (iv) how national training programs in media education and educational use of ICT can be streamlined and made accessible to the international audience. The outcomes of the project will be models and didactic principles, which can be used in design and assessing NBE.

Keywords: Network-based education (NBE); teaching-studying-learning (TSL) process; learning and studying environments; pedagogical models; designing and assessing principles; meaningful learning; information and communication technologies (ICT).

Introduction

The Finnish virtual university project (KasVi) aims at developing: 1) teacher education curricula in technological environments, 2) flexible training systems based on distance and flexi-mode teaching, 3) continuing teacher education, 4) qualitative ICT training programs, and 5) innovative pedagogy for NBE. The Universities of Helsinki and Lapland initiated the joint HelLa project in 2001 as part of the national KasVi project. The objective of the HelLa project is to study the following areas in 2001–2003: i) the pedagogical models of NBE in training programs of media education and educational use of ICT, ii) the further development of the principles and characteristics of designing and assessing NBE, iii) the support of NBE for the media skills of the individual and the community, and iv) the standardization and internationalization of national ICT training programs. This article examines the pedagogical models for NBE and the principles of design and assessment.

The Challenges of Assessment

Quality can be defined as a relation between the object and the aim of the study. The assessment of quality is always related to the situation; it is dependent on time, space and context. (Raivola 2000, 19–22.) In this article, the quality of NBE is primarily studied as the realization of the objectives of education. The quality of university.
education is always closely related to research. Research creates knowledge, and assessment, again, is deeply rooted in this knowledge obtained. Teaching based on research is seen as quality teaching. In this respect, quality is also understood as a corresponding principle. (Raivola 2000, 38–51.) In this study, quality is also defined as fundamental, goal-oriented, curriculum-oriented, meaningful, and profiting from the didactic principles of NBE.

When assessing NBE certain issues should be raised to fore: the operational context of NBE, communication and communalism, research into the role of the teachers and students, and modes of studying and teaching. (Ruokamo & Pohjolainen 1999; Tella et al. 2001.) According to Duffy and Jonassen (1992), learning and studying environments that have focused on users and their needs and a problem-oriented approach have been successful. (Vahtivuori 2001). It seems that NBE should be assessed at all levels; a study restricted to the surface level is insufficient. Thus, social perspectives, media culture, communication and mediation should be taken into account. (Tella et al. 2001.)

Pedagogical Models of Network-Based Education and Learning Theory

Based on pedagogical models of NBE and theoretical models of learning (e.g., Jonassen 1995; Ruokamo & Pohjolainen 1999; Tella et al. 2001), the HelLa project will study the didactic thinking involved in the teaching-studying-learning (TSL) process (Uljens 1997). We aim at presenting different pedagogical models that can be used to define the principles for designing and assessing NBE. Our study focuses especially on those pedagogical models that can be used to realize cooperative and communal modes of learning and studying. In this article, cooperative means that students work together and build their knowledge in cooperation with others, using their knowledge and skills beneficially (Jonassen 1995; Ruokamo & Pohjolainen 1998; 1999; 2000). Cooperative learning is based on the socio-constructivist perspective. By communal learning and studying, we refer to the philosophy of interaction and to the individual way of life. In communal studying, a common culture of activity and the process of work are strongly emphasized (Vygotsky 1934/1962; Panitz 1996; Tella 1998; Passi & Vahtivuori 1998; Hakkarainen et al. 1998).

Uljens (1997) emphasizes the teaching-studying-learning process (TSL) as central for didactics. According to him, both teaching and learning are important but equally important is studying. (Cf. Kansanen et al. 2000.) Uljens (1997) argues that teaching cannot directly influence learning; rather, teaching affects learning indirectly through the individual's study activity (Uljens 1997, 39). For this reason, we also need to examine teaching, studying, and learning as equally important components. (Kynäslahti 2000, 25; Tella et al. 2001.) We argue that these concepts are the most beneficial way to organize and assess NBE.

The multi-dimensional model of media education is a conceptual framework for NBE, in which designing and assessing NBE are handled in an integrative way. In the model, the concepts of media education and the didactic TSL process are incorporated to communication and mediation. This model attempts to avoid the problems contained within earlier analytical criteria and the simplification of the complex realities involved in NBE. (Tella & Mononen-Aaltonen 2000.) Another model used is that of different uses of ICT, partly based on Goldsworthy's (1999) lenses of learning. It deals with four categories that examine the relationships between studying and technology. The four categories of the model are pedagogic, instrumental, communal, and communicative use of ICT. NBE profits most from several or all four different ways of using ICT being linked to the same educational program or to a TSL situation. (Vahtivuori & Masalin 2000; Vahtivuori 2001)

Our study also focuses on the shared and divided expertise (Oatley 1990; Brown et al. 1993), which is based on research into the theory of learning, and the reciprocal teaching method (Palincsar & Brown 1984) in NBE (see also Hakkarainen et al. 2000). We have organized some experiments in this field in media education and NBE courses (Ruokamo & Syrjälä 2002). In addition, we shall examine problem-based learning (Norman & Schmidt 1992) and meaningful learning (Ausubel 1968; Jonassen 1995). Experiences were promising for increasing quality of NBE. Research-focused teaching has also been used to study interaction and dialog in NBE. One of the key observations points to the significant role of the teacher in creating research-focused dialog. The meaning of social interaction in studying was also emphasized strongly alongside interaction which handled substance-specific issues. (Mononen-Aaltonen 1999; Lintula 1999). Observations of the NBE courses showed that groupwork software supports communal modes of learning and studying, different styles of studying and students' developing skills. (Cf. Sharan & Sharan 1992; Vahtivuori, Wager & Passi 1999.)

Some Principles for Designing and Assessing NBE

In the following, a few principles for designing and assessing NBE will be presented, based on the pedagogic models above. In terms of the TSL process, our key observation is that, as far as design and assessment go, the
same kinds of principles and characteristics apply to all the three components of TSL. (Ruokamo & Pohjolainen 1999; Tella et al. 2001.) In designing learning and studying environments, NBE and educational use of ICT can be understood as broad trends in which different tools and environments are used in many ways to support the TSL process. Networks are not to be understood simply as tools; rather, they can also serve as intelligent partners and new contexts (Jonassen 1995; Tella 1998). The entire context of NBE should be examined. The materials, the users' activity and needs and general didactic planning are crucial for the design and assessment of NBE (see also Bonk & Reynolds 1997). NBE also calls for user-oriented applications and customized models at the local level. In designing network-based environments, attention should be paid to their functionality to enable multi-level teaching and guidance. For meaningful and purposive learning and studying, we need, for instance, a fully operational tutoring and mentoring system in addition to the activity of the teacher. We will now present eleven characteristics of meaningful learning and studying and describe the corresponding didactic and learning theoretical network-based environment together with the desired teacher orientation.

1. **Constructive and Cumulative.** Students build new knowledge upon the basis of their earlier knowledge (de Corte 1995; Jonassen 1995; Lehtinen 1997; Ruokamo & Pohjolainen 1999; Mannisenmäki 2000; Nevgi & Tirri 2001). Well-organized, complicated skills for constructing and justifying information structures are emphasized in a learning and studying environment (Sinko & Lehtinen 1998; Manninen et al. 2000). The students' earlier knowledge controls the acquisition and interpretation of information (Lehtinen 1997). The teacher should construct learning and studying situations and contexts (Tella et al. 2001) in such a way that a student can build on his or her prior knowledge. Initial mapping can clarify the students' preparedness to receive information and skills. The learning and studying environment can be adapted to suit students' activities best and to fulfill their needs through the support of the teacher, tutor, and the peer group. (Manninen et al. 1999.)

2. **Active and Self-Directed.** The roles of the students and other members of the learning community are active. The students commit themselves to objective-oriented (Uljens 1997) and sensible processing, for which they are responsible. (Jonassen 1995; de Corte 1995; Lehtinen 1997; Ruokamo & Pohjolainen 1999; Mannisenmäki 2000; Nevgi & Tirri 2001.) A learning and studying environment enables a new kind of teacher-student relationship, which emphasizes communalism and the personal expertise of the students. (Sinko & Lehtinen 1998; Manninen et al. 2000.) Students can ask practical, informative questions, acquire information, and critically evaluate that information. The teacher creates and maintains students' activities with challenging and interesting settings for tasks shared with the students themselves. Students are encouraged to express new ideas and models of thinking. This way the entire community can see and profit from the "media traces" born during the process of learning (Sharan & Sharan 1992; Vahtivuori, Wager & Passi 1999; Mannisenmäki 2000; Tella et al. 2001).

3. **Cooperative and Communal.** Students work together and build new knowledge in cooperation with one another while benefiting from the knowledge and skills of others (de Corte 1995; Jonassen 1995; Lehtinen 1997; Ruokamo & Pohjolainen 1999; Mannisenmäki 2000; Nevgi & Tirri 2001). Communalism is embedded in dialogic thought (cf. Vygotsky 1934/1962; Vahtivuori, Wager & Passi 1999; Tella et al. 2001). Based on the theory of shared expertise, social interaction and communal modes of learning and studying are emphasized. The teacher is expected to maintain dialog and contact with the students in NBE (Passi & Vahtivuori 1998; Sinko & Lehtinen 1998; Ruokamo & Pohjolainen 1999; Manninen et al. 1999, 2000.)

4. **Conversational and Interactive.** A central element of the TSL process on the net is dialog (Jonassen 1995; Tella & Mononen-Aalto 1998; Mannisenmäki 2000). Dialog and dialogic communication, i.e., comprehensive understanding of and respect for one another as well as interaction and interactivity are at the core of NBE (Tella & Mononen-Aalto 1998). The quality of interaction has to be considered when an environment for NBE is being designed and assessed. Many different channels of communication should be used in learning and studying environments (Lintula 1999). The well-designed environment includes, among other things, common and shared conversation and working spaces in which documents can be worked on together.

5. **Contextual and Situational.** There are some problematic issues related to the physical environment the situation as well as to time and place. On a network, the place and the situation gain new forms. When teaching and studying on a net, it is necessary to consider the changes in these phenomena and how they affect designing and assessing NBE. (Vahtivuori 2001.) According to the features of meaningful learning and studying, learning tasks support meaningful solutions to the problems of the real world, or are simulated through certain case-specific or problem-based examples of the real world (Sharan & Sharan 1992; de Corte 1995; Jonassen 1995; Lehtinen 1997; Ruokamo & Pohjolainen 1998; Mannisenmäki 2000). Gaining experiences in NBE is at least as
important as in the face-to-face TSL process (Ackermann 1994; Boud & Feletti 1999; Vahtivuori 2001). The links with school are essential in the professional practices of working life and the rest of society (Sinko & Lehtinen 1998; Manninen et al. 2000). Among other things, simulations, videos, Internet links, implementations in the microworlds and applied problem-based situations are used in the learning and studying environment (Mannisenmäki 2000). Especially promising are on-line strategic and role games that include the principles and criteria linked to the community and experience (Vahtivuori 2001). In teaching we should find examples and connections to the real world and to the personal world of the students through questions touching on their interests. Through joint discussions, the teacher can perceive the external world and widen his or her own perspective substantively. (Sharan & Sharan 1992; Manninen et al. 1999.)

6. Transferable. Students know how to use their knowledge and skills in other situations and how to learn, adopt and benefit from them when learning new topics (Ruokamo & Pohjolainen 1999; Mannisenmäki 2000; Nevgi & Tirri 2001). A learning and studying environment supports emerging learning skills, problem solving skills and the skills of self-directed learning. (Sinko & Lehtinen 1998; Manninen et al. 2000.) A learning and studying environment includes cognitive tools, hypertext, professional systems, and databanks that underpin meaningful learning (Mannisenmäki 2000). The deep-going discussions between the teacher or the tutor and the different groups of students are fruitfully conducive to enabling the transfer of learnt knowledge to future situations and contexts (Manninen et al. 1999).

7. Goal-Oriented and Purposive. Students achieve a cognitive goal proactively. They can define and set objectives of their own (de Corte 1995; Jonassen 1995; Lehtinen 1997; Ruokamo & Pohjolainen 1999; Mannisenmäki 2000). The guidance and support given by the teacher are related to goal-oriented and purposive studying (Uljens 1997; Mononen-Aaltonen 1999). Self-guidance and a genuine attempt to learn also contribute to creating a learning and studying environment (Sinko & Lehtinen 1998; Manninen et al. 2000). A learning and studying environment includes various tools for planning and monitoring one’s learning process. Here, a teacher helps to support the materialization of his or her own curriculum (Manninen et al. 1999; Mannisenmäki 2000).

8. Guided. Learning itself as well as the learner’s assessment of his or her own skill are promoted by the teacher and by the feedback and support from other students and actors (cf. Vygotsky 1934/1962; Nevgi & Tirri 2001). The need for guidance increases rather than decreases in NBE. On the other hand, the roles of the teacher and the student gain new dimensions and emphases in that in NBE they alternate and, at the same time, they enrich the TSL process. Students and teachers take turns in acting as guides and experts. (Tella et al. 2001.) The learning and studying environment has such tools for cooperation and discussion that enable feedback and support for both the individual and the studying community. The most important characteristics of the learning and studying environment are functional interaction, the opportunity to communicate informally, and to get immediate (synchronous) and delayed (asynchronous) feedback.

9. Individual. Humans have individual learning styles and strategies. Learning and studying are always influenced by the students’ prior knowledge, concepts of learning, focus of interest and motivation (de Corte 1995; Lehtinen 1997). A learning and studying environment is basically individual (Nevgi & Tirri 2001), that is, it is never the same to all students. Learners can construct their own individualized interpretation of the challenges and opportunities posed by the environment. Each learner constructs his or her own learning and studying environment, where the immediate feedback given by the teacher supports the learner’s individual process of handling and coping with information. (Lehtinen 1997, 20.) Here, the individualized guidance given by a teacher is of primary importance.

10. Reflective. Learners express what they have learnt and they examine the thinking processes and decisions required by the learning process (Jonassen 1995; Ruokamo & Pohjolainen 1999; Mannisenmäki 2000; Nevgi & Tirri 2001). Information retrieval and processing as well as the skills of critical assessment are emphasized in the modern learning environment (Sinko & Lehtinen 1998; Manninen et al. 2000). A learning environment includes the tools, such as diaries and the tools for a portfolio, necessary to support the assessment of one’s learning and active output (Mannisenmäki 2000). The environment should also include the tools that the teacher can use when guiding students to assess their own studying process.

11. Abstract. Learning can be defined as the construction of new ideas at an abstract level; the development of theoretical ideas reaches from practical experience to the deeper level (Lehtinen 1997). The learning and studying environment enables students to review the socio-constructive process of abstract scientific theories and ideas (Lehtinen 1997). Here, the support given by the teacher is the more important the younger the students are.
Conclusions

The above-mentioned characteristics of NBE should be seen as flexible in their nature. Through them, it is possible to examine how different pedagogical models realize the principles of design and assessment and how pedagogical models can be further developed. New learning environments apparently demand new cultural skills and media skills that call for further practice. Teacher educators have the key position to develop the media skills of future teachers in educational use of ICT and in designing goal-oriented and purposive NBE. The design and assessment of NBE presuppose that the teacher and all users have sufficient media skills and an ability to use their skills for the benefit of the community and themselves. (Tella et al. 2001.)

This article has examined the objectives and pedagogical models of the HelLa project, the principles of didactics and the teaching–studying–learning process as applied to NBE, and, most importantly, the development of the characteristics of meaningful learning and studying as principles of designing and assessing learning environments. The aim has been to analyze certain didactic and learning-theoretical issues in order to develop NBE and educational use of ICT in the context of network environments.

To sum it up, the principles arising from the didactic models of NBE are in harmony with the principles emerging from the learning-theoretical models, e.g., the model of meaningful learning. In particular, both approaches underline the significance of contextuality, the importance of guidance, working together, dialog and social interaction. The training programs in educational use of ICT being implemented in Finland provide a versatile opportunity to experiment with different concretizations of NBE that can be tested against the principles of design and assessment. In the HelLa project, the aim is to summarize and further develop pedagogical models, on the one hand, and the principles of design and assessment, on the other.

Abstract. This article presents the solution developed at the University of Lapland for organizing local activities to support the Finnish Virtual University. The Centre for Media Pedagogy (CMP) was established in February 2001 and its fields of operation include research, support services, and training. The focus of research is based on network-based learning environments. Support is provided to meet the needs of pedagogy, technology, and content production. The objective of the support service is to help university personnel and students to face the challenges of the educational use of information and communications technology (ICT). The objective of training is to support and produce the preparedness for those things the teaching staff need in educational use ICT. The University of Lapland is participating and coordinating several Virtual University network and internal projects. The CMP has also other national and international cooperative projects with businesses and other universities.

Background

The establishment of the Virtual University was taken as an objective in the Information Strategy for Training and Research for the years 2000–2004 by the Ministry of Education (Ministry of Education 1999). The Finnish Virtual University was established in February 2001, when the representatives of all universities signed an agreement. The Virtual University is not a new or independent university; rather, it is a new means for the universities to act as a network. [http://www.virtuaaliyliopisto.fi]

An objective of the Virtual University is to provide students the opportunities for flexible and open study, where information and communications technology is utilized in teaching. The Centre for Media Pedagogy (CMP) project started in the University of Lapland at the beginning of 2001. The research and product development, support services of the Virtual University and training are centred in the Centre for Media Pedagogy [http://www.urova.fi/home/mpk] as a synergistic entirety. The objective of the CMP is to support and coordinate the development and use of new teaching methods and the activities of the Virtual University in the University of Lapland. (Ruokamo & Syrjäkari 2001a.) The organization and fields of operation for the CMP are presented in Figure 1.

![Figure 1. The organization and fields of operation for the CMP](image)

The development group of CMP consists of representatives from different faculties and departments and its support group was formed of the representatives of the projects by the Virtual University working in
cooperation with a team consisting of researchers and staff from the CMP. The team, with its pedagogical and technical expertise, is responsible for the operation and realization of support services and realizes the training provided to university personnel and students in cooperation with professionals from the faculties. The responsibility for directing research rests with the faculties.

Research and Cooperative Projects

The activities of the CMP include research (e.g. Ruokamo 2001a, b, c) and product development, which in turn support the activities of the Virtual University and the design, realization, and assessment of network-based education (see Ruokamo et. al.). The Faculty of Education is responsible for directing research. It initiated a seminar on network-based learning environments in the autumn 2000, the realization of which utilized the BSCW group work program. The research topics relate to, among other things, online interactive curriculum representation (see Lehtonen), interaction in cognitive science network studies (see Johansson & Ruokamo) and the effectiveness of training.

The CMP has underway and in progress some national and international cooperative projects with universities and the business world. The Centre for Media Pedagogy has operated as a cooperative actor with the Spanish University of Catalonia in the Scottish University of Highlands and Islands (UHI) project. The aim of the UHI project was to create a decentralized university that is based on cooperation between local institutions of education. The UHI is part of the EU-funded ADAPT-LINC project that was realized from April 2000 to June 2001. (Ruokamo & Syrjäkari 2001b.) In 2002, the CMP initiated the IMPEL FIN_2002 project. The objective of the project is to design, realize, and pilot a web-based period of study as part of the subject sphere of the Ministry of the Environment, in which students will be from several European countries.

Support Services – Support for Personnel and Students in Multiform Education

An objective of the Virtual University is to provide university students with opportunities for open and flexible studies. For example, through flexibility and openness, the barriers to study will be removed, in that university students can participate in the education provided by another university without the need to travel to another locality. The opportunities for flexible and open study require education to be multiform, which often means that teaching utilizes video-conferencing and web-based learning environments. In some cases, an entire course will be fully realized by studying on the net. The development of education to become multiform sets new challenges in front of teachers: it is necessary to know how to utilize information and communications technology in an appropriate pedagogical manner. Even today, the development and realization of network-based education are the activities of a small group of pioneers, and neither has it yet become established as normal practice. A network-based learning environment is a student-centred mode of action that requires the development of a new form of study skills and self-direction (Syrjäkari & Abrahamsson 2000). For this work of development, teachers need various forms of preparedness (technical, pedagogical, and content production) as well as a ring of support around them. Besides support activities, the follow-up and continuing education of teaching staff is one of the most central means to meet these challenges. (Ruokamo & Pohjolainen 2000.)

The CMP organizes developmental projects for university personnel for the pedagogical, technical, content production, and material support of teaching utilizing information and communications technology. The support team provides advice, guidance, and training. The support is provided either personally or as guidance for a small group of university personnel, and it is also provided to students. With respect network-based learning environments, teachers are offered either the WebCT [http://www.webct.com/], or the Discendum Optima [http://www.discendum.com/] platforms. Experience is also being gained with other platforms, such as Humap [http://www.humap.com/humap/default.htm] and Future Learning Environment [http://fle3.uiah.fi/].

The CMP organizes an extensive range of support in the educational use of information and communications technology, which corresponds to the needs of the representatives of Virtual University projects and other personnel. The training needs, that relate to net pedagogy and the multiform nature of education as well as to the content production of network-based education, of university teachers and the teaching support staff were surveyed in the spring 2001. Thirty-five people responded to the questionnaire. Figure 2 below shows the earlier experience of teachers in multiform education.
As can be seen in the diagram, over half the respondents were unfamiliar with the production of web-based learning materials and almost half stated that they had no personal experience of web-based education. The utilization of video-conferencing in teaching was familiar for many either in the practice of a meeting or in the role of a student during a video lecture. Based on the survey of training needs, the training of personnel was planned for the 2001-2002 semester and it began in the autumn 2001. Its contents include the development of a web-based course as a process, net pedagogy, the WebCT, Sonera eXperience Training, Sonera eXperience Learning and Discendum Optima platforms, the ABC of video-conferencing, the production of web-based learning materials, and the strategic preparation for the educational use of information and communications technology. In addition, the training is organized through linking sound, picture, and video to web-based learning material.

At the beginning of 2002, the support training was redesigned. The objective is to support the diversification of staff teaching projects even more effectively. The provision of training was planned to originate from the idea of the project and supports the teacher through to its realization. Teachers have the opportunity to participate in content courses so that they can if wished also complete media education studies as credits. In addition, teachers can select courses in skills according to their own needs, which include handling sound, picture, and video and attaching them to the web-based learning materials. In addition to these, teachers can participate in courses on using different media such as the use of video-conferencing in teaching.

In allocating support for 2001-2002, the projects aimed at what the Virtual University has to offer are in a very special position. The University of Lapland is participating in the following 8 network projects by the Finnish Virtual University. SOSNET is a national university network for social work coordinated by the University of Lapland [http://www.urova.fi/home/mpk/Sosnet.htm]. KasVi - The Virtual University of Educational Sciences is a joint project by the Finnish Faculties of Education [http://www.urova.fi/home/mpk/Kasvin%kuvaus.htm] and its sub-project HelLa is a research project for the design and assessment of pedagogical models in network-based education [http://www.urova.fi/home/mpk/HelLa.htm] (see Ruokamo et. al.). CONNET – Cognitive Science and Cognitive Engineering National Education Programme is realized through the cooperation of eight universities and the objective is to train multi-disciplinary professionals to meet the needs of the information society [http://www.urova.fi/home/mpk/Connet.htm] (see Johansson & Ruokamo). Network projects include also Postgraduate Studies of Law, Finland Futures Academy (TVA), a network-based teaching project for the acquisition of scientific knowledge (TieDot) and the Virtual University of Women’s Studies (Naisverkko).

The University of Lapland is also participating in 2 national projects by the Virtual University; IT-Peda is a network for enhancing knowledge on online teaching and learning in Finnish universities and TieVie is a national teacher-training programme for the use of information and communications technology in higher education. The University of Lapland has its own Virtual University projects in content production including a course on the community, art and the environment, subject studies in quantitative research, a Swedish, English, and German language module for students of economics, the use of mobile services in teaching, and developing constitutional rights.
The activity of the Virtual University realizes the existing information administration strategy for the years 1998–2001 and especially its focus of development “New Learning Environments – the Diversification of Teaching”. In cooperation with the Faculty of Education, the Centre for Media Pedagogy participates in the information strategy process initiated at the university, especially in preparing the strategy for the educational use of information and communications technology.

Training

The CMP arranges and acquires funding in order to organize long-term training. An example of such is the 15 credit study program New Learning Environments in the Work of the Teacher (NET), which is directed by the CMP [http://www.urova.fi/home/mpk/Koulutus.htm]. NET, which is financed and realized with funding from the European Union’s European Social Fund (ESF), is a development project of university-level teaching methods that promotes the development of employment by supporting employability, entrepreneurship, adaptability, and equality as well as by investing in human resources. It has been aimed at the university teachers and teaching support staff in the University of Lapland, in the Rovaniemi Polytechnic and in the Kemi-Tornio Polytechnic. The study program is realized 2 times in 2000–2001. At the beginning of 2000 there were initially 74 participants and 72 participants in the autumn 2001. As of the autumn 2001, the studies are in accordance with the requirements set by the Faculty of Education at the University of Lapland. Research into effectiveness will be performed in relation to the NET studies.

The CMP functions as the local actor responsible for supporting the TieVie training project initiated by the Virtual University. The objective of the TieVie training is to familiarize participants with information and communications technology from the perspective of pedagogic, technological, and organizational change as well as to research the challenges and problems of networked education. Representatives of the personnel at all Finnish universities are participating in the training. The CMP is responsible locally for providing information, support services, and mentoring.

In the University of Lapland, the CMP coordinates the Virtual University’s CONNET – Cognitive Science and Cognitive Engineering National Education Programme. This project was coordinated by the University of Helsinki in 2001 and will be coordinated by the University of Jyväskylä in 2002–2003. The curriculum, the purpose of which is to train multi-disciplinary professionals to meet the needs of the information society, consists of eight different subjects. Each of the eight universities coordinates the practical organization of the information, registration, and teaching at its own university. Basic studies in cognitive science began in the autumn semester 2001 and research related to the interaction for their realization is underway. (See Johansson & Ruokamo.) Subject studies in cognitive science will begin in the autumn semester 2002.

The University of Lapland has responsibility for a course on Organisations and Modern Communication, which is held in cooperation with the University of Helsinki. The course was realized for the first time in the spring 2002 and the Faculty of Education at the University of Lapland was responsible for the professionalism of its content. Students from six different universities participated in the section of the course prepared by the University of Lapland. They were divided into small groups both according to university and between universities. The course consisted of an introductory lecture realized through video-conferencing and two separate parts: a web-based reading group and study tasks. In the web-based reading group, each student wrote an introduction based on course literature and these were discussed in small groups utilizing WebCT. In the study tasks, the student groups wrote cooperatively an essay based on course literature, which they also presented through video-conferencing with other universities. The small groups also commented on each other's presentations in video-conferences. Overall, 59 % of the students that had registered for sections of the course completed it. The experiences of the first realization of the course were encouraging and motivated the continuing development of the course. The learning tasks for the next realization of the course in the autumn 2002 will be developed to become problem based and the guidance for students will be further increased.

Conclusions

The operations of the CMP are in their initial phases and the modes and means of action are still being created. The objective in the future is to firmly establish its activities and the status of the unit. Information and communications technology is developing quickly and it enables new forms of realization for the development of teaching and study. Finland, and especially Lapland, is a sparsely populated region with long distances between
places, so flexible opportunities for study are necessary in order to expand the possibilities for participation in training. The preparedness of teaching staff for the educational use of information and communications technology is growing and the attitudes that accompany it are becoming more positive. The increase in research knowledge for the educational use of information and communications technology supports the development of teaching more than ever before to correspond to the needs of the student.

A Case Study on the Use of Video Teleconferencing to Study Geography at the United States Air Force Academy: Lessons Learned

Barbara Rusnak

Introduction

As some instructors have discovered, guest speakers can greatly enhance courses (Davis, 1993). Guest speakers can provide expertise and special skills that courses' instructors may lack. However, it is not always feasible to get a guest speaker to the classroom, given geographical separation, travel expenses, time constraints, and conflicting schedules. Video teleconferencing (VTC) helps bring speakers to classes as moneysaving and timesaving alternatives.

VTCs link geographically separated groups with two-way audio and visual displays, providing synchronous connectivity. With synchronous connectivity, both ends of the connection have television monitors with speakers, enabling them to see and hear each other nearly simultaneously. This connectivity enables interactivity and provides both ends with immediate response and feedback.

My interest in VTCs began when I developed a new course at the United States Air Force Academy (USAFA) on the geography of the British Isles. Believing it was important for cadets to experience the cultures and other geographical aspects of the region, I decided a VTC would be an interesting, educational learning experience.

I felt a VTC would be a valuable supplement for a cultural geography lesson because cadets could interact with people from the distant culture. Davis (1993) recommends enhancing courses by augmenting them with speakers from diverse ethnic communities. My intention was for the cadets to observe the linguistic, ethnic, and sociological differences during the interaction. Conducting a VTC was more cost effective than sponsoring a guest speaker to fly over from the British Isles. The results of the VTC were promising and cadet interest was high. This paper focuses on the lessons learned from the use of this technology in the course and provides some suggested guidelines for its effective use.

Conducting the VTC

The VTC was performed with Dr. Gerald Mills at University College of Dublin (UCD). The focus of the session was on Irish culture and politics. We devised a lesson that would give cadets an opportunity to talk with and ask questions of himself, a geography instructor, and two undergraduate students in their final year at UCD. The objectives of the lesson were for the cadets to understand the cultural differences between them and the Irish subjects, know the current events that shape the lives of the Irish, and understand the role that politics has in Irish culture. Cadets were tasked to read The Irish Times prior to the VTC to get a flavor of Irish culture through the current events and local interest articles, editorials, and advertisements. In addition, the cadets were instructed to prepare questions based on both the readings and their intellectual curiosity.

Dr. Mills prepared a 10-minute presentation to begin the session, which centered on his view of the readings in the newspaper. The remainder of the session was an open question and answer session, with both cadets and UCD students asking questions of each side.

USAFA is fortunate to have a high-tech VTC lab with an excellent staff to maintain and operate it. We held the session in the lab, connecting our students with the Irish panel. Each side of the connection had two monitors—one with a view of themselves and the other with a view of the other end of the connection. Microphones were on desks, making audio communication simple and clear. As this session was the first VTC for all involved, I asked a colleague experienced with VTCs to begin the session by providing a four-minute PowerPoint lesson on VTC protocol (communication techniques). My colleague discussed time delays, background noise, speech
delivery, and visual limitations. Participants on both sides then introduced themselves and the session proceeded as planned.

Lessons Learned

I went into the session blind, having neither previously conducted a VTC nor studied the background on procedures and techniques. I thought it important, however, to evaluate this attempt with the VTC process and prepared a questionnaire based upon one created and used by Heckman, Whitford, & Lawyer (2000). The cadets each completed a questionnaire anonymously. In the future, I will administer the questionnaire to all participants, not solely students, to capture all perspectives. The cadet comments revealed that some aspects of the session went well, while others areas needed improvement. Following is a synopsis of the results of the questionnaire in which a score of “1” is “strongly disagree/no value” and a score of “5” is “strongly agree/great value.” The data is limited, as there were only six cadets in the class. However, there was consensus among most of the cadets, as many provided similar answers to questions.

One of the major benefits of using the VTC as a learning tool is the visual picture that helps create a human connection. Extolling the virtues of the use of video in geography classes, Gold (as cited in Gold et al., 1991) states that “sight is of prime importance in human sensory perception” (p. 15). VTCs especially aid those who are both aural and visual learners, as long as effective visual aids or gestures are used. For example, talking heads do not enhance the visual portion of the session.

