Ninety-seven percent of students reported using the VSP functionality (acceleration) and found it very useful. The majority found that by accelerating the lecture speed to between 1.3x and 2.3x normal speed, comprehension was retained while time to move through the lesson content was decreased. Most reported accelerating during lengthy explanations or examples they felt irrelevant or redundant. One student commented that "when my attention started to wander I would speed it up and sort of 'skim' until I got to a part that I needed to pay closer attention to where I would slow it down again." The ability to individually control the rate of acceleration through the lesson materials appeared to be very valuable. Rather than present the lectures at a predetermined rate—perhaps at the 1.6x normal speed, students were...
able to find their own "sweet spot." Three non-native English speaking students were among the very few who reported not using VSP and would have been disadvantaged by fixed acceleration. One student remarked, "Initially, I listened at 1.5, then at about 1.7. . .I hypothesize that my brain was adjusting to intaking so much information. Shortly after adjusting to 1.7, I bumped up to 2.5 with no problems whatsoever. I feel that I have really been intellectually stimulated while listening at this high speed." This VSP ability is further supported by Harrigan (2000), Omoigui (1999) and Short (1977).

The study took an interesting turn upon evaluating data from the second semester. In the first semester, respondents reported using speeds from 1.3x to 1.8x, averaging out at 1.6x normal speed. Interestingly, the most recent data shows students reporting an average acceleration rate of 2.1x normal speed—reducing the time to view a lesson by half. The highest number of students reported an acceleration rate of 2.5x. This startling increase might be attributed to a number of factors, with "ear training" being perhaps, the single most influential. "I found that the more I used it, the faster I could listen," wrote a student. "I started at 1.5 and worked up to 1.8." A 1965 study (Orr et al, 1965) noticed that listeners could tolerate acceleration up to 2.0x, but that with 8-10 hours of training, significantly higher speeds were possible. "He grows on you," said another student, "and you can understand him, even when it is at twice the normal speed. The brain is an amazing thing." Voor (1965) also found that comprehension levels of time-compressed speech increased with practice. Harrigan (2000), on the other hand, concluded that comprehension declines significantly with time-compression in the range of 33-50 percent. Intelligibility will decline for users at some point of acceleration, directly compromising comprehension (Heiman et al 1986). It would appear, however, that after using VSP for 3.5 months, processing roughly 52 hours of 1x video instruction, this group of students became quite conditioned to viewing lectures at unusually high rates of speed.

Other probable factors that contributed to this average speed increase between semesters, include qualities of the instructor, students and technology. Is the instructor naturally an unusually slow speaker? Does he have exceptionally good diction? Students complained about his repetition in the lectures. Does the fact that concepts were repeated, and multiple examples presented, encourage students to accelerate? They’ll hear it twice more before he moves on to a new topic anyway! Is it because rewinding was so easy? When complicated or new concepts were presented, students reported that they could easily step back and hear it again—slower? Was it because students procrastinated, and were forced to view content at highly accelerated rates in order to pass quizzes or exams? Finally, did the combination of multiple lecture enhancements Galbraith (2000) employed in the course (video of professor-body language, supporting synchronized slides and animations, custom navigation features) contribute to students’ ability to comprehend the material at such high rates? The level to which all of these factors contributed is not known, but combined, they may proffer an explanation.

An important question yet to be analyzed is whether or not students are accelerating the lectures beyond their ability to fully comprehend the material. As if anticipating such a question, one student wrote, "very rarely would I jeopardize understanding for speed or timeliness. I found that at a faster rate, my mind wandered less than when I listened at a slower rate, because I was forced to pay attention." While mean scores did not go down for all participants in the class, was there a correlation between individual student exam scores and their reported acceleration rate? This remains to be seen, although Harrigan (1995) and Short (1977) indicate that learning and scores, in fact, increased with moderate acceleration.

Conclusion

Studies have shown that VSP is primarily desirable on information-based content rather than entertainment (Omoigui et al, 1999). Survey results clearly show the high value of the 2xAV plugin and VSP to the students in our study, where a high number of users reported viewing the lecture material at the plugin limit of 2.5x normal speed. Furthermore, the ability to intermittently decelerate and/or accelerate lectures according to individual comprehension level and interest, has the potential to fundamentally change the nature of video from a traditionally, "lean back" and "passive" medium, to a "lean forward," "active" instructional medium.

It is perhaps arguable whether such an amount (52 hrs) of lecture-format material represents sound instructional design in any setting or course. While this may be true given some circumstances, there are a number of good reasons to incorporate such material in many courses. Regardless of one’s philosophy or preference on this matter, if the lecture format is to be used in asynchronous instruction, no learner should be with out the tremendous power of variable speed playback control. "It is pure information flowing into my head without air bubbles." concluded one student.

Educational Potential of eBook Technology

Abstract

The presenter will discuss and demonstrate the current state of eBook technology. More importantly, he will share experiences with using eBook technology within the framework of existing college courses. Characteristics of this new technology, both positive and negative, in relationship to accessibility and effectiveness will be presented. Implications for educators, such as content access and intellectual property concerns, will be discussed.

Proposal

The World Wide Web has emerged as a powerful force for education. Courses and expertise can be accessed outside of the traditional bounds of a school or university. In the classroom, the web provides a seemingly endless source of information and resources. Although the Internet is increasingly becoming a delivery system for multimedia, educators continue to rely on it to deliver text-based materials.

Unfortunately, the web lacks the portability of the most traditional educational medium, the book. A popular solution is to envision students equipped with laptop computers and Internet access provided by wireless and/or wired additions to a school's network. Unfortunately, this is an expensive solution, especially when the student can acquire a more powerful, cheaper desktop system (albeit a less portable one).

In the meantime, students and faculty achieve portability by printing copies of needed web content and assignments (a wasteful, inefficient use of resources). Outside of the computer classroom and away from a home system, the student is no more "connected" or "empowered" than a previous generation carrying a similar load of textbooks and papers around campus.

An emerging, potential solution is the development of handheld electronic books (or eBooks). The term "ebook" is often used to describe portable reading devices and the content they contain. Current models are somewhat bigger and slightly heavier than their paperback counterparts. Connectivity with a computer and/or the Internet provides a ready source of material. In addition to electronic versions of traditional books, existing web pages can be downloaded and read by these devices.

Many eBooks have accompanying software that allows the presentation of the same material on any desktop or laptop system. The price of some eBook hardware has dropped dramatically over the past few years and is likely to continue to decrease as the devices become more common. One current model, which sells for just under $300, can hold 55,000 pages of text and at least 20 hours of battery use without recharging. It is likely that the use and availability of
eBooks will increase dramatically, regardless of their application (or not) in education.

Unfortunately, the book and electronic media have often been portrayed as competitors for the hearts and minds of students. Traditionally, books and literacy have been closely associated with education. Electronic media are a vast wasteland and contribute to the shortening of attention spans. Consuming technology requires isolating yourself in front of a television screen or computer monitor. On the other hand, young turks promote the new media as providing richer, alternative representations of knowledge. Dusty books contain outdated information; in the information age only the uninformed have to resort to RTFM ("reading the manual").

The integration of these apparently divergent viewpoints can be realized through the proper use of eBooks. Although a traditionalist will likely bemoan the loss of a certain tactile pleasure in the reading of an electronic version of a book, it is hard to argue that a portable, virtual library of readings in the students' hands (whether in the classroom, on a bus, or under a convenient shady tree) does not enable the depth of learning formerly confined to a library or well-stocked study. Electronic books do not provide the high-tech frills associated with current desktop and laptop systems. However, the lower cost and increased portability extend the reach of available content. This economy and accessibility are important concerns for the equitable use of technology in education.

Presumably, they are more environmentally friendly than the laser-printing alternative. It has also been estimated that at least 50% of the books printed by current publishers are destroyed after failing to sell (hopefully, a significant number are recycled and not totally wasted).

The presenter will discuss and demonstrate the current state of eBook technology. More importantly, he will share experiences with using eBook technology in existing college courses. Characteristics of this new technology, both positive and negative, in relationship to accessibility and effectiveness will be presented. Implications for educators, such as content access and intellectual property concerns, will be discussed.
Performance of Remote Anatomy and Surgical Training Applications Under Varied Network Conditions

David Gutierrez, Amol Shah, and Dale A. Harris
SUMMIT / Department of Electrical Engineering
Stanford University, U. S. A.
degm@stanford.edu, amolshah@stanford.edu, and daharris@stanford.edu

Abstract: SUMMIT (Stanford University Medical Multimedia and Information Technologies) is currently developing hypermedia applications for remote anatomy and surgical training. These applications include interactive high-resolution 3-D imaging, 3-D streaming video and haptic (force feedback) tools to be used in both self and collaborative study modes. These applications are network-intensive and the perceived performance quality of each one changes in a different manner to varying network conditions. Part of the research conducted at SUMMIT has been focused on determining the network requirements for medical training applications like these. This paper first presents the results of experiments that study the usability of these applications as the network conditions change and then discusses the implications that these results have on the development of similar networked hypermedia educational applications and on the design of networks to be used for them.

Introduction

SUMMIT is currently developing 3D applications and haptic tools that will be used for remote anatomy and surgical training. The 3D imaging applications allow, for example, anatomy students to view high-resolution images, such as those of particular body structures, in 3-D with the use of special glasses. The 3-D streaming video applications allow the broadcast of surgical procedures. These applications are greatly enhanced by adding haptic tools to them, which provide the user with a force feedback mechanism that creates the illusion of a sense of touch on the images or models. Thus, the student actually receives tactile feedback through a computerized model of a particular organ or structure, or when practicing a surgical procedure.

The ultimate goal is to be able to run these applications over the Internet. Today’s Internet, however, cannot meet the demands generated by this new generation of applications as it does not offer the networking functionality and Quality of Service (QoS) guarantees necessary. As a result, a good amount of research today, such as the Next Generation Internet (NGI) and Internet2 initiatives, is focused on developing an advanced Internet that can provide enhanced functionality. While most people think of these improved networks in terms of additional bandwidth, it is important to note that there are other parameters such as packet loss, delay and jitter, which significantly affect the performance of sophisticated applications such as these. Part of the ongoing research at SUMMIT is to study the effects these network parameters have on hypermedia applications. The remainder of this paper discusses the methodology and results from tests conducted at SUMMIT to determine what minimum network characteristics are required to support this kind of applications. These results are of importance both to the network planners and to the developers of future remote educational applications.

Background

The two applications studied in this paper are the JPEG Server (3D-imaging) and the AutoHandshake (haptics). The JPEG Server application provides interactive access to high-resolution stereo image sets. An example of such a set is the full 360° rotation views of a dissection through several layers of the hand (Fig. 1). This application allows students to perform a virtual dissection of the organ or structure being studied (such as hand, leg, skull), by removing different layers (such as skin, fat or tissue). It thus helps anatomy students to gain a better understanding of organs and structures at different layers and to create better mental models of them. The JPEG Server uses the TCP (Transmission Control Protocol) network transport protocol to establish the session, do initial setup procedures and transmit user requests. The actual image data is transmitted using a
modified UDP (User Datagram Protocol) that implements reliability. This reliability feature ensures that every received image is correct when displayed. Due to the high-resolution characteristic of the images, a high bandwidth network connection is required. Depending on the size and complexity of the image, the required bandwidth may go up to 40 Mbps (megabits per second).

(a)  
(b)  
(c)  

Figure 1: Sample 3D-imaging pictures: (a) Hand with all layers, (b) Hand with some layers (skin, fat, etc.) removed, (c) Same image as in (b) rotated.

The other application described here, the AutoHandshake, is a variant of the Handshake application, which is intended to train students remotely in surgical procedures. This is done by using a haptic device at each end and having the instructor guide the movements of the student remotely. The AutoHandshake variant is used when no instructor is available and the movements have been previously recorded on a simulator. This application uses the TCP protocol for initial setup in the same way as the JPEG Server application and then UDP to transmit the haptic data. For this particular application however, the UDP protocol is not modified to be reliable, since there is no time to correct network transmission errors while doing a movement. Unlike the JPEG server, the AutoHandshake is a low-bandwidth application that uses only up to 128 Kbps.

Method

The purpose of the experiments was to study the performance of the 3-D imaging and haptic applications under varying network conditions. Since it is difficult to actually test these applications on different networks in different geographic locations, it was necessary to recreate the network conditions in the laboratory. To do so, software tools were used to investigate different networks in order to get an idea of how much network parameters (throughput, packet loss, delay and jitter) differ among different networks. This provided ranges of values for the parameters of each of the networks examined. A network emulator was then used to recreate these conditions in the lab. Then, by connecting the applications across the emulator, the perceived quality of the applications was evaluated as the network parameters were varied.

Network Characterization

Network performance can be described quantitatively using four basic parameters. These are: (i) throughput, the available bandwidth, (ii) packet loss, how many IP (Internet Protocol) data packets are lost during transmission due to congestion, link failures or other problems, (iii) delay, the time it takes for a packet to get from one end to the other and (iv) jitter, the statistical variance of the delay. These parameters vary constantly, even on the same network. For example, depending on the route a packet takes to get from one point to another, it might need to go through a different number of routers along the way leading to different delays. Also, the amount of traffic that goes through a particular router changes constantly. Thus, the amount of packets queued waiting to be serviced at each router varies constantly, causing different per packet delays and, when the buffers are full, packet loss. Due to the best effort design of the IP protocol, packet loss is not unusual.

A commercial software package by NetIQ Corp called Chariot was used to characterize various network connections. Chariot operates as follows: small memory resident programs called Performance Endpoints are installed on computers that are located on the ends of the connection being evaluated. There is
also a controlling module residing on one of the endpoints or on a third-party computer. This module communicates with the endpoints and provides them with a script that simulates a particular network application, which can have a particular network transport protocol (TCP, UDP or others), data rate, session duration, packet size, etc. During the test, the endpoints measure, among other things, the average throughput, packet loss, delay and jitter and report these back to the controlling module.

For this experiment, network characterization was performed for four different types of two-endpoint network connections: a) connected across a 100 Mbps local area network, b) connected across a wireless local area network (WLAN) using the IEEE 802.11 standard, c) across an Internet connection with one endpoint at Stanford University and the other at the University of Wisconsin – LaCrosse, and d) across an Internet connection with one endpoint at Stanford University and the other at Sweden’s Royal Institute of Technology (KTH). The latter two connections go through Internet2 research and education infrastructures, which provide higher performing connections than across the commercial Internet. Table 1 shows the results that characterize the four networks using the throughputs and protocols used by the two applications under study.

Network Emulation

Having obtained the values in Table 1, the next step was testing the perceived quality of each application under varying network conditions. To perform these tests using different values of packet loss, delay and jitter, a network emulator was used. The setup consisted of a gigabit fiber-optic connection between the server hosting the applications and the client computer. The network emulation occurred on a computer in the middle of the two endpoints. This computer used a public-domain network emulator software called NISTNet to manipulate the data traffic going between the two endpoints. NISTNet allows the emulator to behave like different networks by changing the values of packet loss, delay and jitter in a controlled fashion. Thus, using the values of the packet loss, delay and jitter obtained from the real networks, the emulator parameters were varied while running the applications to determine the boundaries of acceptable performance.

Application Evaluation

As mentioned earlier, the two applications studied were the JPEG Server (3-D imaging) and the AutoHandshake application (haptics). To determine the application quality, a conventional subjective grading scheme was used. The values for packet loss, delay and jitter were changed one at a time, and the users were asked to grade the performance of the application. It is worth noting here that the users were familiar with its performance under normal conditions. Each user graded their experience on a scale of 1 to 5. A score of 5 indicated “Excellent: network degradation is not noticeable”; a score of 4 indicated "Good: network degradation is noticeable, but not annoying"; a score of 3 indicated "Fair: network degradation is evident and annoying"; a score of 2 indicated "Poor: network degradation is severely affecting the user experience and the application is minimally usable"; and 1 indicated "Bad: network degradation has made the application unusable". This grading scheme is similar to what has been extensively used previously for subjective video coding and transmission quality assessments (Webster et. al 1993, Watson, Sasse 1998, Jones, Atkinson 1998).

To test the JPEG Server, a set of 3-D images of the human hand was used (Fig. 1). Six test subjects familiar with the JPEG Server were asked to rate the performance of the application as the values of packet loss, delay and jitter were randomly changed. Similarly, for the AutoHandshake application, a subjective evaluation was performed using six test subjects that were familiar with the application and its capabilities under no network degradation. A Phantom Desktop haptic device, developed by SensAble Technology, was used during these tests. The AutoHandshake evaluation involved having the user make a certain movement with the Phantom device, and then having the server repeat the movement. The user would then determine if the accuracy and smoothness of the movement being repeated was equal to that of the original.
Results

Figures 2(a)-2(f) display the results for the JPEG Server and AutoHandshake under different packet loss, delay and jitter network conditions. In these figures, the characteristic parameter values for each of the four different network connections mentioned in Table 1 are indicated with markers ("100LAN", "WLAN", "U.Wisc" and "Sweden"). In Figures 2(a)-2(c), the "WLAN" marker is crossed out since this technology currently does not provide the necessary bandwidth for the JPEG Server application.

Figure 2: JPEG Server performance affected by (a) packet loss, (b) delay and (c) jitter.
AutoHandshake performance affected by (d) packet loss, (e) delay and (f) jitter.

Figure 2(a) shows how the JPEG Server performance degrades with increasing packet loss, reaching "Bad" performance levels at about .8% packet loss. Since the application retransmits packets that are in error, packet loss causes the images to be delayed or not shown at all. Figure 2(b) illustrates how the performance also
degrades gradually with increasing delay, but never reaches the "Bad" level. It never reaches this level because the application will always eventually show the desired image, unlike the situation caused by packet loss, where it may never be shown due to continued retransmission requests until it fails. Figure 2(c) shows how the application is fairly insensitive to reasonable values of jitter. Jitter causes the JPEG server to have to wait just a few milliseconds more before displaying the image. This effect is barely noticed by the end user.

Figures 2(d)-2(f) show the results for the AutoHandshake application. Figure 2(d) shows that the application is very resilient to packet loss, starting to degrade only at values higher than 1%. Packet loss simply causes a few misses on points that describe the path that the haptic tool should be following. Since the sampling of points along the movement path is high, these missed points are averaged from the ones that do arrive, making the application fairly insensitive to packet loss. Figure 2(e) is different from the other ones, since the effect that network delay has on the application is different: it either works fine or it does not work at all. This is due to the force feedback loop in this application (Niemeyer, Slotine 1998). When the network parameters force the feedback loop into an unstable mode, the application effectively becomes unusable. In the studies, the application was run 10 times under a given delay and verified if it would work or not. The markers indicate the number of times the application did and did not become unstable. The results differ depending on whether the movement is gentle or abrupt. Again, this dependence occurs because of the dynamics of the force feedback loop. The application performance is particularly sensitive to jitter, as Figure 2(f) illustrates, reaching "Bad" performance levels at around 15 ms of jitter. Jitter causes this degradation as the arrival of data points out of order causes the path to lose smoothness, which is easily perceived by the end user.

The graphs on Figures 2(a)-2(f) can be used to determine the minimum network requirements for these applications. Table 2 summarizes the requirements that these two applications impose on the network. These requirements have been taken as the values where the evaluated performance is in rated "good" or better. The threshold for the JPEG Server is at about 0.01% packet loss and 100 ms one way delay, as can be seen in Figures 2(a) and 2(b). For the AutoHandshake, the thresholds are at 10% packet loss and 1 ms jitter as Figures 2(d) and 2(f) illustrate. For its delay threshold, it depends on the movement: for abrupt movements it would be at around 20 ms, while for gentle movements it would be at around 80 ms, as Figure 2(e) illustrates. It is worth noting here that this evaluation has been made on a per parameter basis: that is, each parameter was treated independently. The results that different combinations of these parameters may bring have not yet been studied.

Table 2 illustrates one important point: simply providing more bandwidth is not sufficient to support these applications or others like them. For example, even though the AutoHandshake application needs only 128 Kbps to work properly, it has minimum delay and jitter requirements that may be hard to meet even for east coast to west coast connections within the U.S. This delay constraint for a haptic real-time application results in a limitation on the geographical distance allowable between a client and server or between two peers. This can become a serious problem since irrespective of the network functionality available, certain delay requirements cannot be met for geographically dispersed locations as the transmission speed is bound by the speed of light.

Discussion

The previous results illustrate how these two applications impose a series of requirements on the network being used. These results can be used along with the ones obtained for network characterization to estimate the performance of the applications on different real networks. Table 3 illustrates this. For example, the network connection from Stanford University to University of Wisconsin-La Crosse would support good to excellent performance of the JPEG Server application, but only inconsistent use of the AutoHandshake with abrupt movements. The connection from Stanford to KTH, Sweden would not be good enough for the JPEG Server due to packet loss, and delay requirements would not allow the normal operation of the AutoHandshake application. It is worth noting that both of these connections go through the Internet2 infrastructure, but even so,
the application requirements are higher than what they can provide. The only network connection of the ones characterized that can fully support both applications is the 100 Mbps LAN, which is local.

The delay requirement for haptic applications is particularly hard to handle from the point of view of the network implementers. First, there is a theoretical minimum delay, bounded by the speed of light. Then there is the delay that each router along the path causes during its normal operation due to queuing and switching. A QoS implementation that would allow minimizing the number of routers along a path or guaranteeing a maximum per router delay would be needed.

Table 3: Application performance in some characterized network connections

Conclusions

These experiments have shown how applications for remote medical training have stringent network requirements. Contrary to common belief, it is not just a matter of higher bandwidth. Other network parameters, such as packet loss, delay and jitter, are also very important. There is a need to better understand the limitations that current and near-future networks have (Tab. 1) and design the applications accordingly. The sensitivities and requirements that a particular application may have on a given network may be modified by adjusting a variety of design factors, including whether the application is real time or not, the kind of media that is being transmitted, the expectations of the end users and the network protocols being used.

A public network infrastructure that is expected to support remote medical training will need to provide QoS guarantees in terms of packet loss, delay and jitter (Tab. 2) and mechanisms that go beyond those provided today. Internet2 infrastructures today are not capable of appropriately handling these applications.