When asked if they thought the session was valuable in gaining insight into the geography of the region, the cadets gave an 86.67 percent approval rating (4.33 mean score). One cadet commented that linking to the panel at UCD was “better than just reading a book.” I could not have provided the same learning experience for the cadets had I been the sole instructor of the lesson because I have never lived in Ireland and could not share the same thoughts and feelings as did the Irish subjects. I could have accomplished the objectives through means other than a VTC—assigned readings, in-class discussions, presentations, or group activities, for example. However, the real-time audio and visual exchange provided more insight and left us with a more lasting impression of Irish culture. Online chats, email exchanges, and telephone conferences can be useful in exchanging information, but they lack the ability of the VTC to present a nearly face-to-face lesson and provide the two-way visual interface. The VTC provides the nuances (language and mannerisms) that are particularly important in the realm of cultural geography.

There are some limitations in conducting VTCs. There are constraints on days and times you can connect. With the popularity of VTCs, instructors are increasingly using the facilities. There are also limitations to the times that the lab is open and support staff are available. Due to the time difference between USAFA and UCD, we were unable to conduct the VTC during our class time and had to deconflict student schedules to find a good time.

Thanks to my colleague’s guidance and the assistance of the lab manager, there were no glitches in the session. Once the connection was made with UCD, we found the VTC to be very user-friendly and maintenance-free. Cadets commented that the session “seemed quite natural,” “ran smoothly,” and was “relaxed and flowing.” Cadets gave the format a 73.33 percent approval rating (3.67 mean score).

All of the cadets noted that the key factors in making a VTC successful are the preparedness of the students and the quality of the speaker(s). For example, those who had studied the material and prepared possible questions before class enjoyed the session much more than those who had not. The two who had not prepared questions commented that they wished they had. They also claimed that an instructor who is uninteresting in one delivery format will most likely be just as uninteresting in another setting.

One of the most significant ideas that I developed as a result of our VTC was that a VTC can only be as effective as the instructor or facilitator can make it. Many of the same methods that are used effectively in a VTC (e.g., active or problem-based learning) should be similarly effective
in face-to-face classes. Mishra (1999) states that "most learning theories suggest[s] that for learning to be effective, it should be active" (p. 243). Conversely, many of the same methods that are not as effective in a VTC (e.g., traditional lecture) should be less effective in face-to-face classes. If the VTC had consisted solely of a lecture by Dr. Mills, the cadets would not have appreciated or learned as much from the session. The same can be said of a face-to-face class. Therefore, the major benefit of a VTC versus a face-to-face class, in this scenario, is the ability to reach out to a native and an expert. The cadets would have experienced nearly the same learning experience if the panel had appeared in person in our class, however, that luxury wasn't financially or logistically possible. In this case, the VTC was the technology that allowed us to connect and create a positive learning experience.

Although cadets emphasized the benefits of seeing visual images of the other participants, visual aids could have been used to make the session even more valuable. The visual aspect of VTCs is one of the key areas that should be exploited. Photos of Ireland would have further enriched our discussion of culture through examples of the architecture, landscape, and human subjects from the area.

For a course focusing on a region so geographically separated, the VTC was particularly effective in that it allowed cadets to ask questions of and exchange information with students of their own age and to observe a few of their cultural traits first-hand. In that 50-minute session, the cadets observed the Irish subjects' language, dialect, appearance, dress, and mannerisms, which are all aspects of cultural geography. The Irish subjects also shared some of their thoughts and feelings on subjects ranging from college life to terrorism, which helped paint a picture of Irish culture. When questioned about the value of interacting with the Irish panel, there was a 98.33 percent approval rating (4.83 mean score). Five of the cadets wrote comments similar to one, who wrote that it was "great to get a current perspective from native Irish students" on current events affecting Irish culture. The sixth cadet wrote that the interaction with the instructor was good, but that "the students seemed indifferent and unprepared". A better approach may have been to pass along prepared questions to the Dubliners prior to the session to better prepare them. Cadets also noted that listening to the panel was "much more interesting than [listening to] speculation of non-natives". Most cadets were well prepared and asked questions that could be best answered by the panel. For example, one cadet asked the Irish students how the conflict in Northern Ireland impacted their daily lives and if the conflict was a daily topic discussed in coffeehouses or pubs. Their USAFA instructors could not have adequately answered this question.

Cadets agreed we should pursue using VTC technology in this and other courses at USAFA, with a 96.67 percent approval rating. This information was forwarded to USAFA’s instructor education office to possibly encourage other faculty members to use the technology in the future.

One cadet went so far as to suggest a specific course, comparative politics, which could benefit from the technology. Another cadet suggested that we use VTC sessions to interview subject area experts in performing research for papers and presentations. Given the expenditure of resources (time, personnel, and money) to conduct a VTC, it might be difficult to justify using the technology for such a limited audience and objective. Another cadet suggested that VTCs are more effective with small class sizes.

During his discussion of VTC protocol, my colleague informed us that one limitation of our connection would be that UCD had a slower baud (transmission) rate. Because of the slower rate, there would be a slight delay in transmission. He instructed us to begin a response to the other side by predicting and interrupting at the end of their question or statement. I found this to be as awkward as it sounds, although the briefing helped me mentally prepare for the limitation. There were pregnant pauses and interruptions on both sides. The situation improved, however, as the session progressed and both sides became better accustomed to the procedures. Although the delay was a bit awkward, the students thought the VTC provided them a valuable, interactive learning experience.
Many cadets did not find the introductory protocol briefing as useful as did I. They gave the briefing a 66.67 percent approval rating (3.33 mean score). Most commented that the briefing was useful, but based on common sense. They followed the guidelines fairly well throughout the session, providing comments such as "it ran smoothly, relaxed, and free flowing". One cadet commented that the briefing started the session out with a formal atmosphere and suggested instructors discuss the guidelines on their respective sides prior to the session. Given the lack of enthusiasm over the briefing, the suggestion is a good one, especially since it adds more time for achievement of objectives.

Suggested Guidelines

Although VTC technology has been used extensively for quite some time, it is not necessarily being used appropriately. Yes, quality equipment is an important component of VTC sessions, but "any successful program must focus on the instructional needs of the parties, rather than on the technology itself" (Muller, 2000, p. 225). Following are a few aspects of both technology and instructional methodology to consider when preparing for a VTC.

Instructors should become familiar with equipment operation. "Learners get more from the courses when the instructor seems comfortable with the technology" (Willis, 2001, Guide #1, ¶ 6). Communication checks should be performed prior to the day of the session and just prior to the session. Once participants are in place, microphone and camera placement should be checked, ensuring all participants are close enough to a microphone and camera angles are such that they center on the group. Some cameras can zoom and pan the room during the session (Video Development Institute (ViDi), 2000, Guide #2, ¶ 3).

Heckman et al. (2000) suggest that time and experience are necessary for instructors to become comfortable with this technology. They note that VTCs require more preparation time than face-to-face classes and that instructors must be more vigilant in monitoring the various aspects (equipment, students, and activities at each end of the connection) of the session. Hearnshaw's (2000) VTC discourse content analysis shows a marked increase in student interaction and, thus, comfort with the technology as a course progresses.

Visual aids are important materials to incorporate into VTCs, although they are not as easy to use as they are in face-to-face classrooms. Images are sometimes obscured or blemished through transmission. VTC equipment is available that allows users to incorporate high quality visual aids into sessions. The New England Medical Center has a camera that allows them to view x-rays in real time. Using this type of equipment can greatly increase the overall quality of the session, as it can provide clear, professional images. Demonstrations, experiments, and videos can help enhance the VTC as well. Regardless of the tools and methods used, they should be tested in the lab prior to the session to ensure connectivity and quality. As with face-to-face classes, images and other products should be accurate and large enough for participants on both sides to see clearly.

At the beginning of the session, all parties should be given a short briefing on VTC protocol, unless they have all participated in and are familiar with this type of session. ViDi (2000) highlights several protocol items to help ensure a smooth-flowing session. Unnecessary movement should be avoided, as it can adversely affect (break up) both audio and video, particularly on lower quality systems. Proper etiquette used in face-to-face classes, such as maintaining eye contact with the speaker and avoiding personal conversations, is even more important in VTCs. "Side conversations at remote sites seem to spring up more readily that they would if everyone were in the same actual room" (ViDi, 2000, Etiquette section, ¶ 5). These side conversations are disrespectful in any setting. In a VTC, however, these distractions add unnecessary noise to the session, causing disruption and moments where sometimes no one can hear the conversation at hand. To compound the problem, open microphones placed around the room allow these conversations to be readily picked up by the other side. Instructors must constantly monitor the session and discretely put a stop to all personal conversations.
Cultural differences are of particular concern in VTCs connecting people from different countries. Cultural sensitivities should be discussed and stressed prior to the session to avoid offensive comments or gestures. Willis (2001) states “that students may have different language skills, and that humor is culturally specific and won’t be perceived the same way by all” (p. 5). We experienced this in our VTC, as a couple of the jokes that the cadets made were not understood by the Irish panel. Although there was no offense by either side, the jokes created uncomfortable pauses while the panel attempted, unsuccessfully, to comprehend the jokes.

Finally, participants should be briefed on the limitations of the equipment, such as transmission delays. This can help reduce awkward silences. It is no easy task, however, and does take practice. In our VTC, participants began to better anticipate the other side and silent periods were reduced toward the end of the session.

Our geography class consisted of only six cadets. VTC sessions should limit class size in accordance with seating and equipment limitations. If we had more than 14, there would have been difficulty getting all cadets within an effective range of the speakers and camera. As with face-to-face classes, successful discussions are much easier to conduct in relatively small groups of approximately six to twelve each. Bates (1995) claims that “the opportunity for any individual to participate in questioning or discussion decreases in proportion to the number of students viewing a live interactive programme” (p. 101). Small class numbers are essential when conducting interactive VTC sessions. The classes should not be too small, however (much less than six), or the opportunity to share multiple perspectives is reduced.

Instructor presence during VTC sessions is necessary. VTCs are not television programs or films for students to sit and watch inactively. Without guidance from the instructor, students can stray off of the topic and are more easily refined in their participation. Students are more compelled to participate under the watchful eye of their instructor. In addition, an observant instructor can analyze participants’ non-verbal cues and refocus or redirect the session. Because of transmission delays and varied levels of participant comfort in conducting VTCs, instructors should plan to cover fewer objectives in a VTC than in a face-to-face class. (Willis, 2001).

Many VTC guidelines stress an avoidance of pure lecture. Mishra (1999) concludes, “teleconference is a medium of sharing rather than lecturing” (p. 247). A sharing environment is one that promotes interaction between all participants rather than unidirectional instruction. Willis (2001) suggests an instructional design for VTC lessons to stimulate student learning through diversity of activities. McKeachie (1994) recommends that students prepare critical questions when a guest speaker is featured. Questions help encourage human interaction and help students with the relevance of covered topics.

Evaluations should be administered immediately following any VTC session. There is not much literature on VTC evaluations. However, Hearnshaw (2000) suggests an objective method for evaluating the learning processes of VTCs. In his evaluation, he assigns codes to types of questions and comments made by students. These codes are based on the depth of discourse and the learning types (cognitive vs. affective) involved. The results are then used to determine the progress of student learning throughout a series of VTCs. The difficulty in applying his approach is that it was designed for a distance education course using desktop videoconferencing where all participants (students and instructors) are geographically separated. Applying the approach to two-way VTCs that take place in classroom settings must be evaluated. The contrast between the desktop and classroom settings could produce dissimilar results, as students in desktop videoconferencing may perform and react differently than they would in classroom VTCs. The perception of anonymity may enhance their readiness to participate more freely and critically in the desktop setting.

Finally, instructors should have all participants, not solely students, complete a questionnaire. The lessons learned can be extremely beneficial for future VTC attempts, as I discovered in our session.
Conclusion

In courses such as geography, where the experts (native, empirical sources) are at such a great distance, it is not often possible to physically connect students with guest speakers. The current global crisis surrounding the threat of terrorism may even reduce the opportunities to physically connect, as people fear public transportation. The VTC is a fitting alternative in such cases. Instructors need to provide clear, structured guidance to both students and speakers prior to the session and should follow the aforementioned guidelines. In order to promote the effective use of this technology, institutions must support faculty by providing training and development programs and quality services. VTC sessions are not the answer to every situation and cannot replace the use of in-person instruction, but they are wonderful alternatives when needed and used appropriately.

Higher education, including teacher preparation programs, is rapidly becoming technology-based. Educational Technology (ET) is expanding opportunities for effective learning, penetrating into both campus-based and web-based curricula. ET offers the means to improve the quality of teaching and enhance learning. However, along with the numerous potential benefits, it brings new problems and complications. One of the counter effects of increasing technology dependence is a growing distance divide, both physical and social, between students and instructors in today's education that is grounded in the paradox of contemporary social life and technology.

A similar picture can be seen in strictly pedagogical terms. Nowadays education is (or at least, should be) unequivocally learner-centered. Learning, we believe, in order to be efficient, needs to provide the learner with a multiplicity of options of customized reality-based curricula. Nevertheless, due to some social and technological factors, among them the rapidly spreading use of information technology (electronic media in general and online education in particular), learners are becoming increasingly distanced from their schools and instructors. Reality-based experiences seem to disappear from the instructional process as the learner becomes more and more divorced from hands-on practices. This leads not only to the growing divide between the key participants in the educational interaction but to the disappearance of the teacher as a role model from the student's perspective as well. Moreover, it is not only the teacher's personality that may well become obsolete in online education (as classes are taught mostly by merely sharing text files), but also life and professional experiences that the teacher brings to class may become lost through text dominated technology. It becomes vital to preserve "human dimension" in a technology-based learning environment (Serdyukov 1999). In our research we address important pedagogical issues attempting to bridge the physical and social distance emerging in online education by capturing and bringing reality-based experiences straight to the student's computer.

In various methodology classes comprising, together with foundational courses, undergraduate as well as postgraduate preparation teacher preparation, e.g. "Methodology for Second Language Instruction", there is an inherent need for reality-based visual approaches to classroom practices. It is only through visual representation of reality-based situations that a student can attain a truly comprehensive teaching model as a premise to develop their own instructional techniques. In terms of online classes which purport to teach a methodological approach we posit this solution set: visual presentation of the instructional content through Streaming Video (SV). The rationale is straightforward. You cannot fairly ask a student to efficiently demonstrate an approach without the antecedent of a competent presentation. In other words, for methodology classes visual expert presentation precedes actual student demonstration. The pedagogic focus of online teacher preparation is, after all, on how to adapt and transform traditional teaching practices and the content of courses to include students for whom the traditional onsite practices and interactions are
restricted due to the nature of their distance learning. In teacher preparation it is imperative to find ways and means to compensate for the lack of real-life instructional situations.

The infusion of SV in online education is based on the situated learning model (Lave and Wenger 1991). It is not so much that learners acquire structures or models to understand the world, but they participate in frameworks that have structure. Learning involves participation in a community of practice. (Cit. from Smith 2001) In other words, the complexity of the online course should not be on the screen but in the interaction between a student and the instructor (Ryan 2002).

To create authentic experiential and reflective environments for learning, we can use a number of professionally made video materials, including special instructional videos, documentaries and even feature films. "Best practices" videos are one of the best resources for teacher preparation programs. However, often we cannot find the video that suits our topic or objectives. Then we can create one within our means, e.g. record our own video introduction to the course, videotape the lecture we are going to teach, or present a tape with a demonstration of some situation we want to use in classroom activities.

The advent of professor's video presentations leads us to a student-produced demonstration of a given methodological approach. The value of having the student send a video demonstration (new via mailed VHS, soon via video streaming) with age appropriate learners (after viewing a professor's chosen video presentation) of a discreet methodological approach cannot be underestimated. This kind of student produced video assignment is one that can almost never be replicated in the traditional higher education classroom where age appropriate students (5 to 17 years old) are simply not available. Thus, in a very special way, this highly documented approach takes us one step further in reality-based education. Clearly, online education, especially in a methodology class, engages the human element via video, which enhances the student's range of social and pedagogic skills.

There are several goals in using video. They are as follows:
- To deliver the course content (videotaped lectures and instructional video)
- To illustrate some points of the lecture presented orally or in a text format (video clips)
- To use videotaped materials for analysis and discussion ("Best practices" documentary and demonstrations video, students' videos)
- To offer visual reality-based models for a comprehensive view of practices which work best in today's classroom.
- To use videotaped material as an instrument for self-evaluation or assessment (students' self-video)
- To incorporate a more holistic (i.e. intellectual, social, emotional) dimension to classroom learning, spurring both cognitive and affective growth (feature film, videotaped demonstrations).
- To humanize the online class by presenting both the instructor and students in video format.

The advantages of a SV-based approach are not exclusive to online instruction. In fact, any traditional onsite class may avail itself of the SV reality-based benefits (e.g. working with age appropriate learners). This is to say that SV is as a hybrid tool which can be used in literally any instructional format. It is so because it adds a reality-based human dimension to learning. Students are best prepared for teaching when instruction brings the real world into the classroom.

SV is opening new opportunities for online education. It brings the human dimension back into students' learning - in a specific, technology-mediated format: students can now see their instructor on the screen, watch real-life situations like teaching practices that are used to prepare them for their own teaching. It enhances new content acquisition by combining the multiple modalities, text and image. It creates the platform for situated learning based on observing reality-based classroom situations. Finally, it permits students to perform actual demonstrations in real classroom with live students, allowing professorial feedback on a "hands-on" approach.

How Does Learner Transform Knowledge Through Hypermedia Authoring: A Case Study

Jeeheon Ryu
Department of Educational Psychology and Learning Systems
Florida State University
jjr7148@garnet.fsu.edu

Abstract: This case study was to explore how a learner transforms knowledge structure in hypermedia authoring. As a data collection method, think-aloud protocol, stimulated recall interview, and open-ended interview were used to examine the transformation process. The study revealed that the participant mainly used two distinctive cognitive processes to transform his knowledge: 1) top-down approach and 2) chunking strategy. Regarding top-down approach, the participant searched his knowledge structure to identify highest knowledge component; then it was followed from the highest knowledge component to organize it into hypermedia. Also, he used a chunking strategy in considering whether or not each piece of knowledge is appropriate for the chunk. Additionally the participant's thinking flow might be constrained with the authoring tools' function.

Knowledge Transformation in Hypermedia Authoring

Hypermedia Authoring

There have been some studies to explore the benefits of implementing hypermedia authoring, also referred to as students-as-multimedia-author, with two main premises. First, it is assumed that authoring hypermedia can provide learners high authenticity of a given task. Beichner (1994) insisted that learners regarded the work they were doing had importance outside of the classroom. Furthermore, learners showed that they were highly involved in the given tasks. High degree of learner engagement was found throughout the project (Lehrer, 1993; Lehrer, Erickson, & Connell, 1994).

Second, hypermedia authoring is assumed that it provides more opportunities of having learners develop sophisticated knowledge structure because they have to use multiple and linked mental representation to author hypermedia as a final product. Learners working with authoring environments outperformed than control group in terms of articulating and defending essay topics (Spoehr, 1993). Learners' knowledge structures became more sophisticated, their design skills emulated a cognitive framework and a problem solving process. As a result, their problem-solving skills increased and became more complex (Oughton & Reed, 1998). Similar result was reported that students in hypermedia authoring showed the increased cognitive process such as finding, interpreting, and articulating information and knowledge (Lehrer et al., 1994). These cognitive processes seem a promising advantage of hypermedia authoring.

In an effort to design an instructional material, a learner also has to reflect on his/her own knowledge in terms of transformation of an author's knowledge into a hypermedia product. In other words, learners need to refer to their structural knowledge in order to produce the given task. Along with this process, the learners in hypermedia authoring demonstrated high creative thinking (Liu, 1998). Additionally non-linear structure of hypermedia enabled learners to be more reflective (Koehler & Lehrer, 1998; Lehrer, 1993).

Cognitive Process in Hypermedia Authoring

There are various frameworks representing author's cognitive process during hypermedia authoring. For instance, it consists of collecting, organizing, and displaying information in a multimedia format (Nicaise & Crane, 1999). However they did not provide in-depth descriptions about what cognitive process should be
implemented in each phase. Moreover, there was no phase for revising or assessing the author's knowledge structure.

Unlike Nicaise and Crane's cognitive framework, Lehrer (1991, 1993) and Lehrer, Erickson, and Connell (1994) modeled a cognitive framework including evaluation and revision as (a) planning, (b) transforming, (c) evaluating, and (d) revision. Brief description was listed in the below.

- Planning the design of a hypermedia document involves deciding upon the nature of the problem and developing ideas about the overall structure of the document.
- Transforming is to modify information into knowledge. Knowledge is distinguished from information by its systematicity—a network of relationships that sustain one or more themes.
- Evaluation relies on designers' abilities to solicit feedback, which in turn relies upon their skills in articulating their goals and intentions to others.
- Revision requires multiple cycles of drafting and revision in order to make a successful product.

Moreover Oughton and Reed (1998) suggested a cognitive framework very similar to Lehrer's though they proposed 3 stages as 1) planning, 2) transforming, and 3) evaluation and revising.

**Summary of Hypermedia Authoring**

Planning plays a role as an initial step to locate required information; however, the identified information can be discarded depending on the author's decision when he/she transform and/or revise a hypermedia. Among planning, transformation, and revision, transformation and revision are more critical to produce an artifact as a final product in hypermedia authoring process. In this sense, transformation and revision will be a main activity, which learners involve in authoring hypermedia.

Therefore, main benefits of implementing hypermedia authoring may come from transformation and revision. By performing transformation and revision, learners modify and adopt their knowledge structure as an artifact, hypermedia. However, little is known about specifically focusing on cognitive strategies of transformation and revision.

Indeed the previous studies have loosely authenticated how learners use the authoring tool for their project. For instance what functions would be effective on learners' authoring is not identified. More specifically this question is to identify key components of developing ideal authoring tools. It is assumed that if there are distinctive learning process or pattern they can be applied for developing an authoring tool.

**Research Questions**

This study was focusing on examining how the learner transforms own knowledge into hypermedia authoring. The purpose of this research was to identify cognitive strategies with hypermedia authoring and to explain how he/she transforms knowledge to develop hypermedia. In particular this study will examine 3 questions; 1) How did the participant plan for the authoring tool, 2) What features of the authoring tool did the participant use, and 3) How did the participant use the authoring tool.

**Method**

**Selection of Study Participant**

In order to select an appropriate participant of this study the following criteria were used: a participant of this study should have (a) a familiarity with a given subject matter and (b) knowledge of instructional designing or experience of developing instructional materials. The first requirement is strictly related to the purpose of this study. It was to explore knowledge transformation process in hypermedia authoring process rather than knowledge acquisition. Knowledge transformation process is a manipulation of already acquired knowledge. In order to meet this purpose, it was necessary that a participant was knowledgeable to a given content. Second, knowledge of instructional designing or experience of developing instructional materials was
also required for a study participant because hypermedia authoring requires designing skills of developing instructional material.

The Participant

One participant was selected with fulfillment of two criteria described above. The participant, Chris (a pseudonym), is a first year doctoral student who has enrolled in a doctoral program of instructional design at a southeast public university. Chris took two courses related to instructional design theories. He was regarded as an intermediate instructional designer with satisfying the second criteria of selecting a participant of the study. Regarding the first criteria of selecting a participant, one of the classes, which Chris was taking, was selected as a subject matter. The selected class was about theoretical studies of learning and cognition for graduate students.

Materials and Tasks

The selected material is about Ausubel’s meaningful reception learning (Driscoll, 1999). Thirty concepts were selected, and they were developed in a printout material as well as a digitalized format as a package. Each concept was called as a slide, and one slide contained only one concept. All slides were text-based format without any graphics or charts. The slides were sorted in an alphabetical order. The following 6 sequential tasks were assigned to Chris.

1. Rating Slides with 5 Points Likert Scale: It was given to verify whether Chris was familiar with the given material. 5 points Likert scale was used from 1 point with very-well-unfamiliar to 5 point with very-well-familiar.

2. Practice of the Authoring Tool: After rating the given package, Chris was asked to practice using the authoring tool. He was able to use the authoring tool without any problems in a given two trial.

3. Practice of Think-Aloud Protocol: It was the first time of performing think-aloud protocol for Chris; hence, practice of performing think-aloud protocol was needed. This task was conducted during the second trial of practicing the authoring tool. The researcher asked what he was thinking to prompt his think-aloud. During this practice, the following sample questions were used. Why are you selecting the slide? Are you looking at that slide? What are you thinking the relationship between the slides? What does the line mean?

4. Authoring Hypermedia: Prior to authoring hypermedia, planning session was given as proposed in the previous studies. In order to visualize Chris’ planning process, a blank paper proved to draw a planning map of how each slide will be connected and what would be master or non-master slides. It was also asked to draw links. After completing the planning session, Chris rearranged and linked the given set of slides by using the authoring tool.

5. Evaluating and Revising the Developed Hypermedia: The final product was created; then, Chris was told to evaluate and revise the developed hypermedia. He looked through all master slides and linked slides to revise whether there are non-logical sequences. This phase was given to Chris to verify his initial plan for authoring. Then he revised the first planning map and re-authored the authoring tool.

6. Concept Mapping: At the end of all tasks, Chris also was asked to make his concept map about the content without consideration of implementing the content to the authoring tool.

Authoring Tool

An authoring tool was developed for this study by using Toolbook version 5.0. The authoring tool had a function of rearranging the given materials. Composing, editing, and managing multimedia objects were not implemented to this authoring tool. The authoring tool contained slides, and each slide contained one concept of the subject matter. The user was able to rearrange the order of slides by selecting slides.

Data Collection

This study employed three ways of collecting data; an observation with think-aloud, stimulated recall interview, and open-ended interviews. These methods were to gain unbiased observation, to increase credence in the interpretation, and to demonstrate commonality of an assertion for data source triangulation (Stake, 1995). For the observation the researcher videotaped each reviser’s utterances, and interrupted as little as possible, except to answer direct questions from the participant, to offer expressions of support, and to give Chris prompts to keep continuing thinking aloud. With videotaping, the researcher took notes for stimulated
recall interview, which was conducted at the end of all assigned tasks. The stimulated recall interview was to investigate particular utterance or behavior observed in his authoring process during think-aloud protocol. The notes were used to stimulate Chris’ recall. Finally all examines were ended with the open-ended interview.

Findings

The participant’s rating of the given slides with 5 points Likert scale showed that 17 (57%) slides were rated as very familiar, 12 (40%) were familiar, and 1 (3%) was just familiar. It indicated that Chris was so familiar with all given thirty slides.

How did the participant plan for the authoring tool?

Observation with think-aloud protocol and stimulated recall interview showed that Chris was trying to follow his knowledge structural of the given content in order to establish main structure. In this process he mainly used two strategies: 1) top-down approach and 2) chunking strategy.

Regarding top-down approach, he tried to identify which slide could be the highest concept. After setting several highest concepts, Chris narrowed down from them. During identifying the highest concepts, he compared slides in terms of hierarchical structure. The following excerpts represent protocols from think-aloud and stimulated recall interview.

> Let’s see this slide is conceptually higher than number 5 (each slide had its unique identification number)...Oh! It is right. That slide (number 5) is definitely lower than this slide. Then which one can be equivalent with this slide? (Chris is shuffling slides to find another one.) I got it (picking up another slide). I need to make sure if these two slides are equally highest one.

Top-down approach is a conceptually driven processing guided by information already stored in memory. This process screens structural knowledge from higher level to generate expectations and hypotheses relating to the interpretation and evaluation (Eysenck, 1990). It supports that Chris was already familiar with the contents; hence, he did not need to figure out the concepts. Rather, as an author, he tried to establish key structure that can be easily conveyed to target audiences. To accomplish the cognitive task, he compared the given slides with considering how the slides were related to each other. In other words what he was seeking were procedural knowledge in terms of reflecting on each slide’s relation. It can be supported from the result of Nicaise and Crane (1999) showing that all students reported having learned procedural skills.

Another strategy mostly used in planning stage was chunking strategy. Chris spent more time to determine whether which slide could be chunked in a particular highest concept. More cognitive efforts were made to chunk with the same conceptual structure. As a result, he created four key chunks, and each key chunk consisted of from 4 to 9 slides, and it was well-structured one. Regarding the total number of slides of the given package, each chunk contained from 13% to 30% of the total slides. The percentages of each chunk were relatively high in terms of total numbers of slide. This feature is consistent with the study supporting that hypermedia authoring increased number links within the same concept (Reed & Rosenbluth, 1995). During using chunking strategy, Chris applied two criteria: 1) degree of contiguity and 2) sequence within the same chunk. The following from think-aloud and stimulated recall interview proves what criteria he used.

> I think that number 10 (slide’s number) is closer to that slide rather than this one. Is it correct? (Picking up another slide). This one should belong to that category and it won’t be a problem. Still this slide is unclear. Um... Although this slide has different title (for that reason he is confused), I bet it is closer to this category. [From think-aloud protocol]

> Actually I got confused because that slide could belong to another category. However, I thought that I should decide one category. Sometimes deciding only category was not easy decision, but it was very important. If I made a wrong category (chunk), my students might have misunderstandings. Just I wanted to prevent that kind of situation. [From stimulated recall interview]
Um... Which one should be a first one? This one or that slide? Let's see... This should be place in advance, then that slide should be second one (Two slides were already categorized into the same chunk). [From think-aloud protocol]

What features did the participant use the authoring tool?

Regarding the difficulties of using the authoring, there was no problem and any confusion for Chris to rearrange and link the given slides. He could finish authoring itself very quickly. In fact, using the authoring tool would be easier to use than the other authoring tools due to the restricted function of the authoring tool of this study.

Although the authoring tool was so easy to sue, the think-aloud protocol and open-ended interview disclosed potential problems. Chris was in troubles of presenting some slides that did not have a hierarchical structure. This problem might come from the navigation methods of the authoring tool based on linear ways of rearranging the given slides.

It may not be a right way of putting this slide. However, this authoring tool just has linear-way of presenting information. How can I compromise this problem? [From think-aloud protocol]

Sometimes it was hard to prioritize slides when they do not have concrete hierarchy. In addition, the authoring tool was based on linear navigation though it had a function to link related information to any master slide. I think that if you add some function of showing non-linear relationship between more than two slides it would be much better way to convey my concept mapping on the hypermedia product. [From open-ended interview]

The discrepancy between the picture of planning step and concept mapping supported that the observation and suggestions from think-aloud protocol and open-ended interview. In the planning step he draw a very linear fashioned picture in both of initial and revised plan. However, his concept mapping showed non-linear directions and dynamic relationships between any single concepts. It may come from difficulty of making appropriate technique representing learners’ knowledge structure. Although representing learners’ knowledge structure is very important, finding the technique is very challenging (Jonassen, Beissner, & Yacci, 1993).

It may reflect that functions of authoring tool can be a constraint of organizing knowledge. In this study, as mentioned early, the authoring tool was designed to produce linear based hypermedia by rearranging the given slides. For this reason Chris needed to fit the authoring environment. It suggests that various ways to represent different characteristics of knowledge should be considered in designing authoring tools.

How did the participant use the authoring tool?

Revision process was pretty simple because of the simplicity of the given authoring tool. Chris still employed the same criteria (degree of contiguity and sequence) used in the planning step. Most processes he performed were very similar to those of planning step. However, it may not reflect cognitive process associated with actual revision because this study did not provide any feedback to Chris. In other words, his revision was based on self-evaluation. In general revision requires interactions with audiences in authoring hypermedia method with specific feedback.

Implications

There are two implications from this study. Firstly, Chris evaluated the information in terms of hierarchical order. It reflects if an authoring tool has a function to evaluate value of information the user can easily organize information into knowledge structure. In addition, this function will be helpful to chunk the information in terms of the degree of importance within the same chunk.

Secondly, this study suggests that an authoring tool should indicate multiple relationships between information. Due to the linearity of the authoring tool, Chris was not able to connect certain information with another chunk if the knowledge did not belong to the chunk. It was a hard decision for Chris to make a decision to link information with a single indicator. For instance, some information may be connected into another
information in multiple ways such as prior, currently related, or advance knowledge. These multiple layers of indicators showing types of knowledge can be represented with different colors within an authoring tool.

Children's Participation in the Design of an Interactive Encyclopedia: An Exploration of Cooperative Inquiry

Bonnie Sadler Takach
Department of Art and Design, University of Alberta
bbs@ualberta.ca

Sally Brenton-Haden
Department of Educational Psychology, University of Alberta

Abstract. Today's children are discerning consumers of learning media in an interactive world. They explore computer programs and on-line environments at home and at school for different purposes, use many different learning strategies and develop perceptions about the usefulness of various types of interactive media. In this study, we consulted with five children in Grade 5 to explore their experiences learning with interactive reference media, and to document their participation in the development of a rapid prototype for an interactive encyclopedia. We explored qualitative methods synthesized from the disciplines of educational psychology and information design to study how and what we can learn from children's educational experiences with interactive media.

Introduction

Children are active learners who interact with teachers, fellow learners and educational media, to actively construct their knowledge of the world. Their opinions, insights and interpretations of their experiences are invaluable to the development of effective learning tools.

Approaches to studying children's learning with interactive media and their participation in the design of interactive media bridge disciplines, encompassing ideas, theories and practices embraced by constructivism, constructionism, user-centred design, participatory design, cooperative design, design-centred learning, collaborative learning and cooperative inquiry. In bridging the disciplines of educational psychology and information design, we may coordinate, synthesize and strengthen our approaches to the design of effective educational media. Educational psychology brings knowledge of how children learn and how to apply this knowledge effectively in learning situations. Phenomenology offers a relevant, practical approach to explore the experiences of learners with interactive media. Data analysis consists of deriving general or universal meanings from individual descriptions, to gain the essence of the experience. Researchers must bracket their own biases (Creswell, 1998). Information design stresses a socially responsible, user-centred focus to the design of educational technology and media. In the emerging culture of participatory design, the user becomes a proactive participant in the design process (Sanders, 1999).

In this study, we explored appropriate methods to study children's participation in the design of interactive educational media and how can these experiences inform the design of interactive learning media. Cooperative inquiry (Druin, 1999) is a design approach to creating new technologies for children, with children, and involves discussion and hands-on working groups in the rapid iterative creation of prototypes. This approach has been adapted from the methodologies of cooperative design, participatory design and contextual inquiry. Participatory design processes have generally involved adults, but cooperative inquiry employs intergenerational teams. We consulted only with children as learners, users, experts, researchers and designers to find out what kind of interactive encyclopedias would be useful and usable for them. We focused on the process of the cooperative inquiry, rather than the outcome (a prototype of an interactive encyclopedia).
Method and Results

Five Grade 5 children, aged about 10 or 11 years, were chosen at random by their teacher, and participated in three sessions for a total of two hours over three days. During the first, 30-minute individual session, participants searched for lemmings and ptarmigans, using a think-aloud protocol, and responded to structured interview questions about the design and use of interactive encyclopedias. During the second, 30-minute group session, five participants responded to semi-structured interview questions about their experiences in the first session. They were also asked to comment on how CD-ROM encyclopedias should be designed to help the user find information. Finally, during a 60-minute session, the five participants worked collaboratively to design a rapid paper prototype of what they considered to be an effective CD-ROM encyclopedia in the form of sample ‘pages’. Comments were noted, and the working process was documented with sketches and photography.

What are appropriate methods to study children's participation in the design of interactive educational media? Any methods that can directly and actively involve children as consultants are valuable. These methods may need to be adapted from bridging disciplines, and to determine their usefulness. How can these experiences inform the design of interactive learning media? These experiences can be analysed to find common themes that would support the development of guidelines for design. For example, participants were quite aware of how information can be presented effectively, and wanted to see all images next to elated text. They were able to judge features that provide easy navigation to get at desired information. The students were quite concerned with appropriateness of features and their functions ("no weirdo stuff," must be "easy to understand if you don't speak English," must have "access for all ages" and we should "add voice button, in case people can't read"). They felt that the search function should be easier to use, and they surprised to note that they had trouble using the help function. The children found it "frustrating to work this quickly" during the design activity, and wanted to continue the task to use authoring tools to design an improved interactive encyclopedia. They incorporated into the design of the prototype what they considered to be essential functions: search function, back button, bookmark and a place to store notes and documents. This group was highly effective at working together to organize their materials and process in a short time period. They demonstrated flexibility and innovation in thought and action, possibly learned from experience in problem-solving and group work.

Conclusion

Children's insights regarding the effectiveness of such media, and their participation in its design, are essential to developing learning materials that are best suited to their needs and interests. Synthesizing research methods promises to be beneficial in designing studies that involve children in cooperative inquiry, as consultants, researchers and designers in developing interactive learning tools. Being involved in this type of research-based, design-centred learning was enjoyable and beneficial for the participants. We would like to continue to study the design process with children, and would like to move to the next step of authoring technology so the participants can see some of their ideas in action. Further research could involve the development and evaluation of an interactive encyclopedia incorporating the guidelines outlined by the child designers, in comparison to a commercial product.

Abstract. In many jurisdictions, the use of computer-based learning tools is endorsed at a curricular level. Looking at how children search, select, organise and visually represent information can challenge our assumptions about learning and technology, to guide the design of effective learning tools. We report on the preliminary findings from a study involving 43 Grade 5 students designed to explore the effect of information presentation in print and CD-ROM encyclopedias on children’s retrieval of information and design of research posters. We outline the effects of prior media experience, topic knowledge and attitude towards using interactive reference media to do research. Children may come to a research task with flexible strategies and mental models. Ease, convenience and speediness of use, and the availability and relevance of different types of information appear to be at least as important as the presentation of information.

Introduction

In our visually-oriented world, children learn with computer technology and interactive media, encountering different types of information presentation and using different strategies to respond to research tasks. Just providing children with technology does not necessarily increase learning. Well-designed, user-centred interfaces facilitate children's information-seeking (Zammit, 2000; Bilal, 2000). The presentation of information may influence children's use of these learning tools. Even the way a computer program is constructed influences the search strategies chosen by the user (Zammit, 2000). Due to "shortcomings in design and research the potential of hypertext/hypermedia for enhancing learning may have been underestimated" (Tergan, 1997, p. 209). Crook suggested that studies that evaluate academic performance may fail to investigate how media is used for research, synthesis and investigation. In our learner-centred study, we integrated methods in developmental science, instructional technology and information design to study how information presentation in print and CD-ROM encyclopedias affects children's retrieval and visual representation of information.

Study Method and Results

Forty-three Grade 5 children, aged about 10 or 11 years, participated in this study using the Junior print version of the Canadian Encyclopedia, and a Macintosh PowerBook laptop computer displaying the starting interface for Student CD-ROM version. In individual sessions of 30 minutes, using a think-aloud protocol, randomly-assigned participants searched for information about lemmings and ptarmigans using both encyclopedias, and sketched a small poster to show the life cycle of each animal. Participants then
responded to semi-structured questions about their experience using encyclopedias, topic knowledge and attitudes towards searching for and presenting information.

Results and Discussion

All participants reported some prior experience with encyclopedias (print, 88%; CD-ROM, 77%; on-line, 21% and with the Internet (95%). Over half (56%) of the participants preferred the CD-ROM version (print, 28%; no preference, 16%). The print encyclopedia was "more hands-on" and "gives more information." The CD-ROM version was "easier to read" and "easier to find [the topic]" since "you can type in what you want and it takes you there with no page-flipping."

On average, participants spent almost twice the amount of time to search the CD-ROM encyclopedia (7.0 min) as the print version (3.3 min). Some participants suggested that the CD-ROM encyclopedia was not well designed, as it wasn't clear where to type in a search term. Even children with previous media experience were temporarily confused. Difficulty with navigation, increased options or motivation to explore may explain the difference in time.

On average, participants spent about the same amount of time to create posters after the print version (9.1 min) as after the CD-ROM (8.7 min). This may support children's having prior mental models of how to present information in research reports. Comparing features found in posters and in encyclopedias yielded only two features of significance: the use of comfortable margins and the inclusion of paragraphs or paragraph-like chunks of textual information. Comfortable margins are found only in the print encyclopedia, and paragraphs were found in both encyclopedias, so it difficult to find a direct effect of information presentation. Throughout the study, participants focused on the need to have easily accessed, relevant, readable information, with images close to related text.

Almost half (42%) of the participants included "life cycle" through a variety of layouts using diagrams or words in their at least one of their posters, although there were no life-cycle diagrams or textual descriptions for either topic in either encyclopedia. This suggests that they may have had a prior mental model about how life cycles could be visually represented. Indeed, students commented that they had learned about animal life cycles in science classes in earlier grades.

Conclusion

Children may have flexible learning strategies and may fit new information to pre-existing mental models. Ease, convenience and speediness of use, and the availability and relevance of different types of information appear to be at least as important as the specific arrangement of the information. These findings have implications for research-based design. We must challenge some of our assumptions about the design of learning tools. Studying the learner provides a powerful opportunity to focus not only on information presentation and other aspects of design, but on learners’ motivations, preferences and learning strategies, which are critical factors affecting the optimal design and use of learning tools.

Abstract: Learners taking an online course often develop implicit expectations as to what they can expect from traditional classrooms. The purpose of this study was to determine student expectations of an online collaborative learning environment, as well as to examine how students adjust their expectations when the course ends. The results from an online survey indicated that student expectations before taking the course and after the course are different. Overall, the students raised their expectations at the end of the course, except for their expectations of the instructor and the level of effort and convenience. In addition, students significantly gained more understanding of an online learning environment after the course was completed.

Introduction

Learners construct their own meaning based on the beliefs, understanding, prior knowledge, and cultural practices they bring to class (Bransford, Brown, & Cocking, 2000). With prior knowledge formulated in traditional classroom settings, learners taking an online course often develop implicit expectations and faulty expectations as to what they can expect based on their prior experience in traditional face-to-face classroom instruction (Bigelow, 1999). It is believed that a deeper understanding of students' initial expectations of online learning may be helpful in addressing the erroneous expectations leading to a higher success rate with novice online learners. As a result, the goals of this study are to determine student expectations of an online collaborative learning environment, as well as to examine how students adjust their expectations based on a one-semester experience.

The Study

The participants of this study consisted of seven voluntary graduate students, six females and one male, enrolled in a graduate Web-based course on Computer Supported Collaborative Learning (CSCL2001). The CSCL course was offered to both on-campus students and the University of Texas System TeleCampus students. The course was previously offered in a face-to-face format for four years. The course emphasized collaborative learning with students working together in virtual learning teams in completing learning tasks and projects. After the course had been completed, the online survey was administered. The Student Expectations Questionnaire consists of 45 questions. Of the 45 questions, 43 used a Likert-type response scale (strongly disagree to strongly agree). The other two questions also have five options. The questionnaire contains two response columns: Initial Expectations and Present Expectations. Each column provides the same five-point Likert scale (strongly agree to strongly disagree). The data was processed using the SPSS. To obtain an insight of student expectations, the entries from students' introduction and reflections posted on Teachnet, a primary communication tool based on FirstClass Groupware used in this course, were also examined.
The Findings

According to students' entries posted on Teachnet, students came to the course with an expectation that the course would provide them with in-depth knowledge of the course subject matter (CSCL) with hands-on experience in the online learning environment. At the end of the course, several students showed their satisfaction with the course organization. In their final reflection papers, most students expressed their feelings and positive impressions towards working collaboratively with their online team members. This could imply that their expectations from the course activities/course content, course design, and the online community had been met, or have even been exceeded. Besides reflecting on their expectations and perceptions toward the course and the online community, some students indicated the need for immediate feedback, especially when they had problems with a task.

The results revealed that students' initial expectations and their expectations when the course finished were different. At the end of the course student expectations were higher in most aspects, except for their expectations of the instructor and the level of effort and convenience. The three expectation aspects that significantly increased at the end of the course were expectations of the online community, learning outcomes, and understanding. In contrast, students lowered their expectations for the instructor at the end of the course. It is possible that, before taking the course, some students might never have had experience with Web-based collaborative learning. Thus, they came to class with high expectations based on prior knowledge from traditional classrooms and expected that the instructor would be continuously available and give them immediate feedback all the time. In fact, the communication patterns in this course had been shifted from vertical to horizontal communication. That is, students are supposed to communicate with and learn from other team members as well as the instructor, rather than focusing only on the instructor. In other words, the instructor takes a supportive but less directive role (Wegner et al., 1999). As a result, online students might feel a sense of increased distance on the part of the instructor.

Conclusions

The findings of this study reflect the views of one group of students taking a one semester Web-based course. Based on the very limited sample, it is not possible to generalize the results of the study to the broad array of online courses. However, the survey results and the entries from student reflections posted on the course bulletin board system do give some insights into what expectations students brought to the online course, emphasizing collaborative learning, and the differences between the expectations of students before and after the course. The results suggest that, the students had higher expectations about online learning when the course was completed. With experience in online learning, students also gained a greater understanding of the online collaborative learning environment.

Abstract: This presentation reports on our current and on-going R&D efforts towards the design and development of an instructional system that supports individual learning preferences through an adaptive web-based learning environment. The aim of the system is to facilitate individualized instruction by providing both content-level as well as link-level adaptations through the exploitation of the user's particular learning style. In order to accomplish this, different learning style models are explored and compared. These learning style models have been formulated and used in classifying students according to their preferences. The implementation of the adaptive instructional system is based on the use of learning object technology on the one hand and an inference engine (JESS) on the other. The former provides the framework for the structuring of the domain model while the latter renders the rules upon which the adaptation is defined.

Introduction

In the present study we seek and analyze state of the art learning prescriptions for designing an adaptive web-based environment, which is a) pedagogically sound through the exploitation of the student's particular learning style and b) economically feasible based on emerging technologies and notions of the semantic web.

Research has shown that learning is more likely to occur if instruction is matched to the student's learning style. Examining the instructional system in this perspective, the notion of adaptiveness presupposes that the system will be able to initially determine and subsequently accommodate the specific learning characteristics of each learner.

The keywords here are "determination" and "accommodation".

- Which are the elements that define these learning styles and how can they be determined? Researchers have proposed different approaches without, however, having provided statistically significant evidence to date as to how effective these models are.
- How should the word "accommodation" be defined? Do students learn better when instruction is adapted to their learning style preferences or can and should they, at certain times, be trained to adopt a particular learning style? Do learning styles remain stable over time or are they dynamic? Are there particular learning style dimensions that remain stable and others that are modified over time? Which are these and how should the system deal with them?

This study reviews and compares prevalent learning style models. These models have been taken into consideration in designing the system prototype of the web-based instructional system.

Thus, this paper discusses our efforts towards the design and development of an adaptive instructional system that supports individual learning preferences through a web-based learning environment. The primary characteristics of the system are the following:

1. It adapts instruction to user learning needs according the particular learning style.
2. It provides adaptation of instruction both in terms of the content presented (content-level adaptation) as well as in terms of the navigation of the instructional material (link-level adaptation).
3. The key architectural components of the system are its domain model, its learner model and its inference engine.
4. These components are implemented through the use of learning object technology and JESS rules.
The role of learning styles

Learners are characterized by different learning styles. Learning styles are distinctive strengths and preferences for dealing with intellectual tasks in a specific way. This means that learners receive and process information in different ways, preferentially focus on different types of information, tend to operate on perceived information in different ways, and achieve understanding at different rates (Pask, 1988; Schmeck, 1988). In fact, according to the particular learning style mode, some learners may prefer to think about the nature of a task and determine a detailed plan before moving on to a specific course of action, while others may prefer to act on the first idea they have and see where it leads them. Some students prefer focusing on data, facts, and algorithms, while others rely more on theories and mathematical models. Some perceive information more effectively when it is in visual form (pictures, diagrams, graphs, demonstrations), while others respond better to verbal information (sounds and spoken words or formulas).

Educational researchers have been concerned with the implications of learning styles for instruction for many decades (Tobias, 1990; Kolb, 1984; Bruner, 1966; Gagné, 1967). Research to date has been attempting to identify robust relationships between learning styles and instructional methods (Tobias, 1990; Yin, 2001; Frick, 1990). The lack of statistically significant evidence to support the robustness of these relationships may mean that traditional learning style models need to be revised and modified taking into consideration new learning approaches and theories. Once this is achieved, learning style models could be used to provide a framework for designing learning environments (whether this means designing a course curriculum, creating class activities or assessment methods, writing a textbook, developing instructional software, or designing more adaptive instructional systems) that will be compatible with particular learning preferences, strengths, weaknesses, and behaviors of students.

Learning style models

Different learning style models have been formulated and have been used in classifying students according to their preferences and in helping educators to provide students with instruction that addresses their learning styles. The authors have been exploring the strengths and limitations of these models in order to exploit those particular learning style dimensions that would be more effective in serving as the basis of the user model module for an adaptive instructional system.

One of the first learning style models proposed during the early 1960s by Jerome Kagan was based on the dimension of reflectivity/impulsivity. Kagan suggested that some students seem to be characteristically reflective while others are characteristically impulsive. Reflective students prefer to collect and analyze information before acting whereas impulsive students prefer to act briskly.

Herbert Witkin proposed the dimension of field-dependence/independence for classifying students, referring to the extent to which an individual’s perception and thinking about a specific piece of information is influenced by the surrounding context. Field-dependent students prefer to work within existing structure whereas field-independent students prefer their own structure and they are more capable of isolating target information, despite the fact that it is embedded within a larger and more complex context. The importance of this difference in approach becomes clear when the student is dealing with ill-structured tasks. Field-independent students usually perform better in these situations because of their willingness to create a more meaningful structure.

According to another such model, formulated by Robert Sternberg (2000), there are five dimensions (functions, forms, levels, scope, and leaning) which compose the learning style of each learner. There are legislative, executive, and judicial functions; monarchic, hierarchic, oligarchic, and anarchic forms; global and local levels; internal and external scopes and liberal and conservative leanings. Most people have a preference for one style within each dimension. For example, legislative style learners prefer to create and plan, executive style learners like to follow explicit rules, while judicial style learners are keen on evaluating and judging.

A learning style model that has been widely used is Kolb’s learning style model (1984). Kolb proposes the classification of students in terms of how they choose to take in information (in which case they may prefer either: a) concrete experience or b) abstract conceptualization) and in terms of how they prefer to internalize that information (in which case they may have a preference for: a) active
experimentation or b) reflective observation). This establishes four types of learners. Type A learners are concrete and reflective and respond well to explanations of how course material relates to their experience, their interests, and their future careers. To be effective with Type A students, the instructor or the instructional system should function as a motivator. Type B learners are abstract and reflective. These learners respond well to information presented in a logical, organized fashion and benefit if they have time for reflection. To be effective with this group of learners the instructor or instructional system should function on the role of an expert. Type C learners who are abstract and active, like to be given opportunities to work actively on well-defined tasks and to learn by trial-and-error in an environment that allows safety in failing. To be effective, the instructor or instructional system needs to function as a coach, providing guided practice and feedback. Finally, Type D learners are concrete, active learners and like applying course material in new situations to solve real problems. To be effective, these students need to be given opportunities to find things out for themselves, maximizing their time and freedom for exploration.

The Myers-Briggs model (Lawrence, 1994; McCaulley, 1990) based on psychologist Carl Jung's theory of psychological types classifies students according to their preferences into: a) extraverts (who try things out while focussing on the outer world of people) or introverts (who think things through while focussing on the inner world of ideas); b) sensors (who are practical, detail-oriented, and focus on facts and procedures) or intuitors (who are imaginative, concept-oriented, and focus on meanings and possibilities); c) thinkers (who are skeptical, tending to make decisions based on logic and rules) or feelers (who are appreciative, tending to make decisions based on personal and humanistic considerations); d) judges (who set and follow agendas and seek closure even with incomplete data) or perceivers (who adapt to changing circumstances and resist closure to obtain more data). The Myers-Briggs type preferences can be combined to form 16 different learning style types. For example, one student may be an EITJ (extravert, intuitor, thinker, judger) and another may be an ISFP (introvert, sensor, feeler, perceiver).

Another learning style model, accredited to Felder and Silverman (1988), the Felder-Silverman learning style model classifies students according to the following dimensions: a) the type of information that the student preferentially perceives: sensory—sights, sounds, physical sensations, concrete, facts and procedures or intuitive—memories, ideas, insights, conceptual, theories and meanings; b) the modality through which the sensory information is most effectively perceived: visual—pictures, diagrams, graphs, demonstrations, or verbal—sounds, written and spoken explanations and formulas; c) the type of information organization that the student is most comfortable with: inductive—presentations that go from the specific to the general, facts and observations are given, underlying principles are inferred, or deductive—presentations that proceed from the general to the specific, principles are given, consequences and applications are deduced; d) the way in which the student prefers to process information: actively—by trying things out, by becoming engaged in physical activity or discussion, or reflectively—by thinking things through, by working alone; e) the type of progress toward understanding that the student is more capable of achieving: sequentially—linear, orderly, by learning in small incremental steps or globally—in large leaps, holistically. The dichotomous learning style dimensions of this model (sensing/intuitive, visual/verbal, inductive/deductive, active/reflective, and sequential/global) should not be considered as either/or categories but should be regarded as continua. A student's preference on a given scale (e.g. for visual or verbal presentation) may be strong, moderate, or almost nonexistent, may vary over time, and may change from one subject or learning environment to another.

The Herrmann Brain Dominance model (1990) classifies students in terms of their relative preferences for thinking in four different modes based on the task-specialized functioning of the physical brain. The four modes or quadrants in this classification scheme are: a) Quadrant A (left brain, cerebral): logical, analytical, quantitative, factual, critical; b) Quadrant B (left brain, limbic): sequential, organized, planned, detailed, structured; c) Quadrant C: (right brain, limbic): emotional, interpersonal, sensory, kinesthetic, symbolic; d) Quadrant D (right brain, cerebral): visual, holistic, innovative. The needs of students with strong preferences for C and D quadrant thinking are often not met by traditional forms of classroom instruction or by instructional systems that are not oriented toward taking these particular preferences into account.

Discussion
The above learning style instruments use lists of verbal statements or different visual forms prepared for people to choose or rank. Our initial research questions related to the determination and accommodation of the learner’s specific style coincides with some of the issues raised by Sewall (1986). Sewall compared several of the above popular instruments and found that their scores have limited validity, are difficult to interpret, and that their reliability estimates are unstable. He also raised many questions such as the issue of whether learning styles are constantly modified by the educational environment and social context or are too dynamic to be measured on a predetermined and predictable scale, the issue of whether it is possible for learners to be trained to adopt a particular learning style, and the issue of whether a significant change in life situations result in changes in learning styles. Researchers dealing with learning styles will need to explore these issues in order to assert that these learning models are effective tools and not merely artificial instruments, in which case other tools that will be able to appropriately survey the dynamic nature of learning styles will have to be proposed.

Yin (2001), suggests that these predefined assessment tools require people to fit in the limited and selective choices with “I think this is who I am” or “I think this is what I will do or how I will react,” which may not predict how one actually reacts to, or interacts with, a problem in a specific learning situation. He proposes that we observe and faithfully record the event changes of a learner-demonstrated process over time.

Table 1: Learning Style Models and Dimensions

Learning Orientations

We would consider the previous discussion on learning styles incomplete without touching upon the idea of learning orientations, a different classification scheme for students introduced by Margaret Martinez (2001). Without disregarding the importance of learning styles, Martinez considers them to be of secondary importance since they focus only on cognitive factors of learning (i.e. on how learners receive, process, build and store knowledge) and overlook emotions and intentions as being equally important factors in the learning process. For Martinez the basis for providing individualized instruction lies in what she states as “a whole-person understanding about key psychological sources that influence how individuals want and intend to learn online.”

The primary difference between learning styles and learning orientations is that whereas learning styles recognize the dominant power of cognitive factors (and degrade other factors to a secondary or no role), learning orientations recognize the dominant influence of emotions and intentions. As Martinez states, this perspective reflects recent neurological research that provides evidence for the dominant influence of the brain’s emotional center on learning and memory (Ledoux, 1996).

According to the Learning Orientations model, learners can be classified into four types:
Type A: Transforming learners, who are generally highly motivated, passionate, and highly committed learners. These learners respond better to discovery-oriented, ensequenced, and mentoring environments. Type B: Performing Learners, who are generally self-motivated in learning situations (task-oriented, project-oriented, hands-on applications) that interest them. These learners respond well in task- or project-oriented, competitive, and interactive (hands-on) environments. Type C: Conforming
Learners, who are generally more compliant and will passively accept knowledge, store it, and reproduce it to conform, complete routine or assigned tasks (if they can), and please others. They need scaffolded, structured solutions, guiding direction, simple problems, linear sequencing, and explicit feedback. Type D: Resistant Learners, who lack a fundamental belief that academic learning and achievement can help them achieve personal goals or initiate positive change.

Prototype and implementation issues

The above analysis has been used as the basis for designing the adaptive elements of the system functioning within a Semantic Web environment. The Semantic Web is an ideal environment for personalized learning especially when combined with the use of learning objects. Learning objects were used for the design of the present adaptive web-based instructional system. A learning object is defined as an entity that can be used, reused, or referred to as a learning resource by a computer-based environment. Learning objects (LTSC, 2000a) are considered to be the predominant choice in terms of the pedagogical design, implementation and distribution of educational content due to their ability to provide reusability, productivity, adaptivity, and scalability.

The personalization of the system takes many forms as it adapts content, tasks, feedback, or navigation to match individual progress and performance. For example, two individuals using the same course simultaneously may see two completely different sets of learning objects. The greatest benefit of learning personalization is the ability of the system to make complex instruction easier by presenting only suitable information that a particular learner wants or needs according to specific preferences expressed by the learning style.

The adaptive instructional system consists of the following modules:
  (a) The knowledge of the system is stored in a database (DB) and is:
      (a1) Knowledge regarding the learner. This knowledge comprises the user model and includes knowledge corresponding to the learner's knowledge level as well as knowledge related to the characteristics of the learner's learning style.
      (a2) Knowledge related to the domain that the learner is learning about (i.e. the domain model).
  (b) The monitoring and evaluation modules. During the course of a lesson the monitoring and evaluation modules examine the learner responses and behavior and renew the DB data (user model) in terms of the learner knowledge level and learning style. It then gives the output variables "learning style" and "knowledge level" to the lesson creation module.
  (c) The instructional strategies module. This contains a set of rules corresponding to the instructional method that will be applied. The rules have been derived from the fields of didactics and cognitive psychology.
  (d) The lesson creation module. This module receives the input variables "learning style" and "knowledge level", and composes the lesson that will be presented to the student by selecting the appropriate educational content from the DB and a suitable strategy from the instructional strategies module. The lesson creation module determines the form and arranges the sequencing of the educational content.

The intelligence of the instructional system is derived from its capability to:
  (a) Diagnose the knowledge level and learning style of the student, based on the data in the user model and according to the learner's responses and
  (b) Adapt the lesson appropriately to the student's needs by drawing suitable educational content from the domain model, by using the proper instructional strategy, and by determining the form and sequencing of the educational content.

The underlying technology is based mainly on freely available software components: an Apache webserver, an Access (Microsoft Corp.) database management system, an Apache Java Servlet engine (Tomcat version 3.2.1) and the Jess scripting environment, which is a rule engine written entirely in Sun's Java language.

---

**Figure 1:** The modules of the system and the way they communicate
Future research

Our priorities for future studies are to attempt to reconsider and redefine the concept of learning styles. In order to extend the presently implemented system, which is based on existing theories and models, we should consider future research (both on a theoretical as well as an experimental level) regarding:

1. The suitability of the questionnaires corresponding to the determination of the learning styles. Are these questionnaires appropriate and to what degree can they be interpreted reliably by the system?
2. The particular implementation of the system (currently based on the use of servlets) and extending the way that it presently allows for the progress of the students to be recorded correctly. How could the recording of these events lead to the definition of learning styles?
3. The stability of learning styles over time. What is the stability of each learning style dimension over time?
4. The issue of adapting the educational environment according to the learning style of the student. Is this always necessary or would it be beneficial if, at certain times, the system trained the learner to adopt a different learning style imposed by the nature of the educational content or the particular learning goals? How would it be possible to achieve this?

Obviously, many research studies to date have attempted to deal with issues related to learning styles. However, on the one hand these studies have not yielded statistically significant results and on the other the web has emerged as a new environment with unique characteristics, which need to be explored, since it is expected to play a particularly important role in education.

Utilizing SMARTBoards to Enhance Technology Integration in University Classrooms

Abstract

This paper presents the preliminary results of a university-wide effort to enhance technology integration in the classroom. The College of Education at Idaho State University has received a grant to disseminate SMARTBoards, computers, and projectors to all seven colleges within the university, to train faculty in the use of the equipment, to provide support and ideas for implementing the new technology, and to collect information on faculty and student attitudes towards, and use of, the technology. It is projected that the use of a non-threatening but extremely flexible digital technology, like the SMARTBoard, will encourage faculty to develop their own original digital classroom materials, to incorporate computer technology on a regular basis, and to encourage pedagogical changes in higher education classrooms.

Introduction

The College of Education, Idaho State University, received a State Board of Education Technology Incentive Grant to place SMARTBoards in classrooms in each of the seven colleges. The purpose of the project is to facilitate the integration of technology into higher education curricula, to enhance faculty productivity, to amplify the rate and quality of student learning, and to increase classroom access to educational programs. With a user-friendly delivery medium such as the SMARTBoard, it is hoped that university faculty will become more motivated to create their own applications, including web courses, original digital graphics and movies, electronic presentations and CD-ROMs. The project was begun in the fall of 2001 and, although not yet complete, has garnered preliminary indications of faculty skills and predisposition toward computer technology.

Preliminary Results

As of this writing, 75 members of the ISU professional community have participated in the SMARTBoard training, preparatory to using the technology in the classroom. Of these, 61 identify themselves by faculty rank (19 Full, 11 Associate, 18 Assistant Professors, and 13 Instructors); the other 14 are staff positions, graduate students, or teaching assistants. The initial attitudinal survey indicates that many of these trainees already exhibit a moderate to strong disposition toward integrating technology in the classroom. Most respondents (more than 75%) indicated that they were comfortable using computers in instruction, that they believed technology could enhance learning, and that they wanted to learn more about integrating technology into their instructional
methods. A slightly smaller majority disagreed that traditional lecture methods of teaching were preferable, or that computer technology had no place in their discipline. Almost all the participants indicated that they used both the Internet and email in teaching, but less than half were using WebCT (the on-line curriculum program used at ISU).

In terms of their skills, this faculty considered themselves as intermediate or advanced users of the Internet and word processing. A sizable minority considered their skill level as low on electronic presentations. Approximately half considered themselves as novices (or less) in terms of statistical software, spreadsheets, databases, and subject specific software. The majority rated their skill level as none or novice on the SMARTBoard technology, multimedia authoring software, and WebCT. Thus it appears that, if these faculty are indeed comfortable integrating technology into their teaching methods, the technology they use is primarily confined to word processing and the Internet, with PowerPoint skill levels still being developed. However, more "difficult" applications, or applications which have not been traditionally presented in direct-instruction environments, are not usually part of the faculty's technology repertoire.