Some of these applications are currently in use at the Medical School, such as the JPEG Server for the course "Surg 219: Human Anatomy and Development". Future work at SUMMIT includes the evaluation of other network intensive applications, such as streaming 3-D video and peer-to-peer haptic applications, studying the network traffic patterns that are generated when the applications are in use and evaluating their scalability.

Abstract

This paper focuses on examining the various kinds of pedagogical, organisational or technical elements and constraints of successful application of collaborative learning in distance education. Our research relies on case studies concerning collaborative learning and work in several courses in virtual learning environments. Firstly, based on the implementation and analysis of educational practices with clearly differentiated goals, contents and methodologies, our research revealed that the progress of virtual learning groups goes across four critical moments: Group formation, consolidation, development and dissolution. Finally, we propose, explore and evaluate tools and technical functionalities that mediate collaboration and support effective virtual collaborative work and learning.

Introduction

Net learning based on global interactivity is emerging as an important element of a new educational paradigm which puts collaborative learning and lifelong learning at the center of the stage (Harasim, 2000). The net facilitates access to resources asynchronously without geographical and temporal limitations, promote interactions and information exchanges, due to larger opportunities of interaction.

In this context, one of the basic present educational challenges is to prepare people to be able to participate in an information society in which knowledge is the critical source of social and economic development (Comella, 1999). In this society, productive collaboration is the key issue of interactive organization networks that are open to constant changes.

A group of professors from the Multimedia and Information Sciences department at the Open University of Catalonia (UOC), from Barcelona, we are looking for ways to enrich the learning capabilities of the virtual classrooms in our university campus. Within our teaching practices, we explored strategies for putting in place virtual teamwork, thinking that this learning methodology will provide and promote agile and quality interaction between professor, students and resources.

Pursuing this aim, we focused our work in two main objectives: 1. To analyze, from a pedagogical viewpoint, cooperative working processes in a virtual campus environment to facilitate learning and apprenticeship processes to student and professor. 2 To identify the requirements that communication tools have to fulfill in order to be adequate for learning cooperatively in a virtual campus.

Description of reviewed cases: A pilot experience

In this article we present a Case Study experience. It is the result of our practice with teamwork learning in the virtual campus of UOC, within four courses with different goals, activities, and methodologies. In each case, the general methodology had to be adapted depending on size and group composition (heterogeneous or homogeneous), rules that should direct the activity, types of organization of working spaces, evaluation strategies, and roles that students can play. Four courses that included team project curricular design were chosen. We followed 154 groups of the different subjects.
Experience Analyze

By implementing cooperative work in these courses, our research allowed us to identify, of a methodological point of view, that the progress of learning groups in a virtual environment goes across four critical phases (Guitert, 2002) that require defining specifications which are quite different from those applied in individual learning in virtual environments. In particular, based on the two main objectives defined before, we obtained the following results:

In virtual cooperative work, a group goes through four phases or stages during its learning process. These phases can be more or less evident or flexible depending on the working goal and methodology of the course at hand.

A. Group formation: This is the period in which working groups are formed. It is important that students themselves are actively engaged in forming the groups, being conscious that this phase forms part of their working process. At this phase, the guidance the tutor may give to the students can be materialised in the following tasks: Information: guides and resolves issues that a group may set as regards group work in a virtual environment. Regulation: influences on the direction task organisation of the group should take; inform to the group, if it is necessary, on task organisation, how to initiate an activity, how to adapt the planning system better, etc. Support: promotes the proper conditions that enable group consolidation and better task development; encourages group organisation, shows his/her support explicitly when the group needs it and tries to be always aware of how the group proceeds its work in the shared space.

B. Consolidation: At this stage, the groups have been formed and they are prepared to initiate the laboratory activities proposed to them. Before real work starts, though, it is the time when the group members should break the ice and get to know each other more deeply. In a virtual environment, this moment is important for two main reasons:

1. It constitutes a warm-up activity before the group starts working on real learning activities. It gives members the necessary time to make initial contacts with each other. In a non-distance educational environment, once formed, a group sets up a meeting and can start working immediately; instead, in a virtual environment it is advisable for a group to spend some time trying to establish good organisation and planning of the work before starting working.

In this stage, the group has to decide who is going to be in charge of co-ordinating tasks. It has also to make decisions about the organisation of the shared space, decision making processes, the work planning, as well as, the frequency the group is going to communicate.

C. Development: This is the phase when the group applies and puts into practice all the decisions taken as regards scheduling and organisation forms, task sharing, etc. and when each member work cooperatively to carry out the assigned tasks. Once a group has started working on the task at the Development phase, the tutor will just wait to give his/her support whenever students will ask for it. She or he will give support in case they have a doubt about the content, or get stuck with a process or even when a conflict arises among them.

D. Closing: Once a group has reached the definite resolution of the project, every member realises a self-assessment of the work process carried out. The aim of this self-assessment is to give the chance to each member to evaluate the process they have been through, the results obtained by comparing them with the effort made, and the way they handled media and information and communication resources to accomplish the learning goals. Finally, at this phase of the group work, it is important that the group would be able to close the process followed by evaluating not only the resulting work but also the attitudes and relationships that have been maintained among all members. For this reason, the tutor establishes and foments a common discussion space where students can consolidate their cooperative work process by generating common feed-back capable of assessing both positive and negative aspects of the experience.

In relation to the second objective of this case study, we identify the functionalities that tools have to have to help collaborative learning processes in virtual environments. The following are the main characteristics: focus on student needs, user-friendly, easy to learn and to use, a clear interface, and an Internet tool.

Main functions

The tools we used allowed these two essential processes take place:

1. Communication and information exchange (between students and between students and teachers)
2. Organization and management of information in the team

1. Students of the Virtual Campus use very common tools for interacting and communicating the electronic mail (asynchronous communication) and Chat (synchronous communication). Chat is frequently used for quickly make decisions. In very specific moments, synchronous communication may be necessary. Instead, electronic mail, among
other functions, allows information exchange in a more elaborated way. It allows answers to questions be more
analyzed.

2. The Virtual Campus offers the group a common disk. Therefore, the group has an instrument for exchanging and
storing information. This way, group members can share documents and elaborate them together. Each member of the
group is allow to create or eliminate fields.

The case study, clearly showed beyond its own scope, that for learning processes take fully advantage of the new media
capabilities, it is crucial to understand how a virtual team exchange information and builds on knowledge. Moreover, it
is not only necessary to have technological support for allowing team cooperation and interaction, but it is fundamental
to better handle the learning process, and control all the elements that intervene on cooperative work on the net
environments.

Abstract In building an online course or transforming a traditional course for online delivery, the most critical element is not the selection of appropriate media but the selection of the most effective teaching strategies. Competitive online courses are those that are designed; 1) to involve students in the learning process, 2) to engage them in conducting learning activities, and 3) to enable them to readily apply what they learned in the real world. This paper presents a case scenario where an undergraduate course was designed based on the instructional theory model of collaborative problem solving (CPS). It demonstrates the rational for choosing the theory and the design of the course following the guidelines suggested by the model. Student feedback and suggestions on improvement are also presented in the paper.

Collaborative Problem Solving

Collaborative problem solving (CPS) is a newly developed instructional theory that combines two instructional approaches: cooperative learning and problem-based learning (Nelson, 1999). It emphasizes cooperation—the key of cooperative learning—in the context of “a carefully constructed problem scenario”, which is the essence of problem-based learning (Savery & Duffy, 1995). As a theory model, CPS provides guidelines that address the whole process of collaborative learning including: a) building a readiness in students to learn collaboratively; b) developing group skills; c) forming groups; d) engaging in collaborative problem solving; e) finalizing the process through appropriate analysis, synthesis, assessment, and closure activities (Nelson, 1999).

The goal of CPS theory is to develop knowledge of a content area that consists of complex domains. In the meantime, it emphasizes the development of problem-solving, critical thinking, and collaboration skills. CPS holds the pedagogical values of maximizing the natural collaboration processes of learners; creating a situated, learner-centered learning environment; honoring ownership of the learning experience for students; encouraging content analysis and exploration from multiple perspectives; acknowledging the importance of social context for learning; and cultivating supportive relationships among learners (Nelson, 1999). With group problem solving being a common practice in this age of information, collaborative problem solving prepares learners with the most necessary skills in the workplace—the ability to collaborate and a desire for lifelong learning.

Using Collaborative Problem Solving in INS 344

INS 344, Commercial Liability Risk Management and Insurance was offered by the School of Business at Indiana State University as a required course for undergraduate students majoring in insurance and risk management and as an elective course for other business majors. It is also part of the DegreeLink program, which offers students with associate degree an opportunity to get a baccalaureate degree by completing two additional years of coursework in the areas of insurance and business administration. Since most of the DegreeLink students are working adults who are not able to attend classes on campus, DegreeLink courses are delivered over the distance using the Web as the major modality.
that previously was offered as a face-to-face class, became available online in the fall semester of 2001. Sixteen students enrolled in this solely web-based course, seven students were majoring in Insurance and Risk Management and nine identified other areas of business including Business Administration, Finance, and Commercial Law and Accounting.

The design and development of INS 344 from face-to-face to the online format took place a year before the delivery. The transformation brought dramatic changes to the course not only in terms of its delivery media but also the instructional approach. Instead of using the traditional textbook chapter-by-chapter coverage, the instructional designer and the instructor decided to change the instructional design to a project-driven course with strong emphasis on interaction and collaboration among the learners themselves. Among the various available instructional theories, collaborative problem solving (CPS) was chosen because of the good match between the course and the CPS conditions including type of content, learning environment, and characteristics of both learners and instructor.

**Course Content**
INS 344, Commercial Liability Risk Management and Insurance, focused on an examination of the major commercial liability loss exposures including premises, products, completed operations, contractual, workers’ compensation, and other miscellaneous liability coverage. During this class, students were asked to identify and analyze different corporate liability risks and then to select optimal combinations of risk treatment and insurance for financial protection against liability losses. The assignments in this course were mostly heuristic in that they required a complex system of knowledge and skills that could be combined in a variety ways to complete the task successfully. The content of the course therefore suited the conditions for using CPS, which is found to be most appropriate with heuristic tasks as opposed to procedural tasks (Nelson & Reigeluth, 1997).

In addition to the complex nature of the project scenarios and the variety of knowledge and skills needed for completing the assignments and obtaining project solutions, the individual projects also varied from one group to another. Thus, there would not be a single question or one best way of doing something – a situation in which CPS is found to be most appropriate methodology to use (Nelson, 1999).

**Learning Environment**
A learning environment conducive to collaboration, experimentation, and inquiry was found to be the most effective environment for CPS (Nelson, 1999). Therefore, building this type of learning environment was the intent of the instructor and the designer of INS 344, including a component that would provide sufficient time for individual groups to become established. To support interaction among project team members, group space was created to enable online communication via email, discussion board, file exchange area, and virtual chat room.

**Learner Characteristics**
Nelson (1999) pointed out that having self-directed learners who are comfortable with, and willing to take responsibility for their own learning is an essential factor for the successful implementation of CPS. The characteristics of a CPS learner coincide with that of a successful distance learner in terms of independence and self-discipline (Nipper, 1989 & Guan, 2000). Other findings indicate that students who choose to take distance courses demonstrated lesser need for control and affection. They had more need to initiate actions than to wait passively for actions (Guan, 2000).

**Instructor Characteristics**
Having taught three different online courses, the instructor was comfortable in his role as a facilitator who would spend most of his time observing students’ interactions and would intervene only when it was absolutely necessary. He was therefore well suited to the CPS approach, which requires that instructors be flexible and tolerant of a certain degree of ambiguity in what exactly is to be learned and how the learning will take place (Nelson 1999).

**Designing and Developing INS 344 with CPS**
As a comprehensive instructional theory, CPS provides two general categories of guidelines to assist the implementation process: (a) comprehensive guidelines, which support the entire process, and (b) process activities, which provide step-by-step guidance for designing the appropriate learning activities.

Based on the comprehensive guidelines, the roles and the responsibilities of the instructor and the learners were clarified as the following:

**Instructor:**
- Provide resources as needed by the learners
- Identify roles in each project team
- Establish project timeline
- Formulate questions to focus learner on the critical elements of the content
- Facilitate group building
- Collect feedback from students and modify learning activities
- Offer just-in-time instruction when requested by learners

Learners:
- Prepare for team project by completing a mini project
- Select roles in the project team
- Collaborate with team members in identifying a problem pertinent to the subject area
- Collect background information of the company where the problem was identified
- Propose and conduct cost-benefit analyses for alternative solutions
- Complete online learning exercises over commercial liability content areas
- Present recommended solutions to the problem
- Share the final project report with the whole class

Instructor & Learners:
- Collaborate to determine learning issues
- Exchange/share learning resources
- Conduct formative and summary evaluations
- Provide group and individual evaluations
- Offer suggestions for course revision

In contrast to the comprehensive guidelines, which help clarify each party’s responsibilities during the learning process, process activities provide guidelines for building the learning events. As a project-driven course, the content of Insurance 344 was structured around the need to recommend solution(s) for a major business problem facing a large corporation. As shown in Table 1, the learning process consists of seven learning modules, each carrying at least one process activity suggested by CPS.

Although the learning modules were in accord with the CPS process activities, the sequence of procedures was slightly altered. Because the course was offered totally online, adjustment was made in a few areas: a) introduction to online learning, b) pre-defined roles of project members, and c) instructor-built project timeline.

Introduction to Online Learning
An introductory module was created for the very beginning of the course to prepare students for online learning. In this module, each student was asked to find results for a given problem related to risk measurement. To complete this assignment, students would learn to navigate the course site, review online documents, open an attached sample report, and use the Class Discussion Board to post their own responses.

Pre-defined roles of Project Members
Instead of letting students define their own roles in the project team, the roles were defined by the instructor before the team was built up. Each project team consisted of four members: a project manager, a risk manager, an insurance analyst, and a financial analyst. Job descriptions and responsibilities of each role were posted on the course site for students to review. Position selection took place in an online discussion forum that contained four discussion threads named after the roles, such as Project Manager, etc. Students were asked to claim their roles by replying to the appropriate thread. Since there was a total of sixteen students signed up for the course, four project teams were to be organized, with only four opportunities available for each role. In other words, once the role of Project Manager, for example, had been claimed by four people, that position was closed. A rule was made clear that "the person with the first date and time claiming a position has priority in the selection process."

Identifying the principal roles needed to complete a design plan is a critical part of the learning process (Bridge, 1992; Johnson & Johnson, 1997; West, 1992). It is also a time-consuming task that requires significant interaction and communication and negotiation among the team members. Considering the overall semester time limit and the amount of content to be covered in the course, the activity of identifying the separate groups was conducted by the instructor instead of the students. Thus, students could quickly find their position and be ready for the forthcoming tasks.

Instructor-built Project Timeline
The combination of the web-based format and project-driven approach doubles the chance for students to lose track of time. So, instead of allowing project team to develop their own individual timeline for their project, a milestone chart was shared with the students at the beginning the semester to provided them with a clear understanding of due-dates and deliverables. Within individual modules, there was also a timeline chart that highlighted the time frame expectations for that module.

Researching Design of INS 344
Since collaboration is "the hallmark" of the CPS theory and is built upon interaction (Nelson, 1999), investigating the collaboration and interaction among students within project groups became the main focus of the research. By tracking the quantity and quality of online interaction and by surveying students, the course instructor and instructional designer intended to examine: a) students participation of interaction, b) the effectiveness of interaction, c) students perception of interaction, d) students reaction to CPS, e) students preferences of interaction media, and f) suggestions for improvement.

Students Participation and Interaction
In general, interaction among students in this class was quite intensive with a total of 133 messages posted on the class discussion board. Additionally within the separate group space, the intensity of group interactions was strong in three of the four groups, although as seen in Table 2, the quantity of interaction turned out to be quite unbalanced.

</tbody>
</table>
Effectiveness of Interaction
All of the students agreed or strongly agreed (28%) that they learned more by doing the course project collaboratively with other team members than they would have by working by themselves. Comparing with groups in other classes, 53% of the students rated their INS 344 project group as excellent, 33% rated good, and 13%, fair.

Students Perception of Interaction
The survey showed that 60% of the students expected to have the greatest amount of interaction with their team members while 27% expected to interact mostly with their team project manager. One student expected to have the greatest amount of interaction with the instructor and another one chose the textbook as the major interaction object. In reality, 73% of the students said that they ended up having the greatest amount of interaction with their team members while some (13%) doing so with classmates outside their team.

Students Reaction to CPS
When asked, “how do you feel about problem-based-learning as the instructional methodology used?”, 93% of the students chose “Favorable” and 7% chose “Very strongly in favor.” All but one student was in favor of the course being primarily project driven. Some of the comments made by students in regard to the project:

"loved my group!”

“I liked the course because the project gave me a chance to see a real world thing.”

“I liked the structure and the project based learning.”

“I really enjoyed the group project for this class. It was really nice to know the group members. This way it was easy to get ahold of them and be able to communicate with them. I know that my group was taking the class to learn and it wasn't just a class to blow off.”

“Communicating with member was easy”

“Our Instructor was very helpful, and he put us in groups with people that we all work really well with.”

“I liked the group project.”

“Got to work on actual real world company.”

All the students either agreed (60%) or strongly agreed (40%) that they were motivated by the effort their team members had put into the group project. No one was discouraged by the lack of involvement of any team members. They all believed that their group was able to work effectively as a team and that their team members’ contribution were equally distributed. Of their own contribution to the team project, 80% of the students described themselves as “a strong worker with fair amount of input” while 20% called themselves “THE major contributor”.

Students Preferences of the Interaction Media
In terms of the communication channels used for interaction, the discussion board was used most extensively, followed by email and then face-to-face meetings.

Suggestions for Improvement
A content analysis from students’ feedback offered the following themes:

1) Information & Resource Sharing
   - Several students indicated that they “had difficulty finding some information” and were “wondering if I was getting a broad enough knowledge base for achieving objectives.” Suggestions for improvement include “giving an example of the final project at the start of class” and “post a suggested reading list/schedule.” It was also suggested that “(Instructor should) require postings of other group materials, so that we way (will) learn from others.”

2) Project Direction, Schedule, and Pace
   - 53% of the students said that “keeping up the project schedule” had been the most challenging aspect of the course. Some student felt that it is difficult to “complete everything by due dates. It was tough to lay it out at
beginning. Falling behind, then catching up, quite sporadic.” One student found it difficult “having to follow a schedule, rather than work at our own pace.”

3) Web Access and Navigation
--Learning the structure of the site was found to be difficult by some students. Others encountered technical problems accessing the course and the learning exercises.

Conclusion

As indicated in the Learner-Centered Psychological Principles (APA Online, 1999), learning can be enhanced when learners have the opportunity to interact and to collaborate with others on instructional tasks. Collaborative problem solving (CPS) provides a theoretical framework for instructors and course designers to build a learning environment that allows for social interactions, and that encourages flexible thinking and social competence. By using the CPS model, the undergraduate business course, INS 344 broke down the traditional lecture-and-exam structure and brought students closer to the real world situation. This approach cultivated a teamwork environment that mirrors the most common and natural situations in the age of information.

This paper outlined the design and delivery of an online business course using Collaborative Problem Solving instructional approach. It has been demonstrated from the learning outcomes and students’ feedback that the CPS offered effective instructional methods that were well suited to the content and the context of the course. Also, from analysis of the groups’ learning process, it was concluded that there is need for continuing evolvement and more creative usage of the CPS guidelines.

Abstract: This paper briefly describes the WebNize system and how it applies a Metro Map metaphor for organizing guided tours in Web based resources. Then experiences in using the Metro Map based tours in a Knowledge Sharing project at the library at Aarhus School of Business (ASB) in Denmark, is discussed. The Library has been involved in establishing a Learning Resource Centre (LRC). The LRC serves as an exploratorium for the development and the testing of new forms of communication and learning, at the same time as it integrates the information resources of the electronic research library. It is the objective to create models for Intelligent Knowledge Solutions that can contribute to form the learning environments of the School in the 21st century. The WebNize system is used for sharing of knowledge through metro maps for specific subject areas made available in the Learning Resource Centre at ASB. The metro maps now serve as the entrance to learning resources for several hundred students.

1. Introduction

Support for structured navigation in large bodies of information has been an issue for hypermedia research since Bush (1945) introduced the notion of Trails. In hypermedia research (Trigg, 1988) the trail concept is called guided tours and a number of systems have been implemented to support trails and guided tours also for the Web.

Among the systems supporting guided tours for the Web, are: Pooh's Guided Tours Service (www.infosys.tuwien.ac.at/GuidedTour/GuidedTour.html), Footsteps (Nicol et al., 1995), Walden's Paths (Furuta et al., 1997), and Ariadne (Jühne et al., 1998). All of these systems provide value-adding services for the WWW making it easier for the prospective users of the WWW to find their way through relevant information. This paper presents a hypermedia based guided tour system for the WWW (Berners-Lee et al., 1992), which was developed as an integrated part of the open hypermedia system called Webvise(Gronbæk et al., 1999), which is now a commercial product called WebNize. The WebNize guided tours can be used by readers in plain browsers without using Java or any plug-in. The WebNize system is a full-blown open hypermedia system, with an integrated guided tour editor. WebNize generates guided tours in plain HTML and PNG formats for access through a plain browser.

The WebNize Guided Tour System is inspired from open hypermedia (Gronbæk & Trigg, 1999), classical hypertext (Trigg, 1988; Zellweger, 1989), and the recent Web initiatives mentioned. WebNize improves support for users in navigating through prepared presentations of subjects. In addition to inspiration from the classical hypertext systems we have been inspired from the ideas of simplified metro or bus maps to communicate information on routes in a complex city. This idea came across when our pilot users pointed to a handcrafted web page at Chalmers, Sweden (educate2.lib.chalmers.se/demopath.html). The WebNize system including the Guided Tour System as described in this paper is available from www.hypergenic.com.

The paper is organized as follows: First we describe the context in which WebNize has been brought into use for organizing learning materials. Secondly, we describe the how WebNize support the organization of learning materials. Then we describe experiences and results and finally we conclude the paper.
2. Learning Resource Centre (LRC)

The Library at the Aarhus School of Business presents the results of co-operation between the Library and the Faculty of Modern Languages at the Business School. The purpose of this co-operation has been the development of a knowledge sharing platform and tools to facilitate knowledge sharing in a modern international environment of education and research at the Aarhus School of Business (Bang, 2001). With the Library as the centre, the co-operation resulted in the establishment of a Learning Resource Centre (LRC) primarily aiming at servicing students, teachers, and researchers at the Faculty of Modern Languages.