In order to understand how faculty determines whether or not they can commit to learning a new technology, they were queried as to which factors they considered important. Although all of the factors were rated as important or very important by most participants, there was a pattern as to which of these factors were rated as very important by increasing numbers of participants. Figure 1 illustrates those factors, which were rated as very important. Surprisingly, faculty rated the simple, practical factor of Availability as Very Important, more than any other factor. Time to devote to the technology and Ease of Use were also rated as Very Important by a large number of respondents.

![Factors which are Very Important](image)

**Figure 1.** Number of faculty rating specific factors as Very Important to their integration of technology into classroom teaching. 1. Learning Curve; 2. Personal Comfort Level with Software; 3. Advantage of Technology over Traditional Teaching Methods; 4. Compatibility with Discipline; 5. Administrative Support; 6. Time; 7. Ease of Use; and 8. Availability.

**Conclusion:**

Although this project is on going, some interesting trends are already identified in the data collected. The most important appears to be that, although faculty are well disposed toward using computer technology in their communication with students and in teaching, they actually have limited skills and confine their use to email, the Internet, and word processing. Only a few produce electronic presentations for the classroom, and fewer still use the capabilities of the web to post presentations or other material for their students.

It is hoped that the SMARTBoard project will encourage faculty to expand their technological skills, producing original web sites, multimedia projects, digital video and audio, and other electronic media to incorporate into their instruction. Whether the project succeeds will be determined by faculty and student evaluation of courses, which are held in SMARTBoard-equipped classrooms by project-trained faculty. These final evaluations and surveys will be conducted at the end of spring semester 2002 and again in fall semester 2003.

Abstract. This paper investigates the accommodation of learning styles research in personalised learning (PL) systems. The paper outlines some of the most well-known learning styles theories and models, as well as some criteria for selecting among them. It also outlines some PL systems which are utilising learning styles research, with emphasis on the system which is being developed in the context of the KOD “Knowledge on Demand” European Project.

Introduction

Personalised learning (PL) systems are attracting increasing interest, since they bear the potential to meet the requirements of the knowledge society and knowledge-based economy for high-quality education and training. PL systems can be defined by their capability to automatically and continuously adapt to the changing attributes of the “learning context”, which can, in turn, be defined by the individual learner characteristics, the type of the educational material, etc.

In the context of this paper, PL systems are categorised and differentiated in terms of their adaptation logic, which is defined by:

- **PL constituents**: the aspects of the learning context which are subject to adaptations; that is, is the educational content being adapted? and if so, how do we categorise educational content so that we can select it?
- **PL determinants**: the aspects of the learning content which “drive” adaptations; that is, are adaptations based on the learner’s profile? and if so, how is the learner profile defined?
- **PL rules**: the rules which define which PL constituents are selected for different PL determinants (Sampson, Karagiannidis, & Kinshuk, 2002).

PL systems can be quite diversified according to their adaptation logics, depending on the requirements of the specific learning context. For example, PL determinants can include learners’ characteristics, which can, in turn, include learner’s background, expertise, prior knowledge, skills, requirements, preferences, etc.

This paper addresses the incorporation of learning styles research in the adaptation logic of PL systems. That is, the definition of new PL determinants, constituents and rules which are based on, and reflect specific learning styles theories and models. The next section provides a short overview of the most well-known learning styles theories and models, as well as some criteria for selecting among them when developing a PL system. Finally, the paper outlines some existing PL systems which utilise learning styles research, with emphasis on the PL system which is being developed in the context of the KOD “Knowledge on Demand” European project (see acknowledgements section).

Learning Styles Research: A Brief Overview

There is no single way to describe learning styles, as a number of definitions appear in the literature. Learning styles can be generally described as “an individual’s preferred approach to organising and presenting information” (Riding & Rayner, 1998); “the way in which learners perceive, process, store and recall attempts of learning” (James & Gardner, 1995); “distinctive behaviours which serve as indicators of how a person learns
from, and adapts to his/her environment, and provide clues as to how a person's mind operates" (Gregorc, 1979); "a gestalt combining internal and external operations derived from the individual's neurobiology, personality and development, and reflected in learner behaviour" (Keefe & Ferrell, 1990).

Existing learning styles models can be presented through an onion metaphor (proposed in Curry, 1983), consisting of three basic layers which categorise learners in terms of instructional preferences (outermost layer), information processing (middle layer) and personality (innermost layer). Social interaction, a fourth layer placed between Curry's two outer layers, was proposed in (Claxton & Murrell, 1987).

The most well-known and used learning styles theories and models are presented in Table 1. For each model, the presentation includes
- the learners categorisations proposed by each model,
- the existence of an assessment instrument for categorising each learner in the above categories, and
- indicative references for each model.

Table 1: Overview of Learning Styles
Some Criteria for Selecting Among Different Learning Style Models in PL Systems

Given the variety of learning styles theories and models that are available in the related literature, we need to define a set of selection criteria for selecting the most appropriate learning style model to be accommodated in a specific PL system. Of course, the most important criteria are the theoretical and empirical justification of the model. In addition, the learning style model should be suitable for the specific learning context. For example, if all learners of a specific learning context are "experts" in the domain (e.g. an educational application for aircraft pilots), then it might not be reasonable to select a learning style model which categorises learners according to their expertise in the domain. Similarly, if all the educational material that is available for a specific case is in textual form, then it is not reasonable to select a model which differentiates content according to its medium.

A set of additional important selection criteria are briefly summarised below.

Measurability

We need to be able to "measure" whether learners belong to the categories defined by each model. For example, one model may differentiate learners according to their emotions. While this may be reasonable from a theoretical point of view, since emotions can affect learning, it may not be reasonable to select such a model for a PL system, since it may be difficult to measure learners' emotions. Felder and Silberman model, for instance, is supported by the Felder and Solomon questionnaire, which easily determines how a learner is categorised according to the dimensions proposed by the model. The lack of such an assessment instrument (questionnaire) can be a reason for not selecting one model.

Time effectiveness

The assessment instrument related to each learning style model needs to include a reasonable number of questions in order to be time effective. For example, if an assessment instrument consists of 200 questions, then the instrument may not be effective time wise. The user may not be willing to dedicate his/her time in order to complete a large questionnaire before starting using the system.

Descriptiveness and Prescriptiveness

From a practical point of view, it is important that the model describes not only how learners are categorised, but also how instruction should be adapted for each learner category; that it, apart from the descriptive information (e.g. learners are categorised into "active" and "reflective"), the model should provide prescriptive guidelines, which can lead to specific rules for designing instruction and adaptation (e.g. what types of educational content should be selected for active and reflective learners).

Cost

The cost of a learning style model along with its assessment instrument is another parameter that system designers may need to consider. The situation here varies, as some assessment instruments are only available for use after payment, while others are available to be used free-of-charge. In this case designers need to consider the cost of the model and its assessment instrument. Then, the availability of the test in relation to the number of users needs to be considered.

Some Examples of Accommodating Learning Styles Research in PL Systems

Learning styles research has formed the basis for the development of a number of PL systems. TrainingPlace.com is a notable example of a commercial PL system which is based on learning styles research. The system is based on Learning Orientation Theory, which categorises learners as transforming, performing, conforming and resistant. Based on this categorisation, the system presents different "learning experiences" to each learner. For example, the system selects "loosely structured environments that promote challenging goals, discovery and self-managed learning" for transforming learners, and "semi-complex, semi-structured, coaching
environments that stimulate personal value and provide creative interaction" for performing learners (Martinez & Bunderson, 2000).

SMILE, a web-based knowledge support system aiming at promoting intelligent support for dealing with open-ended problem situations, utilises a learner profile which takes into consideration the learner's learning style, following Honey and Mumford’s categorisation (Stoyanov & Kommers, 1999). The same learning style model is also used by the INSPIRE system, which aims to generate different lessons for each individual learner, for meeting his/her learning goals (Grigoriadou et al, 2001). The 3DE European Project (www.3deproject.com) categorises learners into activists, reflectors, theorists and pragmatists, in order to create courses customized to their needs.

The KOD European project aims to deliver an adaptive learning environment for personalised learning (Karagiannidis, Sampson, & Cardinali, 2001). In this context, the aim of the project is to facilitate the development of adaptive educational content which can be easily interchanged and re-used across different e-learning applications and services. In particular, the KOD project is working on the knowledge packaging format (an extension of the existing IMS Content Packaging Specification (IMS, 2001a), for the description, in a common format, of knowledge packages (i.e. collections of learning objects), together with the rules which determine which learning objects should be selected for different learner profiles. As a result, the KOD e-learning system (or any system compliant with the knowledge packaging format), can import a knowledge package (a collection of learning objects described through the knowledge packaging format), interpret the rules included in it, and present different knowledge routes to each individual learner, according to his/her profile, thus facilitating personalised learning.

The KOD project includes an authoring environment (the KOD Packager) for describing adaptive educational content through the knowledge packaging format. Through the KOD Packager, the user (learning material author, tutors, publisher, etc) can define the PL logic (determinants, constituents and rules) which drive the personalisation of the knowledge package.

In order to assist the developer of knowledge packages, the KOD Packager includes parts of different PL logics, which can be easily imported as “templates”. For example, the KOD Packager includes all the elements which are proposed by the IMS Learner Information Profile Specification (IMS, 2001b) for describing learner profiles. The designer can easily select which of these determinants are suitable for the specific learning context, and include them in a new knowledge package. Similarly, the KOD Packager includes the elements which are proposed by the IEEE Learning Objects Meta-Data Specification (IEEE, 2001) for describing learning objects characteristics; as well as a set of PL rules, which select different PL constituents (learning objects characteristics) for different PL determinants (learner characteristics).

Parts of the PL logics which are built-in in the KOD Packager are based on specific learning styles models, for assisting the user to easily accommodate these learning styles models into the development of adaptive educational content. For example, the user can select to accommodate the Felder and Silverman learning styles model; in this case, the learner profile which is created by the KOD system for each learner, includes an element for representing whether each individual learner is visual/verbal; similarly, the educational meta-data file which describes each learning object includes a specific element for representing whether the learning object is visual or verbal. Finally, the PL rule “IF Learner is Visual THEM learning object is Visual” is ready to be included in a knowledge package.

Conclusions

This paper has investigated the accommodation of learning styles research in PL systems. It has briefly reviewed the most well-known learning styles theories and models, as well as some criteria for selecting among them when developing a PL system. The paper has also outlined some PL systems which utilise this line of research for delivering personalised learning, with emphasis on the PL system which is being developed in the context of the KOD European project.

Our current and future work in this context includes the development of different knowledge packages (through the KOD tools), which are based on different learning theories and models. This will provide to us a testbed for further investigating the use of learning styles research in PL systems.

Abstract: In this paper we present the way a multi-criteria decision making methodology is applied in the case of agent-based selection of offered learning objects. The problem of selection is modeled as a decision making one, with the decision variables being the learner model and the learning objects’ educational description. In this way, selection of educational content is based on dynamic data input collected at the time of the decision. This methodology is studied in the context of an agent-based e-market for educational content brokering, and is engaged by the broker agents recommending learning objects to learners, according to their cognitive style.

Introduction

In agent-mediated educational content brokering, artificial agents are responsible of locating offered learning objects, negotiating with the content providers on the terms of the service provision, and for presenting the learner with those offers that best match his/her needs and preferences. Successful completion of this task is based on two parameters: the capability of the mediating agent to understand and model the user needs, and its capability to evaluate all available learning objects and recommend the most suitable. The most common ways to introduce intelligent brokering for educational content are based on techniques from Artificial Intelligence (AI): knowledge representation, reasoning, and expert systems, often offer tools and techniques in the developers of such systems since they allow the agent to behave intelligently in two ways; first, with the ability to store the knowledge of the experts (for example using a knowledge base); second, using the previous knowledge to infer rational decisions.

In the last years though, most agent-based e-commerce systems engage methodologies and tools which originally come from sciences other than AI; these include methods and techniques from Game Theory, Optimization and Decision Making (Guttman et al, 1998). In this paper, we are going to approach the problem of content selection (know as the recommendation problem in e-commerce systems) from a decision-making point of view. We are going to introduce how a multi-criteria decision making (MCDM) methodology is applied in the case of agent-based educational content brokering, and we are going to discuss the benefits and drawbacks of this approach.

There is an interesting feature in this approach: it replaces searching knowledge inside a knowledge base, using constraints posed by logical expressions and logic rules, with an evaluation of knowledge using mathematical formulations. It can therefore provide measures of “how much better one decision is compared to another”, even if both decisions are rational and solve the constraints problem. This usually sounds rather awkward though – how can we represent the expert knowledge in terms of mathematical expressions? Logic variables (CategoryOfUser="This") and logic rules (IF CategoryOfUser="This" THEN TypeOfContent="That") are simple, and easily comprehended; how is the learner going to be modeled using mathematical variables, and how is the expert going to express the experience in a mathematical form?

We will try to give answers to these questions by introducing the example of modeling the learners with the classic Honey and Mumford cognitive styles model (1992). We will introduce the basic principles of a multi-criteria decision making methodology, and study which parameters of the Honey & Mumford model serve as criteria for the selection of the available content (learning objects); we will also study a method that can be used to carry out this selection. Finally, we will present how this decision-making procedure is incorporated into an agent-based system, and how the broker agents operate it.
The Honey & Mumford Model

Tennant (1988) defined cognitive style as "an individual's characteristic and consistent approach to organizing and processing information". There are several learning and cognitive styles theories and models, which categorize learners in terms of instructional preferences, information processing and personality styles, and are usually employed for the realization of individualized instruction (for a survey, see Sampson et al, 2002). In order to demonstrate how a cognitive style model can be used in order to create the multi-criteria selection model, we will engage the classic Honey and Mumford model. The Honey and Mumford model (1992) is a cognitive style model, developed for use in commerce, management and training situations. It categorizes learners according to the following dimensions of a person's learning style: Theorist, Activist, Reflector and Pragmatist. In order to rate learners on each one of the categories, the model uses the answers in a specially designed Learning Styles Questionnaire (LSQ) of 80 questions, with binary answers of "Correct" and "False", and after an internal processing of the results, it provides a percentage weight for each category. Therefore, the learner's style is defined depending on the weight at each learning style category.

![Learning Styles Analysis](source: PSI-Press, http://www.psi-press.co.uk/)

From a practical point of view, it is important that a learner's model describes not only how learners are categorized, but also how the instruction method should be adapted for each learner category (Spector, 2001). The real complexity for the designers of e-learning systems arises when they try to match subject matter with learner characteristics and appropriate instructional methods. Such a process includes both learner modeling (using the Honey & Mumford model results—see Figure 1) and description of the educational properties of the learning content (that is e.g. a description of how suitable a course is for the learners having a specific cognitive style). The matching procedure involves all these parameters as input— and still a proper matching mechanism has to be found. We address this problem as a decision making one.

Multi-Criteria Decision Making Methodology

According to Roy (1996) the general methodology of decision making problems includes four steps: (i) defining the object of the decision, that is the set of potential actions, and the problematic of the decision; (ii) studying the parameters influencing decision and defining so a set of criteria; (iii) choosing an appropriate multi-criteria aggregation method; (iv) proceeding at the activity of decision aid.

Step One: The Object of Decision

The first step includes definition of the decision variables in a form of a consideration set A. In the case of educational content brokering, this set includes all the available learning objects, which will be evaluated by the decision maker (in our case, the brokering agent). What is called 'the problematic of the decision' is the definition of what kind of evaluation or choice does the decision maker want to make upon the different objects available in set A;
in the case of broker agents recommending a learning object, the decision problematic is “selection of one”. That is the selection of one action from the consideration set of the form $\mathcal{A} = \{a_1, a_2, \ldots, a_n\}$.

**Step Two: The Criteria**

The next step is deciding what will be the criteria upon which the learning object will be evaluated. This means defining a consistent family of criteria, assuming that these criteria are non-decreasing value functions, exhaustive and non-redundant. Each criterion is defined on $\mathcal{A}$ as it follows: $g_i : \mathcal{A} \rightarrow [g_{i}, g_{i}^\ast] \subseteq \mathbb{R}$, where $[g_{i}, g_{i}^\ast]$ is the criterion evaluation scale, with $g_{i}$ the worst level of the $i$th criterion, $g_{i}^\ast$ the best level of the $i$th criterion, $g_i(a)$ the evaluation or performance of action $a$ on the $i$th criterion and $g(a)$ the vector of performances of action $a$ on the $n$ criteria (Jacquet-Lagreze & Siskos, 2001).

In the case of educational content brokering, there are two ways to deal with the selection of the criteria. Recommendation is usually based on criteria as price, time of delivery, form of delivery, etc. – a common practice in e-commerce systems. We would like to introduce another aspect of recommendation in agent-based learning environments: based on the pedagogical profile of the learner. That is using the categories of the learner model as criteria; each learning object will be evaluated on how suitable it is for each category of learners. This is exactly the same as making an expression as “TypeOfContent='That'”. To be more specific, in a similar case an expert system would need a definition as: TypeOfContent="SuitableForActivists". In the case multiple criteria are used for the description of the content, this definition is transformed (remaining fully equivalent) to something similar to this:

- SuitabilityOfContentForTheorists= "NotSuitableAtAll";
- SuitabilityOfContentForActivists= "Perfectly suitable";
- SuitabilityOfContentForReflectors= "NotSuitableAtAll";
- SuitabilityOfContentForPragmatists= "NotSuitableAtAll";

Therefore, as criteria we will use the four categories of the Honey & Mumford, which can take their values from a 5-scaled climax of qualitative descriptions ["Not suitable at all", "Not very suitable", "Moderately suitable", "Very suitable", "Perfectly suitable"] showing the evaluation of each learning object upon each categories. It is obvious that a learning object (e.g. an on-line course) is never “Perfectly Suitable” for a learner category and “Not Suitable At All” for the rest -it rather addresses some of the needs of other categories of learners too. Therefore, such an evaluation provides the expert with a way to precisely describe the pedagogical ‘profile’ of a learning object. This meta-data description is a criteria definition that fully complies with the definition of the criteria according to Roy (1996).

**Step Three: The Utility Model**

First of all, we have to define the preference model that will be used from the broker agent to make the decision; as we have already stated, in our case we are using the Honey & Mumford learner model as a preference model. The expression of the model is then $p = [p_1, p_2, p_3, p_4]$, where $p_1, p_2, p_3,$ and $p_4$ are the weights inferred after the learner has completed the Honey & Mumford LSQ and the results have been processed.

This is the point where the analyst has to define which evaluation method will be used; that is, which multi-criteria decision making method will be engaged in order for the decision to be best modeled and simulated. In this paper we will use one of the most traditional approaches, that leads to a functional representation $g$ that can be formed directly from the criteria $g_{1}, \ldots, g_{4}$ that constitute $\mathcal{A}$. The goal of using this approach is to present how the methodology works – depending on the application, other more complex methods can be used. Thus, the comprehensive preference model is characterized by a unique synthesizing criterion $g$: $g(a) = V(g_{1}(a), \ldots, g_{4}(a))$, where $V$ is an aggregation function. The function will be in the form:

$$V(a) = \sum p_i g_i(a)$$

where $g_i(a)$ are the evaluations of each learning object $a$ regarding the suitability for each category of learners. The weights $p_i$ consist the preference model, which are the parameters calculated by the Honey and Mumford LSQ. The final value of $V$ is the total utility of each learning object for the learner under study.
Step Four: The Activity of Decision Aid

Let us now introduce the way the activity of decision making will be carried out, in the context of an agent-based system. We define a generic architecture, with agents capable of handling and communicating descriptions of learning objects, as defined in the previous paragraph. The three basic roles are:

The Assistant. The assistant agents are responsible for user needs and requirements elicitation, and formulation of requests into messages understandable by the broker repository system. The LAssistant is the agent that interacts with the user and can identify the request for a learning object. The CPAssistant is the agent that gets the learning object descriptions from the Content Providers, and publishes them as offers in the e-market. The TAAssistant serves as the pedagogical counselor of the learner: it creates the learner model of the user and provides this model to the LBroker. The TAAssistant can also be the expert that describes a learning object using the cognitive styles; this is a task that can be directly carried out by the Content Author too, so we will not focus more on this point.

The Broker. The broker agents represent each human user in the e-market and facilitate educational content seeking or advertising. The Broker agents interact among each other in the Brokerage Pool and either advertise published learning objects, or make requests when looking for them. The LBroker evaluates the available offers from the CPBrokers in the way described in the previous paragraphs. The LBroker then recommends the content selection to the LAssistant. The Brokers are also responsible for negotiation among the participating parties upon the terms of the service provisioning (beyond the scope of this paper).

The Matchmaker. This facilitator agent provides mediating services, by informing agents about other agents of the broker repository and their availability. The Matchmaker provides all necessary administrative support information to the human administrator of the agent pool.

We can see that the Broker agent engaging the multi-criteria methodology previously described is the LBroker. In order to pedagogically evaluate the available learning objects and recommend one to the learner, the LBroker needs the learner model (provided by the user) and the meta-description of the available learning objects (provided by the CPBroker or the Tutor). Other kinds of evaluation of the offers (e.g. based on the price, time, and other terms of delivery) are beyond the scope of this paper.

Usage Scenario

Let us demonstrate how the recommendation procedure works in this agent-based system. A content author creates different learning courses concerning the same subject. The author wishes those courses to address different learner needs, depending on the cognitive style of the learner. When a learning object (course) is created, the content author also provides an evaluation of its suitability for each different category of the Honey & Mumford model. The author creates thus five different learning objects, with different pedagogical descriptions (as depicted in Table 1).

Table 3: The total utilities of the available learning objects (a score upon the '1-Not Suitable At All' to '5-Perfectly Suitable' climax).

Introducing the multi-criteria methodology presented in the previous section the Broker will select a learning object according to these steps:

1. The Tutor provides a multi-attribute cognitive model of the user, according to the results of the Honey and Mumford model (Table 2).
2. When the Learner's Broker receives the five offers for learning objects, it calculates the total utility (that is suitability) of each one, using the methodology described in the previous section.
3. The Learner's Broker selects the most appropriate learning object to be presented to the user (Table 3).

It is interesting to note in this example the difference between the application of a simple rule-based selection of the learning object (in this case the agent would classify the learner as 'Activist' and would propose the learning object LO3) and the proposed methodology. Using the multi-attribute cognitive model and the multi-criteria evaluation model, we observe that the most appropriate learning object seems to be LO4, being the only one suitable for the combination of categories that characterize the specific learner's cognitive style.

Conclusions and Future Work

In this paper we presented an agent-based recommendation system for educational content brokering that implements a multi-criteria decision making methodology. Due to the differences of learners' cognitive models, recommendation can be either carried out by classifying learners into broader categories that are directly linked to learning objects (e.g. with rules like IF 'this type of learner' THEN 'this type of material') or by enhancing the mediating agent with the appropriate intelligence to propose the most suitable learning object available at the market. By engaging a multi-attribute utility (MAUT) model, the brokering agents do not need to possess intelligence in the form of a knowledge base or hard-coded rules but only to include the multi-attribute evaluation logic in their decision making module. In this way learners are modeled in a multi-attribute way, instead of being simply classified into a general learning category, learning objects are described according to their educational scopes, brokering agents dynamically evaluate all available proposals of content, and select the learning objects most suitable for the specific learner's profile, and finally the knowledge the broker agents have to contain in permanent storage is minimized since only the MAUT evaluation formula is needed; all other input is provided at run-time.

In this paper, the decision problem was modeled using the Honey and Mumford LSQ parameters as the preference model, but we believe that the proposed methodology can be similarly applied in the case of other cognitive style models too. Future research will be focused on applying of several other LS models, either separately or combined. An issue to be also studied is the application of more complex multi-criteria decision making methodologies for modeling the user preferences; such methodologies provide easier and more realistic means of expressing preferences, but require more complicated MCDM methods to conclude to the best proposal for each learner, as one of the famous family of the ELECTRE methods (Roy, 1996).

Current international standardization efforts regarding syntax and semantics of a learner model that characterize a learner and his or her knowledge/abilities; i.e. IMS LIP (IMS, 2001), IEEE LTSC PAPI (IEEE, 2000) do not explicitly define information about the cognitive style of the learner. However, both the IMS LIP and IEEE PAPI Learner preference/performance data types provide data elements that allow cognitive style related information to be
stored in an appropriate form. These data types could be used in order to represent a multi-attribute representation of the cognitive style model of the learner, by an appropriate extension of the corresponding XML schema.

The IST Project KOD “Knowledge-On-Demand” (KOD, 2001) engages a multi-agent brokering system for selection of learning objects and dynamic synthesis of on-line courses. In the case of KOD, intelligence is included into the learning objects in the form of rules that express the suitability of the object for each type of learners, so that courses can be constructed based on how the learning objects are characterized. This is a case very close to the problem we introduced, and we are currently studying ways to introduce the multi-criteria descriptions in the learning objects of KOD, in order for the KOD agents to be able to dynamically assess and synthesize courses based on the introduced decision making methodology and not on prescribed rules.

Internet-based education and training offer many potential benefits specific to adult learners with emphasis given to learner-centered and self-directed instruction models empowered by web-based educational resources. Indeed, the recent growth of the World Wide Web (WWW) has greatly increased the amount of information and educational resources available to the education community.

The full exploitation of this mass body of knowledge resources available on the Web, can be, however, compromised, by the difficulty in describing, classifying and maintaining those resources in such a way that they can be retrieved in an "educationally efficient and effective way". Today, the web community has embraced the collection and use of metadata to characterise and index educational resources, which lead to semantically more accurate retrieval of information than search engines. In general sense, metadata is information about data. In the context of resource discovery, descriptive metadata is a characterisation that aims to represent the intellectual content of the resource. The most popular technology for representing metadata is XML (eXtensible Markup Language).

Typically, the educational content providers of an eLearning scenario need an educationally oriented application facilitating editorial and management features for manipulating educational metadata documents. An efficient and effective educational metadata management tool should satisfy a number of requirements derived from different dimensions such as:
- The need of addressing user categories (i.e. learners, content providers)
- The availability of different educational metadata specifications/standards (i.e. IEEE LOM, DC)
- The emerge of metadata enabling representation technologies (i.e. XML, DTD, XMLSchema).

The basic requirements towards an integrated and generic educational metadata management tool are:
- creation of new and modification of existing educational metadata documents
- data and structure validation of the educational metadata document
- support of any educational metadata standard/specification
- creation of new metadata specification that applies to user's requirements for each case study (e.g. extension of existing metadata standard)
- support enabling metadata technologies (XML, DTD, XMLSchema)
- mapping of educational metadata files between different specifications/standards
- facilitate content management of the educational metadata documents (e.g. search, retrieve, update data)

The proposed architecture of the EM² tool (Sampson, 2002), combines all the required components towards the implementation of an educational metadata management tool (editors, repositories, associations, management, validation and mapping components) and fulfills the above requirements (Figure 1).

This paper proposes an educational metadata management system using a deductive, object-oriented database approach. The EM² tool can provide storage and retrieval of data from the XML metadata files in addition to its features (i.e. authoring, editing, etc) by integrating the X-DEVICE system (Bassiliades, 2000). In Figure 2, a graphical representation of the proposed architecture for the cooperation between the two systems is presented.
EM² provides the graphical interface for the interaction with the user. The user can create a new educational metadata file based on metadata specifications, open or edit/update data on an existing one, convert metadata files between specifications as well as create maps for these conversions. The created or modified XML documents after structure and data validation (whenever it is possible) are stored to the associated XML repository of EM². The XML Repository is a system folder storing the XML documents as files, and it is not a database system. In addition the DTD and XMLSchema files are stored in their associated repositories respectively. By integrating -DEVICE to the EM² tool, database storage and data retrieval can be provided based on the user’s queries. Each stored XML document, together with its associated DTD is passed to the X-DEVICE system where the mapping to OODB system takes place. The EM² tool can generate a DTD in case there is no DTD or XML Schema that defines the XML document. In addition, if only an XML Schema exists for a specific XML document then transformation from XML Schema to DTD is also an available feature. The transformation of XMLSchema generates a sample DTD, which may lack information compared to the XMLSchema. The OODB holds the data of every educational metadata file that has been created, updated or stored in the EM² XML repository. In addition, the EM² will provide an interface to the user, for query submission. When specific data is required from the XML documents, the user should compose his query following the syntax of the X-DEVICE system query language. The query is then passed to the X-DEVICE system, which will obtain the required information from the OODB. The information is in XML format and it will be presented to the user through the user interface of EM².

Abstract. GAIA is a microworld-based learning environment aiming to provide means for exploratory learning to secondary school students in the fields of physics, mathematics and geosciences. This paper presents Gilbert, one of GAIA's microworlds aiming to familiarize students with contemporary geosciences.

Introduction

Unlike in other fields of studies, such as physics and mathematics (Thornton and Sokolo, 1990), most of the available commercial educational software related to Earth School Studies, is either drill-and-practice oriented, where students are presented with problems to solve and they receive feedback about the accuracy of their responses, or tutorial-based oriented, following the archetypal form of text, graphics or multimedia information associated with relevant self-evaluation tests. However, such environments (Kali et al. 1997) do not strongly facilitate students towards constructing their own knowledge through open-ended experimentation (Jonassen, 2000). On the other hand, microworld-based educational software can provide the means for exploratory learning, by providing the environment for students to learn-by-doing, rather than just watch or listen to a description of how something operates. Briefly, a microworld is a computer-assisted problem exploration and experimentation space in which one can explore and construct. Typically, they are constrained versions of reality that enable learners to manipulate variables and experiments within parameters of some system. Furthermore, the most advanced microworld-based educational software provides the means to educators and learners to construct their own exploration spaces. This is the case of GAIA which allows learners to represent their own thinking in the ways that they explore, manipulate and experiment with the environment.

Figure 1. Overview of the GAIA Project Design and Development Process (Papageorgiou et al, 2001)
GAIA is a microworld-based exploratory learning environment in the field of geosciences education, physics and mathematics. This is accomplished through constrained simulations of real-world phenomena in which students can navigate, manipulate or even create objects, and experiment with their effect on each other. In the current version of GAIA, seven microworlds - named after great scientists - are designed and developed to provide the environment for replicating the essential functionalities needed to explore phenomena about the Earth and the planets, regarding their interior, atmosphere, morphology, magnetic field, their orbits in space as well as their astronomical environment. Figure 1 gives an overview of the GAIA project design and development process (Papageorgiou et al., 2001). The development of GAIA is based on the component-based educational authoring environment “E-Slate” (Birbilis G. et al., 2000), which provides a workbench for creating highly dynamic software with rich functionality (Roschelle et al., 1999).

The Gilbert microworld, presented in this paper, deals with Earth’s magnetic field, within the frame of the school curriculum. This microworld aims to the comprehension of Earth’s magnetic field concept and how contemporary science studies and explores this field. The Earth’s magnetic field is one of the most attractive concepts to students’ imagination, but its teaching becomes difficult as it is hard for them to resolve its vector within the 3D space in relation to geographical coordinates, and to precisely comprehend its existence as they do for instance with the concept of temperature. The Gilbert microworld contributes to all the aforementioned and familiarizes students with the existence and nature of Earth’s magnetic field.

Earth’s magnetic field study through GAIA software

The Earth’s magnetic field can be directly noticed by the students with the use of a magnetic needle and that is the reason why they must be familiarized with the compass use in school laboratory. This is usually done through the measurement of the field’s direction. Although laboratory measurement is useful, it limits students to identify and measure earth’s magnetic field, only at the place they are.

The GAIA interactive software presented in this paper allows students to virtually travel everywhere on Earth, and measure earth’s magnetic field elements (Figure 2). Students have also the possibility, besides the compass, to use a total magnetic field magnetometer. The selection of the virtual site for the experiment is accomplished either on a 3D rotating globe (see Figure 2: top left window) or on a plane geophysical map. The altitude where the measurement is taken place is set in another window (see Figure 2: top right window), by pointing the mouse on a magnetometer sketch on the screen, or alternatively by regulating a properly designed “slider” (see Figure 2: bottom right window). The perspective of earth’s projection is done in such a way, as to show the magnetometer’s sketch on the screen. In another window (see Figure 2: bottom left window) students can observe and use three instruments: a horizontally positioned compass that measures declination, a compass placed in the magnetic meridian plane that measures magnetic inclination and a total field magnetometer.

In parallel to the virtual measuring of the field, students can also observe the resolved components of the magnetic field vector at any point around the Earth (see Figure 2: top middle window). In this resolution the quantities of field’s intensity, declination and inclination are clearly noticeable. The students have also the possibility to visualize and resolve the vector within the Cartesian system coordinates. In addition, they can rotate the projection of the vector representation for more convenient observation of the relative angles and vectors.

At a higher knowledge level, students can also change the value of the measurement date parameter, provided that they have been introduced in the field’s variation with time. Of course, it is assumed that the students have also learned some basic notions about the origin of the Earth’s magnetic field. Measurement values are simulated to real ones as they based on the IGRF (International Geomagnetic Reference Model) geomagnetic field model of International Association of Geomagnetism and Aeronomy (IAGA 1995). This model is designed to approximately calculate Earth’s magnetic field from Earth’s interior upwards into space without taking into account external magnetic field sources. It is based on the usual expansion of the spherical harmonics of the potential in geocentric coordinates (Campbell, 1997; Lowrie, 1997) and describes the field’s variation within time. At regular times, new spherical harmonics coefficients supplement it in order to renew and fix its anticipation in the future. In view of the educational purposes for which the model was used, the magnetic field values had no higher accuracy than that of the order of 1 μT.
Figure 2. In a special configured environment, students can select whichever place of the world they like on a 3D rotating globe or on a plane map, and to measure the magnetic field's elements at a certain height, meanwhile they can see the field's vector analysis.

The dipole component of the Earth's magnetic field, which consists the 95% of the total field, is presented in another window of the Gilbert microworld (Figure 3). In that window, students can test the field's existence around the whole planet Earth by a number of compasses that can freely move into space. In this environment, students can easily learn the lines of force as well as to magnetic poles natural position. Field's lines of force may be displayed at student's choice.

Displaying the three elements of the magnetic field (intensity, declination, inclination) on maps (Figure 4), it helps students to realize that these three elements coexist in every point and are modified at the same time. For instance, students can observe the magnetic poles in the three maps, to compare their observations and to realize that in all of these three plots the poles have characteristic features. Students also realize that in many places on earth, compass points out to a direction deviating considerably from the North. The coincident display of these three maps reveals the value of the "multiple representations" as well as the "direct manipulation" of the objects (Teodoro, 1990; Shama and Layman 1997).

The introduction of examples from an Applied Geophysics geomagnetic survey was one of the essential innovations of GAIA in the teaching of the magnetic field in secondary education level. Beyond the comprehension of notions as the induced magnetization, the addition of the induced field vector to the Earth's field and the magnetic permeability of the materials, the microworld further aimed to present a simplified example of a practical application of Earth's magnetic field measurements, such as the detection of mineral deposits and the antiquities.

In the environment shown in Figure 5, students experiment with a buried plate of square or rectangular section. The plate is considered infinitely elongated in order to simplify the problem from the existence of edge anomalies. The plate is oriented E-W while the magnetometer is moving and measuring vertically to the plate, to N-S (Figure 6). The plate's magnetization is considered only induced and its material can be selected out of a large variety of geological rocks with different values of magnetic permeability. For each rock, typical values of permeability and susceptibility are given, in companion with the range of these values in the real state.
Figure 4. The coincident display of the magnetic maps facilitates the observation and modification of all Earth’s magnetic field elements at the same time.

Figure 5. In the magnetic survey environment, students can expertise with the buried plate detection by the implementation of a magnetometer. They can also select the material of the plate, and the location where the experiment takes place. Here the experiment takes place with a magnetite plate of square section, at an area close to the North Pole.

Although the virtual experiment can take place everywhere on Earth, we suggest the choice of three places with characteristic inclination (θ) values. These are: the North magnetic Pole (θ = 90°), the magnetic equator (θ = 0) and an intermediate place like North Africa with inclination equal to 45°. Anomalies observed in measurements of the total field above the buried plate in these three areas are advisable for the induced magnetization presentation to the high school students.

Figure 6. The orientation of the buried plate is E-W while this of the survey traverse is N-S

Figure 7. Earth’s magnetic field anomaly caused by the induced magnetization of the square section buried plate in the North magnetic Pole.
At the North magnetic Pole the Earth's magnetic field vector is perpendicular to the plane of measurements. Since the particle magnets of a paramagnetic material are polarized according to the field (a diamagnetic material causes the opposite effect) the induced magnetization will be also perpendicular to the plane of measurements. In the case of paramagnetic materials, which are the most common in nature, the plate's induced magnetization is shown in Figure 7. The lines of force of the induced magnetization field of the body are symmetrical relative to the vertical axis that passes through the centre of the body's section. The values of the measurements are increased at the points where the body's field has the same direction with Earth's field, while are reduced where the two vectors are opposed. At the points where body's field is horizontal (like on body's sides), no essential variation is resulted.

In magnetic equator (\(? = 0^\circ\)) Earth's magnetic field vector is horizontal. Following the aforementioned technique, it is easy to find out that the diagram of the measurements is also symmetric to the body but inversed in sign in relation to the one of the North magnetic Pole (Figure 8). In body's centre, the lines of force of the body's induced magnetization are opposed to the Earth's magnetic field and thus the field's anomaly is negative. In the case that inclination is 45\(^\circ\), the lines of force are symmetrical to body's diagonal (Figure 9). The magnetic field's anomaly has an asymmetrical pattern and therefore its interpretation regarding body's position becomes more complicated. The point where Earth's field vector is vertical to that of dynamic lines is just above the body, and there we observe that field's anomaly is practically zero. With exception to the magnetic poles and equator the diagram is asymmetric at all the other positions (More details in Dobrin and Savit, 1988).

By the final stage of the microworld Gilbert students can comprehend the notion of induced magnetization and how it is depending on the magnetic properties of materials. From the example of the magnetic survey the students are introduced to the field of Applied Geophysics and its contribution to the detection of oil deposits, minerals, antiquities, etc. Contemporary science can provide students with many such examples, possibly exciting their interest for acquiring new knowledge.

Figure 8. Earth’s magnetic field anomaly caused by the induced magnetization of the square section buried plate in the magnetic Equator.

Figure 9. Earth’s magnetic field anomaly caused by the induced magnetization of the square section buried plate in position with magnetic inclination equal to 45\(^\circ\) (e.g. North Africa)
Conclusions

The GAIA software was designed and developed to allow to operate a virtual educational laboratory addressed in secondary school students. Students may comprehend basic notions of Earth’s magnetic field and become accustomed to them as well as with other more fundamental notions of magnetic field theory, such as induced magnetization. A number of activities based on Gilbert microworld have been already created. Students, working in teams under teacher’s guidance, can enhance their knowledge on Earth’s magnetic field by experimenting with Gilbert. Initial evaluation of students performance indicate a significant advantage in their understanding on basic Geoscience concepts when using GAIA as compared to their traditional school teaching methods.

Abstract: In this communication we present how to design and to develop a course in an asynchronous on-line university. It is based on three key aspects: a detailed working plan, interactive and multimedia learning resources and the teacher coaching activity during the course. As an example of a Mathematical course implementation we discuss some aspects of a Statistics course of the Computer Science curricula at the UOC.

Introduction

La Universitat Oberta de Catalunya -UOC [The Open University of Catalunya]- was born at the end of the 1990's to offer university undergraduate and postgraduate degrees in Spain. The UOC is an on-line university based on an asynchronous model, both in time and space. The relationship between the student and the UOC is established through a Virtual Campus, an Internet-based communications environment. The Virtual Campus allows students and lecturers to interact, without having to occupy the same time or space; it also facilitates communication with the other areas within the university itself (the Secretary's office, library, I.T. helpdesk, etc.) through a PC connected to the Internet.

In general, mathematics' subjects suppose a stumbling block for all the students who have to overcome them, more in particular; in distance learning environments the difficulties that are detected are even bigger. In fact, the students who attend a kind of subject like this one only can make use of a text and the possibility of getting in contact with the teacher by writing a message to him. In these conditions, the difficulties for the learning process are, in general, considerable. With the purpose of facilitating the learning process of this type of subjects, a detailed planning of the activities and the use of technological resources compatible with the environment are proposed and also the redefinition of the teacher's role.

The teacher becomes more a learning facilitator rather than an information or content transmitter.

On-line learning strategy

Every semester the student enrolls the different courses selecting those ones of interest from the curricula. Each one of them has a detailed planning. This planning consists on a set of weekly working packages. A working package includes general objectives, theoretical contents, examples, practical activities, and assignment criteria. In an on-line learning environment the student has a computer connected to the net. So, the planning presentation and the most of the learning resources take advantage of the information and communication technology. The learning resources are any kind of multimedia document (even printed text), interactive simulations and self evaluation systems [Mor 2000]. This kind of resources are fundamental to overcome the limitation of learning material based on printed text [Vallverdu 1999]. On the other hand, the planning presentation evolves depending on the student activity and his or her interaction with the teacher. The role of the teacher is no more focused on the information transmission but the
learning facilitation. This means that the teacher coaches the student, promoting activities, moderating debates and reflection, and, of course, has to make the assignment.

An example: a course of statistics

In almost all areas of learning, from engineering and sociology, through to biology and economy, certain issues arise and they are hard to describe using mathematical models which are often too complex or, conversely, too simple. In practice, results are often obtained from experience and from a series of well-organised and appropriately-treated data. Statistics studies how to obtain relevant information from a series of data and can become a fundamental tool in the decision-making process. In view of this, we had a special interest in design and develop a course of statistics, which would help the student attain the objectives established for the subject for which he/she has enrolled. We present a course of Statistics of the Computer Science curricula at the UOC [Sancho 2000].

By following a ‘Learning by doing’ methodology [Smith 98], the chance to perform a statistics-related task is offered to the students, the interest of which lies both in the conclusions he/she can draw from it and the processes and tools used. This task is made up of several parts: collection and organisation of data, descriptive analysis of the data, interpretation and meaning in relation to populations and conclusions and decision-making. Each student’s learning process is built up adaptively, based on how he/she resolves these practical tasks, requiring the student to apply the various concepts he/she has assimilated. The teaching strategy for the student to assimilate the necessary content is provided by the scheme of work in which targets, content and the activities necessary to attain these targets are determined in a personalised fashion.

With the purpose of assimilating by the students the basic contents which have to allow them to accomplish the statistic works, the consultant will propose a pace of work and some weekly activities where the most important aspects to discuss, according to the timing of the subject, will be pointed out. The consultant will also comment the most relevant video units for the weekly theme and the convenience of visiting certain web pages to strengthen the ideas, which have been introduced to the study notes.

It is, then, important to highlight the fact that this learning process takes place on a network where the different agents involved can interact: students, lecturer and content. Interaction takes place through the resolution of exercises and experimentation using simulation tools via the Internet (XML standards, Java applets, J2EE) that helps to set the rhythm of the student’s progress.

Conclusions

The work we have done has given us a new perspective on both the creation process and the design of teaching materials required for a virtual teaching and learning system. This perspective is based on the atomisation of contents and on the creation of all the possible links between them. In this way, we can achieve an adaptive environment, which will help personalise the teaching provided and ensure that the course objectives are met.

In terms of the common, adaptive learning environment for different university degrees, which include “Statistics” within their syllabus, we have explored different didactic materials for the teaching of quantitative subjects. By paying particular attention to the methodology, the content and the technology, the basic pillars which support the following have been established: the basics of knowledge, the interface, specialised strategies and the necessary technology to make everything work correctly.

WebSaber: Solving Problems in a Computer-Supported Cooperative Learning Environment

Abstract: With the Web now providing the infrastructure for cooperation, the opportunity is ripe to create virtual community of problem solvers. We are working to create WebSaber, a computer-supported cooperative learning (CSCL) environment in which teachers have a set of communicating and coordinating tools, for promoting cooperative activities of problem solving. To explain WebSaber, we offer an overview of cooperative learning, and CSCL, describe WebSaber, detailing its features, and, finally, point out the conclusions and future works.

Introduction

Cooperation is acting together, in the pursuit of shared goals, the enjoyment of the joint activity, or simply furthering the relationship (Argyle, 1991). The educational system may not be concerned with fostering cooperation in learning but learners' work together, depending on the particular context. Cooperative learning is a teaching technique that develops problem solving and critical thinking skills through student teamwork. It consists of small groups working together to complete academic tasks, which involve a range of objectives, such as searching for facts, applying concepts and principles, problem solving and creative thinking, and teacher as facilitator and coordinator, setting the guidelines, encouraging cooperation, reviewing performance and joining to the groups.

Cooperative learning can be sustained by learning theories based on the same underlying assumptions that individuals are active agents that purposefully seek and construct knowledge within meaningful context. Sociocultural and Constructivism theories can play this role. In the other hand, the Internet can provide the infrastructure to foster cooperative learning activities.

Despite the potential, CSCL environments met serious problems. Frequently, cooperative learning is assumed as a natural output of teamwork. It is also assumed that the availability of CSCL tools is enough to motivate peers cooperation. However, cooperation cannot occur naturally and needs to be articulated by the teacher. We believe that CSCL environments should provide teachers with a comprehensive set of cooperative tools, able to be customizable according to teachers' pedagogical goals. Face the expressive number of CSCL environments, WebSaber was created to offer to the teacher safe, flexible and customizable cooperative learning setting.

WebSaber – an Environment for Cooperative Problem Solving

WebSaber was developed following the four phases of Software Engineering classic life cycle: analysis, design, implementation and evaluation and tests. The analysis phase aims to define and clarify the problem to be solved with the proposed software. In Brazilian software market, CSCL environments available in Portuguese, are lacking. Addressed solution was the development of an open CSCL environment for the domain of problem solving to be publish in the Internet and oriented to elementary school teachers and learners. The design phase requires the understanding of the nature of what is to solve problems in a cooperative way. In WebSaber, to solve problems is a social and technical step-by-step process. Five steps of a simplified approach of classic scientific method was adopted: the analysis of the problem, the building of preliminary ideas, the choice of good ideas, the planning of solution and its implementation. Current online system basically contains coordinating tools, with which teachers pose problems to be solved, choose steps and tools and control tasks, goals, dates, and cooperative tools, with which the learners cooperate and communicate among them, and build shared solution. The prototype main interface provides links to system components: Available Problems library, Selected Texts, the Tutor Mode and the Environment itself. Available Problems is a library that lists existent problems.
The Tutor Mode is the teacher working space. Accessing system at the first time, teachers must to fill a form for obtaining free access. They can choose one of the available problems to be solved, in the problem library, or register a new problem. The system automatically includes the new problem into the problem library. Two distributed tools help the coordination of the work: a schedule form allows the teacher to include, manage and publish activities, tools and dates; and an distributed agenda informs the learners about synchronous meeting dates and schedule adjustments. Teachers can also register URLs to be used as online complementary bibliography. The system automatically displays and distributes the information. Planned the tasks, the system opens its infrastructure to support cooperative problem solving activities. For that, it displays selected steps, allocates tools, creates a mailing list and a forum room and opens a room chat, allowing users to access the Environment itself.

The Environment itself is the learners working space. The system metaphor is a meeting room, where users can interact and work in. WebSaber provides three main locales: a Hall, a SittingRoom and a WorkRoom. Each locale has a clear purpose, its own activities, communicating and coordinating tools and a temporal dimension. The Hall displays available problems in a virtual wall. The Sitting Room is the space for social changes, where users can chat, send messages and write and show off personal annotations. The WorkRoom is the work place and it supports the problem solving dynamics. The dynamics follows enchained steps, and these steps are related to specific tools and to the teacher coordination support. Some steps of problem solving demand a shared whiteboard. The WebSaber central component, that makes it different from similar environments, is precisely the whiteboard. Cardoso, Lima e Silva (2000), in the context of a Computer Science bachelor degree project, advised by the author of this paper, developed a whiteboard, that can be accessed from WebSaber environment. The tool is composed of the whiteboard itself, a chat software, an individual notepad and mechanisms for awareness, brainstorming and voting. The whiteboard allows file downloading and importing. The multi-user interface is based on the tightly cooperation mode, using the WYSIWIS (what you see is what I see) approach. It assures the sharing of the work context for all logged users. System scalability does not restrict the number of participants, whose access the whiteboard by typing valid username and password. It is the security mechanism. WebSaber also has its own e-mail and chat servers.

The evaluation and tests phases met problems. A critical point in the trajectory of WebSaber 1st version was the lack of a community of users, whose could evaluate the system in real use, and give feedback to enhance future versions. Maybe, the system security politics had inhibited its use. Tests indicated that WebSaber fulfills technical requirements. Over 100 Computer Science undergraduate students tested the prototype performance, attesting its scalability, extensibility and security. In these cases, the protocols, the priorities and restrictions mechanisms have performed well. These users related that it is easy to work in the Tutor Mode, but they are not the intended audience.

Conclusions and Future Works

The Internet client-server architecture allows the WebSaber gradual extension and upgrading. We received Governmental grants to rethink and improve the system. We are, at the moment, refining coordinating mechanisms, designing a new interface and developing a set of tools (a forum, a graphics editor, a new whiteboard) and adding two software agent to improve cooperation. WebSaber is primarily a work-in-progress and an academic project. Our research goal is to put available an experimental space, where teachers, undergraduate students and researchers can think and rethink about cooperative learning, new ideas and innovative features for CSCL environments.

Abstract: The way to obtain information has exceedingly evolved thanks to the development of new technologies and the possibilities that multimedia offers. The project presented in this paper aims to create a Community of Digital Libraries that allow euskaltegiak (schools to learn Basque), and more concretely, their students, study Basque language by using multimedia applications. CyberBiblio, our particular Digital Library, is a local solution with contents of general interest. It is based on a simple scalable architecture and uses resource-sharing mechanisms to achieve its objectives. This paper describes in detail aspects that should be considered if one wanted to implement such a service, highlighting some problems one must resolve.

Introduction

The explosion of educational multimedia applications is a reality, and some euskaltegiak (schools to learn Basque) have embraced this option. These euskaltegiak have added some workspaces where people can develop their Basque language skills on their own through books and computer programs. The first step begun in 2000 with HEZINET (Pérez, T. A. et al. 1999), a system for distance language learning called Hezinet. This product uses multimedia and artificial intelligence techniques to offer adaptation to the user. At the moment the system is being used in about 2500 workstations in the Basque country and Latin America.

In order to complete the system more reference material is demanded. Not only books, but also interactive programs to complete the workspaces already mentioned. The use of one of such programs is simple, but when there are several ones to manage the use becomes not so easy. For example, some of them need to have the original CD in the drive to work properly. This would be fine if we used only one of such CDs, but becomes unmanageable when the number of these systems increases. If we also wanted to optimize the number of CDs, we had to restrict the use or install and uninstall such systems based on the users’ demand.

To overcome these drawbacks we have developed a digital library (DL) to be used in the environment previously described. We call this DL CyberBiblio. It contains interactive multimedia programs. Users have the opportunity to access every material included in the system from their workstations without being worried about which CD is in a drive, or which requirements the software has or without having to install or uninstall any of the programs in their workstations.

The challenge has been to build such a system having in mind the idea that the system would grow in the near future and the architecture for the system would have to be stable to support that problem. Besides the response time would have to be acceptable in such cases. In other words, the system was required to be scalable: if we wanted to increase the number of workstations or the quantity of material included in the system the architecture have to adapt itself to those changes without [major] changes in the system. Even to add new services the system has to be able to include them. Also, the architecture has had to be simple: easy to understand and build. The users of the system would be non-specialized people. The administrators of the system will be people with a limited experience on computers. So a complicated organization can guarantee the failure of the system. Finally, the system has to be fault tolerant and economically affordable, that is to say that some of the requirements can vary slightly in order to get a cheaper (let us say, not so expensive) system.

In this paper we present the major problems we have faced to build a system like the one described before, and the way we have solved them. To do this we first introduce a taxonomy for digital libraries, then we describe with some detail the library and then the architecture of CyberBiblio. Afterwards, we discuss some problems overcome during the implementations of our particular DL and some conclusions and future lines.
A Taxonomy for Digital Libraries

There are several criteria to classify DLs. These include (1) the media used on their documents, (2) the kind of documents they store, (3) the geographic scale of the network they use, (4) deployment of the information, and (4) user-access policies.

According to the media used on their documents, DLs may be classified in text file, audio, image libraries or multimedia libraries. The library created by the Gutenberg Project (http://www.promo.net) contains basically texts. Texts are usually formatted or digitized from a printed book, a map or from an Egyptian papyrus such as the documents in Tebtunis, one of the sections of the Berkeley Digital Library (http://sunsite.berkeley.edu). Texts usually also include some pictures or graphics. The Printed and Photographs Online Catalog (PPOC) from The Library of Congress (LOC) (http://www.loc.gov) or the Microsoft Design Gallery Live (http://dgl.microsoft.com) are examples of image libraries. The LOC also contains a catalog of its audio section of the library, called SONIC. Another audio library can be the "biblioteca de voces" (library of voices) included in the Miguel de Cervantes Digital Library (http://cervantesvirtual.com), which is a result of a project to make available best-known books (such as Don Quixote) to visually challenged or illiterate people. Even the Napster Community (http://www.napster.com/) can be considered an audio library which requires a specific software to browse it. Although a library can contain several of these types of documents, we cannot say it is multimedia unless it works and relates with all those media altogether (or, at least, some of them). We could describe some of the libraries as "multiple libraries of one specific media".

Considering the contents of the documents, there are different kinds of libraries. There are general-purpose DL such as the LOC. This DL is open to many topics, whilst other are devoted to a more specific purpose, such as the ACM Digital Library (http://www.acm.org/dl), which is about computer science.

If we look at the geographic dimensions of the network, two types of DLs can be found. On the one hand, those that cover the worldwide area, based on the use of Internet. On the other hand, the ones that constitute a local solution, based on an intranet. The former ones are accessible from any computer connected to Internet while the latter ones offer their services to a more concrete audience, restricting access to a local area network.

Another criteria are the number of places used to store the documents. In that sense, centralized libraries store the documents in one place and distributed ones have several document containers spread out according to the geographic dimensions of the network they use.

Finally, we include the user-policy as another criteria to consider. Free-access libraries allow users to browse through their virtual premises and read or consult anything they want. Some other libraries only allow browsing and charge users for reading. Others charge even for browsing. The latter ones are restricted libraries.

CyberBiblio

The project CyberBiblio has been carried out between the Hypermedia and Multimedia Group of the University of the Basque Country and with the help of a private foundation dedicated to the development of Basque Language called Aurten Bai. The principal tasks have been done during 2000. In 2001 we have started to install some units of these community of libraries through the Basque Country (in either euskaltegiak or city libraries).

CyberBiblio is a DL of interactive programs published in the Basque Country. The catalog shows a list of the available titles at that time (Fig. 1). The main characteristic of the shared material is that use multimedia presentations like animations made with Macromedia Director, Flash, ToolBook, etcetera. Also, users could find other documents, like mp3 audio files, pdf or word documents, and so on. In general, all kinds of material available on CD-ROM. Usually, it contains atlas, encyclopedias, learning material for children, games, monographs, Basque music... everything one can use to learn Basque or increase his/her knowledge about Basque culture.
Corresponding to the criteria given in section 2, we could say that CyberBiblio is to be used in an Intranet. Since we do not hold the copyrights of all the programs we use in the DL, we are not entitled to share them with all users in Internet. There would be no problem to show the catalog, but anything beyond that point would violate the rights of some of the programs the DL includes. It also has been designed as a distributed library since the programs can be stored in different computers. The catalog is in charge of indicating where to find the desired resource. The target environment would decide the user policy. In the case of CyberBiblio we have both policies. When it is installed in a euskaltegia the only users allowed to use it are the students of that school. However, we have also installed the same DL in public libraries, in which every user of the library (or a visitor) can access to the computers (of course, if there is some space available).

In order to classify the purpose of CyberBiblio, we should say that the main purpose was to provide contents to learn Basque. Nevertheless, these contents have grown and the purpose is to spread Basque culture, as a traditional library could do. So we can say that it has a specific purpose for a group of population (Basque students) and a general purpose for those who already know the language. Currently the contents are limited to Basque Country issues. The implementation is always in a library either in the Basque school or a public library.

Architecture of CyberBiblio

Since CyberBiblio has been developed to share multimedia applications distributed on CD-ROM, it is necessary to find a way to do it. During the design phase of the system we consider two main ideas: *install on-demand* and *resource sharing*.

**Install on-demand**

This configuration emulates the behavior of a jukebox. When users browse the catalog, they can select (ask for) any application included. The system first controls whether the application has been already installed in the system, if not, it searches through the CD-ROM base and installs the application on the corresponding PC. When he stops using the software required, the catalog would be shown again.
This option assumes than periodically the system would clean the workstations, because the installation, uninstallation and reinstallation process leaves sometimes files on disks and the registry is not left as it was found at the beginning. Also, the system has to be able to uninstall some software due to space requirements (there is not enough disk space for another application). Finally, the process of install and uninstall applications add a delay (usually several minutes) to the system that may not be assumed by the users.

To accomplish this alternative, there is some software available. For example, WinInstall from Micro-mouse (www.micromouse.com) or Microsoft Windows Installer (http://msdn.microsoft.com/library/default.asp?url=/library/devprods/vs6/vstudio/vsinstall/veonmicromousetsoftwindowsinstaller technology.htm) from the Microsoft’s Zero Administration Kit (ZAK) or Microsoft System Management Server (http://www.microsoft.com/catalog/display.asp?subid=22&site=650&x=22&y=11).

Resource Sharing

In this approach, the resources are shared from the place(s) they are stored. This is not a new concept. In fact, every operating system includes this functionality. Microsoft Windows 2000 includes, for example terminal server services and sharing of file system.

This alternative presents some advantages when compared to the previous solution. First of all, it is not necessary to wait for the applications to be installed. Although they have to be installed, this process is done only once. Besides, there is no need to use the network to do that. However, in this case the network is more frequently used.

The terminal server let each terminal establish a session in one of the computers that contains the required resource. The user works directly against the application container, but the execution seems to be happening on the local computer. This is a cheap and simple solution unless you have to use local peripherals from the server execution (for instance, if you want to listen to an audio file on the speakers of your computer instead of the ones on the server; or local disk drives; etc.). This problem can be overcome using the Independent Computer Architecture (ICA) from Citrix (http://www.citrix.com/products/clients/ica/technology.asp) at a not so cheap price as the operating system software like Windows 2000.

An alternative is to use the file-sharing feature of the operating system. Using this approach, each workstation would have to have access to the files installed in one common place and there will be necessary to do several small actions in each workstation (modify the register when appropriate, add some dll’s, etc.)

Decision taken

Our choice has been resource sharing using the file system sharing of the operating system. The aspects we have taken into account to make a decision include the quality of the solution, the difficulty of its implementation, and its cost (one of our main handicaps). In our case, the price avoided the election of ICA protocols, one of our best choices. We also consider using Windows 2K, but its price push us to choose to use it only in a server machine and use other operating systems like Windows Millenium, also from Microsoft. This choice implies a more difficult way of implementing the security in the system but accomplishable (although less transparent to users).

Problems Overcome

Most of the problems of the implementation of CyberBiblio arose when adding applications to the library (at installation level) and others to maintain system security (avoid users misuse the system). In the following paragraphs we will detail both.

Problems at application level

Multimedia and interactive applications shared in a system usually try not to overload the computers in which they are executed. So only a small part of data is copied in the user disk, being necessary the CD-ROM to access the rest of information. Based on our experience with the installation of multimedia applications, we can distinguish four types of installation:

1. Direct copy. In fact the applications in this category do not need to be installed. There are some executable programs and data files. The installation process is as easy as copying the files to a shared device (commonly a shared hard disk).
2. *Files with a specific reader.* In this case, the installation process is similar to the one above. However, there are common (freeware) reader programs to access to these types of documents. In this category we could find pdf, word or postscript documents; audio files in mp3 or wav; video documents in quicktime or mpeg format. Or even navigable documents in HTML. In this case it is necessary to install the specific reader at each workstation.

3. *Simple install applications.* Our experience tells that most of the applications belong to this type. In this group we include those applications that include an installation program responsible of putting the files in the appropriated location. This program is generally called *install* or *setup.* What makes this process simple is that the program does not need to modify the workstation computer registry. Sometimes it is necessary to include some library files (DLL) on the workstations to achieve a correct execution. Sometimes there are incompatibilities between requirements of one application and another. For example, two applications use the same DLL. But one of their installation programs do not care about which one is available in the system at one moment. So, they allow the substitution of newer DLLs with older ones interfering with the other application execution.

4. *Complex install applications.* The applications in this group include installation program as the previous ones, but during this process or during executions some problems arise. For example, some of the applications check if the CD-ROM is present on the machine during their execution. These types of applications have been the most difficult ones to install in order to achieve sharing access. Though we installed most of them, there are only two that we couldn’t share through the network. In these cases we should establish an alternative method to use them. For example, traditional CD-ROM borrowing.

**Problems at security level**

We have considered very important to prevent the workstations from potential malicious use. Sometimes users know more about computers than librarians. So we have spent some time determining a security policy. This alternative could prevent from actions that do not let the system remain configured. We have considered that the best option is to prevent people to access the workstations with other purposes than accessing the catalog. The operating system can help to reach the desired security level. For example, in Windows 2000 Server in combination with Windows 2000 Professional it is easy to establish a security policy and to spread it to the workstations.

However, if we want to do it in simpler operating systems (like Windows 9x or Me) it is necessary to work directly with the registry. Also, we must define which resources we want to show in the desktop (none) or which ones at the start menu (only applications from the catalog). And disable some common functionalities (for example, right mouse button at desktop).

In our case, we decided to limit the access to the resources. Users only have access to the catalog and the applications it shows. So, if the identification is correct, he/she will be able to access the information, but only to CyberBiblio (Fig. 2). If identification fails, the only available option is to close the session and back to the user identification screen.

![Figure 2: Operating system interface (limited to CyberBiblio)](image)

Another problem we had to solve during CyberBiblio implementation process has been the need to write some own data of several applications. Some applications need write permission in some folders. For
example in those that contain configuration files. Other folders, also, offer some free space where user can write information. This has been a very important aspect considered, because it is not recommendable to let users modify system files and folders in order to prevent an stable behavior of the system.

Conclusions and Future Work

In this paper we have presented CyberBiblio, a DLs community centered on Basque culture. CyberBiblio represents a significant contribution to scientific community, because, as far as we know, there is no other DL within CyberBiblio characteristics. Also to Basque society, because its installation will notably improve the Basque language learning and normalization. And by extension, to society in general, because it is very simple to implementing DLs with similar characteristics in other sites and in other contexts.