The LRC has been established in close cooperation between the three environments: research, teaching and library. This co-operation has been prompted by an urgent need of initiating experiments with new forms of learning and education. Experience shows that new teaching methods generate quite new demands for developing new ways of giving students, teachers, and researchers access to quality-assessed information resources and to technology support. A modern research library must be capable of supporting the new learning environment with a wide selection of services matching the needs of the users.

Thus, the LRC has been organized as an “exploratorium” for students in new forms of learning and for training of teachers who are to act as facilitators in the virtual learning environment. The LRC centre both functions as a physical meeting place and as a place where electronic information resources and learning tools are available to the users via well-arranged and clear user interfaces accessible 24 hours a day.

2.1 Learning portal based on Metro maps

The Metro map metaphor has proved to be a suitable user interface for at learning portal for students and teachers in a LRC exploratorium. The Metro metaphor is fascinating, familiar to most people and easy to comprehend. It provides a general view, is useful for structuring a very large amount of web sites and it is next to impossible to get lost in. The METRO allows a graphically oriented user an easy navigation round the information and learning resources displayed in the show window of the electronic study of the LRC. All along you can follow a predefined search route for the drive of your journey from station to station on a key map. You can even get off and on as you like, without losing track of where you are.

The Library uses the metro map metaphor as a basis for constructing paths in the form of guided tours to the learning and information resources in the LRC (Jensen & Harbo, 2000). The Metro in the LRC at the Library of the Aarhus School of Business is based on the use of the open hypermedia system called WebNize.

2.2 New Learning Environments and Guided Tour Systems

In recent years the study and learning environments at the institutions of higher education in Denmark have changed. The frames earlier set by the traditional class- and lecture-room education do not suffice. The students still follow conventional lectures, but the responsibility for own learning is growing. To a large extent they work problem-based and project-orientated and need to meet in seminar rooms with facilities giving access to a wide range of quality-assessed information resources - electronic and printed - and user support tools side by side with teaching materials and learning tools. New and different physical and intellectual demands on facilitation of the study and working processes arise as a natural consequence of modern teaching methods. This only draws a picture of the facilities supporting the traditional daytime students at the universities and the institutions of higher education. Distance learners and part-time students have special needs.

Teachers and the research library only reach the students in these environments via an electronic user interface on the Internet. The support for studies and learning of such dimensions is a pedagogical challenge to institutions of higher education and to research libraries. The development of entirely new tools and methods for presenting library resources and guiding the students is necessary to ensure optimal use of information content.

At the LRC of the Business School we have chosen to use the Metro metaphor and the concept of ‘Guided Tours’ as the educational concept, which is to support user access to electronic information resources, to the learning content and to the tools supporting the learning process itself. The concept of ‘Guided Tours’ in the learning portal offers the opportunity of guiding the user via pre-defined routes in the shape of linear courses. The users may also choose to plan their own individual course based on their needs.
3. The WebNize hypermedia System

We believe that support for guided tours is needed in many application domains. Teachers, librarians, Web journalists, portal editors, publishers, governmental administration etc. often wish to present procedures or collections of information in a homogeneous manner.

This is supported by the fact that the notion of a guided tour has become quite common on the Web. The search terms "guided tour" gave in December 2001 more than 550,000 hits on Google (www.google.com). Many of these hits actually represent sites that present a certain topic in a sequence of web pages and commented links like, e.g. the Visual Human (www.madsci.org/~lynn/VH), Wind Energy (www.windpower.dk/tour) and the Chalmers Library guide (educate2.lib.chalmers.se/demopath.html). The WebNize system has been designed to overcome problems and limitations of manually created guided tours and existing guided tour systems.

3.1 The metro map metaphor

As described in (Sandvad et al., 2001) the metro map has been used in WebNize, because:

- It is an intuitive metaphor – navigation resembles familiar ways of navigating metro and bus maps
- It creates an overview of a large complex of related guided tour modules – the Metro Map
- It maintains focus and overview for the user navigating a specific guided tour module – the Route Map

Usage of the metro map metaphor in guided tours has shown to be an efficient technique for providing overview over a set of web documents because the metaphor is intuitive and simple. Many people around the world know how to read route maps for metros or busses. Given the destination station it is easy to find which route to take even in large cities like Paris and London. Designing metro maps in the real world is, however, not a simple matter (Garland, 1994; Tufte, 1997), and it is not either simple on the Web, where we don't have a fixed underlying map of the structure to traverse similar to a city map. But we provide a general tool that allow map designers, i.e. the domain experts, a large degree of freedom in the design of simplified maps of arbitrary complex underlying structures.

The main idea in using the metro map metaphor in guided tours is to consider each major subject in the web information as a route in the metro map. When the reader wants to know something about a certain subject s/he just has to "take the metro" on the route that deals with that subject. If the reader is very unfamiliar with the subject s/he should start at the central metro station whereas more experienced readers can enter the metro farther out on the route (see Figure 1).

Hence, metro maps are used to provide overview when entering the information infrastructure by showing an overview over all routes. But the metro map metaphor has more to give. Inside the real metro wagons a horizontal route map is shown with all the stations on the route, and every time the metro stops at a station the traveller can see where s/he is on the route, which stations have already been visited, and which stations are yet to be visited (see Figure 2). This has inspired the presentation of a route map above the Web document as will be shown in the following.
To take full advantage of the structure of the guided tour, the user should be able to view the relevant part of the tour while following a route. The user should be able to monitor the stations in the tour that have been visited and where the user is currently located within the tour. Finally, the author of a tour should help the user by adding names or/and annotation to the stations.

This is supported in the WebNize Guided Tour System. It helps users keep their orientation in the tour, e.g. if the user has lost orientation because s/he has gone off the tour by following links from a page in the tour, a quick look at the graphical presentation of the tour helps the user regain the focus. The annotation support gives the author the possibility to add comments about Web pages within the tour. This can be used in a variety of use situations, e.g. if the author wants to review the sites in the tour, draw the readers' attention to a specific topic in the page or — in an educational situation — adding questions to the topics touched in the page.

4. Usage of WebNize generated tours

This section presents the metro map metaphor and shows an example of how it has been used in a user guidance system at the Library at the Aarhus School of Business. We present a metro map and one of the route maps that are generated from the WebNize guided tour editor. The generated metro and route maps can be visited at www.hba.dk/metro.

4.1 The generated metro and route maps

Figure 1 shows the metro map of the user guidance system. The different routes in the map present different recommended ways through the user guidance system. Each route represents a certain topic. The topics are: literature, library orientation, study guidance, project writing, Internet, vocabularies, writing laboratory, virtual librarians and information retrieval. If the user wants to follow the recommended sequence s/he just has to click on the oval figure of a route. Otherwise s/he can jump directly to a particular station by clicking on it. When clicking a station in the metro map, a route map is shown together with the contents of the particular station. If the ‘Virtual Libraries’ station is clicked in the yellow route the frameset in Figure 2 is presented.

The frameset consists of two frames: a navigation frame and a contents frame. The navigation frame shows the selected route and the position on the route by red colouring of the current station. The contents frame shows the contents of the current station, i.e. the URL that the station represents. Each station can be selected directly by clicking on it, and the route map highlights the current station. The Metro and Route maps helps maintaining an overview of where the user is in a large body or related learning resources.

4.2 The user interface of the WebNize Guided Tour System
The guided tour editor is a drawing editor (see Figure 3) that makes it possible to define the sequencing of stations in the guided tour in a general graph. Stations can be added to the graph in different ways. One way is adding a URL to the guided tour by using the command ‘Add to guided tour’ in an extended popup menu of the Internet Explorer. URLs (from the Address field and links in the web pages) can also be dragged into the guided tour editor. More facilities are described in details in (Sandvad et al., 2001)).

![Figure 4: The Danish Electronic Research Library instruction Metro map running in the LRC.](image)

![Figure 5: The route map for "Subject Portals".](image)

5. Results and experiences

Till now, WebNize has been used as a developing platform for the Metro concept and to create Guided tours for the use of establishing learning platforms in the LRC exploratorium at the Business School. Feedback from students and teachers confirm that the concept presenting large amounts of information, courses and teaching material in a linear and transparent manner is valuable. This gives occasion for the further development and use of the concept in professional learning platforms of other Danish research libraries.

The Business School Library has recently made use of the WebNize tool in designing a portal for knowledge sharing for a cross-departmental research team working with e-Business (www.hba.dk/webnize/00server/tours/e_business/index.htm). E-Business Forum is a platform for knowledge sharing across professional environments and frontiers, and it will develop into a dynamic site with researchers sharing their knowledge, commenting on research results, and automatically ‘reap’ information from databases.

The Business School Library has also utilized the Metro concept for experiments with user instruction for The Danish Electronic Research Library Project (DEF). Here the Guided Tours have been used for structuring the content of the DEF Project as search instructions for users (www.hba.dk/uec/) as well as Figure 4 and 5.

6. Conclusion and future work

This paper has described the WebNize guided tour system, which consists of an editor/viewer helper application and a generator to create a stand-alone guided tour website consisting of only HTML and PNG files, which can be used through plain browsers. The status of the WebNize guided tour system is that it is now a product, which is being developed and used for a number of portal projects on consulting basis by Hypergenic.

The Metro Map based guided tours have been in use at the Aarhus School of Business since September 2000 (www.hba.dk/metro). The guided tours have been used as basis for introducing all first year students to library use and information search. In addition the Metro Map is the start page on all PCs (70) in the Learning Resource Centre with 1250 students and 130 teachers. The response is very positive from the students as well from the teachers and the Aarhus School of Business are using to the approach in other domains beyond library introduction. A new route ‘Courses’ with a station for each course is currently being developed in collaboration with the teachers and the use of the system is by teachers as well as students expected to increase in the future.

To a larger extent the Metro Map is being used for structuring ‘Virtual Libraries’, that is, targeted vertical portals holding parts of the information resources of the research library, targeted at a department, a team of...
researchers, students or a company. Next step is developing the tool, thus enabling the user to download it and use it for creating personal learning platforms ‘my courseware’ or personal libraries ‘my library’. In cooperation with Hypergenic A/S, the LRC is experimenting on the development of such facilities.

Acknowledgements

The Metro Map metaphor was inspired by the Chalmers Library guide (educate2.lib.chalmers.se/demopath.html) and part of the development of WebNize was developed by Mjølnar Informatics (www.mjolner.com) under contract with the Library at the Aarhus School of Business (ASBL). We wish to thank: Finn Nyborg and Birgitte Eltzoldt at ASBL who were our first pilot (author) users. They inspired our development of support for the Metro Map with useful feedback in a highly iterative development process. Finally, we wish to thank Elmer Sørensen Sandvad, Lennert Sloth, and Kristine Thomsen from www.hypergenic.com for the development of WebNize and the support given to ASBL.

Introduction
Companies are increasingly becoming aware of the importance of knowledge for their competitiveness and success. Knowledge should be kept and distributed in the company. For this reason, the preservation of expert knowledge is becoming an important challenge for knowledge management. We argue that knowledge acquisition techniques can help to meet this challenge: we are using expert interviews to elicit knowledge from experts and compile this knowledge into a XML-based information system.

Up to now the contribution of video components in the process of knowledge presentation in information systems has been underestimated. Therefore we present a concept for including automatically generated context-dependent video sequences from the recording of expert interviews. We explicitly focus on the requirements for attribution of video sequences and information concepts with metadata and outline the idea of a “fuzzy” metadata attribution scheme which is used to control automatic selection and combination of video sequences.

Process of Knowledge Acquisition
Our research group raise knowledge in cooperative sessions with experts of a company. We use structured interviews, a well known knowledge elicitation technique (cf. [4]). Just before the interview the expert obtains a special structured questionnaires for preparation. The interview is recorded with a video camera but so far only audio information is (semi-)automatically attached to the questionnaire and retrieved later in the information system. During the interview mindmaps are generated by the knowledge engineer (cf. [3]) whose information modules are filled up by information gathered out of the interviews. The preparation of questionnaires, the presentation of interviews and the identification of knowledge are also conducted by the knowledge engineer.

Structure of an Information System
An information system can be understood as an electronic reference book for browsing and finding knowledge of practical experience from experts. This knowledge could hardly be made explicit so far. As stated in [6] the basis for such an information system is a knowledge map consisting of hierarchically arranged knowledge items which are called concepts or information modules. These modules may contain contextual information, images, links and other resources which are needed for a comprehensive presentation of the concepts. These different entities are tagged with metadata which are an essential requirement for connecting the information system with other systems, e.g. learning systems or tutor/training systems. So far we use a custom metadata scheme and encode the descriptors into a XML-representation.

Automatic Generation of Context Dependent Video Information Resources
In the previous sections we have motivated the usefulness of video sequences for technical oriented information systems. A realization which tries to generate context dependent video sequences from the expert interview recordings needs to address the following topics:

- linking and synchronization of video recordings with concepts from the knowledge pool
- necessary metadata for automatic recombination
- integrated and interactive visualization of concepts and video presentation

“Fuzzy” Video Attribution
The problem with temporal media - like video or audio recordings - is to find a precise and sufficient attribution of presented concepts. Normally knowledge experts won’t describe a single concept from beginning to end...
before they start discussing the next one, but they jump between describing interrelated concepts. An attribution mechanism for such interrelated descriptions should be able to define a temporal varying degree of relevance of presented semantic concepts in the recording. We therefore suggest a method for attribution of video recordings called "fuzzy" video attribution. It refines the concept of overlapping attributes or conceptual structures (cf. [1, 2]) by specifying a time-dependent relevance curve for each attribute.

**Metadata Requirements for Automatic Video Information Resource Generation**

A metadata scheme which can be used for automatic video resource generation has to address mainly the issues of video sequence selection and combination. We therefore suggest the creation of four additional metadata descriptors for video sequences:

- **Content Type**: Characterization of video sequence, e.g., description, example
- **Content Level**: Characterization of complexity, e.g., introduction, detailed technical description
- **Audience**: Specification of user roles for which recording is intended, e.g., beginner, technical experienced user
- **Concept Relevance Level**: Time-dependent degree of relevance of recording for specific topic

The first three descriptors can easily be mapped to Learning Object Metadata (LOM, cf. [3]) educational category data elements (5.2 Learning resource type, 5.5 Intended end user role, 5.10 Description). Unfortunately there is no possible mapping for ConceptRelevanceLevel as this descriptor needs to encode time-dependent values for different concepts. Possible implementations might be to specify a value for each second in the corresponding video sequence or to conduct a Fourier transformation for the specified relevance curve and assign calculated parameter values to the descriptor.

**Integrated and Interactive Visualization of Concepts and Video Presentation**

Presentation of video sequences is only useful if it is tightly integrated into the underlying information system. This implies that navigation between different topics must be possible from within the video stream and that the semantic context for the presented video sequence should be indicated. Furthermore the relevance level information needs to be presented to the user (e.g., by showing a "relevance meter").

The constructed video presentation also needs to be customizable by the user, e.g., in order to tell the system to generate only technical video sequences. Another possible customization would be to specify a lower limit for the relevance level which therefore gives the user some control over the length of the generated video sequences.

**Outlook**

Information modules should be processed efficiently by a reasonable linking to templates of an task-oriented tutor system. Through this it is firstly possible to develop specified task types, secondly to adjust the proposals of solution delivered by the students. Taken the presented requirements into consideration an implementation of a prototype video sequence construction system based on the Synchronized Multimedia Integration Language (SMIL, cf. [7]) specification is currently planned. Navigational elements to different topics and presentation of semantic context will be realized by producing a SMIL document.

Orienting Students to Distance Learning: Strategies for Success

Since 1995, the University of Northern Colorado has offered a graduate program in speech-language pathology that is delivered through distributed learning environments. Two cohort groups have completed the program, a third group will graduate in August, 2002, and a fourth group began the program in August, 2001. One of the challenges in designing and implementing a program that uses distance technologies is insuring that the students, many of whom have not participated in formal education for several years, have basic competencies in using technologies to access courses, find reference materials, prepare and transmit class assignments, and communicate with faculty, library personnel, administrators, and fellow students. A second, and no less important, challenge is to assist students in evaluating their own learning styles and strategies to facilitate their success as independent, adult learners in nontraditional learning environments. Introductory orientation materials, which incorporate basic information about program procedures (e.g., class registration) and an introduction to technology are provided prior to the initial semester; however, the faculty felt a more in-depth experience was required.

This session describes the objectives, content and outcomes of the class that was designed to meet these challenges. An earlier version of this course, which focused primarily on development of graduate level writing, was offered to the first two cohorts. Evaluation of student and faculty experiences revealed that the course needed to be redesigned to orient students to distance learning strategies, skills, and technologies. While a writing component is incorporated in the course, it is used as a mechanism to meet the orientation goals, as well as introduce students to faculty expectations for graduate writing. This course was offered to the third and fourth cohorts.

The redesigned class incorporated the following six objectives that students meet as they participate in the class:

1. Students will evaluate their learning needs, learning styles, learning strategies, study habits, and technology experiences to facilitate participation as successful adult learners in distributed learning environments.
2. Students will demonstrate competencies in accessing and transmitting course information and assignments online and using email, chat rooms, and listservs to communicate with fellow students and the instructor.
3. Student will develop appropriate topics for review papers in communication disorders.
4. Students will use appropriate strategies to access and obtain reference materials through the UNC library.
5. Students will demonstrate strategies for accessing and evaluating internet documents of research purposes.
6. Students will write a review paper that demonstrates competence in using a word-processing program and APA editorial, writing, and manuscript styles.

Activities designed to help students meet these objectives included:

1. Accessing the course webpage and using it to retrieve course information and communicate with other students and the instructor.
2. Readings and activities in How To Be a Successful Distance Student, Marguerita McVay (2000), including completion of surveys for self-analysis of learning needs, study skills, learning strategies, and technology experiences.
3. Maintaining a learning journal on at least a weekly basis to facilitate development of reflective learning strategies.
4. Developing annotated bibliographies of print and internet references using OVID databases (e.g., Psychinfo, Medline, ERIC) and online search strategies.
5. Evaluating internet references using criteria presented in the McVay text.
6. Selecting a topic in speech-language pathology of appropriate scope for a short (8-10 page review paper).
7. Completing the paper using APA style guidelines.

Students are instructed how to submit assignments online through the course webpage or as attachments to email and strongly encouraged to do so.

Finally, examples of student products and communication, from the third and fourth cohorts, were presented along with an analysis of learning journal entries from the third and fourth cohorts. These entries provide insights into students' unique learning styles, strategies and challenges, their perceptions of readings, their development in use of technologies, and their reactions to the assignments. Patterns of entries will be presented, as they provide a clear picture of student outcomes for the class. For example many students expressed increased confidence in using technology. Midway through the course one student wrote,

This class......is really helping me to relate what I've learned to my professional environment. In times past, I would never have attempted to even turn on a computer at work. I've always relegated myself to "working" at home where I could be under the watchful eye of my husband who is always quick to lend a hand with helping me understand and maneuver the computer.

As I am acquiring more knowledge of the computer, I am excited about it. (PB, 10/22/99)

At about the same time, another student wrote, "I have become more confident using the Internet, finding different links, getting focused on what information I am looking for." (CR, 10/23/99). Patterns that reflect frustrations and successes with using the tools of technology, developing communicative competence in an on-line environment, and building interpersonal relationships among students and faculty were highlighted.

Using Threaded Discussions As A Discourse Support

Gregory Gray
Irvine High School, Irvine, CA, USA
ggray@iusd.k12.ca.us

Abstract: Students construct meaning from text through conversation and social interaction. The aim of this research was to examine how the use of an online, threaded discussion, as a discourse support, can facilitate deeper levels of student understanding. The basic assumption being tested is that using discourse supports, applying various discussion strategies like reciprocal teaching, creates an underpinning to do intellectual work and that these supports can be employed in an online discussion environment. Four online discussions were conducted over a period of two months, two in my Advanced Placement American Government classes, and two in my college-prep American Government classes. In an online discussion, the students and the teacher have a visual record of the conversation and the quantitative and qualitative aspects of the conversations. The online discussion environment allowed more students to participate in a class discussion and increased the amount of their participation.

Introduction

Students constructing meaning from text through conversation and social interaction, teachers creating scaffolds to support those activities—these are ideas that I have only recently begun to consciously apply to my teaching strategies. Intuitively and through my model for teaching, the Socratic method, I know I have been basically doing the good things for my students. However, I realize that I have missed the theoretical underpinnings that might allow me do more or be more consistent in what I do. Equipped with a better theoretical understanding, I am energized by the prospect of creating a stronger environment for my students in both classroom work and the use of the Internet as supports for learning.

My experience as a member of the CHSSP-TRIP project, in early February 2001, provided the inspiration to research the use of online discussions as a way to support deeper understanding of course content. It motivated me to investigate the literature about constructivist ideas and learn about the use of discourse strategies like reciprocal teaching.

Many teachers have "ah ha" experiences in their classrooms without a lot of background in the learning theory to explain the results. They have difficulty repeating the same outcome in other elements of their teacher strategies; successful activities become hit and miss. However, if more teachers had access to examples of teacher research, they could use these as templates for their own research. Far more beneficial than obtaining sample lesson plans, teacher research models provides teachers with ways to apply sound learning theory while transforming their classrooms into learning laboratories. This is an exciting way to teach.

Research Question

How can the use of an online, threaded discussion, as a discourse support, facilitate deeper levels of student understanding?

Assumptions

1. Discussion engages students in more thinking than listening to lectures or just responding to teacher questions.
   a. The discussion experience contributes to deeper understanding and retention of concepts. Studies into the effects of reciprocal teaching strategies confirm the relationship between discussion and understanding (ncrel.org).

2. The use of discourse supports, like reciprocal teaching, create an underpinning to do intellectual work in ways that provide assistance in deeper levels of thinking and understanding. As Professor Robert Bain has stated, "Until internalization occurs, all performance must be assisted" (Bain, TRIP).
   a. The reciprocal teaching strategies, as I used them to support content comprehension were presented and explained to the students in the following order: prediction, clarifying, summarizing, and questioning.

3. The use of a internet discussion board creates the opportunity to extend a discussion outside the class time, allowing for more reflective responses and create a record of the discussion that can be referred to at a later time.