Introduction of CyberBiblio, the first DLs community in the Basque Country, has being a revolution in divulgence of multimedia material. This is because it guarantees almost all population access to a large amount of multimedia information published on CD-ROM. And everything in a quickly simple way.

As a result of this project there is a commercial product now implemented in different places of the Basque Country. At the moment there are three DL in the local libraries at Amorebieta, Balmaseda and Baracaldo. There is another DL located at Zornotza-Amorebieta Barnetegi, a school dedicated to the learning of Basque language. Now we are in contact with other town or city halls of the Basque Country to show them the product, its possibilities and characteristics. Our main objective is creating the major number of public places dedicated to Basque language learning and practice. Also we pretend to include there other computing tools like HEZINET.

Apparently, this is only the beginning of a progressive and constant settlement of Multimedia DLs in the Basque Country. Librarians’ experience by now has been very positive. As well as users’ opinion, which has flooded all our perspectives, and give us enough courage to improve the library and introduce new services. In fact, we are now working on a version of CyberBiblio to Spanish culture.

Abstract: In most universities, the required undergraduate courses have high enrollment (multiple sections) and are frequently taught by part-time instructors or graduate students. Part-time faculty are an important asset to any university, but this group can also present a wide range of professional qualifications and teaching experience which can result in significant variations in the depth and quality of instruction. This paper reports on the collaborative effort by full and part-time faculty in an urban Midwestern College of Education to improve the consistency of course content and quality of instruction between multiple sections of a core undergraduate course. One strategy used to reduce the threat of "course drift" was the development of web-based resources to support both the instructor and student.

In most universities, the required undergraduate courses have high enrollment (multiple sections) and are frequently taught by part-time instructors or graduate students. The National Center for Education Statistics reported that as of Fall 1998, 43 percent of postsecondary instructional faculty and staff were employed part time as defined by their institution (2001, p. 2). An additional survey by the Coalition on the Academic Workforce of humanities and social science disciplines showed that less than half of introductory undergraduate courses were taught by full-time tenured faculty, and approximately 43 percent of all undergraduate courses in those disciplines are taught by part-time faculty or graduate students (Townsend 2000, p. 2).

Part-time faculty are an important asset to any university, but this group can also present a wide range of professional qualifications and teaching experience which can result in significant variations in the depth and quality of instruction (Lankard 1993, p. 1). In the case of large classes with multiple sections, the use of part-time instructors or graduate students contributes to significant problems with consistency and coherence to learning objectives (Roberts 2001, p. 2).

This paper reports on the collaborative effort by full and part-time faculty in an urban Midwestern College of Education to improve the consistency of course content and quality of instruction between multiple sections of a core undergraduate course. One strategy used to reduce the threat of "course drift" was the development of web-based...
resources to support both the instructor and student. The web site of shared course materials was intentionally designed to:

1. Improve consistency and quality of instruction throughout all sections of the course.
2. Reduce the preparation time for faculty.
3. Provide class materials such as PowerPoint presentations, web links, assignments, and other related materials in one easy to find location.
4. Model Internet resource use

The web site was developed using Microsoft Word, PowerPoint, and FrontPage, and was made accessible to students and instructors approximately one month after the start of classes in the Fall 2001 semester. The web site has been enhanced and modified during its use in the Spring 2002 semester. A survey and set of interview questions have been developed to collect data from students and instructors on the utility of the shared web resources. Student work will be collected from sections that used the web resources and from sections that did not to compare the quality of the products. Additional sources of information include grades, course evaluations, and student comments on those evaluation forms.

Online Discussion Techniques for Teacher Trainers and Language Learners

Kathleen M. Saville
English Language Testing and Training Program
CACE/USAID
American University in Cairo
Egypt
ksaville@aucegypt.edu

Abstract: Are there online activities that can encourage exploration, risk-taking, cooperation and experimentation that both teacher and learner can benefit from? This brief paper will include a discussion of two effective discussion techniques for teacher trainers and second language learners that have been used in an online format. Kiva, a discussion technique adapted from the Native Americans of the America Southwest, can be used as a forum for discussing issues of professional interest such as the role of the teacher trainer and contemporary topics of interest to language learners. Six Colored Hats is a technique that promotes whole brain thinking and problem solving from varied points of view. Both techniques can be used in an online forum to invite reflection upon issues related to teaching, teacher training, and learning. Both Kiva and Six Colored Hats are carried out in a CALL lab using the LAN to post questions.

Introduction

Techniques for creating successful online discussion are similar to techniques used to facilitate face-to-face discussion. Both are characterized by the following:

- They emphasize active participation and interaction
- They have a task, theme or goal
- They gather a range of ideas, opinions and concerns
- They are usually run by a group leader or facilitator

There are many discussion activities that encourage exploration, risk-taking, cooperation and experimentation that both teacher and learner can benefit from. "Talk is a major means by which learners explore the relationship between what they already know and new observations or interpretations which they meet." (Barnes, 1976; in Cullinan, 1993)

Computer Mediated Communication (CMC) and Discussion

Computer mediated communication permits the learners to benefit from the shared experience of a group engaged in the same study and the opportunity to measure his or her ideas against those of others in the group. (Tam, 2000) Many group discussion techniques can be facilitated through the use of a Computer Assisted Language Lab (CALL). Two such techniques, Kiva and Six Colored Hats have been used in a CALL lab to great advantage.

KIVA

Kiva is a discussion technique that has been adapted from the Native Americans of the American Southwest. It develops critical thinking skills by causing participants to identify and cite reasons for their decisions making within the group. Kiva also encourages creative language learning as second language learners combine (orally) ideas and responses in novel ways to produce complex thinking patterns.

How does it work in the CALL lab?

Traditionally, participants in the Kiva are placed in two concentric circles, the inner circle consisting of four to five members. Only the inner circle speaks, discussing the chosen topic. Members of the outer circle...
listen. After a set time has been called, inner and outer circle members exchange places with each other and the discussion continues. In the CALL lab, the format is basically the same. The teacher/facilitator posts a question to 4 – 5 students/participants. These members of the “inner circle” discuss the discussion topic in an asychronous discussion. After three days, the “inner circle” changes, teacher appointed or participant volunteers, and the discussion continues. After a week or 10 days, the discussion ends with the teacher/facilitator summarizing the salient points of discussion. If the topic was a problem solving one, then a course of action is recommended and posted to the group. An example of an appropriate question for teacher trainers might be: What is the role of the teacher trainer? A student topic might be: English should be the official language of the United States.

Six Colored Hats

Six Colored Hats is a management technique developed by Edward DeBono (1985). It has been adapted to the classroom in order to promote whole brain thinking and problem solving. It also incorporates lateral thinking as well as critical thinking.

How does it work in the CALL lab?

Six Colored Hats represents six modes of thinking, represented by six colors, which are considered directions to think in rather than labels for thinking. For example, when given a topic to discuss, the white hat represents facts and figures, the red hat: feelings and emotions, black hat: judgment and caution, yellow hat: positive aspects, green hat: creative ideas (related to topic) and the blue hat: a summary of topic discussion. In the online environment, the topic for discussion is posted and the group is divided evenly to one color apiece. Each group is therefore responsible for discussing the topic according to the aspect of the hat color they are assigned. The blue hat group will provide a summary at the end of the discussion. This online discussion activity requires advance in-class preparation before it is attempted online. An example of an appropriate question for teacher trainers might be: Egyptian university graduates are often assigned to teach English whether they want to or not. Is this an appropriate policy and what can be done to solve it? (actual question used in teacher training session in Egypt by author). An appropriate problem solving task for students might be: Students are talking while others are talking or teaching. What can be done?

Conclusion

Kiva and Six Colored Hats both provide a means of initiating online asynchronous discussion between teacher/facilitator and student/participant. With effective moderation and preparation by the teacher/facilitator, participants will be able to achieve their educational and professional goals. The potential of telecommunication technology lies in its ability to function as a gateway; a gateway to resources, collaborative learning and individual achievement. (Tam, 2000)

Teaching the Woburn Case Study

Rob Schadt, Ed. D. Office of Teaching, Learning and Technology, Boston University School of Public Health, USA, rschadt@bu.edu
Richard Clapp, D. Sc, Department of Environmental Health, Boston University School of Public Health, USA, rclapp@bu.edu
Nancy Maxwell, D.Sc., Department of Environmental Health, Boston University School of Public Health, USA, nmaxwell@bu.edu

Abstract In this presentation we will demonstrate an instructional CD-ROM, Investigating Community Environmental Health Problems, and describe how it was incorporated into the cooperative learning technique called structured controversy to teach public health students in a Masters level course in Environmental Health. The program was designed as a resource for students regarding the various lessons that were learned in a well-known case. The CD-ROM was produced to help users determine the environmental health of a community, particularly as it relates to the presence of hazardous chemicals. The CD-ROM relies heavily on the experiences of citizens and public health professionals working in the community of Woburn, Massachusetts around the contamination episode publicized in the book and movie “A Civil Action”.

Background of the Course

The Woburn Case Study was used in a survey course in Environmental Health, EH708 Introduction to Environmental Health. EH708 is a required course enrolling approximately 100 students not concentrating in Environmental Health. Although student interest in the course content is highly variable, the course must introduce students to the widest range of environmental health problems. This may be the their only exposure to an environmental health course. However, it is highly likely that these students will work in communities facing environmental health challenges, which have implications for other dimensions of public health within that community.

The used of the traditional case method and a classroom strategy called structured controversy was enhanced through the use of multimedia CD-ROM technology. The Woburn CD provides a rich context for students to identify environmental health data, to better understand the implications of epidemiological principles and how to apply these principles in community settings. We tell the Woburn story through audio and video segments taken from local cable documentaries and expert panels, as well as documents, photographs and other media used in or produced in connection with the trial.

Using the Case Study and Structured Controversy

Several weeks before the scheduled class during which the case was discussed students were asked to explore the CD-ROM, Investigating Community Environmental Health Problems, along with several printed study aids, study questions and websites. One week in advance of the scheduled class meeting, the class was divided into six groups, each group taking the role of one of the key players in the Woburn story. The six groups were organized into three pairs, forming the basis for the structured controversy exercise. During the first 30 minutes of the two-hour class period each group met separately. Each group was given a controversial question and was asked to prepare a response directed to the other group in their pairing. During the second part of the class period a facilitated, spirited discussion ensued with students speaking in their roles as lawyers, scientists, etc.

Pairings and Discussion Questions
Question for citizens group and Department of Public Health group:
Like many environmental health problems, the possible link between drinking contaminated water and risk of childhood leukemia in Woburn was laden with uncertainty. Which kind of error do you think would be worse in assessing a situation like that in Woburn: incorrectly concluding that there was an association between the water and leukemia if in fact there wasn't; or incorrectly concluding that there wasn't an association if there was?

Question for scientists group and press group:
In Woburn, government agencies, scientists, local residents, and the legal system all tried in their own ways to figure out whether industrial pollution of drinking water was causing excess leukemia. What role do you think community members should play, if any, in scientific studies of pollution and health in their neighborhoods?

Question for WR Grace (the industry named in the civil lawsuit) group and plaintiffs' lawyers group:
Local activists who took on WR Grace and Beatrice Foods had a lot of community support from residents who were concerned about their health. On the other hand, some residents accused the activists of giving Woburn a bad name, pushing property values down, and driving industry out of town. How do you think a community can best balance its concerns for environmental health and economic development?

Session Objectives
1. At the end of this session, students will be familiar with some of the details of the Woburn case, such as the scope of the childhood leukemia cluster, the source of drinking water contamination, the various health data and follow-up studies, the lawsuit, and the clean-up activities.
2. At the end of this session, students will be able to articulate problems faced by various stakeholders in Woburn, including the difficulties citizens faced in getting health studies done and clean-up begun, the concerns of health officials not to create false alarm but also not give false reassurance, and the conflict between economic development of the community and health and well-being of its citizens.
3. At the end of this session, students will have an understanding of the role that citizens and citizen organizations can play in creating pressure on government agencies to act, in engaging and working with scientists in conducting health studies, and in following through on efforts to reduce harmful exposures.

Observed outcomes from using the case study
The case study, as presented via the CD-ROM, met the objectives of familiarizing students with many details of the Woburn case. More importantly, when combined with the structured controversy class activity, it allowed students the opportunity to "walk a mile in another person's moccasins," or understand another point of view about the meaning of the toxic contamination problem for a community. Because the format of the class activity required students to consider and articulate their answers to specific questions, several commented that they had learned something in a new way. The level of energy and interaction in the small groups and the class wide discussion combined with student feedback on course evaluations confirmed that this was an active learning process that largely succeeded in meeting our objectives.

Summary
During our presentation we will demonstrate this highly engaging CD-ROM and share video clips of these paired dialogues and subsequent class wide discussion. We will also discuss our lessons learned from producing the CD-ROM and facilitating its use in a public health curriculum.

Accessible Distance Education Based on Collaborative Learning –
A Research Approach

Katarina T. Schenker
Doctoral student in Education, Malmö University
Katarina.Schenker@lut.mah.se

Abstract: This paper provides a short description of the theoretical foundation, accessibility criteria, and the research approach related to the project "Accessibility and learning in higher education" conducted by Malmö University in Sweden. The criteria of accessibility are developed in connection with a pilot course under the project's management, and the research approach is related to course accessibility and how disabled students participate in the collaborative work within a course.

Introduction
Many disabled people do not enter universities even though they have the intellectual ability. The situation in Sweden and US is similar (Horn & Berkold, 1999; National Agency for higher education, 2000). New technology has given disabled people better opportunities to get information and to communicate with people from different places all over the world. Distance learning can be a good studying alternative for disabled students, just as it is for non-disabled students. Malmö University in Sweden is conducting a project entitled "Accessibility and learning and higher education", which is an integrated research, development and training project. The theoretical goal of the project is to combine recent contributions in collaborative learning theory with advances in information technology. The programme focuses on making online university education more accessible to students by intelligent use of the potentials of computer support. In November 2001 a pilot course started under the projects management. The course design is based on a theoretical foundation and on criteria of accessibility that have been formulated within the project. To receive more information about the project, read Schenker's and Scadden's paper “The design of accessible distance education environments that use collaborative learning” (Schenker & Scadden, 2002). The theoretical foundation, the criteria of accessibility and a research focus of the project will shortly be presented below.

Theoretical foundation
In the social oriented learning theory the context for learning is central. The existing situation drives the learning process (Lave & Wenger, 1991; Vygotsky, 1978). The theoretical foundation is partly based on Bakhtin's and Vygotsky's theories which have been developed by Dysthe (1996). According to these theories, dialogue promotes learning, and understanding is seen as an active process. Learning through dialogue means that it is important to give and to receive responses. Trying to understand the other person's thoughts and intentions is necessary, when giving a response. Dysthe outlines also that the differences between thoughts presented orally or in written text, are a learning-potential. Furthermore, there must be a confrontation between voices to make learning occur – people must meet in a dialogue (Bakhtin, 1981; Dysthe, 1996). The viewpoint is thus that learning is a social process. Even if learning is a social process, the process is also individual. It is important to help students to be aware of and reflect upon their learning approaches. Bruner (1996) states that a teacher who supports and encourages students’ learning processes is more important than a lecturer.

Criteria of accessibility
The degree of course-accessibility for disabled students depends on several issues. The section below identifies some of these issues. For every issue, one or more criteria are formulated. The criteria are a synthesis of the theoretical foundation, experiences carried out by project members, and their recommendations. The criteria relate the entire spectra from course providers, students, educational design, and technological issues.
1. Educational design: (A) Course assignments help students to explore their personal learning preferences. (B) Flexibility in the conduct of course assignments and activities is provided to ensure that students can select the most appropriate learning environment and style.
2. Presentation of course content: (A) Course materials that are obligatory are accessible for all students. (B) The design of the course content and its presentation in formats allow students to select the most appropriate and preferred mode to meet their learning needs and preferences. (C) The guidelines for the design of accessible educational software developed by the CPB/WGBH National Center on Accessible Media [1] are followed.

3. The courseware system (a web-based environment for distance education courses): (A) It is possible to enroll in the course without installing additional software beyond that which is normally needed to use and communicate via the Internet. (B) The courseware system is built using guidelines for accessible web content developed by the World Wide Web Consortium (W3C) [2].

4. The approach used by the course providers: (A) The course providers are service minded and give individual support when it is needed. (B) The course providers are flexible and prepared to make decisions that promote course accessibility.

5. The capacity of the student’s hardware, browser, and adaptive technology: (A) Students with disabilities have current computer hardware, modems with speed adequate to handle the kind of presentations required in the course, and the most appropriate adaptive technology and display parameters. (B) Course providers assist students by providing guidance and hints on improving accessibility through optimal use of students’ hardware and software.

6. The student’s disability and degree of functional limitation: (A) No student is disconnected from any part of the course due to his or her functional impairment.

Research focus
The research focus relates to disabled students who are participating in a distance-learning course that has a collaborative net-based environment. The first sub-focus is to test the criteria of accessibility in the course. The students will be asked to rate the accuracy of the criteria. The students will also be asked to give feedback on how the criteria can be developed further. Another sub-focus is to interview the students about their written contributions in the courseware system. Are the written contributions comparable with the student’s actual participation in the dialogue? The purpose is also to learn more about the context in which collaboration on the web are experienced as engaging and touching. Research will attempt to assess whether Bakhtin’s and Dysthe’s theories appropriate in this context.

Telephone: +33 (0)3.81.99.47.34
Colin.Schmidt(a),pu-pm.univ-fcomte.fr

Abstract: A recent article in Educational Technology Review describes 3 types of learning. The tendency today is towards the lesser-planned associative methods seen in electronic learning. Teachers would like to combine such ‘surfing’ methods with their more traditional Information Retrieval techniques (IR) tailored to their own acquisition needs, and habits. Metaphor is the concept we use to construct a way of envisioning the tools of the future for exploring specialized information through multi-link media. The proper manipulation and communication of facts will depend on such tools.

What KING et al define as “Exploration without Objectives” or “Serendipity” in their article on e-learning is the type of activity the scholar of literature loves to delve into. Learning ‘within the framework of’ the total freedom of thought can be quite exciting. One of the greatest tools for knowledge transfer of all time offers such liberty: the Internet. E-learning simply through looking at various web pages and discovering the links they offer—and then the links they offer—is a leisure that lends itself very nicely to general long-term knowledge acquisition. There is room for improvement though.

Personal goals-driven e-learning (exploration) or e-learning by chance (serendipity) when “stumbling across seductive details on a page irrelevant to the individual’s initial purpose for browsing” (KING et al 2001) breaks away from the traditional setting—good ol’ in-school, in-person education. It is thus totally different from performance-related information accumulation through programmed “Instruction” ‘shoved’ at us by the Other (the teacher). As many teachers and researchers get in the know using the rather unstructured approaches, we will follow-up on this trend to learn on one’s own and endeavour to build an approach for improving it.

Ad hoc information research devices on the World Wide Web impede writers of web pages from effectively communicating their knowledge to us.

The problem with having too much freedom in learning is that the links one follows—say in an hour’s time—will most likely yield information pieces that have little in common with each other. This will not do if e-learning is to be taken up by specialists of any sort, whether in literature, medicine, technology, sports, business or handicrafts. In order to succeed, the structure of e-learning must show a few constraints.

We take professors as our example; we however could have used top-notch students, children or the inquisitive retired as our example of a user. Our idea is that professors, say of Philosophy, are quite apt of refusing to read texts on the screen because they cannot circle important passages, they cannot write their comments in the margin, and the pleasure of fondling a book written by an inspiring writer or just flipping through its pages is lost. Indeed, targeting finicky users challenges the interface designer. Professors tend to opt for the more traditional setting, i.e. having 7 or more books open on the desk in front of them, on their lap and on the floor, and of course having the gall to earmark pages, sitting pen-in-hand to question their earlier annotations... some professors in this situation are even inclined to ask a loyal wife/husband or a mediocre student to bring them another book! Why can’t they just use computers like everyone else?

Their behaviour is only suitable to have at home with one’s own books. So can’t the Internet be the professor’s big in-home book? Quite often, his computer is in his home.

Just as “serendipity” is a little too unconstrained a framework for a professor to learn in, being limited to one screen will not do. But isn’t reading out of 9 books at once a little too ‘loose’ of an approach to constructively learning something?! No. The reader must not lose track of the fact that a professor is bright and always chooses books and articles from within the domain he is very at ease with. In fact, few professors truly like the Internet because they never know which section they are in (in a regular library, you can always find your professor next to the same rack of books unless they change it around).
In the end, e-learning and constructing technological responses for others who desire to learn is about the business of correctly communicating information over the Internet. In communication, since the linear image of the telegraph proposed by SHANNON & WEAVER (1949), we have seen metaphors like the orchestra conceived at Palo Alto by BATESON (1981), and the desk-top metaphor from Apple Inc. just to mention a few. The latter is the least important, as it is used simply to communicate to users how a new work environment should be perceived in order to better use it. The other two endeavour to explain ex post facto how human communication functions. What we are trying to do is define a metaphor to be used beforehand, that is in communicating to designers and programmers of software—and eventually hardware builders—the functionality required by professors who like to ‘hog’ a small bit of the library in order to read and quote related passages and ‘wear out’ books. This would require an original interface integrating the activities of more than one person. Perhaps we should modify the activity.

Today we have the capability to surpass the present library work environment taking into account the goals of specialists. Until now, the friendly librarian would simply help a philosopher put Physics, Math and Cooking, etc. to find just Philosophical texts, eventually pinpointing certain authors. But can a librarian out-perform a specialist on, say Descartes, when it come to IR on Descartes texts? Such a user has half of the information he will use in his head already, though he is not sure of the rest yet. He will only know what he is looking for once he has it. Here the problem of reference (JACQUES 1990; SCHMIDT 1997) surfaces; the specific information-seeking context of the problem is nicely formulated by Le Coadic (1994): “A user tries to describe something he wants to another person (librarian) without being sure of what it is, and that person will quite likely not know what it is either”. Our specialist is calling out for a more individualized activity.

Apart from putting the total works of Descartes on-line, we propose to offer, thanks to indexing techniques, the specialist simultaneous reading of his favourite passages. Displaying a number of documents all at once (possibly using depth as a further dimension) would enable a parallel reading of this precious material. The main question is twofold: 1/just how much complexity should he have at his finger tips? ...should he be required to take a course? ; and 2/in what form exactly should he see it? He is so used to doing this at his desk, on the floor or the kitchen counter. Obviously, his efficiency as a teacher or researcher is at stake. Once these questions are answered, we can implement an on-line version suitable to our enthusiastic scholar or the mad scientist metaphor outlined here (to be developed to guide design).

We are therefore entering into the era of the personal alibrary in which one may ‘treat books mischievously’, scribbling notes on then so as to establish a multi-linked environment suitable to being accepted as a new on-line professors’ workbench. Professors always try to find their way back to the bookrack where they read a related passage 3 years before, so keeping track of milestones and the lesser important stops on their voyage through a large corpus of literature could be useful too. Scholars do have difficulty convincing themselves to use two-dimensioned vertical glass screens. And in a domain-bound multi-link Hypertext system it is important to be able to set one’s own “home” or anchor text (i.e. Discourses). Weeding out the non-pertinent is a challenge to e-learning.

Community, Content and Collaboration Management Systems:
Socio-Constructivist Scenarios for the Masses?

Daniel Schneider, Catherine Frété, Paraskevi Synteta
TECFA, Faculté de Psychologie et des Sciences de l'Education Université de Genève
{Daniel.Schneider|Catherine.Frete|Paraskevi.Synteta}@tecfa.unige.ch

Abstract: While there are dozens of "e-learning" platforms, not many systems support the "orchestration" of rich socio-constructivistic learning scenarios. We suggest to explore the pedagogical potential of the increasingly popular portals we call "Community, Content and Collaboration Management Systems" and we present our work strategy.

The Problem

Currently, there exist many variants of web-supported pedagogies, e.g. transmission of contents, web-based instruction, learning by apprenticeship in virtual environments, pedagogical work flow scenarios. Constructivist (e.g. project or problem-based) scenarios are quite popular (Wilson & Lowry, 2001) but supporting technology is hard to find and there is a particular need for tools that support socio-constructivist learning at the activities level. Empirical research (e.g. Dillenbourg 1999) reveals that collaborative or collective constructivist learning is not per se an effective learning method. It is more effective if individuals and groups have to evolve within well-specified scenarios, i.e. sequences of phases within which group members do tasks and play specific roles. While teachers can orchestrate complex scenarios with very little technology, the effort can soon become cumbersome.

Remember 1993's slogan of "shifting the focus from teaching to facilitating"? Todays "E-learning" systems are mostly anchored in the behaviorist CBT tradition. They focus on content delivery and the teacher's "facilitator" role is degraded to deal with web contents, quizzes and grading. They fail to support rich socio-constructivist scenarios engaging students in active project-based learning. Therefore we argue that R&D in educational software should not just focus on improving passive "interactive" courseware but on tools supporting students to solve more complex and open-ended tasks.

The Work Plan and Strategy

Implementation strategy #1: Imitation of "Internet culture". Web pages, forums, e-mail and FTP are successful because they support the basic needs for exchange, communication and collaboration. While simple web technology does enable creative educational scenarios it has 2 drawbacks: (1) Maintaining static web-sites is time-consuming and simple discussion systems do bad knowledge management. (2) More sophisticated scenarios (like co-authoring or work-flow) are badly supported. Now, community web-sites facing the same problems found an answer. Within the last two years have sprung up what we coin C3MS (Community, Content and Collaboration Management Systems). Inspired by personal weblogs, news systems, simple CMS and various groupware like file-sharing or calendars, C3MS are modular tools for configuring interactive community web-sites. Systems like PostNuke or PhPWebSite offer a good set of core portal functionalities, such as user administration, a news/journal system, web-links sharing, search, FAQs and polls. Extension mechanisms allow third parties to contribute additional functionalities like collaborative hypertexts, picture galleries, simple content management systems, event calendars, chats, project managers, file-upload, and glossary management. Since we believe that a large number of rich educational scenarios can be supported by modular C3MS systems at reasonable cost, we started deploying a few systems with teachers to investigate.

Implementation strategy #2: Adapt to teachers. Success stories of new technologies in education are often related to the teachers' ability to insert it into existing knowledge. It is easier to promote change when technology is simple and when teachers can relate to "models" they know, even if they are not necessarily related to teaching. Teachers must have an operational awareness (vonGlaserfeld) in addition to operational control. Inspired by
Guzdial’s (2002) work with CoWeb, we start by presenting simple activities that can be enhanced with C3MS. At the same time, we also introduce these portals as community tools (for teacher support) and we hope that the perception of their usefulness for “professional life” will help introducing them to education in the narrow sense. A first version of the catalog of educational scenarios and C3MS bricks is available (http://tecfa.unige.ch/proj/seed/catalog/) and we hope to observe and report interesting experiments within the next 2 years.

Implementation strategy #3: Support different user categories: Such a system in order to be acceptable by the teacher community should appeal to different levels technical competence and “activeness”. We discriminate four levels of use with respect to how teachers appropriate learning technologies: (1) Reusing: teachers who appreciate ready-to-use material. In our case, this is a scenario that has been instantiated with content. (2) Editing: teachers who feel the need to modify the content of a scenario they appreciate. (3) Designing: this means in our case to compose completely new scenarios by re-assembling basic components. (4) Programming: some teachers like to program and we can expect them to develop modules. The originality of our approach is to enable teachers to work according to their technical skills, to the personal investment, to what is available.

Implementation strategy #4: Use synergies. C3MS are by definition a space for communities. This first means that we could integrate educational activities into existing community portals, e.g. create campus portals that are actually useful to education and not just an underused presentation/information tool designed by some central service. Conversely, since people learn a lot from informal exchange within tightly or loosely defined communities (fellow learners, professors, experts), we could open educational portals to other activities (news, sharing of links and contents, forums for professional activities). Additional synergies can be gained from making contents available (as MIT’s OpenCourseWare or Berkeley’s IU Project) and allowing the outside world (other classes, teachers, parents, experts) to annotate. Lastly, while each small community may want to run its own portal, contents can be syndicated. Building information and communication networks has become easier than ever.

Implementation strategy #5: Don’t overdo it. We do not know yet the boundaries of C3MS portals. One major drawback seems to be the lack of provision for integration (e.g. data-flow) between applications which are required for more complex CSCL scenarios. Another drawback is the management of contents over time. Handling these issues require the same sort of planning that a traditional user-driven educational web site does and future systems (on which we started design work) should address these issues.

Conclusion

This research on the use of “Community, Content and Collaboration Management Systems” for socio-constructivist scenarios is at its beginning stage. So far, we initiated a few field experiments and we produced an initial catalog of socio-constructivist activities with C3MS bricks. We plan to support further sites, will prepare more dissemination materials and hope to report results within the next 2 years. We are aware that C3MS portals are not fit for complex CSCL workflow scenarios, but we believe that there is an important need to actively support educational scenarios with simple technology under the control of teachers. Finally, C3MS may be a chance to maintain the Internet Spirit in education which is threatened by the philosophy of many e-learning systems.

Abstract The aim of this project is to design a prototype for a web-based tool to provide direct feedback regarding clinical content and outcomes experienced in residency training to both medical residents and their educators. This tool, the Resident Assessment Performance System (RAPS), will provide residents, program directors, and, eventually, accrediting organizations with a comprehensive record of residents’ patient care experiences. To ensure the tool’s usefulness and before any actual programming is done, it is essential to have an understanding of the stakeholders’ needs and desires. Thus, our initial effort was a needs analysis, structured around specific individuals and themes. The results were combined with pilot data to develop draft screens that were reviewed by residents and educators to illustrate how resident profiling might improve the quality of resident training.

RATIONALE

Because of the greater variety of medical treatments available today, more emphasis is being placed on making evidence-based medical decisions and documenting the patient outcomes achieved from treatment. Also, changing patterns of medical practice, including reduced length of hospital stays and increased use of ambulatory services, necessitate increased experience in ambulatory settings for internal medicine residents. These changes are increasing the need for appropriate accountability measures that will assure the profession and the public that the medical education system is both monitoring the content of training and documenting how well it prepares graduates.
for future practice. As such, residency program directors need to assess and continually monitor the content, balance, and outcomes of both the inpatient and ambulatory care clinic experiences of their residents.

Methods often used to assess resident competency, such as surveys and knowledge tests, are limited in scope and do not provide a complete assessment of the residency experience. The Accreditation Council for Graduate Medical Education (ACGME) Outcome Project outlines criteria for evaluating residents and residency programs, including use of dependable measures to assess residents' competence in patient care and mechanisms for providing timely feedback. Residency programs are encouraged to use these outcome assessment results in their evaluation of educational effectiveness (ACGME 2000).

The RAPS project aims to address these needs and requirements through the design of a new user-specified and user-friendly web-based tool that would record and evaluate a resident's patient care experience and outcome performance, track hospital resource utilization, and compare performance to local and to national peer groups. Our review of the literature did not reveal any projects similar to RAPS. The development and evaluation of the RAPS tool will be an ongoing, iterative process. In keeping with our user-centered design methodology, tryout and revision cycles will continue as usability testing is done and end-user stakeholders will be actively involved to provide feedback on the content and usability of RAPS to meet their requirements.