The Research Plan and Observations During the Process

Phase One - Instruction in the reciprocal teaching strategies

First, I modeled the four parts of reciprocal teaching strategies for them: prediction, clarifying, summarizing, and questioning. Second, we used the reciprocal teaching steps to read another short selection of text together. Finally, after organizing into groups, I assigned the class to do another short part of the text applying the strategies.
Phase Two - Checking for understanding of the short readings and feedback on their first use of these strategies

The initial reaction from all six of my classes was positive; students recognized that support from the group aided their individual understanding and extended their thinking to other government related topics. These are all seniors. Not all of them are particularly willing to volunteer, to the whole class, that they just learned something helpful. Ironically, the shy or “too cool” groups of students will later find their voice in the online discussions.

Phase Three - Integrating reciprocal teaching strategies into the daily life of the class and then practiced in online discussions

Before I could give them an assignment to use the discussion strategies online, I wanted to be sure my students were comfortable with the reciprocal teaching process. Based on my observations of their notes, group conversations, and the follow-up whole-class discussion, more of the students had a better understanding of the pertinent concepts than if they had read the article by themselves before discussing it in class.

At the conclusion of the two online discussions, all of the classes, approximately 170 students, completed an evaluation of their two online experiences.

Findings

Despite having used a reciprocal teaching strategy to facilitate an online discussion of text materials only once with the American Government classes, the test scores in two of three classes slightly exceeded the test scores, on the same exam, of the class the first semester. There are many variables that can account for the differences, however, the online experiences of my classes demonstrated, to me, the usefulness of online discussions. In an online discussion, the students and the teacher have a visual record of the conversations, both in the quantity of talk and quality of the conversations. While the teacher can give students “robust” comprehension strategies for face-to-face talk, the teacher does not usually require a transcript of the conversations. The online record creates links between assessment and student accountability. The students also noticed the value of both the reciprocal teaching strategies and the online discussion. One of the student comments was:

“At first, I didn’t understand how to predict, clarify, or summarize, the documents correctly. Yet, with practice, I was better able to understand the document. Now that I know how to read and study compositions, I have a better understanding of homework and what I read everyday. After reading and discussing articles online each night, I was able to come to class and discuss and share with my table what I took to be the meaning of the article. Table discussions allow people to share extra information with others giving a deeper insight into the significance of writings.”

Concluding Thoughts about Teacher Research

One important question is how to bring in the scaffolding tools to “do” political science as students cover course content. This is an area requiring more research.

Another question, which I continue to explore, is whether or not the online conversation about a reading can improve a subsequent, whole class discussion? Can the students’ understanding of the reading enable the teacher to add additional things for the students to think about? There might be issues and ideas that the students would not otherwise been able to see or reflect on without a good understanding of what they had read. This is particularly important with readings that are more difficult than the basic textbook.

This project has made an impact on my teaching and creates important implications for the teaching strategies of other social science teachers. If discourse supports are effective in increasing student understanding of content, teachers not using discourse supports in their strategies, need to alter what they are doing with students. If online use of discourse supports can extend those effective strategies even further, teachers need to rethink their use of the Internet.

Incorporating Concept Maps in a Slide Presentation Tool for the Classroom Environment

Kreshna Gopal, Karthik Morapakkam
Department of Computer Science
Texas A&M University
United States
kgopal@cs.tamu.edu

Abstract: We present a slide presentation software that incorporates a concept map, which explicitly shows how the various slides (and other multimedia components) presented are related to each other. Furthermore, presentations are conceived as hypermedia systems, where the presenter can navigate among slides (and the concept map) instead of the typical linear ordering of slides. This approach will alleviate the load on the audience to memorize, recognize and process perceived information. This tool can be extremely useful to enhance understanding of presented material, which is particularly valuable in the classroom environment.

Introduction

Slide presentation software systems are very widely used teaching aids. Tools like PowerPoint have contributed enormously by making the preparation of slides efficient and convenient, and by providing numerous features that enable high quality display of slides. Nonetheless, they offer limited facilities to automatically organize the slides in a logically coherent manner. These tools typically provide a linear ordering of the slides, and the presenter usually goes forward from one slide to the next, and occasionally goes back to previous slides. This approach has its limitations, especially when the subject matter presented is complex. It is a very common experience to feel “lost” while attending a presentation because the information currently perceived (visually or orally) cannot be placed in its appropriate context. Furthermore, a complete grasp of the information being presented often necessitates considerable memorization and processing of material contained in previous slides. But the Model Human Processor (Card et al. 1986) describes the limits of the human mind in perception, memorization, processing, recognition, discrimination, etc.

Also, a linear ordering of slides often encourages linear thought (Zuhn 1995) i.e. following a sequential association of ideas, linking each concept with a single pre-requisite concept and the next logical concept, instead of the more instructive global thought (i.e. choosing from divergent paths of multiple linkages of concepts to reach a conclusion).

Typically the individual slides in a presentation are logically connected to each other, and the relation among slides can be represented by a network. This can be viewed a small-scale hypermedia system. The objective in this research project is to design, develop and evaluate a slide presentation tool that makes the relation of individual slides to the overall network visible throughout a presentation. That is, each slide is placed in a wider context. This will make understanding easier for the audience as well as enhance the expressive capability of the presenter.

Related Work

Computer-Human Interaction research can enormously contribute to the effective dissemination of knowledge in the classroom environment, especially when the design of hardware and software systems is
sensitive to human and psychological factors, such as capabilities and preferences of users. In (1995), Zuhn describes the use of concept maps in a hypermedia system to help teachers organize and deliver teaching material. The system encourages global thinking about concepts and skills to be learned by students. Franklin et al. (2000) show how PowerPoint can be enhanced with a speech-based interface in the context of the Intelligent Classroom Project. The use of multiple input modes (particularly visual ones) to eliminate reliance on a single constraining input mode in a classroom environment is described in (Flachsbart et al. 2000). Visualization of information, particularly in the context of hypermedia systems, is a related research area. Conventional interactive systems provide inadequate views of the information space being explored and hide most of the information, especially about the organization of the information. Many researchers have suggested graphical overviews for the users (Nielsen 1990, Zizi 1996). For example, Zizi (1996) describes topic and document maps, which provide an abstract global overview of documents and their contents. Other research on information visualization includes the Visualizer Project (Card et al. 1991), Tree Maps (Shneiderman 1992), Starfield Displays (Ahlberg et al. 1994).

Design and Implementation

The system we present consists of mainly the following: (1) a graphical representation of the network of slides, and (2) individual slides which essentially contain the material to be presented with some added information, such as hyperlinks to other slides. We use a concept map to represent the network. The nodes in the network can be slides or documents (document map) or topics (topic map). The links are logical relations among nodes. These links can be represented in various ways (such as directed lines) to depict different types of relations among slides or topics. We also group nodes into concept regions which associate logically related slides based on proximity on a concept map. We can use scrolling facilities when there are many slides, and a hierarchy of maps when the subject matter can be more naturally presented at various levels of abstraction, thereby avoiding cluttering one map with too many details. As the presentation progresses, the nodes on the concept map are updated (by changing their color, for instance) to show that they have already been presented. The concept map also contains hyperlinks to connect to individual slides.

The individual slides also have hyperlinks to the concept map and other directly related slides. Furthermore, a smaller version of the concept map (without any text) is displayed on individual slides. This scaled-down concept map is made up-to-date i.e. it reflects where we have reached in the presentation and how it is related to the slide currently being displayed. The presenter has the flexibility of moving directly from one slide to the next or via the concept map. It should be pointed out that the design of the system should be simple and intuitive, such that its cognitive load does not outweigh the gains in enhancing understanding. We now describe in detail the precise design choices we made for a prototype of the system that was developed.

Design of the Concept Map

Fig. 1 is a concept map of a presentation on this paper [1]. The concept map is based on a combination of the document map and topic map approaches. That is, each node in the concept map can be a slide or a topic. For instance, “Related Work” is a topic, whereas “The Organizer Project” is a slide. Nonetheless, these two types of nodes are not graphically differentiated, so as to avoid confusing the audience with too much information. The title of the presentation is also displayed at the top, which is a useful reminder of what the talk is about. The links are represented by lines of various colors and thicknesses to show various types of relations. In Fig. 1, only two types of links are shown: (1) black, uni-directional lines for parent-child relationship in a tree structure, and (2) a brown, bidirectional line to connect two slides at different parts of the tree. Other types of links can also be used, but they should be clear and intuitive or based on standard diagrammatical notations. Otherwise they should be explained to the audience.

[1] Although colors are not shown in Figures 1-4, the use of colors is essential in this system.
Concept regions group a few logically related slides/topics together and show them in a blue area (Fig. 1). A concept region is shown on single-clicking anywhere in the region (except on the boxes for nodes). Only one concept region is shown at a time. If there are too many slides to fit one screen, then we can have a multi-level concept map, where a topic node at a higher level map opens up another map. This enables display of information at different levels of abstraction. Another option is making the concept map large, which can be viewed through a scrolling facility. At the beginning of a presentation, all nodes are shown in green on the concept map, to indicate that the corresponding slides have not been completed yet. The presenter can open an individual slide by single-clicking on its box. If a topic box is clicked, then it connects to its leftmost, nearest descendant which is a slide. If no such slide exists, then nothing happens on the mouse click. When a slide is opened, then it is said to be active. On returning to the concept map after showing an active slide, the latter becomes completed. Once a node is active, it remains active as long as at least one of its descendants is active or non-completed. If all its descendants are completed, then the node becomes completed. Active slides are indicated in a yellowish color and completed ones in deep pink (Fig. 2).

If the text in a node box is not adequate to convey what it contains, then we have a longer narration on a mouse-over action on the box (Fig. 3). Clicking on the narration will remove the narration. The relation between particular pairs of nodes can be emphasized by a mouse-over action on the corresponding links, whereby the related nodes are highlighted (Fig. 3). In fact, a link can be further emphasized by opening a slide to illustrate the relation. We can also connect a node directly to a graphic, audio or video component. In our example presentation, we include an audio component and indicate it by an appropriate icon on the concept map.

Design of Individual Slides

Individual slides are made of four frames (Fig. 4). One central frame contains the material being presented. The three frames on the right respectively contain: (1) a smaller version of an up-to-date concept map to reflect the current status of the presentation; this map does not have any text, but shows the concept region which contains the current slide; (2) named hyperlinks to all slides connected to the current slide; as a convention, we opted for the topmost hyperlink to be the parent node (if any); (3) a hyperlink to the concept map (or maps at various hierarchical levels). The presenter can always choose to show only the information being presented (i.e. omit the last three frames) in situations where more space is required on the screen, or additional information like hyperlinks are redundant.

The slides have a default ordering. The presenter can show the next slide through one of the typical PowerPoint-like actions: single-click, PageDown or Return. Besides these options, the presenter can choose to go to any slide by doing one of the following: (1) click on a named hyperlink, (2) click on the appropriate box on the smaller version of the concept map, or (3) go via the concept map. The presenter should choose the option which will make the presentation clearer and the flow smooth and intuitive.

Implementation

The prototype was implemented in PowerPoint, using macros and modifying the Visual Basic code generated. In the current prototype, many of the functionalities have been hard-coded to suit a particular presentation. We can envision a more generic tool, where most of the features are automated and the user has the flexibility to customize the presentation by, for instance, choosing color schemes, disabling some features, choosing templates for organization of nodes on the concept map, automating the creation and maintenance of maps and slides, etc.

Extensions

There are many ways in which this prototype can be extended, and individual features can be variously implemented. Some examples of new features and variations of existing ones have already been discussed. A few more suggestions follow:
• Place anchors within the presented text in individual slides;
• Flexibility of organizing the contents (and sizes) of frames on individual slides;
• Explicitly distinguish among nodes, which can be topics, slides or other entities like audio, graphic or video objects; suitable graphic and auditory icons can also be used;
• Differentiating between the user actions (like mouse clicks) that the presenter wants the audience to see and those which should be hidden, and using short-cut keys for the latter;
• Different ways of showing the current status of the presentation. For instance, a node can be shown as completed as soon as any of its descendants is completed;

A good design of the system would have to be based on factors like feedback from target users, the particularities of the teaching environment (type of learning institution, subject matter, etc.), familiarity of the audience with the features, etc. One approach is to provide a wide range of features, options and templates, and let the presenter customize the system.

Evaluation

Our prototype was used for actual formal presentations in graduate classes in the Department of Computer Science at Texas A&M University. The system was evaluated through a questionnaire, which essentially queried students about the effectiveness of individual features added to PowerPoint to help understanding the presented material. More evaluation was performed informally with students and faculty of the department. The response obtained was largely positive. Over 85% of the people queried felt that the use of concept maps has a potential to facilitate learning during a presentation. Around 39% of the students who attended the formal presentations found our prototype useful. 10% felt that the system made it more confusing. The remaining 20% saw no significant benefit of our extensions to PowerPoint. We obtained many suggestions during the evaluation phase, some of which were subsequently incorporated in our design. But there were some criticisms as well; the most common ones are summarized below:

• Invoking the concept map can be obtrusive to the general flow of the presentation;
• The audience can be confused by the extra information provided; familiarity with the features is necessary;
• The smaller version of the concept map and the named hyperlinks take up too much space on individual slides;
• The presenter should fully master the tool; it is very easy to perform an incorrect action (such as clicking at the wrong spot), which can send the presentation in an unintended direction;
• The presenter may be confused when faced with too many optional actions. (This problem can be partly solved by a subtle indication of one preferred action at each stage of the presentation);
• The current status of the presentation (indicated by non-completed, completed and active nodes, using different colors) is not always obvious;

It should be noted that the proposed system focuses on the audience as the “user”. As far as the presenter is concerned, it is clear that he/she has to spend more effort in the preparation of a presentation, in mastering the various features and in organizing the presentation to ensure a smooth flow and logical coherence.

The benefits of the system, as reported to us during the evaluation, are summarized in the following:

• The ability to constantly perceive the “big picture” rather than merely focus on individual slides;
• More awareness of what the presenter is really thinking about;
• Induces the presenter to organize his material more logically;
• Questions can be answered more effectively by conveniently accessing relevant slides;
Decisions about which slides to show and which ones to pass over during a presentation can be made on-the-fly in a convenient and logical way - for instance, parts of the tree or hierarchy of nodes can be left out from the presentation, without the inconvenience of opening slides, examining them and finally deciding to skip them;

- The possibility of catching up with the talk even if you come in late or doze off for a while!

Conclusion and Future Work

We hypothesize that the slide presentation tool described in this paper has considerable potential to facilitate learning in the classroom, especially since slide presentation systems are so widely used. The key advantages of the system we propose are: (1) The ability to graphically perceive the inter-relationships among various fragments of information, and (2) the possibility of smoothly and logically navigating through the network of ideas, topics and documents.

Myriad variations and extensions of the design we have presented can be thought of. The tool will need to be customized to suit the target audience: classrooms with different types of students, and other audiences like seminars, conferences, marketing, etc. In fact, we advocate a high degree of automation and customization, so as to reduce the effort required to prepare a presentation, and to efficiently and effectively tailor the tool for different situations. As future work, we envisage the development of a fully generic, customizable prototype, and its evaluation by objectively assessing how different features (or sets of features) impact understanding (as well as ease of presentation) in various environments.

Incorporating Concept Maps in a Slide Presentation Tool for the Classroom Environment

Summary of benefits

- “Where are we?”
- Reduce “cognitive load”
- Ease understanding and presentation
- Navigation, global thought and abstraction
- Encourages logical organization
- Answers to queries
- Managing many slides

Abstract: This paper describes an innovative study that collected data through personal interviews from one-hundred members of a faculty of education to investigate the barriers and enablers to using technology in communication, teaching and research. The findings and recommendations are of value to faculty who are interested in learning and using technology and to those responsible for implementing technology and its infrastructure.

Introduction

Through research and development, a plethora of technologies and applications are available for faculty to use in their communications, in their teaching and in their research. Researchers, such as Chizmar and Williams (2001), support the need for studies to investigate technologies, services and products that faculty members want and can successfully use. Chizmar and Williams compared their assertions with the results of a faculty survey to determine faculty needs. With a range of interests and abilities from early adopters to wary adopters, this study was implemented to investigate the enablers to faculty members' use of technology.

The Study

The research study was conducted to investigate the faculty member's use of technology. A convenience sample was used. Each participant was personally interviewed by one of three experienced graduate student interviewers. Of the 120 invited for interviews, 100 participated. The interview followed a guided question approach with an open-ended question to capture any input from the participants that the participants deemed necessary to include. The data was then carefully read and sorted and entered into an electronic database for sorting, resorting, queries and classifications. The findings from the study were condensed and presented to the faculty at an open invitation meeting.

Findings

Several themes emerged from the participants' comments in the study including barriers and enablers to implementing technology in their communication, in their teaching and in their research. All of the participants in the study indicate that they use technology to communicate, and most participants are interested in learning more about technology and how it can be incorporated into their communication, teaching and research. Two barriers to incorporating technology that emerge from the study are a lack of time and an increasing lack of contact with colleagues.

Participants comment that their most complex barrier is their lack of time and that evolving technologies are demanding of their time to continuously learn. Participants suggest it is not just a barrier to wary adapters, but it is also a barrier to those who are adept at using technologies. Participants comment that learning new and updated technologies is time consuming, and that self-teaching or troubleshooting is often the least effective use of their time.
Recognizing that technology drives learning, and their learning will never end, participants look for a supportive technology infrastructure, templates and technical services, and access to ongoing help to enable them to use their time more efficiently to learn and use technologies.

Participants comment that technology allows them to work from home or elsewhere; and to communicate with students, colleagues and administration locally, or with colleagues with similar interests globally, all without leaving their desks. Participants also comment that as they gain confidence in using existing technologies, they become less dependent on their colleagues for help. Although being able to work off campus, and communicate without leaving their workstations increases their productivity, it limits opportunities to personally communicate with faculty of education colleagues. Participants recognize that limited access to colleagues within the faculty of education can be a barrier to discussions on the impact of technology on education and learning, and to the sharing of new technologies and best application practices. To overcome this barrier, participants suggest faculty of education colleagues need to meet to enable discussions. Participants look for opportunities for faculty of education members to meet to discuss technology issues such as ethics, intellectual property, copyright, permanence of electronic data, and impact on education and learning as a broad issue and from a perspective from their disciplines. Participants also look for opportunities to learn about new technologies and best practices from early adapters of technology through casual conversations or from demonstrations in order to determine the relevance of the technology to their work. Participants ask early adapters not to make any assumptions—colleagues are relying on early adapters to communicate with them, to show new and emerging technologies and to make suggestions how technology could apply.

As technology drives learning, learning never ends. To this end, participants suggest enablers such as a strong infrastructure that supports access and technical support, and an interconnected support system to provide help at the right time for the right needs. Participants also suggest open communication with colleagues to discuss issues relevant to technology in education, and best practices. Specific findings and recommendations from this study are of value to the users of the applications and to those that are responsible for implementing the technologies and infrastructure.

Abstract: In this paper we present the main results of a study concerning students' e-learning needs at a Belgian university (VUB). Our analysis focuses on the type of academic education they prefer, which e-learning facilities they expect and how they perceive the consequences of internet based education. The data reveal that students want a blended educational system, with considerable e-learning aspects but no genuine distance education. They show a multitude of negative and positive attitudes toward the impact of e-learning.

Introduction, objectives and methodology

In October 2000, the staff of the Vrije Universiteit Brussel, a mid-sized Dutch speaking university in Belgium, accepted the new concept of 'competence based learning in flexible education'. By 2005 university policymakers expect a series of powerful learning and teaching environments, where information and communication technologies (ICT) play a significant role. Initiatives have been planned which will be characterized by (Derks, 2000): (1) an extension of the ICT infrastructure (e.g. wireless campus) and system administration, (2) more and better ICT support for educators, (3) an integral ICT approach and (4) bottom-up and top-down methods. In order to fulfill the various educational functions, i.e. 'facilities for stimulating specific student learning activities', e-learning modes are to be implemented. According to Webb (1997) an Internet based learning environment consists of different major players: the teacher, the learner, the technical support officer and the central administration. To be successful when implementing any educational innovation one has to keep in mind the role of the student, otherwise the university risks to make heavy but useless capital investment. Consequently, it is crucial to conduct exploratory research, because there is a strong need 'to consider the characteristics of our target audience when designing and exploiting educational provision' (Valcke, 2000).

In this study we attempt to explore the future prospects of e-learning at our university. We investigated three research domains: (1) which kind of academic education do students prefer - traditional, blended or pure online?, (2) which aspects of e-learning are most wanted? and (3) how do students perceive the outcomes of e-learning? Data were collected through an anonymous questionnaire administered to 470 undergraduate and graduate students from different education levels and disciplines (representative multiple stratified sample, N= 9451).

Results

University Type
The majority of learners (88.6%) of learners have positive associations with a combination of a traditional and a virtual study environments. Only 3 (exclusively male) students think pure e-learning is convenient, while 11% want to stick to the traditional approach.
E-learning facilities

Despite these rather conservative attitudes toward e-learning, students do want a lot of practical and pedagogic facilities to be online. By means of the data modes we defined what students most prefer (table 1). Practical study organisation, access to information and communication are wanted online but not elements like distance courses, chat sessions or interactive classes. Surprisingly, students do not favour a compulsory computer and internet course.

Table 1: Students' preferences for specific e-learning facilities

Perceived outcomes of e-learning

Using a 5-point Likert-type scale ranging from strongly disagree to strongly agree, respondents were asked to provide their opinions on a variety of issues related to the impact of e-learning. The majority of students believe that e-learning will bring some educational benefits like more attractive education and better preparation for the job market. However, a significant proportion of students are undecided about the potential of e-learning for increasing the quality of the learning experiences. Almost six out of ten (57%) do not know if more enrollments can be expected, whereas the remaining 43% are almost equally distributed over the disagree and agree categories. The benefit of lowered inhibitions (where education is more accessible) is recognised by 46% of the respondents. More than 50% of the sample fear encroachment on social contacts and life on campus. On the other hand students do not think it will threaten their privacy. Students anticipate difficulties with self discipline and pace of study. They express more or less neutral feelings toward control and security issues. Opinion is divided over whether e-learning is more cost effective than other forms of learning.

Conclusions

Students at the Vrije Universiteit Brussel reject e-learning as a substitute for other forms of training. They strongly opt for a blended model of online and face-to-face education. E-learning is thought to be convenient, allowing to use online course material, organize and communicate easily about their studies in a flexible way. Our findings contradict the opinion of the educators adopting a booster opinion towards ICT in education.

Abstract: The Discetech project, which has started in 1996 in Northern Italy, aims at experimenting the introduction of new technologies within the teaching-learning activities of high school classrooms. Since 1998, a similar project, Bimbotech, has been developed for initial classes (from 4 to 10 years old children). Several hundreds experiences involving several thousands pupils have been carried on by the teachers who have been previously instructed and assisted by the project’s staff. This paper briefly introduces a case study, one of the most interesting Bimbotech experiments analyzing the organization, the phases, the results and the learned lessons. The final section wants to suggest a few useful remarks upon mutual connection between multimedia and knowledge.

1. An overview of the project

DISCETECH and BIMBOTECH are twin-projects, which try to experiment new technologies to teach and learn in the Italian school system. Discetech started in the city of Como\(^1\) in 1996, while Bimbotech in 1998, under the initiative of Politecnico di Milano\(^2\); in 1997 it also branched out in Lecce\(^3\), for the initiative of the Faculty of Engineering of the local University. Finally last year a new branch was opened in Milan.

The Discetech project as target has high school teachers and students while the Bimbotech one aims at children from 4 to 10 years of age (this is equivalent in Italy to “scuola materna” and “scuola elementare”).

First of all, we attempt to support teachers to achieve the basic ICT knowledge necessary to their teaching activities using computers. In a second time, on the other hand, teachers are asked to plan and realize a didactical experience in the classroom in order to:

- Try to employ multimedia technologies within the class curriculum to find out their useful potential;

---

\(^1\) Como is a town near Milan, where another headquarters of Politecnico has been placed.

\(^2\) The largest technical University in Italy, with Faculties of Engineering and Architecture.

\(^3\) Lecce is a town in the south of Italy.
Evaluate the efficiency of the above goals regarding:

- Content acquisition
- Knowledge building process (e.g. focusing on and selecting information);
- Behavior skills acquisition (e.g. co-operative skill and teacher-student communication).

Our vision aims at improving the teacher’s background and skills with the purpose to experiment new didactical solutions with students where new technologies must be involved and projects carried on collecting data all the school-year long. These attitude answers the purpose to acquire expertise mainly in experimenting with computer and interacting with multimedia instruments rather than discussing what should be done and so stopping just on theory.

Besides, there’s no intention to judge the relationship between teachers and pupils or to give advice about the pedagogical approach that teachers choose to make use of: they have total autonomy on selecting the one they prefer and wish.

The project would require a three years commitment:

- the first year (basic level) looks after the off-line and on-line multimedia employment;
- the second one (advanced level) focuses on planning and carrying out a simple hypermedia product (off-line, e.g. a power-point presentation, as well as on-line e.g. a small HTML hypertext);
- the third and last one (experimental level) encourages teachers to realize (with Discetech staff support) a complex and complete multimedia project.

The first two years are organized in three phases:

- formation (from October to January): teachers acquire the ICT knowledge necessary to the experience that Discetech suggest them to realize in the classroom;
- modeling (February): teachers are guided by the staff to think about a proper personal project;
- working within the class (from March to April): each plan is developed during the school time.

Overall 600 teachers joined the Discetech program (some of them for more than 1 year) and more than 300 educational projects have been carried out, involving nearly 9000 students up till now.

In the next section we will present one of the best experiences, according to the originality and the quality of results, made during last year (2000/2001) in Como.

2. A Case Study: The Pinocchio’s tale

This experience has been carried on by one of the most active group of teachers taking part to the Bimbotech program. The classes involved were two, both consisting of thirty 7-8 years old children.

| 7 years old children | 30 |
| 8 years old children | 30 |

4 The school is Scuola Elementare di via Giussani – circolo Como 4, via Giussani - Como. The teachers involved are Raffaella Ciceri and Francesca Rossi.
The overall aim of the experience can be summarized as it follows:

a) Get children used to the PC in the day by day class activities, promoting self-interaction with computer.
b) In particular, knowing and using the Microsoft program called Power Point as a tool to realize a slide each of the children as a part of a global classroom work.
c) Employing the new technologies to unify all the different experiences of the knowledge building process including both the traditional teaching method (like frontal lesson) and new attempts concerning theatrical activities, drawing, creative writing.

The project took up several subsequent months trying to make the Pinocchio’s tale the topic of the entire school year.
The teachers started with the reading of the tale, followed by the comprehension of the text. In a second time they made the children split it up in several sequences, one for each of them so that every child has been able to make a little abstract and a drawing in color, interpreting the characters in theatrical laboratories and thinking over the whole tale plot, interacting successively each other in the classroom. After that, the last step of the experience concerned the employment of computers: children are put in the position to scanner their drawing and to realize a Power Point slide. In this phase teachers just guided and supported them on demand to do themselves every step, letting them using entirely the PC.

The Power Point presentation contains:

- **The complete tale** developed slide by slide in order of time, each one made by a singular pupil, which includes the insert of a colored background, some buttons, a text, a scanned drawing and an animation (see the picture below as example – figure 1–).

![Figure 1: The screenshot of an explicative slide.](image-url)
• The cast of Pinocchio's tale developed in some slides, one for each character, realized by children who thought about the most relevant qualities that marked them out, as you can see in the next picture, illustrating the cat and the fox, two bad characters who want to lead Pinocchio astray. According to the hypertext structure every slide has a special button that allows to turn back to the home page.

The cat is blind while the fox is limping. They are two scamps and that's why they try to cheat Pinocchio: they want him to plant his money in the miracles field because the morning after he could find a gold tree.

Figure 2: The cat and the fox.

• The theatrical laboratories: according to the school guidelines, which in Italy are fixed by P.O.F.5 since 1999 with the beginning of the self-governing school, the whole work program during the school year has been based on the novel of Pinocchio. That's why teachers chose to stage it involving several classes and let the children socialize from a classroom to another. The hypermedia is a precious support to relate this experience as you can see in the following picture.

We imagined to live in a beautiful and magic town. We liked everything about this experience especially the ballet.

Figure 3: The description of the theatrical lab with photo.

5 P.O.F. is the Plan of the Formative Offer, which defines the cultural and planning school identity and helps to explain and share the pedagogical and didactical directions. This plan allows to fix a specific goal trying out a new strategic lineup to get to it.
- **Different conclusions**: as a creative writing exercise, teachers asked children to invent some gripping imaginary ends and put them in a slide in accordance with each one wish (see the picture showing the opening slide to the different courses).

![Different conclusions](image)

**Figure 4**: The screenshot where you're supposed to explore alternative conclusions.

### 3. Conclusion

The importance of this experience consists on the attempt to combine different activities, which culminate in a multimedia product: its creation allowed a new manner for children to relate each other mutually. Furthermore it helps to renew learning and teaching contents: indeed, *Pinocchio’s* tale has been approached in a different way and this permits to create a new manner of knowing by the development of a radically fresh work. The fact that pupils have found out several different conclusions to the story (see previous picture – figure 4 –) is exemplary for us to explain the innumerable creative powers of a project like this one.

Discetech highlights every intelligence style: in this particular perspective technologies and especially multimedia are very useful to improve all learning and teaching process structures, exploiting a richer interaction across the activities. They keep concentration up as well, feeding a reticular knowledge based on the association’s reasoning and powering every human talent up contributing to make the classroom’s relationship stronger and more complete than usual since computers naturally encourage cooperation, as Maragliano and Moretti say⁶.

We think that an experience like the one we reported could be easily and successfully exported in a lot of other primary schools. That’s why we are strongly interested to spread out this project offering the possibility to share this work and the useful information about it and to approach other works too by Internet.

---

This experience is a meaningful example about the role that multimedia languages could hold inside the school system. The computer-assisted education is important for several reasons: besides the merely technical and application-oriented aspects, new technologies are means for communication’s increase and teaching method’s strengthening widening knowledge searching a new and stronger interconnection between different disciplines. Their employment allow to get over the traditional teaching statute promoting a different way of being together and communicate, which is possible thanks to their ability to actively involve students in learning processes.
WEB-VOCAL: A COMPREHENSIVE CALL-EFL READING DEVELOPMENT PROGRAM FOR ACADEMIC PURPOSES UTILIZING INTERNET RESOURCES

Yutaka TSUTSUMI  
Faculty of Commerce, Kumamoto Gakuen University, Japan  
yutaka@kumagaku.ac.jp

Abstract: Web-VOCAL is a VOcabulary Concordance and Academic Lexis CALL design with integrated web browser functions. Web-VOCAL has concordance and collocation features particularly relevant for study in EFL courses oriented toward the comprehension of factual information: using web-VOCAL a student is able to sort a text for vocabulary types, find word-frequencies and collocations, and use up to four default corpora. Word-families can be displayed throughout a text. Words, phrases and concepts can be searched in dictionaries and through the Internet utilizing site links defined in the program. Internet web pages can be stripped of html tags, converted to text (.txt) files and collocated in various ways. The goal of the program is to enable vocabulary study to be further integrated into English for Academic Purposes (EAP) reading classes, encouraging accelerated comprehension of the target academic language by the student. Current EFL vocabulary research and pedagogical considerations related to the Web-VOCAL project are summarized.

Introduction

The Web-VOCAL program began development two years ago. At that time, research was oriented to program design considerations (Gilbert & Matsuno, 2001). We have now developed a revised, functioning prototype, for the first time incorporating web-resource functions. In this article we will discuss the prototype CALL software implementation, and also examine some of the pedagogical issues relevant to the project. Web-VOCAL is a multimedia “VOcabulary Concordance and Academic Lexis incorporating Web resources.” The program has been designed to provide English for Academic Purposes (EAP) students with options allowing them to discern quickly, from computerized text, words in three parsed hierarchies of vocabulary; to search quickly for definitions and/or translations of terms; to examine collocations from selected corpora; and to acquire new vocabulary through a tripartite General Service List/Academic Word List/Technical Word List approach to vocabulary acquisition.

Using Web-VOCAL, internet web pages and site information can be quickly found, automatically stripped of html/meta-tags and converted to Web-VOCAL-usable text (.txt) files. Online dictionaries, thesauri, encyclopedias and translation dictionaries capable of translating both web pages and text can be accessed from within the pop-up Web-VOCAL browser window (with one mouse-click). Web-VOCAL allows selected parts of reading texts, collocations, and word definitions to be combined, organized and saved. Internet bookmarking features allow site bookmarks to be saved/exported/imported on floppy or hard disk by the student.

The overall purpose of Web-VOCAL is to create a single comprehensive CALL environment in which necessary reading-comprehension study tools are easily available to students as they read the study-text in the “source reading text” (SRT) frame of the program (Fig. 2). Novel CALL-based tools have been created in order to potentially accelerate a student’s reading comprehension by focusing on methods of accessing unfamiliar vocabulary, in both contextual (collocational and encyclopedic) formats and non-contextual (dictionary/translation dictionary) formats.

The SRT module is composed of three frames: the “SRT” frame (largest frame), the “Word List” frame (left side), and the “Collocations” frame (lower frame). “Site” and browser buttons displayed on the main window activate Web browser functions.

Accessing new vocabulary
It should be noted that vocabulary knowledge and reading comprehension are very closely related (Nation, 1999). In fact, the correlation is high and reliable enough that TOEFL researchers at one point considered whether both vocabulary items and reading items needed to be included in the TOEFL test, "and if not, which of the two could be dispensed with" (Read, 1997). Three vocabulary lists are utilized in our current concordance design. They are: 1) the 2000 highest frequency word families included in West’s (1953) General Service List of English Words (GSL), further sub-divided into two subgroups of 1000 word families; 2) Coxhead’s 1998 Academic Word List (AWL) (Coxhead, 1998), a multi-disciplinary academic word list of 570 word families—note that “academic words” will not include all of the terms denoted by “semi/sub-technical vocabulary” as used in ESP nomenclature, but are approximately equivalent, as discussed in Nation (Nation, 1999); and 3) technical vocabulary, representing words or terms that are largely field-specific. Nation points out that, “The division of the vocabulary of academic texts into three levels of (1) general service or basic vocabulary, (2) sub-technical vocabulary, and (3) technical vocabulary is a commonly made distinction” (Nation, 1999).

We might ask, why select particular, limited vocabulary sets for study, while ignoring the bulk of the English vocabulary? The answer lies in a real-world situation having to do with the number of word families in English, the disparity of vocabulary knowledge between typical undergraduate L1 (source language, mother tongue) and L2 (target language) English users, and the limited time available to educate students in order to achieve academic goals in English, e.g., reading essays and research papers in their academic field, the overwhelming majority of which are in English:

Even many journals of smaller nations’ scientific societies, like those of Slovenia for example, publish also in English. When abstracted more widely these are then accessible to a world audience. For a scientist to publish in a language other than English therefore is increasingly to cut herself off from the worldwide community of scientists who publish in English. The work may then be ignored simply because it is published in a language unknown to the rest of the world (Wood, 1997).

Webster’s Third New International Dictionary contains approximately 114,000 word families, excepting proper names (Goulden, Nation & Read, 1990); a number well beyond the knowledge of most L1 or L2 students. Though past measurements of vocabulary size have been found to be erroneous (Nation, 1999), recent reliable studies (Goulden, Nation & Read, 1990; Zechmeister et al, 1995), indicate that educated native English speakers know about 20,000 word families; the educated undergraduate L2 learner of English may only have 10%-15% of this vocabulary, a comprehension of 2,000-3,000 or so word families. This places them at a great disadvantage, as “to read with a minimal disturbance from unknown vocabulary, [English] language users probably need a vocabulary of 15,000 to 20,000 words” (Nation, 1999).

Researchers have attempted to determine what percent of the vocabulary in a given text needs to be comprehended by an L2 learner of English in order to (a) adequately comprehend the text, (b) comprehend a new vocabulary item by context, and (c) read comfortably/read for pleasure. Research (Liu & Nation, 1999) suggests that at least 95% of the running words in a text need to be known to the learner, in order for unknown vocabulary to be comprehended by context. This 95% figure, which indicates that a reader will encounter, on average, one unknown word for every two lines of (10 words average per line) text, and 20 unknown words on a (400-word average) page, seems as well to be a lowest threshold for successful reading comprehension. Laufer (1988), examining successful readers of an English for Academic Purposes text in the “First Certificate in English” exam, found that scores in the 95% percentile and above had a higher number of successful readers. Readers who scored at 90% (one unknown word per line of text) did not do significantly better or worse than others scoring up to 94%; these scoring-groups did not have many successful readers. A recent study (Liu & Nation, 1999) of reading comprehension, examining adequate vocabulary coverage related to reading for pleasure, found that when 80% of the words of a fiction text (i.e. two unknown words per line) were familiar to readers, none gained adequate comprehension; at 90% to 95% some, but not many, gained comprehension. It was found that only at about 98% coverage (eight unknown words per 400 word page) was “unassisted comprehension” gained. A general conclusion is that:

Knowing academic vocabulary is a high priority for [L2] learners who wish to do academic study in English. After gaining control of the 2,000 high frequency words, learners need to then focus on academic vocabulary. Knowing the 2,000 high frequency words and the Academic Word List will give close to 90% coverage of the running words in most academic texts. When this is supplemented by proper nouns and technical vocabulary, learners will approach the critical 95% coverage threshold needed for reading” (Nation, 1999).
Thus, this area of research has been able to establish that the 95% figure is workable as a threshold for known/unknown vocabulary in EAP study.

Nation’s 2,000 highest frequency words (headwords/word families) are taken from West’s 1953 general service list, which, though aging, is defended as remaining “the best of the available [general service vocabulary] lists” (Nation & Waring, 1997). Coxhead’s AWL is composed of the most frequent word families from a 3,500,000 running word academic corpus containing a balance of the four general fields of science, arts, commerce and law—with each of these fields further divided into seven subject areas. Each word contained in the list has a range that includes all 28 (4 x 7) subject areas (the corpus texts are divided equitably across all subject areas), and a frequency in the complete corpus of at least 100. The third list, the technical/other word list, must be either imported or composed by the teacher: this list may be designed as field-specific, syllabus-specific, or as a multi-disciplinary list, at the teacher’s discretion. A breakdown of coverage by the different kinds of vocabulary in a typical academic corpus is seen in Table 1, below.

<table>
<thead>
<tr>
<th>Type of Vocabulary</th>
<th>% of Coverage</th>

Table 1: Percent word-coverage in the academic corpus (Coxhead, 1998)

In terms of EAP coverage, as a rule of thumb the most frequent 1,000 GSL words cover approximately up to 77%, the second 1,000 cover approximately up to 5%, AWL (semi-technical) vocabulary will account for approximately 8.5% -10%, and technical words (words very closely related to the topic and subject area of the text) typically cover about 5% of the running words of a text. The total percent-coverage then, is 95.5%-97%, which provides the target goal for academic vocabulary acquisition, leading to the unaided comprehension of unknown vocabulary by context, and successful reading comprehension, within a particular academic field. The additional “missing” 5% represents vocabulary of lower frequency than the first 2,000 GSL words, and/or words which are semi-technical but not in the AWL list.

We can note the specificity of the AWL to academic texts. The third group of 1,000 GSL word families (words with a frequency of 2,000 to 3,000) covers only about 4.3% of the AWL corpus. Though there has been little comparative research, one study has shown an AWL coverage of only 1.7% in fiction texts, compared to 10% coverage in academic texts (Nation, 1999). These results indicate a high degree of specificity of academic vocabulary, and suggest that while the typical EFL student will have a goal of comprehending the first 3,000 GSL word families, it is beneficial for the academically-oriented student to focus on semi-technical vocabulary after they have succeeded in comprehending the first 2,000 GSL word families. For the “English for academic purposes” (EAP) student then, the GSL 2,000 highest-frequency words represent core vocabulary, while the AWL words can be considered high-frequency vocabulary.

By focusing on words within the academic word list, students will utilize their study time efficiently, as AWL vocabulary has relevance across academic disciplines. Students entering an academic program can be assessed using a measure such as the Vocabulary Levels Test to determine whether they have a satisfactory comprehension of the first 2,000 GSL words, and to what extent semi-technical/AWL vocabulary is known. As well, AWL vocabulary, studied within the context of academic texts, should provide an efficient approach to TOEFL preparation.

EFL design concept

Emerging technologies are leading to the development of many new opportunities to guide and enhance learning that were unimaginable even a few years ago. — Robbie McClintock (1999)

The idea for the Web-VOCAL program began with classroom observations made over several years with students in several fields (science, economics, social welfare, and liberal arts) who were attempting to read content-oriented English texts assigned both in EFL reading classes and in non-EFL classes taught in Japanese. Typically, students read with a translation dictionary nearby, looked up unknown words and wrote the Japanese
translation above the word in the text, and/or in a notebook, paired with the English term. This process was laborious and time-consuming. In some native-language (L1) course curricula, particularly in science and English-language literature classes, students were assigned readings in difficult content-related English-language texts (e.g. *Walden*, *Silent Spring*, scientific essays, literary review essays). In such cases, students would sometimes be looking up several vocabulary items per line in their attempts to comprehend the texts.

One of the principles defining the purpose of reading in "English for specific purposes" (ESP) study as opposed to general EFL study is the functional shift from 'text as a linguistic object (TALO)' to 'text as a vehicle for information (TAVI)' (Dudley-Evans & St. John, 1998): "The key principles [are] that, for ESP learners, extracting information accurately and quickly is more significant than language details; that understanding the macrostructure comes before language study; and that application of the information in the text is of paramount importance." Web-VOCAL's basic goal is to promote the TAVI process by simplifying, accelerating and enhancing the process by which students extract meaningful information from texts—through aiding comprehension of targeted vocabulary items, presenting collocations and providing web resources. The software has been designed to have "low-impact imposition" in that software function avoids complex user-routines (difficulty of use) or conceptual hurdles (high software learning-curves) that might cause the student to have greater difficulty utilizing the CALL resources than the non-computational resources already at hand.

Upon the above pedagogical foundation, cognitive enhancements to the reading process, including (a) vocabulary acquisition, (b) memorization, (c) organization, and (d) novel research strategies, become possible in the CALL design environment. Corpora/collocation features quickly yield sample usage sentences, which can be easily saved for later study. Hierarchic GSL/AWL/Technical vocabulary parsing helps the student categorize and "rate" a particular vocabulary item for generic relevance. Vocabulary analysis of texts provides a rapid means to roughly access texts for difficulty.

CALL in the classroom also has the potential to change the dynamic between student and teacher:

With digital information technologies, what is pedagogically possible changes. Possible educational attainments are different and greater than they have hitherto been . . . Educators are engaging in the social construction of a new educational system . . . in this case from the potentialities arising through the use of information technology in education (McClintock, 1999).

One of the several benefits of CALL in the classroom is that learners are given “freedom to explore alternative pathways—to find and develop their own style of learning” (Berge & Collins, 1995). Synergy between the user, CALL program, classroom environment, curricula, and teacher cannot be determined without pilot and outcomes studies. Nevertheless, certain scenarios become possible which are unattainable outside of the Web-VOCAL environment. Students are able to input their own texts and use the program to analyze any text-based correspondence (e.g. email, internet); they can share study-files and bookmarks. The program may also be used in independent/distance-learning environments. The program is individually customizable, giving students power and autonomy: for instance, students can build up large, subject/field-tailored vocabulary databases, store, organize, and (yet) easily access them over long periods of time; as well, students can be shown how to create their own micro-corpora (see section 4.1). Web-VOCAL is also effective for the second-language reader engaged in independent study: academic researchers/professors needing to read and/or publish (in English) in international journals can make use of the program.