METHODS

RESIDENT RECRUITMENT

We chose the University Medical Associates (UMA) Clinic as our study site. UMA is the primary site for general medical care of adults at the University of Virginia Health System. It is also where Internal Medicine residents receive most of their training in primary care. We recruited a cohort of fourteen internal medicine residents from the University of Virginia Department of Internal Medicine to participate in the design of the RAPS tool. From these residents, we solicited specific content and display recommendations by conducting a formal needs assessment using individual interviews and focus groups. We also conducted interviews with the residency program directors and faculty.

SYSTEM ARCHITECTURE

The RAPS project uses routinely collected electronic data contained in the University of Virginia's Health System's Clinical Data Repository (CDR) (Scully et al. 1997). The CDR is a relational data warehouse that was developed beginning in 1985 to support research and education at our institution. It integrates data from disparate systems and now includes eight years of inpatient data (approximately 30,000 admissions per year), eight years of physician billing data, five years of outpatient data (450,000 outpatient visits per year), six years of clinical laboratory results (750,000 lab results recorded per month), and eight years of surgical outcomes data from the University of Virginia Heart Center Thoracic Cardiovascular (TCV) departmental database. Last year, death registry data from the Virginia Department of Health, Division of Health Statistics was added. Currently, the database contains over 40GB of information representing approximately six million patient visits.

The CDR resides on a Dell PowerEdge 1300 (Dual Intel 400MHz processors, 512 MB RAM) running the Linux 4.3 operating system and Sybase 11.9.1 relational database management system (RDBMS) (Sybase Inc., Emeryville, CA). It uses a custom-built Web-based front end that allows local users to formulate ad hoc queries and download data to their own PC's. Alternatively, experienced users may submit their own Structured Query Language (SQL) statements directly to the Sybase Server or, with the installation of Sybase drivers, may access the Sybase tables directly with Microsoft Access or Excel.

NEEDS ASSESSMENT

The RAPS tool is designed to meet the needs of both internal medicine residents practicing in a general medicine clinic and their program faculty directors and advisors. As such, the results of the needs assessment were analyzed to determine the goals for the RAPS interface tool. A consensus list of priority conditions, patient information, and measurement end-points were assembled from the interviews and focus group feedback.
Overwhelmingly, residents and faculty expressed interest in information to help them manage specific populations, such as diabetes and hypertension patients, and health screening practices compared with published guidelines. Residents are interested in detailed information about their assigned patient panels, such as most common diagnoses, procedures, and demographic information. In addition to this information, faculty desire information describing the continuity of care, such as whether the same resident is seeing the patient on an ongoing basis. Measures of resource utilization are of interest to both residents and faculty. Information desired includes medication compliance, laboratory tests, procedures completed, costs and reimbursement, the amount of time physicians spend with patients, and follow-up appointment time. Other patient care outcomes of interest include hospital length-of-stay, emergency room visits, mortality, hospital re-admissions, patient and nurse satisfaction data, and missed and canceled appointments. To be meaningful, information used for resident physician profiling must associate variation in resource utilization with differences in the disease burden of the residents' patient panels.

CONTENT SELECTION

Our content selection was based on the following decision criteria:

- **RAPS project objectives and scope**
- **Data readily available**
- **Potential sources of new data**
- **Patient-identified data and surrounding confidentiality issues**

OBJECTIVE AND SCOPE

The RAPS project is intended to provide aggregate retrospective patient data to evaluate a resident's patient care experience and outcome performance. It is not intended for direct patient care. A pilot study conducted by the Association of Program Directors in Internal Medicine of its membership identified desired components of quality in residency training. Assessment outcomes of training indicators that were rated highly include appropriate amount of evaluation and feedback to residents, adequacy of patient mix, and applicability of the overall curriculum to future practice as general internists (Klessig et al. 2000). In keeping with the original intent and scope of the RAPS project, we focused on data elements that provide a broad view of residents' patient care experience such as diagnoses most commonly seen, aggregate measures of hospital resource utilization, and disease screening with appropriate guidelines and comparisons.

DATA SOURCES

The core data source for the RAPS tool is the Clinical Data Repository (CDR), a relational data warehouse with a Web browser interface that provides direct access to data for education, clinical research, and quality improvement initiatives at the UVA Health System. The CDR contains inpatient billing and administrative data, physician billing data, clinical laboratory data, the state death index, and various departmental databases. Much of the data desired by the residents and program directors is currently contained in the CDR. Additional data feeds are planned, including outpatient clinic pharmacy data and clinic scheduling data. Both will provide important data elements for our project.

CONFIDENTIALITY ISSUES

The Clinical Data Repository has the functionality to provide detailed information at the patient level. Users can “click” on a patient identification number (an encrypted version of the medical record number) or account number and “drill-down” to detailed patient information such as the results of individual laboratory tests. We decided not to provide this feature in RAPS because the intent of the RAPS tool is to provide aggregate, retrospective data for assessment. Also, patient identifiable data for use in direct patient care is not within the defined scope of either the CDR or the RAPS project. Second, in light of increased emphasis on security and privacy standards brought about by HIPAA legislation (The Health Insurance Portability and Accountability Act of 1996), further assessment is needed before we make patient identified data available via the Web.
RESULTS
RAPS PROTOTYPE SAMPLE SCREENS

The screens contain actual sample data collected during a pilot data collection period, January-March, 2001. The screens have not yet been integrated into the CDR; rather they are mock-up design prototypes. (Figure 1 depicts one of the sample screens.)

Screenshots of the RAPS web-based tool screens may be accessed at the following site:
http://www.people.virginia.edu/~jr5d/RAPS/

EVALUATION

We made substantial revisions (mostly additions) to the content of the RAPS tool following the focus group conducted with the participating residents and presented the revised screens to three of the faculty program directors. In individual sessions, faculty navigated through the RAPS screens, asking questions and making comments. We recorded their suggestions in order to make additional revisions to the content and clarity of the presentations. In June 2001, we sent an e-mail survey to a representative group of residency program directors soliciting feedback about the draft formats and reports for the RAPS tool. Questions were asked about the usefulness of the data and the usability of format. Respondents were all program directors of internal medicine residency programs and were all very positive.

DISCUSSION
DATA ISSUES

RAPS is designed to view information in two basic ways: patient-level and admission- or visit-level. Patient-level data includes information about all of a patient’s encounters with the University of Virginia Health System, both hospital admissions and outpatient clinic visits. Admission- or visit-level data includes only data about a particular encounter, either a single hospital admission or clinic visit. Both views are important and desired by residents and faculty. In some instances, it is important to have access to information about a patient’s entire encounter with the Health System, regardless of whether the assigned resident saw the patient or not. Patient-level information is most useful for disease screening and management. In other instances, it is more meaningful to look at admission- or visit-level information. For instance, evaluating the breadth of a resident’s exposure to various diagnoses would require only information particular to encounters where the resident of interest saw the patient.

MEANINGFUL PRESENTATION
CLUSTERING METHODOLOGIES

An assessment of the content of residents’ ambulatory care experiences necessitates a method to describe the illnesses seen by individual residents in various outpatient settings (Bordley et al. 1987). We used the Clinical Classification Software (CCS), a 1999 update to the former Clinical Classifications for Health Policy Research (CCHPR) Version 2. This classification scheme, which is in the public domain, was developed by the Agency for Healthcare Research and Quality (AHRQ) and, in previous studies, has shown promise for comparing resource utilization among physicians and managed care organizations (Cowen et al. 1998). Diagnoses and procedures for inpatient hospital stays are coded using the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM), Fifth Edition (Public Health Service and Health Care Financing Administration, 1994). ICD-9-CM consists of about 12,000 diagnosis codes and 3,500 procedure codes. The CCS methodology aggregates these codes into clinically meaningful categories, providing a reasonable method for cataloging the illnesses seen by residents. This methodology will accommodate evaluation of individual residents and comparison of the UMA Clinic residency experience with national norms.
COMPARATIVE DATA: WHAT'S USEFUL, "FAIR"

Because variation in utilization of health care resources is associated with differences in disease burden, adjustments for comorbid illnesses are needed before accurate comparisons can be made between patient groups. In addition, comparative data should be useful and "fair". The RAPS report screens are designed to permit each resident to view his or her own patient data and comparative data that will include national guidelines where available (i.e., disease screening) and aggregate data for meaningful comparative groups such as year of residency training, all UMA residents, all internal medicine residents, and total hospital. System logic will be applied to adjust the RAPS screens when comparative data are not meaningful. For example, messages will alert the user when sample sizes are insufficient to yield valid comparisons.

CONTINUITY OF CARE

The value of physicians caring for patients over time includes opportunities to observe the course of illness and treatment and stronger physician-patient relationships. Of the 120 medical school respondents to a 1998 survey, 96% with longitudinal programs indicated that teaching continuity is valuable, yet only 73% were designed to foster such continuity. The logistics of accomplishing continuity of care are often the most difficult obstacle (Vogt et al. 2000). We developed a measure of continuity of care for the RAPS tool to enhance tracking. This measure provides an index of how many of a resident’s patients' visits have been with that resident.

CONTENT ORGANIZATION

RAPS is designed for both residents and their educators. At the logon screen, users select either the resident or faculty screens to view. The logon identification determines which screens the user will be able to access. The screens are grouped into two main categories: 1) the resident’s outpatient panel, and 2) the resident’s patient care experience. The outpatient panel selection provides information related to a resident’s assigned panel of patients from the UMA Clinic. This information will provide patient-level data whether or not the resident actually saw the patient. The second grouping of screens provides information about only those patients that a resident actually saw, whether or not the patient belongs on the resident’s panel, in the case of the UMA Clinic choices. Faculty will have access to all resident data, individually and compared to various desired groups.

CONCLUSION

We have completed the initial design of the RAPS web-based tool, both its content and technical specifications, and have developed prototype screens. Our user-centered design and iterative tryout and revision strategy is an ongoing process that will continue as we operationalize the tool over the next year. Internal and external reviews have been extremely positive.

The value of RAPS as an assessment method to evaluate individual residents and the overall residency program will require selection and application of appropriate techniques. We will address the question of whether residents who use RAPS perform better. Event tracking and other administrative tools will be implemented within the RAPS tool to calculate usage statistics. Surveys and interviews will be used to collect feedback. Resident evaluations, in-service exam scores, and other metrics will be used to measure differences in performance by residents who use RAPS to those who do not.

Historically, medical residency programs have been designed using a rotation-based format, based on the premise that by rotating through a series of educational experiences residents will assimilate the skills needed to become competent physicians. An alternative educational approach focuses on attainment of competency, rather than completion of a set of educational experiences. Within internal medicine there is interest in the application of competency-based education, also known as mastery learning or outcomes-based assessment (Bell et al. 1997). RAPS is designed to encourage the transition within graduate medical education from experience-based to competency-based training by providing aggregate information to evaluate a resident’s patient care experience and outcome performance. It is our hope that RAPS will also help clinicians develop the independent quality reporting and accountability skills needed for future practice.

Virtually There: Online Case Studies

Diane M. Schuch-Miller, Greenfield Coalition, Wayne State University, USA, schmild@focushope.edu

Abstract: The candidates enrolled in one of three degree programs offered through the Greenfield Coalition (GC) have a unique learning situation where classroom exercises link with their job experience. Situated at the Focus: HOPE Center for Advanced Technologies, candidates work in a real manufacturing production environment by day and attend courses by night. In order to export these experiences to students enrolled in other manufacturing engineering programs, GC developed case studies accessible online. Cases currently available support courses in engineering economics, statistics in manufacturing product launch, forming technologies, and tool and fixture design. A wealth of resources including interview transcripts, WWW links, raw data and expert advice are accessible online for learners to investigate each case and complete the required tasks.

The Need for Online Case Studies at Greenfield Coalition

The candidates (Greenfield Coalition (GC) students) at the Focus: HOPE Center for Advanced Technologies (CAT) have a unique learning environment. They have an advantage over students enrolled in traditional manufacturing engineering curricula because they have the daily opportunity to apply new concepts learned in the classroom to real situations on the manufacturing shop floor. This characteristic of the curricula at the Greenfield Coalition is not only unique but also provides a natural contextual environment for the application and transfer of new knowledge and skills. In terms of teaching and learning, a better environment could not be simulated. Therefore, it became a critical component of the teaching and learning strategies at GC.

However, in order to share this advantage and paradigm with other students enrolled in similar engineering programs so that they might learn from the experiences of the CAT candidates, GC had to somehow export these experiences. Presenting case studies from the CAT in an online environment seemed the obvious choice.

The Value of Case Studies

Case studies are ideal for illustrating complex concepts, especially common in engineering. Horton (2000) suggests the use of case studies as an excellent way for learners to practice judgment skills necessary in real life situations that are not as simple as textbook problems. As instructional strategies are concerned, engaging critical thinking skills through case studies is among a recommended set of activities (Bonk & Reynolds, 1998).

GC has developed several case studies that challenge learners in ways a manufacturing engineer would. The majority of the case examinations come from real situations faced by Focus: HOPE and other industry partners of GC (such as Society for Manufacturing Engineering, Ford Motor Company, General Motors, and DiamlerChrysler). One case developed as a capstone experience in engineering economics involves identifying the source of lost dollars for a tier one supplier to the automotive industry. Another case involves the redesign of a tie-rod end component used in the HMMWV (commonly known as the Hummer), whose primary customer is the U.S. Department of Defense. As part of a course in Integrated Product Realization, a case requires learners to apply processes and procedures for the launch of a new product. Yet another case supporting a course on statistics in manufacturing requires the analysis of variances of post-production part specifications in order to utilize statistical methodologies to explain scrap lost dollars. Many other cases have been developed by GC to support courses in tool and fixture design, forming technologies, operations management and facilities design. These cases require students to identify appropriate processes to apply in various situations, generate cost/benefit information and make appropriate decisions on the basis of that information, respond to requests for bid for a formed part, investigate and recommend solutions to eliminate tolerance irregularities during machining of parts as well as many other tasks typically found in manufacturing engineering environments.

Through these case studies, learners get practice applying newly learned skills and knowledge to authentic situations not found textbooks.
Online Environment for Case Studies

In the online environment, GC has captured a wealth of resources related to each case and provides it for learners to examine and contemplate much like a student could do if s/he were enrolled in an onsite course. These resources are organized by typical activities that would be performed, to prevent the learner from feeling overwhelmed at any given time during the case analysis.

Case Study Orientation

The home page for the case serves as the learner guide. From this page, students are able to view the recommended set of investigation activities, expectations for assessment of their investigation as well as the full list of resources provided for their perusal. Basic navigation, similar to GC courses, is accessible at any time, from the left-hand side and across the top of the interface, providing constant availability of broad level course information. Further, the web interface is organized to keep learners from becoming frustrated or lost. Figure 1 shows that once a case is selected, the specific scenario is depicted, and instructions and activities are outlined. One level up, at the module level, it is possible to link to several case studies that all meet the same objective and, therefore, would be grouped into the same learning module.

![Figure 1: Engineering Economics case analysis home page with Situation pop-up](image)

Learner Responsibility

Given the situation or scenario description, it is the responsibility of the learner (or team of learners) to investigate and uncover what they believe to be the real problem. Students are challenged to determine what is relevant to the case and process its importance. Exploring the resources helps them achieve this. While each case has a different set of resources, many media formats are used throughout all of the GC cases. In a case examining the scrap rate through the balancing operation for pulleys, a process map and product path are depicted using still images with mouse-overs for additional information (see Figure 2 & 3). Further, MSWord and Excel documents such as part price data, scrap rates and subsequent lost dollar reports are viewable in the web browser (see Figure 4).

Figure 3: Photographic product path for pulleys from arrival through shipping
Students can even simulate a conversation with important personnel by reviewing the interview section of the resources. Here, streaming video clips and transcripts of real interviews conducted by CAT candidates can be viewed (see Figure 5). WWW links to vendors of balancing machines and/or information about new balancing technology make it possible for learners to research new technology or uncover how other companies resolved similar situations (see Figure 6).
Recommendation for Resolution

Once the learner(s) has investigated the case thoroughly, s/he must prepare a report aligned with the guidelines for that specific case. For Engineering Economics, this report requires a comprehensive economic analysis of the situation and related data, and must include the student’s recommendation for resolution to the problem. Supporting documentation such as a decision tree and sensitivity analysis also complement the report.

Although not explicitly required for each subsequent delivery of this case, a presentation to Focus: HOPE management was a component of the pilot of the economics case study. The experience of presenting the alternatives to the stakeholders made the needs of the client perfectly clear to the candidates and had a greater learning impact than initially expected. They were able to better understand the urgency for resolution and the impact in terms of time and money that implementing any one of the alternatives would cost. At the pleasure of the instructor using these materials, this experience could be simulated for other cases by simply asking classmates or industry experts to pose as the customer.

Supporting Teaching and Learning In The Online Environment

Learner Support

If, at any time, the learner feels overwhelmed by the rich set of information provided and feels that the exploration through the resources seems unproductive or inefficient, they may consult the mentor notes. Mentor notes, a series of tasks and issues related to the case and its objectives, serve as a tour guide and give necessary learner support when they need and want it. The learner is not required to follow the tasks and/or consider the issues in a lock-step fashion. Rather, Mentor Notes help to orient the learner to the items necessary for consideration in a learner support when they need and want it. The learner is not required to follow the tasks and/or consider the issues in a lock-step fashion. Rather, Mentor Notes help to orient the learner to the items necessary for consideration in a thorough investigation of the situation. Filipczak (1996) refers to this as scaffolding or “guided discovery”, by retaining learners opportunity to explore while still making certain that the established objectives are attainable. Candidates may choose to execute one, some, or none of the suggested tasks. Additionally, this compilation of expert notes can be applied to many situations. As a result, it functions as a tool for learning as well as a job aid for real manufacturing engineering situations.

Often case studies at GC serve as a capstone for the courses, however, they are not tests. Therefore, learners may refer to the mentor notes as often as necessary without negative consequence. The most important purpose is
that students can apply previously learned concepts and principles, and practice decision-making and problem-solving processes in a non-threatening but very real situation.

Instructor Support

Scaffolding is also provided for the course instructor in an area entitled Faculty Interface, in the event that the instructor using the case study materials is not as knowledgeable about a particular topic as the case study designer and/or developer. These notes, similar to the mentor notes, were recorded during the pilot offering of the case study to assist subsequent instructors adjusting to their new roles as a facilitator of learning and a manufacturing plant supervisor posing a variety of questions and concerns common in a real engineering setting.

Integration with Other Instructional Methods

It is critically important to be aware that the use of the web-enabled case studies does not occur without the leadership of an instructor. The instructor at GC plays several roles simultaneously: traditional instruction of course concepts, mentoring and coaching during the case investigation, and finally that of a supervisor challenging the recommendations from a manufacturing enterprise perspective (Schuch-Miller & Plonka, 2001). Moreover, follow-up classroom discussions, an integral component of the case design, allow learners to reflect, summarize and solidify their own learning and structure it in a way that is meaningful to them (Hidi & Anderson, 1986).

At GC, we strongly believe in a blended approach to teaching and learning, involving the integration of instructor-facilitated classroom activities, sharing of manufacturing experiences of the candidates at the CAT, bestowing course credit for experiences on the shop floor as well as utilizing the web-enabled technology wherever possible in order to enhance manufacturing engineering education. The result is a very fulfilling learning experience that includes learner collaboration, learner support, and innovation. By replicating these experiences in an online environment, it is hoped that other instructional programs can be enriched by using these resources as well.

Japan’s Widespread Use of Cellular Telephones to Access the Internet: Implications for Educational Telecommunications

Douglass J. Scott

Japan
djscott@mac.com

Abstract: In the three years since their introduction, Internet-capable cellular telephones are used by over 47 million Japanese (37% of the population) which nearly equals the number of people using personal computers to access the Internet. If this trend continues, the cellular telephone will overtake the personal computer as the most widely used Internet access device in Japan. However, this development has gone largely unnoticed by researchers. Such a trend deserves greater attention, both to understand the nature of Japanese use of communication technologies and to assess these technologies’ potential for educational application. This paper examines the impediments that slowed Japan’s early acceptance of the Internet, describes how these barriers were overcome by Internet-capable cellular telephones, considers the strengths and weaknesses of these emerging technologies, and assesses the potential for using portable wireless communication devices in educational settings.

Introduction

Despite nearly a decade of general economic stagnation, Japan’s telecommunications industry has continued to grow by developing innovative and sophisticated wireless communication devices. These products, most notably Internet-capable cellular telephones, have been readily accepted by Japanese consumers and the increasingly widespread use of these devices has both changed popular culture and, more importantly, greatly expanded Internet use in Japan. Indeed, the number of Internet-capable cell phones in use has grown dramatically since they first appeared in 1999, and the cell phone may soon overtake the personal computer as Japan’s Internet-access medium of choice.

Despite this trend, few, if any, scholars have formally asked what role Internet-capable cellular telephones may play in educational telecommunications. Certainly, the limitations of current cell phone technology make its near-term use in educational contexts doubtful. However, Japan’s rapid and widespread adoption of cellular telephones as an Internet access medium make this an important area of study to determine if these technologies can be used in educational settings. Examining Japan’s use of these technologies is appropriate as Japanese cellular technology is estimated to be several years ahead of America (Despeignes 2000). Thus, understanding the Japanese case could be a strong indicator of the kinds of communication tools and opportunities that may become available in America.

This paper begins with an description of the conditions that restrained Japan’s early use of the Internet relative to other countries. The next section describes Japan’s rapid acceptance of Internet-capable cellular telephones and shows how these devices overcame the barriers to Internet use. The following section assesses the strengths and weaknesses of current cell phone technologies and the concluding sections considers how these devices might be used in educational settings.
Impediments to Internet Acceptance in Japan

Personal computer and Internet use in Japan have lagged behind the United States and other industrialized countries according to a Japanese Ministry of Public Management, Home Affairs, Posts and Telecommunications' report (MPHPT 1999). Scholarly research on the nature of Japanese computer and Internet use is limited, but Aoki's assessment of barriers to wider Internet access in Japan reflects the conventional thinking behind Japan's slow acceptance (Aoki 1995):

1. Businesspeople prefer face-to-face communications, and access to e-mail in the office is limited.
2. Phone rates are calculated by the minute which inhibits extended online time.
3. Computer use is considered as unfashionable and computer users are often characterized as nerds.
4. Typing is still a relatively uncommon skill among Japanese people, and involves using four types of written Japanese characters.

It should be noted that since Aoki's report was written, flat-rate ISDN Internet access (among others) has flourished in Japan bringing online costs down to more accessible levels. However, lingering negative images of computer users and the QWERTY keyboard interface continue to be strong disincentives to increased computer-based Internet access in Japan. For comparison, one estimate indicates that only 14% of Japanese people use computers to access the Internet versus 37% in the United States (Schmetzer 2000).

In contrast to the slow pace of computer-based Internet use, using cellular telephones (or keitai, pronounced "kay-tie") for Internet access has increased dramatically in Japan since its introduction in February, 1999, and is rapidly becoming a, if not the most, popular way to access the Internet. Computer access of the Internet has shown a large increase over the past couple of years, but cellular phone access rose at an even greater rate; MPHPT statistics show (MPHPT 2001) that between 1999 and 2000, households using personal computers to access the Internet almost doubled (19.1% to 34.0%), but the percentage of households using cellular phones to access the Internet tripled (8.9% to 26.7%).

Additional quantification can be seen by looking at the example of NTT DoCoMo, Japan's largest telecommunications company. Internet-capable cellular phones were introduced by the DoCoMo in Japan in February, 1999, under the brand name "i-mode." Starting in mid-2000, all DoCoMo cell phones were
"compatible with Internet standards such as HTML, http, gif, and Java," so users can surf the Web in addition to checking their mail (Legace 2001). In less than three years, nearly 29 million people subscribe to DoCoMo's Internet cell phone service at the end of 2001 (TCA 2001). The total number of Internet-capable cell phones in Japan is just over 47 million out of an installed base of over 66 million cell phone service subscribers according to the Japanese Telecommunications Carriers Association’s monthly data (TCA 2001). Based on these numbers, nearly 40% of all Japanese people carry Internet-capable keitai.

Keitai Use Increases Japanese Internet Access

Clearly keitai, especially those with Internet capability, have been rapidly and widely accepted by the Japanese consumer. This high rate of acceptance indicates that keitai have successfully overcome the barriers to Internet access—which personal computers failed to do—despite having been on the market for only three years.

Internet access from the office: The first barrier to wider Internet access posed by Aoki was in the business realm where face-to-face meetings and limited in-office e-mail access limited greater use. Certainly, face-to-face communications will edge out most technology-mediated communications in certain business situations. However, business people can use their own keitai to be able to access the Internet despite restrictions on using company computers for personal e-mail or WWW use (see, for example, Schmetzer 2000).

Low cost: As noted above, computer online time has become less expensive since Aoki released her paper. However, since that time, increased competition between keitai service providers has made monthly calling packages more affordable and inexpensive e-mail messages are among the most popular services. Indeed, my students emphatically state (see the next section for additional details of these empirical data) that low cost is the primary motivation for using written communications rather than making a voice call.[1] Perhaps more importantly, the initial cost of buying the necessary hardware (in some cases the phone is free), makes a keitai an attractive choice over even the most affordable computer.

Socially acceptable: While it is rare to see a commuter on a train in Tokyo using a laptop computer (besides himself, the author has seen only one other person using a computer on the train in the last 12 months), it is rare not to see several commuters engrossed in reading and writing keitai mail. Indeed, keitai mail users are so common at coffee shops, on public transportation, and in parks that they would only be conspicuous in their absence. Keitai use has become an acceptable means of communicating with others in public without the negative images still assigned to computer mail users. Indeed, we may have already entered a situation in Japan where not carrying a cell phone is seen as socially unacceptable. A straw poll of 104 of my students in a large, private, Japanese university indicates that all 104 of them have a cell phone, and that 68 of the 104 used their cell phone to access the Internet before using a personal computer. Another indication of how indispensable these devices have become, over half (18) the students in a class of 32 do not wear a watch but rather use their cell phone clock to tell time.

Unique Input Method: The most common input method is using one or both thumbs on the phone’s keypad (see Fig. 2). Typing is possible (using an attachable keyboard) but few people use them in public. While the author, a novice at keitai mail, taps out only a few words per minute, experienced users can achieve remarkable speeds using only their thumb to input text and select graphic emoticons (French, 2000). French also notes that one heavy keitai user can reportedly type out messages solely by touch; this is not as rare a skill as it might sound: Several of my students claim to be able to type keitai mail without looking at the keypad.

Taken together, these points indicate that the barriers to Internet use cited by Aoki concerning Internet access seem to have been largely, if not completely, overcome by the Internet-capable cellular telephone. However, while its ability to enhance Japanese Internet use may be established, the keitai faces greater challenges if it is to become a widely used Internet appliance for educational telecommunications.

[1] Each keitai e-mail message costs about 2.5 cents to send and is free to receive compared with voice messages which run about 45 cents per minute to send but are also free to receive. This difference can add up when one realizes that it is not uncommon for young people to send 10 or more messages per day.
Limitations and Challenges

Despite the many advantages to the keitai, several obvious limitations will need to be overcome to enhance this device’s potential as a general-use Internet application. Initially, the small screen, especially when typing in English, is a clear limiting factor. Generally, the screen can only display 64 characters at one time (see Fig. 1), although total message length depends on the options allowed by the telephone and the service provider. For instance, the author’s phone (shown in all the images in this paper) is capable of creating messages up to 128 characters, or “long mail” messages of up to 5910 characters. However, even with a good resolution color screen, reading (let alone keying in!) a 5000+ character message would strain the recipient’s eyes to the point of exhaustion. Using a keitai for educational purposes would require tasks that can be easily completed within a few hundred characters or modifying the keitai’s output ability to enable the user to read or hear longer messages.

As indicated above, inputting a lengthy keitai mail message is impractical for the average user. External keyboards are available—ranging from roughly the size of a credit card to approximately the size of a postcard—but the author has never seen one being used in public. It is unclear if the difficulty of inputting text can be overcome with practice, but empirical reports from Japanese college students indicates that their typing speed increased the longer they used their keitai. However, after several weeks of inputting English-language messages using my keitai’s keypad, my typing speed is still painfully slow and I prefer leaving voice messages despite the increased cost. Emoticons and preset phrases are one answer (see, for example, French 2000). However, I would welcome a personal digital assistant-like character recognition system using an input stylus. This is still slower than typing on a keyboard, but retains much of the keitai’s portability.

The Potential for keitai in Educational Settings

The Japanese case shows that a large number of people are using their cellular phone to exchange e-mail and receive information from the World Wide Web. Such widespread use should not be ignored as such devices may have a place in educational telecommunications. Despite its potential, it seems clear that keitai technology will require additional development if it is to receive widespread use in educational settings.
Attitudinal Challenges: Many American schools had bans on bringing and using cellular telephones. After the terrorist attack on September 11, 2001, however, some schools are rethinking this prohibition ("Schools Rethink" 2001). While greater access to cell phone use in schools may have started with a national tragedy, additional access will increase only if the potential to provide meaningful educational opportunities can be shown.

Despite gains in many areas, actual computer and Internet use in Japanese and American classrooms is still in its early stages. Access issues in both countries have largely been addressed and more attention is being paid to inservice education and curriculum development. However, computer use in schools is still far from established and commonplace and there is a strong sense that educators in both countries are still in the experimental stage. The prospect of purchasing new hardware, educating teachers, and devising curricula to incorporate a new type of technology may get a cold reception at many schools. It seems reasonable that any new communications technology would have to prove its utility up front, and may need to start with a supplementary role alongside existing equipment and projects, enhancing rather than replacing what is already in place. One can imagine, for instance, a cell phone-like device being used by one group in the field to communicate sounds, text, and images back to their home station computer where these data are stored and manipulated.

Hardware Challenges: The expense of personal computers has usually been borne by schools and made available to students in the form of a classroom computer(s) or a computer lab. Cellular telephones are usually personal communication devices, purchased and maintained by an individual, and are rarely shared. Certainly allowing students to use their own telephones as part of a school exercise has some appeal, as the cost of the phone and connection service is borne by the student. But unlike my economically comfortable university students all of whom carry cell phones, many college and high school students in Japan and America are unable to afford this service. If schools are to provide wireless communications devices to students, they must be able to exert some control over how these devices are used. It may be that this need can be filled by a portable wireless communication device similar to a personal digital assistant-cell phone hybrid that enables the exchange of text, sound, and graphics with a restricted number of other units. In any event, current cell phone technology shows some promise, but may require modification and development before it can be comfortably used in K-12 classrooms.

Conclusion

The greatest benefit of Internet-capable cell phones in Japan has been their ability to bring large numbers of Japanese people onto the Internet in a way that has been useful and entertaining for them. The learning curve is negligible compared to personal computer-based access, and the cost of setting up and using this service continues to attract large numbers of new users. Cellular phones have largely overcome Internet-access barriers where personal computers failed, and future developments should be monitored to see if these devices can be adapted to educational use.

Despite the limitations cited above, the continued development of cellular phone technology, and the potential to blend it with personal digital assistants or other palm-top devices, may allow fourth- or fifth-generation wireless devices to be incorporated as one part of a larger information and telecommunications strategy for use in schools. As schools, in Japan and elsewhere, become more accustomed to using technological tools in the classroom, and the cost of hardware continues to decline, we may see a division of labor where cellular telephones are primarily used for transmitting voice, text, and images while the personal computer is used primarily for more extensive communications and production work.

When NTT launched its i-mode service three short years ago, few observers could have guessed that millions of users would be exchanging text messages on their cell phones, performing online banking services, or reading restaurant reviews on the Web. There is a sense that attempts to speculate where these technologies will be in three more years will fall woefully short. However, I firmly believe that this trend deserves our attention, and we should follow the progress of portable wireless communication devices like keitai with an eye to incorporating them into our arsenal or educational telecommunications technologies.