**Program Description**

Using a browser (e.g. IE-5/6) students download Web-VOCAL from the class homepage (Fig.1). Following simple instructions, the program self-installs, creating two folders (in "C:\Program Files") and a desktop shortcut. All files except corpus files are contained in the “WebVocal” folder. A second folder (“WebVocCorpus”) contains the corpus files. This allows students to export Web-VOCAL to another computer on a single floppy disk, as the program and essay files combined are unlikely to exceed 1.2 megabytes. The main-program view can be seen in Figure 2. After Web-VOCAL installs, students click the desktop shortcut link, the program opens and the student presses the (large orange) “BROWSER” button in the main window (as mentioned on the class homepage). The default browser URL is the class homepage, so the Web-VOCAL browser returns the student to the class homepage where the essays (as .txt file links) are located. Clicking on an essay link automatically downloads the file and places it within the “Source Reading Text” (SRT) frame, where it can be analyzed for word-frequencies and vocabulary sets. Collocations for words/phrases can be found by using one of using four different corpus sets (highlight the word/phrase, right-click the mouse, select “Collocations”). Relevant “micro-
corpora" corpus sets, designed by teacher or student for Web-VOCAL, can be created from a CD-ROM encyclopedia in little time (see section 4.1); individual corpora can be selected through the “Tools” menu. There are two methods for incorporating Web information into the SRT. The Web-VOCAL browser will automatically strip all tags (creating a .txt file) of any HTML page and display the new file in the SRT window (by pressing the “ANALYZE” button in the Web-VOCAL browser). All resulting files can be saved; any .txt file or HTML file can be imported into the program as well.

Vocabulary items found in the reading-text or collocation sentences in the “Collocations” frame (below the SRT frame) can be searched using one of the four “Internet link” buttons found on the upper right-hand side of the main-program window. Experience has shown that often, Japanese students have little idea of the web resources available which may aid them in English comprehension. The four “Internet link” buttons each contain several URLs: “E Site” contains English dictionaries, encyclopedias, thesauri; “J Site” contains similar Japanese resources; “Trans.” Contains English-Japanese/Japanese-English translators (there are translator sites providing real-time, free, side-by-side bilingual translations of English/Japanese web sites). “Search” contains search engine URLs, both Japanese and English. URLs defined by the “Internet link” buttons can be easily changed by the teacher. Voice synthesis is also available, providing text-to-speech ability, aiding in English pronunciation (right-click mouse menu. The “Tools” menu contains a “Web Resources” button; this button links to a teacher-defined set of URLs designed to be subject/course specific links.

When students click on a headword in the “Word List” frame, all words in that word-family will be automatically highlighted throughout the main text. Individual words within a word family can likewise be highlighted in the main text. Often students are unable to save their data on the university’s LAN between classes, and use different computers each day. For this reason, Web-VOCAL is designed to be easily downloaded onto a floppy, and includes a save/delete/export/import feature for internet bookmarks, so students can keep track of their internet research and maintain both a web and an essay database. There are several other features at the student’s disposal. Any text can be sorted to discover high-frequency vocabulary (“GSL button”), academic vocabulary (“AWL button”), and extra vocabulary (“XTRA button”), which contains low-frequency vocabulary absent from any other category. The “TECH button” is designed to provide vocabulary created by the teacher to display low-frequency vocabulary: 1) relevant to the course, 2) the essay(s) under study, 3) an upcoming lecture, 4) scientific terms, 5) proper names, 6) archaic spellings, etc.

Creating Micro-Corpora

Web-VOCAL does not include its own corpora at this time, advocating (and instructing the user on) the construction of micro-corpora. As shown by Tribble (and our own experience) a teacher is able to construct a micro-corpus of some 50,000 words, drawn from a CD-ROM encyclopedia, in about 30-40 minutes:

The non-standard corpus which I am advocating for students with an interest in learning how to write factual texts . . . is the widely available multimedia encyclopedia. I am proposing the use of such a corpus with students who are beginning to learn how to write formal, professionally oriented texts . . . The Encarta Encyclopedia [Deluxe 2002 CD-ROM contains 60,000] separate articles listed in the “search” facility. These contain anywhere between 200 and 5000 words. If we take a pessimistic mean of 1000 words, then the biggest possible “corpus” based on this source of texts could contain [60,000,000] words . . . [One is] able to construct themed, twenty to thirty-thousand word micro-corpora in fifteen to twenty minutes. Although such a corpus sounds insignificantly tiny when compared with the huge corpora which can now be accessed, I would argue that if one wishes to investigate the lexis of a particular content domain (e.g. health) a specialist micro-corpus can more often be useful than a much larger general corpus. (Tribble, 1997) [Encarta Encyclopedia information updated to 2002.]

The corpus files, which may grow large, can be exported on a second floppy disk. With regard to .txt file sizes, the Canterbury Corpus (Powell, 2001) shows that a work of fiction containing 140,000 words yields a .txt file of approximately 750Kb while a non-fiction work of 101,000 words yields a .txt file of 600Kb. A complete Web-VOCAL corpora “set” of four 50,000 word corpuses (containing “general”, “academic”, “journal” and “user” corpora) will thus fit on a 1.2 megabyte floppy disk; if larger corpus sets are needed they can be accommodated on extra floppies.

Discussion
We have found that a fruitful CALL design-approach weds pedagogical considerations to interface metaphors in a co-emergent design process, giving equal weight to educational conceptual structures and application control structures. The psychological space of user-CALL program interaction is a virtual space, which remains largely unexplored in terms of how the design of educational tools should best be implemented. In order to further investigate the potential of the program, Web-VOCAL is being readied for pilot testing later this year.

Teaching mathematics and science: Using global learning for the effective preparation of prospective elementary teachers

Kay Gibson  Mara Alagic  Connie Haack
Department of Curriculum and Instruction, Wichita State University
kay.gibson@wichita.edu  mara.alagic@wichita.edu  connie.haack@wichita.edu

Abstract: Research and experience suggest that structured reflections and metacognitive thinking positively influence prospective teachers' pedagogical content knowledge (PCK), and beliefs and attitudes (dispositions) about mathematics/science learning and teaching. To provide a challenging learning environment for such activities, prospective teachers from different educational cultures will be paired in this global learning project. They will engage in interactive (online) reflective journaling based on experiences that combine content and pedagogy; and design a sequence of activities to teach a mathematics/science concept that will be displayed on joint web pages. The activities will be assessed for evidence of positive growth in PCK and dispositions related to the teaching and learning of mathematics/science. Specifically, the project is guided by the question: How do cross-cultural shared experiences affect the development of specific PCK and influence prospective teachers' dispositions?

There is a basic need to develop greater self-efficacy in elementary education teachers related to mathematics and science learning and teaching. Many of these teachers have negative beliefs, attitudes and anxieties about learning mathematics and science that constitute a significant barrier to teaching these subjects in a meaningful way. Prospective teachers have developed their beliefs over time before they enter the university. To change undesirable/negative dispositions therefore will take time (Hart 2002). Educators in the USA and Australia are recognizing this barrier and making efforts to overcome it (Mulholland & Wallace 2001; Ramey-Gassert & Shroyer 1992; Schoon & Boone 1998; Watters & Ginns 1995).

A number of studies support the belief that reflective teachers positively effect the education experiences of their students both in the development of positive dispositions and pedagogical content knowledge (Abell & Bryan 1997; Clarke 2000; Fennema & Romberg 1999; Francis, Tyson & Wilder 1999; Hart 2002). Abell and Bryan designed their elementary science methods course around "(t)he reflection orientation ... grounded in the belief that learning to teach science, like learning science itself, is a process of re-evaluating and reforming one's existing theories in light of perturbing evidence (p.154)."

At Wichita State University, prospective elementary teachers take an integrated mathematics and science methods class in the first semester of their senior year, just prior to their student teaching semester. Reflective practice is nurtured to ensure a supportive environment that addresses the barrier of teachers' negative beliefs, attitudes and anxieties. Student responses to weekly online reflective questions have focused attention on a number of issues related to teacher dispositions and topics broached during classroom activities. The first result is that, faculty gain insight into the thinking of the students, and the insights guide ongoing efforts for cultivating effective mathematics and science teaching. In addition, students have increased opportunities to form the habit of reflective journaling. Anecdotal evidence suggests that students are particularly motivated to examine their thoughts in relation to those of their classmates. Online synopses of student responses have often raised the level of interest and resulted in further discussions about students' positive growth in pedagogical content knowledge and dispositions.

Reflective thinking is fostered in lesson preparation and teaching assignments. Lesson planning and peer teaching routinely contain a required reflection on the process and product. The course culminates in a five-week field experience with many opportunities and demands for reflection with respect to teaching experiences in the elementary classroom. Often the primary concern expressed in the latter reflections is about classroom management, but it is still felt that the reflective piece is needed that is more directly connected to mathematics and science related pedagogical content knowledge.

For example, Teacher's Inquiry into Children's Knowledge and Learning Evolvement (TICKLE) is an assignment designed to make the connection between content learning and teaching practice more apparent to the students. The TICKLE assignments are given as a springboard to ideas about pedagogical content knowledge. Each student works with a child between the ages of four and twelve and explores the child's thinking about concepts within a broader topic such as volume or light. Before each TICKLE assignment, a collection of activities is introduced to provide the background needed to design activities that they deem developmentally appropriate for the child with whom they are working. After analyzing individual results, students come back to class with new
pedagogical content knowledge. Together they build a deeper understanding of the developmental sequence necessary to teach a given concept. As a result they begin to answer for themselves the question: what is appropriate for the grade level that I’ll be teaching?

Faculty have found that the diversity of learners, even within a single classroom, demands a diversity of teaching approaches. Already the challenges of negative student dispositions have been addressed in a variety of ways. As expected in the presence of student diversity, our multiple strategies have met with mixed success. Some students respond to a given strategy and other students respond to significantly different strategies. However, the common successful thread among the strategies has been an emphasis on reflective thinking about learning and teaching to mathematics and science within the existing learning environment. With this in mind, we are attempting to extend this reflective/metacognitive environment by pairing students at Wichita State University with their counterparts at an Australian university to determine how cross-cultural reflection and communication affects students’ self-efficacy.

Initially, students will engage in guided reflections centered on questions related to their personal beliefs about teaching and learning mathematics and science. To become acquainted with each other’s dispositions, they will co-reflect via email on such questions as: What do you know about reflective practice? Based on past experience, how do you feel about learning science and mathematics? What are your concerns about teaching mathematics/science? What would help you become a better science/mathematics teacher? This ongoing reflective practice will provide a supportive learning environment to encourage the changing of negative dispositions and the development of mathematics and science activities for teaching with understanding (Fennema & Romberg 1999).

For part of the semester, students at both universities will be involved with identical mathematics and science curriculum. Based on that common curriculum, pairs of students, one from each country, will collaboratively develop and publish on the web a collection of activities. In the process of designing these activities, students will be guided to reflect on their individual learning as well as the collaborative, creative process in order to support metacognitive thinking and learning in the development of PCK and positive dispositions. The intent then is to have the students publish their reflections on the web along with their activities. Such sharing will allow both current classmates and future students in these methods classes to observe and learn from other students’ experiences.

A global learning environment designed in this manner will provide reflective opportunities for faculty and students through content-specific dialogue. These cross-cultural shared experiences should positively affect prospective teachers’ development of specific pedagogical content knowledge and bring about positive changes in their evolving dispositions.

School Leaders and Teachers, Strategic Planning, and Technology Integration: A Research Approach to a Five Year Technology Plan

Ian Gibson
Department of Administration, Counseling, Educational and School Psychology
Wichita State University, United States
ian.gibson@wichita.edu

Abstract: How is technology (IT) integrated? When is IT integrated? Where is IT integrated? How much is IT integrated? Too often, little thought is given to determine a school district's response to these questions or to the analysis of current IT usage or future IT needs. The approach to planning for the integration of educational IT into the learning environment described in this paper focuses on the collaborative efforts of school district personnel, and faculty and graduate students from a local university in the mid-western region of the United States.

Introduction

Forward looking school leaders concerned about their ability to effectively lead schools into the IT-based learning environment of the 21st century are aware of certain verities of educational life that should impact school leader behavior. Bracci (1999) suggested one of those truths related to the integration of information IT into learning environments. The questions became not whether IT should be integrated, but; How is IT integrated? When is IT integrated? Where is IT integrated? How much is IT integrated?

Another truth in the world of education suggests that the mere presence of IT has become a measure by which some school districts assessed their effectiveness. Many administrators, parents, and teachers believed that if they had a large number of computers in the classroom, they were "cutting edge" and therefore effective. However, too often, little to no thought was given to determine a district's current IT usage or future IT needs. Jukes (2000) observed, "The key is how you use the technology, not how often" (p. 73). It has been made clear that effective use of IT in the learning environment begins with deliberate and futures-based planning.

The approach to planning for the integration of IT into the learning environment described in this paper focuses on the collaborative partnership efforts of school district personnel, and faculty and graduate students from Wichita State University in the mid-west of the United States. These educators formed a partnership to collaborate on the development of an approach to strategic planning for IT integration that has been effective in revisiting and re-enlivening a school district IT plan that had lost its way.

Research Design

In a recent paper, Gibson (2002) claimed that school leaders must be the focus of new efforts to guarantee the effectiveness of IT integration efforts. While agreeing that significant attention should continue to be paid to the IT development of tomorrow's teachers, he suggested an increasing realization that teachers were not as effective in their IT integration efforts without the support of school leaders capable of motivating, collaborating, and supporting IT integration efforts. The graduate program in Educational Administration at Wichita State University attempted to address these issues through construction of a program of school leader preparation designed to produce visionary leaders for twenty-first century schools. The study reported here emphasizes the collaborative research orientation of this program and the need to use current data on technology usage in planning for IT use. The study was designed to examine the use of IT in the instructional environment of a local school district and make recommendations for updating the district IT plan.

Multiple research methods used to explore the research questions relating to current use of IT, perceptions of IT needs from students', teachers', and administrators', and suggested improvements regarding the integration of IT included focus groups with district students and faculty, interviews with administrators and IT coordinators, and an analysis of district documents. Inductive and constant comparative analysis of these triangulated data resulted in a series of conclusions and recommendations.
designed to assist district staff in revising their district IT plan, and a process that could be used in the future for continued data-based analyses of district IT needs.

Conclusions and Recommendations

The study's conclusions were grouped into seven major themes: current support, parent usage, administrator usage, teacher usage, student usage, perceived needs, and proposed needs. Recommendations related to these findings were:

- Formative evaluations of the IT plan should be conducted yearly and focus on integrating IT into the learning environment emphasizing student-centered activities and targeted staff development.
- The allocation of funds for IT should continue to increase.
- Funds should be allocated to support full-time coordination and assistance throughout the district.
- Resources (personnel, time, financial, equipment, and facilities) should support the plan.
- Access to Internet should be made available for all students and staff.
- Training should be provided for students, parents and teachers to enhance the effective use of IT.
- Staff development should increase awareness of the potential of IT to transform the learning process to focus on student-centered activities.
- Student-free time should be regularly scheduled to assist staff in learning about IT.
- Results-based staff development, designed for IT integration, should be targeted specifically to learner skill levels.
- Support and encouragement should be provided to all staff as they integrate IT into the instructional environment.
- Emphasis should be placed on innovative ways to integrate the Internet into the learning process.
- Specific resources (websites, professional library, examples of lesson plans, network contacts, site visits, expert colleagues) should be developed to assist teachers to integrate IT into learning environments.

Conclusion

As a result of this process, school district personnel identified IT needs crucial to future growth within this district using baseline data comprising a realistic evaluation of existing usage patterns, an understanding of existing attitudes of students, teachers, and administrators towards IT and its connection to the learning process. A clear picture of the gap between what could be currently accomplished with the existing IT infrastructure and skill levels, and what was considered to be realistic future needs of the district resulted.

Further, in the process of participating in this program, graduate students conducting the research gained valuable insight into their responsibilities as IT leaders, at the same time as exploring a process of data gathering, future planning, and realistic program evaluation that will benefit them as school leaders. With data derived from studies like this, and an understanding of the process of data gathering and analysis derived from participation in this program, these school leaders have come to understand the purpose of identifying the IT realities of the district as the first step in the process of district decision-making based on assessing the status of district level IT usage merged with an understanding of future district IT needs.

Most importantly, these students discovered a critical criterion required for IT planning was vision. As Jukes (2000), suggested, integrating IT is far more than just doing computers' or allowing students to spend time online. Effective integration occurs only when IT adds real value to recognized educational needs of individual learners. These graduate students gained experience suggesting that future minded educators must have a vision that integrates IT not just into a school or a school district, but into the learning process.

Developing a Global Forum on School Leadership: Using interactive communications technology to enhance the achievement of learning goals in a school leader preparation program.

Ian Gibson
Department of Administration, Counseling, Educational and School Psychology
Wichita State University, United States
ian.gibson@wichita.edu

Abstract: Challenging tomorrow’s school leaders to develop deep understanding and respect for alternative conceptions and responses to everyday leadership issues is a major undertaking. This paper presents a description of the rationale and development of the Global Forum on School Leadership. Conceived as an extension to existing reflective and dialogic practices of a pre-service leader preparation program in the mid-west of the United States, the forum attempts to incorporate the perspectives of global colleagues on issues related to everyday practices and school leadership conundrums in a mediated, asynchronous, web-based discussion format. This project adds a needed global orientation to leadership preparation in a post September 11th international context.

Project Rationale for the Global Forum on School Leadership

Developing leadership expertise requires foundational knowledge and use of inquiry and reflective practice skills applied in context specific experiences. These experiences provide opportunity for the integration of theory and practice focusing on school improvement. Yet, the contextualizing of leadership experiences in traditional and unvarying cultural contexts often presents its own limitations, particularly during the formative period of leadership philosophies, perspectives, and practices. For that reason, the idea of incorporating a global orientation to leadership preparation, particularly in a post September 11th national and international context, has merit on many fronts.

The Global Forum on School Leadership challenges tomorrow’s school leaders to develop deeper understanding of areas of responsibility and of professional behaviors related to topics of professional concern through involvement in collegial analyses of views and experiences that vary from the norm or the expected. Intellectual and professional challenges to the status quo, to standard and expected culturally derived responses, will result from the global interactions contained within this shared international forum.

Description of the Context of the Project

The Masters in Educational Administration at Wichita State University has been designed to prepare visionary, reflective leaders for Kansas schools. This integrated program prepares future school leaders to be competent in leadership, interpersonal relationships, school law, school finance, school personnel, curriculum management, learning theory, inquiry, human development, school improvement processes, and supervision, and grooms them to become administrators who create and maintain effective schools. This program is a clinically oriented, field-based, applied inquiry program that distinguishes itself from traditional administrator preparation programs through a design that emphasizes the integration and contextualization of the curriculum, incorporation of field-based research studies, a collaborative, team-based approach to teaching and learning, a mediated internship program, and a cohort-based student support structure. Students enrolled in this program participate in mediated on-line discussions as part of the assessment of their performance in the program.

Based upon a theoretical framework derived from problem-based learning (PBL) (Boud & Feletti, 1991; Bridges, 1992), this program functions with the belief that authentic problems of practice, explored in collaborative team settings lead to learner-directed and setting-enhanced learning. The underlying propositions of constructivism (Savery & Duffy, 1995), including the ideas of cognitive dissonance and negotiation of meaning, are core program components. Studies of student thinking during
the initial problem analysis phase of PBL (De Grave, Boshuizen, & Schmidt, 1996) corroborate the belief, clearly in evidence within this program, that exposure to different ideas in a group leads to conceptual change and that group interactions serve to encourage activation and elaboration of existing knowledge and integration of alternative views.

The Global Forum for School Leadership

Pre-service school administrators enrolled in this program will participate in mediated, asynchronous discussions with local and international colleagues to explore issues of professional relevance. Exploration of authentic problems of practice, analyses of philosophical stances on leadership behaviors and orientations, dissection of the rationales governing daily actions and decisions, and challenges to strongly held beliefs, attitudes, and dispositions will constitute the form and the substance of interactions in the Global Forum.

Existing groups of neophyte administrators in training and their professors and mentors will interact on self-selected issues relevant to their profession and to their studies. Topics of discussion would include an analysis of cultural perspectives on any areas of leadership responsibilities such as strategic, organizational, instructional, political, and community leadership.

The technology infrastructure necessary to support this project relies on accessibility to the internet via appropriate computer interfaces. The telecommunications needs of the project require access to Blackboard and to a website via the internet for participants at both ends of the interaction. Threaded discussions, and a web-mediated approach will be supplemented by full text access to a variety of field-based action research reports. A trial website has been established to demonstrate the potential of sharing practitioner-conducted research (http://education.wichita.edu/aces/admin).

Graduate program activities focus around authentic problems of practice, explored in collaborative team settings, and generating learner-directed and setting-enhanced learning. Within this environment, technology integration is modeled by faculty (Blomeyer & Clemente, 1997; Gibson, 2001; Gibson, 2000a). The core tenets of constructivism, including the ideas of cognitive dissonance and negotiation of meaning (Savery & Duffy, 1995), are integral components of this program. Program graduates acquire an understanding of the impact of information technology on their roles as visionary leaders of schools of the future and experience the transformational potential of technology on their own learning process (Gibson, 2000b). Students engage in interactive (online) reflective dialog centered upon specific school leadership topics. This mediated dialog will be assessed on a continuing basis for evidence of leadership insight, reference to the integration of theory and practice, content knowledge, and meta-cognitive development.

AN INTERACTIVE INTRODUCTORY PROGRAMMING ENVIRONMENT USING A SCRIPTING LANGUAGE

David C. Gibbs
Associate Professor, Computer Information Systems
University of Wisconsin Stevens Point
Stevens Point, WI 54481
dgibbs@uwsp.edu

Abstract: This paper provides the rationale and description of a unique programming environment to teach the fundamental concepts of programming (data types, input/output, control structures, functions, arrays, files, and the mechanics of running, testing, and debugging programs) to introductory students using either VBScript or JavaScript. This environment is earmarked for courses that precede the first programming course in computer science. Students can compose and execute scripts from within a text editor that has been configured to invoke the Windows Script Host (VBScript), or a web browser (JavaScript). This creates an interactive environment that matches the functionality of an integrated development environment. The target audience includes students with little or no programming background who need a brief introduction to programming before immersion in their first rigorous course in C++, Java, C#, or Web programming. The advantages of using a scripting language are many: text-based code-writing requires students to construct each programming component rather than setting check-boxes or using drag-and-drop strategies; the syntax is often friendlier than the aforementioned languages; the interpreted environment, where partial execution can take place, can encourage both comprehension and debugging skills; the scripts may be executed directly or embedded within an HTML template file and viewed through a browser with a single click. A complete description and downloadable sample files may be found at http://www.uwsp.edu/cis/dgibbs/EDMEDIA2002/index.htm.

Introduction

Students emerging from today’s secondary schools have more experience with computers than ever before. That experience, however, is typically limited to software applications (word processors, spreadsheets, database managers) and Internet browsing. Too few have received instruction in how computers work from the point-of-view of software instructions. Even fewer know how to create a program and execute it. Those with some exposure to programming often struggle with the breadth of material encountered in the first course in programming (CS1) at the university or community college. The reasons for the struggle are understandable when one stops to consider all that is taking place in the typical CS1 course: the semantics of introductory programming, the syntax of the language, the software development life-cycle (analyze, design, code, test and debug, maintain), use of built-in data structures, algorithm development, and problem solving. In order to write, test, and debug programs, students must also learn a programming environment.

To make matters worse, facets of the CS1 course mentioned above have evolved in the wrong direction, i.e. they have been made more difficult rather than easier for a variety of reasons. Demands of the marketplace and availability of programming tools have resulted in educational institutions adopting syntactically complex languages in their introductory courses. C, C++, and Java all fit in this category. Mastering their difficult syntax actually interferes with the learning of programming fundamentals. LOGO and Pascal, both much friendlier syntactically, were fine languages for learning how to program but have fallen by the wayside because they are not used to any significant degree in industry. Further, the programming environments of C, C++, and Java, currently in use in instructional situations are those provided by the major language developers. They have been created for professional programmers and as such include many powerful features that the novice may never use.
Solutions

What about Visual Basic? While it is true that VB does retain the friendly syntax of its predecessor (BASIC), the graphical environment encourages users to "point-and-click" their way to applications, which is exactly what novices should not be doing. Computing educators have long resisted using graphical programming environments for teaching the fundamental concepts. The fear is that in using forms, drag-and-drop, and check-boxes, students do not learn the fundamentals of input/output, decision structures, looping, subprograms, files, arrays, and data structures.

One of the solutions to the problems outlined above has been to insert a course into the curriculum designed to ease entry into the CS1 course. Described as CS0 ("see-es-zero") the course typically includes the concepts of computing and information processing, algorithm development using pseudocode or flowcharting (often with paper-and-pencil techniques), and implementing simple programming concepts in a user-friendly environment. The CS0 concept has grown to the point where the recent release of the Association for Computing Machinery's Computing Curricula 2001 (ACM 2001) included exactly such a course in its description.

Why a Scripting Language? Why an Interactive Environment?

Why learn introductory programming with a text-based scripting language rather than a graphical forms-based language? To construct a program in a scripting language, students must enter the instructions, usually by keying them in (although copying and pasting can be encouraged later on) rather than pointing and clicking. There are no mysteries; both the code and any error-messages are apparent from the interpreted environment. The programming environment is very easy to use. A freeware text editor can be used to prepare the programming statements. The editor is configured to invoke the Windows Script Host (VBScript) or the web browser itself (JavaScript). Error messages are quite accurate, and generally indicate the line and character position of the error.

Interaction with an electronic text is made possible through the use of hyperlinks within a Word document. (A hypertext document would achieve the same functionality.) Script files saved with a .vbs or .js extension are associated through the Windows operating system with the editor, meaning that double clicking the hyperlinked files from the Word document invokes the editor and loads the file. The scripts can be executed by clicking the configured menu pick.

In summary, the interactive environment includes an electronic text with clickable links that load code samples right into the editor where they can be modified and executed. Students can view, modify, and execute existing code samples, and then create solutions to problem exercises, link them to their own text thus forming an e-portfolio of their work.

Benefits for the teaching and learning of CS0

The case for the introductory course (CS0) has been made in the computing curricula throughout universities and community colleges. This paper argues that the scripting languages of VBScript or JavaScript meet the programming needs of these courses, and does so in a manner fruitful for students and teachers. In addition to the arguments already made, there are other benefits to using scripting and the interactive environment described here. All software is free; there are no compiler or interpreter licensing costs. (The editor is freeware. The "interpreter" is provided in the web browser which is also free.) VBScript has become the default scripting language for writing server side code in the Microsoft (Active Server Page) environment, and JavaScript is the default scripting language for client side code. While beginning students may be a few semesters away from client-server programming, the initial experience will be beneficial. Students can use the electronic book as the basis for building their programming e-portfolio, a collection of programming concepts and their VBScript implementation. In creating their own version of the electronic text, students are linking files, copying and pasting code samples, and developing skills in managing a hypertext document.

Abstract: Academic dishonesty is a concern at any educational level. However, many faculty members feel uncomfortable with delivering courses in the online environment due to a concern that students may find it easier to participate in academic dishonesty than they would in a traditional classroom. This paper looks at factors that are considered to influence academic dishonesty and how these factors can be considered in the design of online courses to promote academic integrity.

Introduction

Academic dishonesty is a concern for many instructors whether they teach in high school, two-year or four-year institutions. Academic dishonesty may include cheating on examinations, plagiarizing, falsifying sources or bibliographies, knowingly helping other students cheat, working together on projects that should be completed independently, or turning in the same assignment for more than one course (Dean, 2000). With the advent of the Internet and the World Wide Web, there seems to be an attitude among instructors that academic dishonesty is easier because of the availability of material that can easily be cut and pasted (Renard, 2000). Course delivery through the online environment may also make it easier for students to cheat since students and instructors do not have the same relationship in an online course as they do in a face-to-face course. Investigating reasons for academic dishonesty in face-to-face and online environments may help shed some light on ways to develop online coursework that encourages academic integrity rather than leaving students to their own devices in which they may be tempted toward academic dishonesty. This paper will investigate the following: 1) reasons for academic dishonesty; 2) academic dishonesty in the online environment; 3) possible ways to design online courses so that academic integrity is encouraged and academic dishonesty is discouraged.
Reasons for academic dishonesty

Measuring the incidence of academic dishonesty is usually done through self-report surveys given to students. McCabe and Trevino (1996) reported that from a sample of 1,800 students at nine different state sponsored universities, seventy percent of students surveyed admitted to cheating on exams. Additionally, it was reported that eighty-four percent admitted to cheating on exams and almost fifty percent admitted to working with others on assignments intended to be independent (McCabe & Trevino, 1996).

Several factors seem to be associated with the incidence of academic dishonesty. Dean (2000) has identified four of these as patterns seen in the literature: individual characteristics, peer group influences, instructor influences, and institutional policies.

Individual characteristics include ideas such as age, gender, social activities and level of academic achievement (Crown & Spiller, 1998; McCabe & Trevino, 1997). Peer group influences indicate that general student disapproval of cheating is most likely to discourage it while peer group acceptance of cheating is likely to encourage it (Crown & Spiller, 1998). Students who take courses with instructors who are perceived as being actively involved and concerned about students are less likely to be involved in academic dishonesty (Crown & Spiller, 1998). Institutional policies that are communicated clearly to students along with the penalties for academic dishonesty are likely to reduce the occurrence of academic dishonesty (Crown & Spiller, 1998; McCabe & Trevino, 1996).

Considering these factors in regular academic classrooms, it would seem that the same kinds of academic dishonesty would occur in the online environment for the same reasons. Additionally, it may be more tempting or easier to engage in academic dishonesty in an online course than in one that is face to face. Renard (2000) states that although plagiarism is not new, Internet “cheat sites” have made cutting and pasting written sections or even entire papers easier. Students involved in an online course would be using the Internet consistently so the ease of using these sites could be tempting. Additionally, the perception of the instructor being less involved in an online course could encourage academic dishonesty since that is one of the factors that can influence a student’s decision to cheat.

Academic dishonesty in the online environment

In recent years the popularity of the Internet has continued to grow among the general population around the world. In the United States alone, what was once considered a communication novelty is rapidly being perceived as an educational necessity in many homes. Along with the increased popularity of the Internet, especially the World Wide Web, many institutions of higher education are rushing to convert an increasing number of courses to online delivery. With the rush to offer courses online, there has arisen questions as to the reasons for both higher education institutions and their students to desire this type of course delivery. Many of these questions devolve down to a question of the quality versus quantity.

There are varied opinions about the correct answers to the questions that arise from the use of the Internet to deliver online courses. In order to be able to answer these questions, we must have a basis of understanding of what both students and instructors
perceive and desire about the use of online course delivery. Many of these perceptions are nothing more than myths or folklore taken from past popular beliefs and science fiction. Others come from a misunderstanding of the perceptions held from the various entities (students, instructors, and administrators) associated with online course delivery (Moore & Kearsley, 1996).

Faculty who design courses to be delivered online may evaluate the time a student should spend in a traditional classroom for an equivalent course, add to it time that should be spent outside of class, and in some cases, add extra requirements due to the student not having to physically drive to a campus-based classroom. Faculty may see these students as being able to connect to the online course and go right to work with the course materials. Often faculty do not consider that the physical environment in which the student is taking the course may not be the optimal environment for student success. As student work begins to be turned in, possibly at a level below the expected standard, the instructor may feel that the rigor of the course is being challenged and therefore try to compensate by adding additional work. On the other hand, if the work submitted by the student is of a higher than expected standard, the faculty member may suspect that the student may be using inappropriate aids in completing course assignments.

In contrast, students may see themselves as being somewhat timid with the technology needed for a particular course. Additionally, these students may not see themselves as having the time to make traditional classroom courses, especially since many online students manipulate their course schedule around work or family obligations (Gibson, 1999). Some students feel that the online courses may be easier than a campus delivery due a perception about having to only interact with course content, not with the instructor. Students who have done poorly with a particular class may feel that taking the professor out of the loop will in some way help them pass the course. In this case, students who may not have the strongest work ethic may be enrolled in courses requiring a stronger work ethic. With all cases, it is easy for the student to become overextended in their time and commitment to the course. This can lead to a situation where students feel that they are required to do too much work for the credit earned in the course.

The above mentioned scenarios for both faculty and students set the stage for many of the factors that can lead to discomfort and the temptation for academic dishonest. Faculty members who are working to move to the online environment may feel detached from their students, feeling that they really do not have the kind of relationship that they would have if the same students were in a traditional classroom. In a traditional classroom, faculty can “look-in-the-eyes” of their students and make some determination about a students feelings and needs. Not having this direct contact may lead the faculty member to begin to be suspicious about the rigor of the course and then ultimately the quality and originally of student assignments.

The lack of direct contact and a feeling of detachment also may profoundly affect students. Students who already have very busy schedules may be compelled to take online courses due to the belief that they can add their academic work on top of an already busy lifestyle. Once the demands of the course become overwhelming, especially in cases where the instructor may feel that the rigor of the course is being challenged, the student may feel that the course requirements are unreasonable for the credit to be awarded. Once students begin to feel that the course requirements are unreasonable, the temptation to use inappropriate resources to complete course assignments may begin to
grow. The temptation can become even stronger when students develop the feeling that they are all alone in their course with little contact or interaction with the instructor of peers.

**Designing online courses that promote academic integrity**

The scenario and concerns mentioned above should not be considered a simple reality of online course deliver. In truth, academic integrity is something that all faculty members must work to promote in any instructional environment. However, with regard to online course delivery, there are design features that can specifically promote academic integrity in this environment.

First, online course materials should clearly state that academic dishonesty is not acceptable and then clear examples should be given to illustrate the kind of activities that the student should avoid. Since institutional policies are seen as one factor that has an influence on a student’s view of academic dishonesty, it is important to clearly outline for the student what the policy is in all online courses. Further, by giving specific examples, faculty can help students avoid misunderstandings about what the policy actually means. While many students would never turn in someone else’s paper as their own, these same students may be tempted to copy and paste sections of their assignments from the Internet, justifying this activity as research.

Secondly, online course materials should include a high degree of interaction. Interaction may be developed in several ways and should work to increase the student’s contact with the content, the instructor, and peers. A variety of tools can be used to increase interaction such as chat, bulletin boards, MOOs, email, etc. Faculty using these tools can achieve variety in their courses and decrease the perception by students that the instructor is really not there or is not paying attention to the work they are doing. Further, an instructor can use these tools to facilitate cooperative instructional strategies where students work in peer groups. Using cooperative strategies in online courses help to enculturate the student into the course by developing a support structure where students can become knowledgeable of course norms. In interactive, well-supported cooperative environments, student peers help to encourage academic integrity and adherence to course policies. Faculty who make good use of interaction strategies will reduce the temptation of the student to seek outside help and increase student satisfaction with the course.

Lastly, online courses should be designed to include a variety of evaluation methods. With a single evaluation method, a multiple-choice test for example, a true picture of a student’s understanding is difficult to achieve. By using multiple evaluation methods, a trend can be identified with regard to student performance and understanding. This is equally true in both online and traditional environments. In a traditional classroom where a student may be very quiet during the semester and three multiple choice exams and a final examination are used for the course grade, it can be difficult to determine if the student understands the material, simply is good at memorization, or cheats. In courses that use multiple evaluation methods, the trend for a student’s work can be compared to individual assignments. If a situation occurs where one paper is turned in at a higher level of understanding or quality than has been seen in other course interactions, the possibility of academic dishonesty may be present. Likewise, a student’s
work trend can be used to guide the student to higher levels of understanding. As students come to realize that their work is being viewed and evaluated, and that feedback is being given, they will feel more attached to the course environment, and academic integrity will be promoted.

Final thoughts

It has been said that perception often becomes reality. In the context of online course delivery, a person’s perception about this type of delivery can directly shape the satisfaction and performance in the course. With regard to academic integrity, there are many different views as to the type of activities that students should or should not be allowed to use to complete their course assignments. Likewise, there are differences of opinion as to the ease in which students could chose to use inappropriate aids to complete course assignments online as compared to traditional courses. However, this paper has attempted to outline three components of online course design that may promote academic integrity. Courses that clearly specify the institution’s and instructor’s policy about academic dishonesty, along with examples, help students to be knowledgeable and understand the need for academic integrity. Courses that have a high degree of interaction between the student and course content, the instructor, and peers can promote a sense of being connected and will help encultureate students into acceptable norms for course performance. And finally, courses that use a variety of evaluation methods can mark trends in a student’s performance that can help a faculty member assist in a student’s growth while at the same time helping to identify potential dishonesty.

There are no easy answers to the many questions that are associated with online course delivery. It is important to understand that many different people who become involved in online learning do so for many different reasons. By understanding these reasons, courses can be designed in a manner that can facilitate a faculty members satisfaction as well as the success students. Through the process students will have greater opportunity to grow, be successful, and have a high degree of academic integrity.

Introduction to Information Technology and its effects on Organisational Control

Rahim Ghasemiye
School of Management,
University of Newcastle Upon Tyne, UK
rghanemiyeh@hotmail.com

Feng Li
School of Management
University of Newcastle Upon Tyne
Feng.li@ncl.ac.uk

Abstract: The explosive growth in IT capabilities and extensive use of IT systems has satisfied the increasing desire of organizations to gain competitive advantage. Advances in information technology and its inherent devices have led to profound changes in organizational rules. This study attempts to build an introduction to evaluate IT effects on control as a functions of management. Modern organizations, based on using modern technology, have to make major modifications to the entire organizations. This study begins by examining concepts of control in organizations following a short review of past work on IT effects on concept of hierarchy. Then present a comparison of conventional control and new attitude in traditional and modern organization.

Introduction

According to management literature one of the most important and constant functions of management is controlling. Controlling is the process of establishing objectives and specifying how they are to be accomplished in an uncertain future (Cook & Coffey, 1997). Researches have indicated that in the organizational hierarchy, each level of management tends to place a different emphasis on the functions of management. However controlling is a function that is widely applied by managers at all levels of management (Rue & Byars, 1997). Unfortunately formal control may have some side effects (Schermerhorn, hunt, & Osborn, 1991) such as imbalance, lack of patience, confusing documentation with action (concern for performance may lead to a stack of impressive-sounding plans but no result), panic and so on. These reasons have forced managers to consider other control mechanism that is social control. The purpose of social controls is to get people to commit themselves to the organization. For social system control to work, people need to know that someone in authority knows what they are doing and is willing to call attention to gaps between performance and objectives. Based on a survey and information gathered from 22 manufacturing and service firms in the UK, Li (1997) highlights a radical change in a basic rule of organizational design. He argues, most existing organizational designs are based on a series of compromises (for example, between central control and empowerment). Researchers have identified two categories of control methods: behavior or personal control that is based on direct, personal surveillance (Rue & Byars, 1997). First-line supervisors usually apply this kind of control. Output or impersonal control is based on the measurement of output, e.g. monitoring sales figures. IT advances facilitate and improve both control method.

Control and hierarchy, traditional view versus modern approach

Miles and Snow (1992) identified four broad forms of organization: 1) The functional organizational: this encouraged internal production of parts and components to assure control. The logic of that is centrally
coordinated specialization. 2) The divisional form: The operating logic of the divisional form is the coupling of divisional autonomy with centrally controlled performance evaluation and resource allocation. 3) The Matrix Form: The operating logic of the matrix form is assure control and centrally coordinated specialization. 4) Network organization: the combination of central evaluation and local operating autonomy is reflected in the dynamic network where independent firms are linked together for the one-time (or short-time) production of a particular good or services. From their viewpoint underlying all of the positive characteristics of network structure is the dynamic of Voluntarism. Applegate (1994) identified two major differences of control issue in traditional and modern company: a) In traditional company the role of control was standardizing behaviour and supervisory control of people, but now in modern firm, the role of control is to sharing information, which enabled control of the operating processes directly. b) In traditional hierarchical organizations, managers automatically inherited responsibility and accountability for decisions made by subordinates, but in modern organization all the employees are responsible for decision making.

Summary and conclusion

Over the past decade a great number of papers have been written about organisations in advanced IT age. One major characteristics of IT is separating work from location (Groth, 1999), IT devices such as email, the Internet, and etc permit tight coordination of geographically dispersed workers across time zones and cultures. Much attention must be placed on trust and coordination mechanism rather than control mechanisms. Here we distinguish some reasons: 1) As organisations perform most of their processing using electronic forms and images, workflow systems will be used to route documents electronically to individuals and work groups that need access to them. 2) Number of employees has reduced so it is much easier to control them by informal ways. 3) The other reason for trust arises from this fact that the nature of work and naturally employees’ expertise have changed. In the IT age, an individual who contributes value by adding or interpreting information is called a knowledge worker. 4) The structure and functioning of the organization will no longer be determined only by living patterns. Programmed patterns, will increasingly influence the structure and functioning of the organization (Groth, 1999), 5) Outsourcing: Successful organisations in 21st firstly must identified new imperatives and then build a proper organisational structure to cope with them. One of these imperatives is outsourcing.

Abstract

The jagged study zone model helps designers to create educational environments which challenge the learner and make the learner to commit to the learning process. The characteristics of a jagged study zone can be explained by showing how its features are related to traditional closed and open learning environments. The requirements for a jagged study zone are identified by extracting the strengths and opportunities of the closed and open learning environments, and by combining them to the opposites of weaknesses and threats of those traditional environments. We show examples how the jagged study zones can be supported and discuss the role of the teacher when considering the jagged study zone model.

1. Introduction

In the recent discussion concerning meaningful technology for learning, the concept of “learning landscape” or open learning environment seems to refer to an environment that provides a learner with an activating, yet safe learning experience. The learning itself has become slightly dull and unexciting. From the arctic Finnish perspective, generations before us have considered learning not an easy or simple fun-like activity, but rather a painful experience that changes the learner at a fundamental level. Instead of referring to a tamed, village-like landscape with occasional woods and meadows for lovely picnics, learning can also be a process of blood, sweat, and tears. In our experience these dull learning landscapes rarely offer enough excitement and realistic challenges for every student. We do not argue that learning or education should always be extremely exciting, but on some occasions the appropriate amount of exhilaration might motivate the student to cope with very difficult domains.

At the same time the learning landscapes or open learning environments do not necessary offer enough guidance and counseling to the poorly motivated student. If the student is not capable of making the right choices, the learning environment most likely will not help her. Hence, the jagged study zone should take also care of a poor student; facilitating her with efficient learning products and support.

In this paper we will propose a model for building educational environments by introducing the concept of jagged study zones. Applying a jagged study zone one can cover most of the demands listed above.

2. Definition of the Jagged Study Zone

We begin our definition of a jagged study zone by examining the properties of two well-know learning contexts: a closed learning environment and an open learning environment. In a closed learning environment the teacher sets the goals and dictates for the tools used, pace, materials, schedule and the learning goals. Wilson (1995) characterizes the closed environment to be a construct, in which the students work by using facilities to collect and interpret information. The closed environment is restricted and rigid; the students are not able to work or express themselves freely. The metaphor for closed learning environment could be a product line of a factory. Student is a product traveling through the product line and the factory (educator) provides him with all the necessary information and knowledge.

To get free from the limitations of the closed learning environment Miller (1997) and Levi (1994) proposed an open learning environment, which is characterized by

1. being learner centered,
2. rich communication,
3. exploratory learning,
Learning environments based on adaptive hypermedia (Brusilovsky 2001) are good examples when closed learning environments have been transformed to be more flexible. Despite the introduction of adaptation, systems based on adaptive hypermedia are still confined environments, where system designers or learning material authors have to decide the rules by which educational materials are presented to the learner.

The open market model (Meisalo, Sutinen & Tarhio, 2000, 69-71; Meisalo & Lavonen, 2000) is a typical construct based on the open learning environment paradigm. This model structures the open environment and the activities of the learner therein. In the original market model, the student is considered to be a consumer in a large supermarket (computer). In the supermarket the customer makes highly individual choices that are relevant only for her. In the supermarket you can forget all the other customers or people, and the only important thing is to think about your own welfare and choices. In the open market model, referred above, both positive interaction of learners in the environment and the access to the world outside the supermarket, even wild nature, electronic workshops, etc., are emphasized. In the original field of application the interest has been primarily in science and technology education. Both the nature and the technological applications show often features that are far from smooth and ideal. This demonstrates that the idea of jagged study zones brings about new features to learning tools, like in our example of extending the original market model into the open market model.

The jagged study zone concept

We see Vygotsky's (1978) zone of proximal development as a component for jagged study zone, in which the student is encouraged to take the learning experience to the outer limits. The jagged study zone can be a harsh environment for the student, and demands serious efforts to explore and reach its limits. The characteristics of the jagged study
zone are derived from the closed and open learning environments. We identify four main requirements for a jagged study zone by combining the strengths and weaknesses of the closed and open learning environments and by countering their weaknesses and threats.