Facilitating Learning Through Different Forms of Interaction With Visual Abstractions

Abstract: Visual abstractions play an important role in many learning situations. They refer to visual structures that represent abstract ideas and encode the meaning of these ideas in themselves. Interaction with these visuals, when well-designed, enables the decoding of their meaning. When using visuals in educational software, designers need to know the different forms of interaction available to facilitate learning. This paper briefly discusses some points to be considered when designing interactive visual abstractions.

Introduction and Background

Visual, image-based representations play an important role in learning. Sometimes, they facilitate reasoning and thinking in ways that may be impossible to achieve using sententially-based representations [Goldstein, 1996]. Visual abstractions (VAs) refer to visual structures that represent abstract ideas and encode the meaning of these ideas in themselves [Pimm, 1995]. An example of a VA is the representation of the concept of rotation in two-dimensional transformation geometry as an arc of rotation found in mathematics textbooks. This VA not only represents the concept of rotation, but also its embedded sub-concepts of angle and center of rotation. Another example of a VA is the representation of the concept of force in physics as an arrow. Researchers have studied the different forms of representation and how people reason using visuals [Peterson, 1996], most of which have focused on the static form of these representations. With the advent of powerful graphics systems, there is an ever greater use of visuals in interactive contexts. Interaction with VAs can play an important role in sense-making and active learning [Card et al., 1999; Sedig et al., 2001].

It is important for designers of learnware to know about different ways of designing interaction with VAs to facilitate active learning. However, literature on the subject is very limited. Instructional technology books, research handbooks, and encyclopedias rarely discuss interaction design techniques, much less interaction design for VAs.

Our research group has been designing a number of systems to investigate different forms of interaction with VAs. This paper briefly discusses a few factors we feel need to be considered when designing interaction that facilitates learning.

Some Design Considerations

One of the first considerations is whether the learner should interact with a VA directly or indirectly. The former refers to acting on and interacting with a VA directly via a pointing device. The latter refers to interacting with a VA through an intermediary representation. The choice depends on the educational goal to be achieved. In general, indirect interaction requires more mental effort [Holst, 1996], which can be an important factor in deep learning. However, direct interaction, combined with visual scaffolding, can also support the learning of concepts very effectively [Sedig et al., 2001].

Another important consideration is whether the learner should interact with a VA by manipulating ("handling") it, navigating ("walking on") it, or issuing commands to ("conversing with") it. These three modes of interaction can serve different purposes. Manipulation can be used to decode the internal meaning of a VA. For instance, in the case of the arc of rotation, mentioned above, performing an operation on its visual representation—e.g., dragging the center of rotation—can help the learner understand the structure and its constituent elements [Sedig et al., 2001]. Navigation can be used to help the learner construct a cognitive map of
the visual abstraction [Chen, 1999]—that is, a mental map of the VA’s structure which is internally available for inspection and sense-making. Rather than manipulating the VA and affecting changes in its form, navigation allows the learner to “walk” on the VA to internalize the structure’s landmarks, geometry, and topology. For instance, given a semantic network as a VA, by navigating the network, the learner can discover its landmark nodes and essential paths. However, if the goal of learning was to have the learner construct the network, then the preferred mode of interaction would be manipulation. Conversation can be used when the goal is to allow the learner to ask for the properties of a VA in a linguistic, sentential manner. Conversation usually requires more mental effort than manipulation or navigation since linguistic commands and visual representations are not cognitively congruent.

An example of an application that uses two modes of interaction is a cognitive tool we have designed intended to facilitate learning of Platonic and Archimedean solids, shown in Figure 1. The learner can manipulate the geometric structure on the right to change its form and observe how it morphs to another geometric structure [Morey et al., 2001]. The learner can navigate the map on the left to understand the relationship among the solids. The learner can also click on the linguistic buttons to select a new visual representation. Although this is not a purely conversational mode of interaction, one can design the interface such that the learner could type a command to query a given geometric structure about its properties.

This paper has presented some points to be considered when designing interactive VAs for learnware. The understanding of many educational concepts can be facilitated using VAs [Glasgow et al., 1995]; therefore, it is important to further investigate different forms of interaction with VAs so that they can support active learning.

Abstract: Many children find mathematics uninteresting and irrelevant, never appreciating its role in artistic endeavors. Computer-based interactive tools can help introduce children to the artistic aspects of mathematics. This paper presents TileLand, a multi-faceted constructionist microworld intended to engage children in the creation of mathematical art. TileLand employs the metaphor of a Magic Tile to introduce children to the world of regular polygons and colorful visual patterns and tilings. It integrates several types of pedagogical interactions: open-ended exploration, goal-directed game play, experiential and reflective thinking, and visual and linguistic information processing.

Introduction

Many children find mathematics uninteresting and irrelevant. This is partly due to the fact that most of their encounter with mathematics is algebraic [Kinsey and Moore, 2002]. As a result these children never develop a mathematical eye. Without a mathematical eye, they never realize the role of mathematics in artistic expressions such as painting, sculpturing, and designing architectural artifacts. It is important for non-mathematicians to experience the beauty of mathematics by venturing into its art form, as visualization of patterns and relationships [Peterson, 2001]. Tilings, tessellations, and visual patterns are examples of mathematical art. The National Council of Teachers of Mathematics [1989] emphasizes the importance of young learners experiencing the deeper aspects of geometry. Novel computer tools can help introduce children to the visual aspects of mathematics (for instance, see [MECC, 1995]).

However, designing technology that is motivating, supports children's deep learning, and is not gender-biased is not an easy task [Alessi and Trollip, 2001; Druin, 1999; Sedig, 1998; Sedig et al., 2001]. This is especially true if the design is aimed at a broad spectrum of children, ranging from kindergarten to the 6th grade. This paper presents TileLand, a microworld designed to engage children in geometric reasoning and analysis through the creation of mathematical art in the form of tiling patterns. As a microworld, TileLand is a self-contained conceptual system embodying underlying geometric principles related to five regular polygonal shapes. Through interaction with the system, it is intended that children develop a sense of spatial visualization, notice the relationship among polygonal figures, and discover the role of different polygons when creating tiling patterns - thereby constructing their own knowledge of the embedded concepts and ideas in the system [Forman and Pufall, 1988].

TileLand

TileLand is a multi-faceted microworld. It allows children to construct colorful tiling patterns using regular polygons, engaging them in creative, mathematical art. TileLand is also a logic-based, problem-solving game, in which children need to re-produce a series of given patterns in order to advance through the game. It is also a programming microworld, where using a simple command-based language, children can describe how to create a tiling pattern, test the program, and observe its behavior.
TileLand is aimed at children who are five years and older. Consequently, it has simple interaction rules. There are only a few commands that children need to learn. Nevertheless, TileLand allows children to construct fairly complex geometrical patterns. Figure 1 shows a screen capture of TileLand. The screen is divided into three sections: Action Panel, Sample Tilings, and Pattern Area. The Action Panel contains the command buttons used to create tiling patterns. The Sample Tilings contains a number of pre-created patterns, with varying degrees of complexity. These patterns are intended to introduce children to a range of possible visualizations that can be created using the environment. Finally, the Pattern Area is where children construct their patterns. Figure 1 shows a constructed pattern made of four types of polygons: triangles, squares, pentagons, and an octagon.

There are five types of tiles with which children can construct patterns. All five tiles are regular polygons: triangle, square, pentagon, hexagon, and octagon. To provide an easy-to-understand conceptual model for how tilings are created, TileLand uses the metaphor of a Magic Tile. The Magic Tile is represented in the Pattern Area by any one of the five polygons. One of the sides of the Magic Tile is designated as a Connecting Side. This side is highlighted to differentiate it from the other sides of the Magic Tile. The Connecting Side is where a new polygon attaches. The magic of the tile is derived from its transformational movement. This movement occurs when a new polygon is attached to the connecting side of the polygon currently in the Pattern Area and the current polygon magically disappears. Clicking on one of the five polygonal buttons in the Action Panel causes the Magic Tile in the Pattern Area to transform to the new polygon. Clicking on the Turn button will change the Magic Tile’s Connecting Side one step at a time in the clockwise direction. A central location in the Pattern Area represents the Home position for starting a pattern. At the start of a session, when the user clicks on a polygonal button, the Magic Tile appears at the Home position.

The Magic Tile can be filled with a color or left blank. For instance, if the user clicks on the red button, the Magic Tile’s polygonal frame will be filled with the color red—creating a red footprint. The user can thus construct a pattern by leaving colorful footprints as the Magic Tile ‘walks around’ the Pattern Area. If the Magic Tile is filled with color while it overlaps existing footprints, the underlying footprints disappear and are replaced by the new footprint. This behavior ensures that the resulting pattern is solely comprised of non-overlapping regular polygons.

The magical movement of the tile and understanding how footprints appear and disappear constitute all the basic rules of the environment which children need to know in order to work with TileLand. Once children know how to operate the mouse, this conceptual simplicity of TileLand is intended to make it easy for them to interact with the environment.

In addition to the above basic rules, there are a few other features to enhance the environment. An UNDO feature allows children to undo their previous actions. They can thus explore and backtrack different visualization paths. A Clear feature allows children to clear the screen. A homing feature (Home button) allows children to reset the location of the Magic Tile and return to the center of the Pattern Area. Children can also turn a background grid on or off. A Look Ahead feature allows children to see the next position of a Magic Tile.

Figure 1: Level 1

Figure 2: Level 2

Our formative usability evaluations suggested that it is easier for very young children to be given a starting position so they do not have to worry about where to begin.
if they were to click on it. Children can also save or print a tiling pattern that they have constructed and open an existing one.

TileLand is an open-ended environment intended to allow children to progress through it at their own pace, gradually developing more sophisticated 2-dimensional visualization abilities. Currently, TileLand has four levels. Different levels have different learning features and can be regarded as different types of learning environments.

**Level 1: Open-Ended Construction Tool**

Level 1 provides children with a construction tool that has a specific focus—that of creating mathematically-based patterns and tilings. Therefore it is based on the constructionist approach to learning [Papert, 1980; Harel and Papert, 1991]. This level is purely exploratory. Children are free to pursue their interests and create any type of pattern they desire. Although these patterns may have little mathematical properties, they help children develop an understanding of the metaphoric language of interaction used in the environment. Additionally, Level 1 provides a motivating environment in which children can construct colorful designs. Figure 1 shows a sample design created by a seven-year-old child. Although this module is referred to as a level, it is a self-contained environment—that is, children need not progress to or explore any other levels.

**Level 2: Logic-Based, Problem-Solving Game**

Level 2 is a typical sequential game-based, problem-solving activity [Alessi and Trollip, 2001]. It is a goal-driven version of Level 1. At this level, children need to solve a variety of geometrical pattern problems using the basic rules of TileLand which they learn in Level 1. Children are given explicit, pre-created patterns to reproduce. Whereas Level 1 is more experiential, Level 2 is more about making decisions, comparing the merits of different sequences and polygons, and reflecting on their relationships to determine how an existing pattern can be created [Norman, 1993; Sedig, 1998]. For instance, Figure 2 shows a simple pattern that children can reproduce. They can produce the pattern in several ways. One strategy is to produce the pattern in a radial manner—i.e., start from the center, move out, return to the center, turn, move out again, return to the center, and so on. Another strategy is to produce the pattern by walking around the central hexagon—i.e., start from the center, move out, turn, walk around, placing other hexagons around the central one (see Figure 5).

![Figure 3: Level 3](image1.png)

![Figure 4: Level 4](image2.png)

**Level 3: Open-Ended Programming Microworld**

Sedig et al. [2001] suggest that interfaces that gradually move learners from a visual thinking strategy to a linguistic (algebraic or command-based) one can be effective in engaging learners in reflective thought and deeper processing of educational concepts. In Level 3, children's interactions with the Magic Tile are simultaneously translated into linguistic commands appearing in a Programming Panel on the right-hand side of...
the screen (see Figure 3). For instance, clicking on the square button produces the command ‘square’, and other buttons produce commands such as ‘pentagon’, ‘red’, and ‘turn’. There are sixteen commands in total which can be categorized into two main conceptual groups—five polygon commands and nine color commands—plus Turn, Home, and Clear. The sequence of commands in the panel corresponds to all the actions the user has performed. This sequence serves at least three goals: 1) it can act as a bridge between the visual and linguistic description of a pattern, 2) it can act as a mapping between the spatial and temporal representations of a pattern, and 3) it can act as an external representation that can be examined and modified.

**Visual-to-Linguistic Description:** All visual mathematical concepts have a corresponding linguistic description [Devlin, 2000]. Additionally, an important feature of educational environments is to provide multiple representations of content [Tabachneck-Schijf and Simon, 1996; Lajoie, 2000]. In Level 3 children learn that visual patterns can be described linguistically. One of the benefits of this multiplicity of representations is that visual representations are processed differently from linguistic representations. The former are processed in parallel, whereas the latter are processed sequentially, requiring more cognitive processing and investment of mental effort [Sternberg, 1999]. As such the two forms of representation complement each other (see Figure 5).

**Temporal-to-Spatial Mapping of Interaction:** When children interact with the buttons in TileLand, their interactions produce a spatial image. This image implicitly contains the history of the steps that led to its creation. However, the only way that children can access this history is to examine their own memory which may contain cognitive residues of their interaction with the system. Instead of relying on children’s short-term memory, TileLand maps their temporal interactions into a spatial representation—i.e., a linearized history of their actions in the Programming Panel.

**Externalization as an Object of Reflection and Interaction:** The externalization of the visual description and interaction—that is, its conversion to ‘code’—affords children to both reflect upon the code as well as interact with it. Children can use the programming panel to modify and augment the sequence of actions (i.e., the code) by copying, cutting, pasting, and typing code. By copying and pasting blocks of code, children are performing rudimentary procedural routines 2. Children can bypass the use of buttons entirely and use the Programming Panel as an editor as well as a dynamic interpreter to write code from scratch to produce their patterns. Code written in the programming panel can be ‘run’, and a visual simulation of its corresponding pattern is generated step by step. This provides children with a very simple programming microworld—a self-contained software environment which embodies a reduced set of principles and concepts from a domain of knowledge [Ginsburg & Zelman, 1988]. Children can augment the history of their actions by inserting comments in the code. This feature helps the reflective practice of coding allowing children to chunk blocks of code into meaningful units.

---

**Figure 5:** A simple pattern, a possible program for its creation, and its corresponding strategy

---

2 Indeed using cutting and pasting, the user may find it easier to produce more elaborate patterns (see Figure 4).
Level 4: Programming Game

Level 4 is a problem-solving game, similar to Level 2. However, the Action Panel is no longer present (see Figure 4). It is replaced by the Programming Panel. In order to advance through the game, children need to produce a purely linguistic description of the given patterns. Children do this in a coding-testing-reflecting-modifying cycle. They can write a few lines of code or an entire program, test it, reflect on the resulting pattern and its code (i.e., discover why it did or did not work), and modify the code as needed. Unlike Level 2 where children can see the immediate result of every action while clicking on action buttons trying to re-produce a pattern, in Level 4 there is a temporal disconnect between devising a solution and testing it. This disconnect implies that children may need to mentally ‘walk through’ the visualization before they produce and test the code and observe its externalization. This mental simulation is one of the most important skills in visualization that a learner can acquire [NCTM, 1989].

Usability Evaluation

TileLand has gone through a series of formative evaluations. These evaluations have greatly influenced its design. Formative evaluations were conducted with half a dozen children, ages ranging from five to eight. In the early stages of its design, TileLand contained such actions as Forward, Back, TurnLeft, TurnRight, and Mark. However, we discovered that children had a difficult time constructing a proper conceptual model of the environment. For instance, the Current Tile had a Current Color while it moved. Children had to click on a Mark button for the tile to leave a footprint. They found it difficult to understand why a tile that had a current color would not leave a footprint while moving and that they needed to click on a ‘mark’ button for the footprint to be created. Additionally, they could not understand the difference between a tile attaching to a current one and moving a tile forward and backward.

After an iterative process of testing and modifying the environment, we minimized the number of conceptual actions and introduced the notion of the Magic Tile. In our latest usability evaluations, several children, as young as five years old, used the system with ease and found it engaging. They produced many printouts and were proud of their designs.

Summary and Future Work

This paper has presented TileLand, a multi-faceted microworld. TileLand allows children to construct colorful tiling patterns using regular polygons, engaging them in creative, mathematical art. TileLand is also a logic-based, problem-solving game which encourages children to explore the underlying geometric principles involved in constructing tiling patterns. TileLand can also be considered a programming microworld. It allows children to use simple descriptive language to express how a tiling pattern should be created while dynamically testing their description.

TileLand integrates several types of pedagogical interaction styles. It involves open-ended exploration as well as goal-directed play; it can be considered an experiential, fun tool as well as a reflective, challenging one; and it requires visual as well as linguistic information processing skills.

Future work involves conducting formal empirical evaluations of TileLand to assess its educational effectiveness. Additionally, the order of the presentation of the tiling puzzles in the game levels need to be examined, as each tiling pattern embodies different mathematical concepts [Peterson, 2001; Kinsey and Moore, 2002]. This organization can affect the way in which children conceptualize and understand the patterns and their underlying principles.

Abstract

This presentation describes a project to educate a team of college students in designing and developing an online course for the National Security Agency (NSA) utilizing constructivist methods of learning.

Constructivist Approaches To Learning And Research

This project involved converting a face-to-face NSA course to a multimedia web-based course. The conversion included a team of undergraduate and graduate students from Instructional Technology, Art Education, Computer Science, Special Education, and Graphic Design. Representation of various cultures was taken into consideration when selecting the students. In addition, two students were already teachers in the public schools and had experience in curriculum development. Two professors directed the project and were part of the team—one from Instructional Technology and the other from Art Education. The team’s focus was on collaborative group work and a constructivist approach to learning. Constructivist approaches served as the basic foundation for organizing and developing the project “…where students develop their knowledge through team collaboration, discuss different interpretations of a problem, and negotiate and synthesize ideas drawing from various disciplines” (Boyer & Semrau, 1995, 14). The constructivist goal was for the students to collaborate and the faculty to facilitate. Technology allowed the students to have more control over their own learning and become more independent in their search for knowledge. Jonassen noted that significant knowledge construction could be facilitated by:

1. Learning environments, which include working with authentic tasks,
2. Providing real world learning environments,
3. Fostering reflective practices,
4. And, supporting collaborative construction of knowledge through social negotiation rather than competition among learners for recognition.

The students were trained in new skills and how to research and work collaboratively with both faculty members and each other. Training was provided on html, Photoshop, Premiere, MediaCleaner, Pagemill and the designing of web pages. WebCT was used for managing the website, communication and collaboration, and uploading pages.

A major course goal was to keep the web course interactive emphasizing learner control. Useful tools for designing constructivist approaches to learning are hypertext and hypermedia because they allow for a branched instructional design rather than a linear top-down approach. It was also important in the distance education course that there be a balance between the text and the use of graphics, diagrams, video and audio to reinforce the learning.

For a foundation in working collaboratively in building a website, the students first designed a demonstration site on streaming media with RealAudio and RealVideo examples. The demonstration site was developed for sharing our research and for communication among the students and project faculty. Emphasis was placed on
demonstrating educational uses of streaming video and audio in education as well as being a source of research data and instruction for creating streaming video and audio for web-based training. Roberts et al state, "...students need to be able to find and use relevant information, share and discuss data and ideas, and collaborate on problem solving" (1990, 116).

In this presentation five stages are described, which are involved in creating a distance education course. Specific strategies are detailed and actual solutions are illustrated for each of the following 5 stages:

1. Planning and Development of the Content
2. Layout and Design of the Website
3. Implementation
4. Editing the Content
5. Assessing Learning and Evaluation

Conclusion

The new web-based version of this course will make the content accessible to more NSA employees located in various places throughout the world. Plus, the online version will include interactive pop quizzes with immediate scoring and feedback as well as streaming media lectures to complement the course content, which is presented as text on the web pages.

In addition as Boettcher and Cartwright (1997) emphasized, web course designers must realize that the "individual learner must be viewed as the key design element." We need to design instruction so that each individual learner can effectively build on what he or she knows and have the resources and assistance to learn (p. 2).

Through this project the students became constructively involved in their own learning and acquired in-depth experiences in collaborative learning and team approaches. New roles were created for both the teachers and the students. The students became empowered to be creators of their own curricular materials and web pages instead of being passive viewers of others'. In this project all of Bloom's higher-level taxonomies were implemented:

- Students analyzed websites,
- Synthesized criteria that they researched,
- Applied their book readings,
- Compared and contrasted their criteria,
- Designed and produced their own web pages focused on sound educational practices.

The faculty worked side-by-side with the students, setting new goals together, and evaluating and problem-solving as a team. As Gibson (1998) noted "...we, as distance educators, need to be learner-centered reflective practitioners" (p. 143).

When You Only Have One Chance: Online Library Instruction

Tracy J. Seneca
DePaul University Libraries
Chicago, Illinois, U.S.A
tseneca@depaul.edu

Abstract: DePaul University has developed the Instruction Builder, an application for creating, delivering and administering online tutorials. This paper discusses how online library instruction differs from online instruction for a semester or quarter long course. It also examines the roles of peer-to-peer, student/instructor, and ongoing communication in an online learning environment.

Courses with a strong research component will often turn to the library to teach a 'one-shot' session on effective library research. The librarian's goal is to foster information literacy: to teach the students the skills necessary to find the information they need. The quantity and complexity of research sources has grown tremendously in recent years, and it can be a challenge to cover anything beyond the basics in these workshops. There is also little chance for the librarian to follow up with individual students, and some students may see the session as busy work if it there is not a visible degree of collaboration between the librarian and the instructor.

Faced with higher enrollments, shrinking resources, more content to teach, and a growing population of distance ed. students, librarians have turned to the web to teach information literacy skills. One of the major challenges librarians face is that while they now teach their skills online, the integration of these skills into the course itself has not changed. Most web-based research tutorials are still a one-shot session, an assignment that students must complete on their own time. Librarians are creating online workshops as opposed to online courses.

The distinction between online workshop and online course is a crucial one in selecting the right tools. Most Learning Management Systems (LMS), such as Blackboard or WebCT are built with the assumption that online instruction will 'mimic' a traditional quarter or semester long course. In his ED-MEDIA 2001 keynote address, David Jonassen argued that these assumptions reinforce some of the worst aspects of traditional in-class education. For librarians, they simply don't work. These systems provide an array of features that cannot be used in a one-shot session and don't provide the tools needed to effectively teach the skills in question.

The DePaul Libraries began offering online library instruction in the Winter of 1998 with the Library Research Workshop. This workshop teaches up to 40 sections of freshman English students per quarter how to search online databases to find journal articles. The library's first version of the workshop used WebCT to create the class navigation. The problem? We were unable integrate teaching materials, demonstrations, quizzes and assignments on the student's own topic. The first version of the workshop forced students to wade through a great deal of material before reaching anything directly relevant to their own interests. In the fall of 2000, the Library needed to bring a more extensive research program for adult learners online. We saw that WebCT and the other LMS systems would not meet our needs, so we began work on the Instruction Builder, an in-house Learning Content Management System (LCMS).

The distinction between the LMS and the LCMS is derived from an IDC white paper. LCMS software is more focused on teaching skills than on managing classrooms. Consequently, rather than offering discussion boards, course syllabi, automatic grading and other common LMS features, it focuses on helping teachers break down their content into small sections, and teaching that content in more interesting ways. It allows both the teaching material and the students' responses to be stored in a database, to better track which skills are taught well and which skills students are frequently missing.

The Instruction Builder organizes content into skill-based modules. Each module ends with an assignment that applies the skill taught to the student's own interests using open-ended questions. Because the system is divided into segments, authors are deterred from creating long pages that attempt to teach too many skills at once. Students are tested on skills based on their own interests as they learn them, rather than having to plow through a long workshop, then take a long test. The student's answers are reviewed by a librarian, who then responds to the student.

When librarians taught these workshops in person, a great deal of emphasis was placed on peer-to-peer communication. Librarians had students work in groups to construct search strategies for one another's topics. This taught the creative process of word choice in database searching. Some students were likely to come up with terms that wouldn't have occurred to others, and it was clear that talking about the topic helped them search it more effectively. There was, however, very little one to one or ongoing communication between the librarian and any individual student. When students were in the lab working on the assignment, there was one librarian attempting to help over 20 students at once!

The move to an online environment has eliminated peer-to-peer communication, but has greatly enhanced one on one and ongoing communication between the librarian and student. As of December 2001, approximately 1,700 students have taken workshops created with Instruction Builder. Each student's assignment is individually reviewed, and the librarian is able to recommend strategies and alternatives when appropriate. In terms of communication with a librarian, the library research portion of these courses is now more fully integrated into the course itself.

Both the loss of peer-to-peer communication and the enhancement of student/librarian communication are crucial. Authors such as Curtis Bonk increasingly point to communication and interaction as the key to successful online learning. In "A Dozen Recommendations for Placing the Student at the Center of Web-Based Instruction", six of the recommendations pertain to peer-to-peer or ongoing communication. 3

The Library has already outgrown the system developed in-house. While there are a number of promising LCMS systems appearing on the scene, including Avalitus and Knowledge Mechanics, these systems don't provide the tools for fostering ongoing communication between student and instructor which we see as the core of our workshops' value. DePaul's Instructional Technology Department has begun work on a more robust Instruction Builder system, to be implemented throughout the University.

The fact that the one-shot research workshop model has been carried over from the traditional setting to the online environment has more to do with the assumptions & habits of librarians and instructors than the limitations of technology. This can (and should) be changed by breaking up the one-long-workshop model into smaller segments, which are taken during selected weeks of the quarter. It was assumed, for instance that since we had an hour and a half in class, that we would also have an hour and half online. But an hour and a half sitting at the computer taking an online course is a very different experience, and can be fairly numbing. Breaking the workshop up would integrate it more completely into the course content, foster more exchange between the student and librarian, and would ease the fatigue of online instruction.

Rejuvenating the Social Foundations of Education Course Using Digital Technology and the Case Method

Keith Whitescarver
School of Education
College of William and Mary
United States
mkwhi2@wm.edu

Abstract: This conceptual essay examines theoretical and methodological problems associated with teaching the Social Foundations of Education course and provides a framework on how to overcome these difficulties. Foundations of Education courses are notable for both their volume and the ambivalence with which students and instructors regard their role in preparation for teaching. The ambivalence is held because foundations courses generally suffer from instructors unknowingly devising incompatible goals for the course while the multidisciplinary nature of the course frequently leads to intellectual incoherence. One way to overcome these deficiencies is to have students acquire an "ironic" understanding using the case method. Case studies that use digital technology make this approach even more powerful because digital technology provides students with a cognitive tool that encourages the profound knowledge necessary to attain ironic understanding.

This conceptual essay examines theoretical and methodological problems associated with teaching the Social Foundations of Education course and provides a framework on how to overcome these difficulties. A staple of teacher education since the 1930's (Cohen 1999; Lagemann 2000), Foundations of Education courses are notable for both their volume and the ambivalence with which students and instructors regard their role in preparation for teaching. The ambivalence is rightfully held by both because foundations courses, from their inception, have suffered two significant shortcomings. First, instructors unknowingly have devised incompatible goals for the course. Second, the multidisciplinary nature of the course frequently leads to intellectual incoherence for all concerned.

As a teacher of Foundations courses, I have struggled with overcoming these embedded course deficiencies. Over time, I came to a realization that the course needed a new goal. I borrowed from Kieran Egan (1997) the idea of having students acquire an "ironic" understanding. Due to the multidimensional representation possible with cases, attaining ironic understanding is enhanced when case methods are employed (Merseth, 1996). Most recently, I have begun to supplement paper copies of case studies with digital technology and believe that the enriched learning experience provided by such an approach makes the case study method even more powerful. Digital technology provides students with a cognitive tool that encourages the profound knowledge necessary to attain ironic understanding.

Many instructors of foundations of education courses have grappled with ways to overcome the incompatible goals and the intellectual muddle of the course. An effective way to resolve the paradox is to create a course that seeks a new goal using new intellectual tools. Vygotsky (1978) argued that people make sense of the world using mediating intellectual tools. Intellectual development, then, is dependent not only on psychological stages, like those described by Piaget, or on the knowledge we accumulate, but also relies on the intellectual tools that society makes available. While Vygotsky focused on oral language, or sign systems, in his formulation, other intellectual tools are available. Using these tools in innovative ways can refashion the social foundations of education course.

For me, the way out of the teaching dilemma presented with a course that has at its core incompatible goals is to radically change the student outcome desired. Guided by the insights of Kieran Egan (1997) on the larger purposes of schooling, I seek to assist students in acquiring an ironic understanding of schools and teaching. Briefly, irony, as we know it today, is tied to a belief that the truth long sought in the western intellectual tradition is illusionary. In place of certainty, irony provides for the centrality of reflexiveness in thinking. Ironic understanding, then, leads to the removal of a commitment to
simple truth of general schemes. The sophisticated ironist, instead, enjoys extensive ways of understanding and recognizes the value of a varied spectrum of perspectives.

Fostering multiple perspectives is at the heart of the articulate ironist. Gliding from perspective to perspective is valued and becomes second nature in such a person. The ironist applies the varying perspectives to make sense of their experiences. A teacher might ironically note, for example, that a new school policy designed to improve math performance in fact creates a wider gap between high math achievers and low achieving math students. A better identification of the problem and a clearer solution is then possible. One must take care, ironically enough, to make sure that the disciplinary incoherence of the social foundations course is not replaced with incoherence arising from seeing events with different perspectives. The value of a case study approach to teacher education is that while cases offer multiple perspectives, they are at the same time grounded in a specific narrative context. General theoretical principles flow from an array of possibilities that build on one another. Out of what seems to be chaos comes not only insight but also orderliness.

Emerging digital technology is allowing the case study method to develop into an even more powerful tool by permitting cases to become more contextually grounded. More specifically, an interactive course web site that supplements the text of a case with multimedia presentations and links to other data sources allows great flexibility in student construction of knowledge. To illustrate this, I shall borrow a metaphor from the world of art museums. Elizabeth Valance (1995) refers to a "public curriculum" inherent in the orderly images found in art museums. This public curriculum consists of the images displayed; the order in which the images are placed; the information provided for visitors; the tours, lectures and workshops and other programs offered to the public; and the publications produced. The curriculum is randomly accessed by visitors and is readily available to anyone who comes to the museum. All visitors, however, study the curriculum on their own and make sense of the images in endless varieties of ways. While visitors may understand the curriculum in a variety of ways, the curriculum is deliberate. Images are arranged in some order (usually by culture chronology but such need not be case) with or without helpful labels. Some images are quite accessible to all but others are difficult, and visitors may even view an image with hostility. Visitors will frequently confront a museum worker with some sort of refrain along the lines of, “Is that really art?”

Similarly, a well-designed course website will be accessible and challenging. Depending on how images, text, video and audio are arranged, one can create different learning environments and attempt to frame relevant issues in key ways. Arranging course materials using digital technology into generative topics allows for students to respond to the realities of classroom practice and educational policy-making in multiple ways. What cannot be controlled, of course, is what students learn. The goal, instead, is to provide as many avenues as possible to allow students to make their own connections and to form their own categories. Like a well run art museum that helps novice visitors find accessible entry points into the world of art, an interactive website can assist the novice teacher into gaining access to the profession of teaching.