Features derived from closed learning environments:

The goal awareness and skill learning identified as strengths of a closed learning environment and the corresponding opportunities of learning by gaming and utilization external motivation translate into collaborative tools for achieving meaningful goals in the jagged study zone (first requirement). The tools help students to understand their goals and to scaffold them in reaching the goals. External motivation and the competitive gaming element can be attained by introducing a collaborative element into the learning process, where the students help each other and may get inspired by each others' progress and skills.

The closed learning environment tends not to support initiative and it supresses creativity. From this emerges the threat of training students into tunnel-visioned robots without inquiring minds. To counter these weaknesses and threats the jagged study zone promotes the students to learn creative problem solving and versatile meta-skills for survival such as self-evaluation in a harsh learning environment. This can be conducted by allowing the students the opportunities to solve fuzzy problems and to deal with uncertainty in the jagged study zone (second requirement).

Features derived from open learning environments:

When combining the best features of open learning environments, we can extract the third requirement for jagged study zones. The open learning environment promotes creative problem solving by letting the students to make their own choices and select their own paths. In jagged study zones the student must take challenging actions by self-initiated and self-regulated construction during the learning process.

The weakness of the open learning environment is that it often leaves the student alone with his choices. There is plenty of space to go, but there is no guidance for a student who gets lost. To counter this threat we need adaptive methods for getting out of deadlocks and traps (fourth requirement). If we do not want to rely on automated methods, it is always possible to use peer-help in identifying the traps. This can be achieved for example by social navigation (Munro 1999), i.e. making the actions of every individual visible to other individuals.

Summary of requirements for a jagged study zone:

1. In the jagged study zone there are collaborative tools for achieving meaningful goals.
2. The jagged study zone equips the students with an opportunity to solve fuzzy problems and deal with uncertainty and unexpected phenomena.
3. During the learning process the student must take challenging actions by self-initiated and self-regulated construction.
4. Adaptive methods for getting out of deadlocks and traps, or peer-help based on for example social navigation.

Example of a jagged study zone as a landscape

The jagged study zone concept can be illustrated by a jagged desert landscape where one can find for example following things:

Oasis:
An oasis is a place where learner can stop at to find inspiration, guidance and even amusement. In the oasis the student can find refuge if she gets lost during her explorations in the jagged landscape. There can be attractions and guides at the Oasis to motivate student. The Oasis can for example include a hut with a mirror, which the student can use as a tool for self-evaluation.

Inspiration points:
Inspiration points provide the student with fresh stimuli, for example as distance thought models operate in idea generation. These can appear to the student as a mirage in the desert. Inspiration points may include ideation tools and they can may be created and inserted by a teacher.

Workshops:
The workshop is a place where the student can find tools that help the student in exploration. The tool may include visualization, writing applications and collaborative devices. For example, learning seeds (Kurhila and Sutinen 1999) can be processed in a workshop.

**Learning seeds:**
In the landscape, the learner can find learning seeds, which are planted by the teacher or fellow learners. These can be parts of learning material, exercises, ideas and visual presentations. The seeds can “grow” from the actions other learners make, i.e. the learners work on a written assignment by commenting each other’s input. The seeds can also grow by some other function, for example by some pre-defined rules. This is particularly suitable if the seeds are a part of an artificial world consisting simulated events in time and space. It is possible that a prosperous, well-surviving and well-nourished learning seed can grow to be an inspiration point in the landscape.

**Viewpoints:**
The learner can use the viewpoint to gaze over the landscape. In this way the learner can review his journey in the landscape. It is also possible that a learner can view his journey in respect to other learners’ journeys, incorporating social dimension also to the evaluation of the learning process. In addition, the more traditional way to exploit the learning history is that the teacher can use the viewpoints to track and possibly intervene (help, guide, advise) learners as they explore the landscape.

### 3. Examples of supporting jagged study zones

**Context 1: Virtual platforms.** In the current course delivery systems, such as WebCT or Learning Space, the jagged study zone idea is not supported. The systems offer rigid, often similar, solutions to the design of learning situations. According to the jagged study zone concept, the virtual platforms should offer ways to implement stimulating learning situations. At the current time the construction of stimulating features to learning landscapes remains almost entirely on the hands of the teacher.

**Context 2: Computer Science teaching.** In the Virtual Approbatur project at the Department of Computer Science, University of Joensuu in Finland, the design and implementation of virtual courses is based on the analysis of students’ needs according to the Candle scheme (Haataja et al. 2001). On the other hand, the Candle scheme is derived from the concept of jagged study zones. For example the visual tools, like algorithm animator Jeliot (Haajanen et al. 1997), offer a student a way to actively strengthen the understanding of programming concepts. Visual tools give students the aid for grasping the theoretical aspects of programming. Furthermore, one of the ways to realize the jagged study zone concept would be to use students’ unfinished learning materials and blurred learning goals (tasks). In fact, the starting point might be an entirely incorrect version of an algorithm. The following trouble-shooting activity by Jeliot is an utmost characteristic of a jagged study zone. Thus, Jeliot inspires the students to work with the material deeply to make it more suitable for achieving the learning goals.

The Empirica Control environment gives a student tools to study a phenomenon that takes place in his physical neighborhood. Thus, the observed circumstances are far from ideal ones describing abstract models. This noise – representing the jagged feature of Empirica – supports him towards his own efforts in the learning process.

**Context 3: Adaptive learning environments.** Adaptive learning environments have evolved from intelligent tutoring systems (ITS) towards more comprehensive hypermedia-based environments with adaptive presentation and adaptive navigation support (Brusilovsky 2000). Most of the intelligent tutoring systems do not provide the learner with learning materials: the knowledge required is acquired outside the system, and the ITS provides only a platform for helping the learner in the process of problem solving. Today the trend is to offer an environment where the learning material is browsed in an adaptive manner. It should be noted that in reality only a few systems can offer this, since providing adaptation is never a straightforward task to design and implement.

When fitting the jagged study zone model to a hypothetical adaptive learning environment, there is a need to think the concept of adaptive learning environments more broadly. For example, collaboration can be achieved when users are not modeled as individuals but as groups. This poses a noted problem (Beck et al. 1996), but one solution is to use probabilistic models to form or just suggest groups of individuals, where the group has sufficient potential to tackle the learning tasks (requirement 1 of the jagged study zone model). Requirement 2 of the jagged study zone can be supported by standard adaptive navigation support if the learning environment is based on hyperlinked material, or with adaptive scaffolding which can mean intelligent and interactive problem solving support. Requirement 3 can be
supported with unpredictable components generated by random algorithm for inspiration points thus bringing up the motivation.

To provide any kind of individual adaptation requires the learner to be modeled in some way. The model is always an approximation of reality and thus imperfect. Therefore, an adaptive learning environment can easily be a “sweatshop” if the environment is too rigid and the modeling is conducted inappropriately. However, slightly imperfect learner modeling is in complete harmony with the fourth requirement listed for the jagged study zone model. If there is a need to shift the emphasis from modeling the learner artificially to human (peer) evaluation, we can incorporate the idea of social navigation to the environment to identify when learners or groups of learners are facing traps and deadlocks.

**Context 4: Woven Stories.** The concept of woven stories can be briefly described as several authors writing a story in a shared virtual space (Harviainen et al, 1999, Gerdt et al, 2001). The difference between the woven stories idea and collaborative writing becomes evident in their functions: the writers of a woven story engage in a dialogue of storytelling rather than concentrating on an effort to produce a joint document. The shared virtual space, where the authors write the woven story is a place where the writers may be inspired by the writings of the others, take part in writing a twist into an existing storyline, compare one’s writings to other contributions or simply write a story for others to read.

A system realizing the concept of woven stories can be used as a collaborative learning environment. The concept of woven stories fits well with the jagged study zone model. The shared functions of the virtual space offer tools to authors or learners, with which they can produce and link texts to achieve goals which are of communal or individual importance (requirement 1). Writing and re-writing text is a good way to reiterate an original problem definition and to elaborate better and better solutions via partial or preliminary ones (requirement 2). A system for woven stories can include mechanisms monitoring the students to notice any lost students. These mechanisms, for example periodical reports and alarm triggers, can be used to inform teachers and tutor students that intervention is needed (requirement 4). This information can be relayed to the lost student too, so that she realizes her situation and may benefit from the scaffolding facilities of the environment.

The authors of a woven story may link their story passages to other authors’ passages, thus including their contribution into a story that is being written by other authors. From an another point of view they may include a piece of somebody else’s story into one’s own story. When the students link their stories to others’ stories and participate in the creation of a storyline they must make challenging choices (requirement 3). The students must relate their creations to writings of others, maybe adapting their contributions somewhat.

**4. The roles of students vs. teachers in learning environments with jagged study zones**

It is important that there is a balance between the student autonomy and the teacher guidance in jagged study zones. In principle, there is always a responsibility for a teacher to make sure that the students are working towards the goals set for the course or equivalent. On the other hand, student autonomy, especially the decision making skills and the readiness to take responsibility do not develop if they do not have situations where to get relevant experience. These aspects can be readily observed in certain types of computer games, but in jagged study zones they appear in more realistic ways.

In a modern learning environment it is important, that the learner is able to work creatively and join various teams for brainstorming and other forms of ideation processes. It is also important, that the learner is able to co-operate with a number of specialists, one of them the teacher, but some being fellow students possibly reached over the Web etc. Even motivating and guiding feedback is available in natural forms in workshops of jagged study zones.

The teacher’s role in a jagged study zone is that of a wilderness guide, a ranger who is aware of potential threats, risks, opportunities, and challenges meeting all explorers in the unknown. Students can be seen as scouts, at a proximal zone of new findings, reorganizing, and changing earlier knowledge structures. While a single hunter and trapper may sometimes have reasonably good life, high mountain tops or most extreme wilderness can be reached only by teams. Positive group dynamics within the trekking team is essential – collaborative learning of higher order (thinking) skills is dependent truly on the success/survival of every team member. The team makes use of heterogeneous and versatile skills of each one. This metaphor relates also directly to research work, but any learner is equally exploring her environment for knowledge and skills that are new to her.
5. Concluding remarks

Today, in our society indifferent attitudes are common. In many occasions the attitudes towards learning and education are similarly indifferent. The student will not succeed with this type of unconcerned attitude in jagged study zones. The students have to make a stand, form an opinion, to act, to really stick their hands on the mud.

It is possible to identify jagged traces in the existing learning environments, as the examples taken from Empirica, Jeliot, and Woven Stories indicate. However, to bring the idea of jagged study zones not just a feature of a computer-supported learning process, but an all-embracing principle thereof needs determined action. This will be our agenda in both designing novel educational environments as well as evaluating their power and usefulness.

Abstract
Qualitative and quantitative methods are often used for understanding interactions in asynchronous learning spaces. Traditionally researchers in these fields have not collaborated. Research on asynchronous discussions provides an ideal arena for collaboration because of the large volume of data available and the relatively under-theorised nature of the field. The presenters are examining communication and decision making in computer mediated teamwork. They seek to bridge the qualitative/quantitative divide by using both approaches to better understand what is happening.

The Topic
The purpose of this paper is to describe a research project/design, which investigates decision making modes in an asynchronous computer-mediated communication (CMC) environment. The multidisciplinary research team (representing the fields of artificial intelligence, international management and education) will employ a design which has iterative quantitative and qualitative elements.

Research Questions and Motivations
We have three primary research questions:
1. What are the dominant decision making modes used by teams in the computer-mediated environment?
2. What is the mix of process, social and task communication used in computer-mediated teamwork?
3. How can quantitative and qualitative approaches be combined to investigate these phenomena?

There are three motivations for this study: 1) To extend past findings from three predominant models of decision making (rational, constrained and emergent) to the CMC context, 2) to integrate qualitative and quantitative findings in an iterative process to better understand CMC decision making, and 3) to attempt to develop a software tool for practitioners that allows simplified analysis and depth of meaning.

The Conceptual Framework
Asynchronous Computer Mediated Communication: The literature in CMC positively characterises the environment as one of time and space flexibility, many to many communication, computer mediated interaction and text based nature (Harasim, et al. 1996). Contributions have a high degree of plasticity in the sense that they can be reshaped (Hammond, 1998). Garrison et al (1998) theorise that there could be a connection between this text based communication and higher order thinking. There is also the potential for equal opportunity for participation (Eastmond, 1994). The literature has also negatively characterised the CMC environment as including dependence upon technology which may not always work (Hara and Kling, 1999), the absence of physical presence which can result in message ambiguity and lack of clarity (Eastmond, 1994), and perceptions of the medium as an act of publishing, rather than speech, which may result in communication anxiety (Grint, 1989). These features represents a significantly different context for research on decision modes.

Group Decision Making: Over the years, the study of decision making has focused on two primary questions: ‘how do decisions get made?’ and what is the most effective approach to making decisions?’. This research focuses on the first question of decision making modes rather than performance. There are at least three modes of decision making that can be taken from the literature: the rational (Gulick & Urwick, 1937), constrained (Simon, 1960), and emergent modes (Allison, 1971). To identify which mode is used in any particular group exchange requires careful analysis of the group’s dialogue. Dialogue in face-to-face environments generally contain three types of statements: task, process, and social. These will be operationalised for our study in the methodology section.
Methods
A group of senior-level university students worked in dyads to analyze and make decisions in a business case solution. In this assessed assignment, the groups were instructed to conduct all their interaction through electronic media which could include e-mails, electronic chats or electronic discussion forums. These CMC media provide a rich and complete transcript of the participants' interaction and these transcripts will serve as the basis of our analysis. The participants in this study have some experience in decision making and less experience in working in electronic environments.

In our qualitative inquiry, content analysis will be used to analyze the CMC transcript data (Henri, 1991) using a 'gestalt' approach (Gunawardena et al. 1997). Statements will be identified as task, process and social and decisions will be identified as rational, resource constrained, or emergent. The resultant description will be merged with further quantitative analysis and then used as part of the machine learning cycle of the project. In our quantitative inquiry, we will use Knowledge Discovery from Databases (KDD) as a means of automatic quantitative investigation. KDD includes a broad number of methods for extracting knowledge from data. In this case we are interested in attempting to discover ways of automatically classifying discussions, and identifying key points in the discussion.

We will employ an iterative process of analysis. The quantitative analysis relies heavily on the coding scheme devised for the qualitative analysis. Initially, the qualitative analysis attempts to identify suitable parameters for classification. The results of the initial qualitative analysis are then applied in the development of the quantitative analysis. Similarly, novel relationships or associations revealed by the quantitative analysis can inform further iterations of the qualitative approach by indicating possible classifications or associations between statements and decisions.

Anticipated Results
We anticipate findings relating to decision making modes and the mix of communication. With regard to the decision making modes, we anticipate finding evidence of all three in the asynchronous environment. What will be particularly interesting will be the patterns that come into view. With regard to the types of communication, we expect to find significant attention being given to social comment and to the establishment of identity and team cohesion as compensatory mechanisms. In terms of process, the absence of physical presence may have a positive impact on giving and receiving feedback and metacognitive activity. Some intermediate categories of process related to task and process related to social factors may also emerge. Finally, with regard to methods of analysis, we hope that the dialogue between qualitative and quantitative approaches will provide new insight into CMC decision making and how we conduct research on it.

SPLACH: a Computer Environment Supporting Distance Project-Based Learning

Sébastien George

Abstract: Our research deals with collaborative learning at a distance and takes place in the field of CSCL (Computer-Supported Collaborative Learning). To promote communications between people learning in a distance context, we think that it is important to involve these learners in collective activities. We suggest to set-up activities using project-based learning in order to stimulate and facilitate collective learning. In order to support distance project-based learning, we designed and developed a computer environment called SPLACH. This environment comprises specific tools for different actors: the project designer, the learners and the project leader. SPLACH was investigated in two different contexts: with pupils in a secondary school in the domain of technology and with adult students learning programming at the Tele-university of Quebec. This article presents the computer environment SPLACH and some of the results of its evaluation.

Introduction and Context of Work

A major interest of computer-supported distance learning is to allow communication among students and to employ a constructivist approach for learning: according to the CSCL (Computer-Supported Collaborative Learning) research domain (Bannon 1989). Our main hypothesis is that conditions have to be created to stimulate interesting interactions between learners. A study of numerous distance learning environments made us realize that the main attention revolves around computer tools that must be provided for distant learners to communicate. Learners working together would theoretically need only communication tools. However, tools that simply offer technical possibilities for communication would appear to be insufficient to ensure collective learning. We feel this is not always sufficient. Indeed, although the learners are offered a possibility to communicate, there is no reason for them to do so if there is no common interest bringing them together. The lack of social cohesion renders truly collective learning impossible.

In order to create social cohesion in distance learning, our main concern is to concentrate on the instructional activity and to the computer environment to support collective learning. Thus, distance should not be seen as an obstacle to which the computer tools provide a solution, but rather as an interesting learning situation in which the computer tools are designed to support new learning activities. These were the principles governing the development of our distance collective activities based on project-based learning practices. Project-based learning (PBL) is an educational method of creating collective classroom learning situations which has been tried and tested for many years (Dewey 1902, Kilpatrick 1918, Johnson and Johnson 1991). It is particularly interesting to use in a distance learning context to encourage collective learning. However, existing distance learning platforms are not really suited to support PBL. Even if there are several experiments of PBL for platforms like WebCT or FirstClass (Christiansen and Dirckinck-Holmfeld 1995), these platforms distort the pedagogical situation (only tools to communicate and to exchange data, lack of tools for the teacher, lack of synchronous work tools, lack of group awareness tools, etc.). We stress the importance of two interdependent conditions for the success of distance PBL: (1) projects need to be set up carefully in order to promote interdependence in a distance learning situation (2) the computer environment has to support all the actors involved in PBL. In this way we decided to create a specific computer environment dedicated to PBL, founded on particular projects and team organization. The organization of each of our projects is structured around a project designer, role played by a teacher, a project leader, role played by a tutor, and a team of learners sharing tasks in the same project. The project designer's role is to define the projects by providing specification documents, structuring the projects and forming the teams, tasks usually pertaining to an instructional designer. The subject of each project should provide the learners with the opportunity to share tasks among themselves.
Indeed, in a distance learning situation it is not advisable to make the learners collaborate all the time, that is to
say carry out all the tasks together (Henri and Lundgren-Cayrol 2001). The project subject is presented as a list
of tasks specifications, chosen so that it can be subdivided by the learners into separate parts which should, of
course, not be independent from each other but, on the contrary, closely dependent. Moreover, in order to take
into account the synchronous and asynchronous aspects of any distance work, the project is divided into stages
where each stage is broken up into an asynchronous work phase followed by a synchronous phase. The intention
of structuring collective work is to facilitate the learners' collective work and to stimulate the learning of how to
work collectively. More information about the instructional design for the collective activities can be found in
(George and Leroux 2001). The work of the project leader consists in monitoring the evolution of the project
and helping the learners both technically and pedagogically. The project leader is seen as the facilitator and
consultant. The teams of learners work to reach the goal set for the project. Each team was composed of three
learners in order to promote high involvement in the project (Caplow 1968). In this paper, we focus on
characteristics of the computer environment enhancing collective project-based learning (PBL).

Development of a Computer Environment to Support Distance Project-Based Learning

The main aim of our work is to provide tools for the different actors involved in project-based learning.
The actors defined in the previous section should have computer environments allowing them to do their specific
tasks: setting-up the projects for the project designer, carrying out the project in team for the learners and
monitoring and intervening for the project leader. So the SPLACH [1] environment was developed to support
PBL; it includes three computer environments which is customized for each of the actors, that is the project
designer, the project leader and the learner. SPLACH is entirely developed in Java and is built on a client/server
architecture (George 2001). We use the Java Shared Data Toolkit (JSDT) library for the data exchange between
applications (Burridge 1999). We describe thereafter the three specific SPLACH environments.

Project Designer's Environment

With SPLACH, the project designer has tools to define and to set-up projects for learners. Firstly, the
project designer can create new projects and specify teams of learners and their project leader who will monitor
the learners. Then, the project designer structures each project in steps according to the pedagogical objectives to
be reached. The project designer defines preformatted documents that will appear as a project progresses.
Finally, the project designer plans project giving a preliminary schedule that could be discussed among the
learners and their project leader (Fig. 1). Indeed this environment can be viewed as a project editor facilitating
the creation of project-based learning in a distance context.

ERIC
Concerning the learner's environment, our aim was to design an environment that incorporates all the tools necessary for the learners' collective activities. While common practice dictates the use of different tools (for instance Word® for editing documents, Eudora® for E-mailing and Netmeeting® for synchronous meetings) when learners have to use numerous software products at the same time, the cognitive workload will be increased. In a learning context, this extra load would not be favorable. The simpler the interface and use of the tools, the more learners will be able to concentrate on their activities. This simplicity calls for an environment comprising all the necessary tools to be designed and available in one environment. The amount of time and energy spent on the development will of course be greater, but this is the only way to develop a system that any learner can use, irrespective of his/her competence in computing. Moreover, there is another advantage to this investment. Existing software is often quite prohibitive, and difficult to analyze in terms of usage traces. Another of our aims was to facilitate collective learning based on information obtained from the computer system. The design and development of our own tools allow for collection of data concerning the learners' and the teams' activities. These data are then analyzed and used by the system to promote the collective activities (Després and George 2001).

Thus the learners' SPLACH environment integrates asynchronous communication tools (E-mail and discussion forum), a synchronous meeting tool which allows textual discussion and application sharing, a scheduling tool in the form of a team calendar which provides the learners with coordination of the project, a tool to write reports during the project (documents are preformatted by the project designer) and, finally, specific tools of the subject matter. These specific tools are the only part of SPLACH that varies from one subject matter to another. A lot of attention was particularly paid to the design of the synchronous meeting tool, intending to support awareness (Dourish and Bellotti 1992) among the participants of a synchronous distance meeting and to stimulate the teamwork. Since good quality multipoint videoconference tools are not yet accessible with standard networks, we chose to display photos of participants during the meeting sessions. Moreover, participants can share a document and work collectively on it using an easy visual system of turn taking (Fig. 2). During a meeting, participants communicate within a semi-structured interface that helps to keep threads of discussion visible.

Figure 2: Interface of the learners
Project Leader's Environment

The project leader is a central key in our conception of distance PBL. S/He has to have tools to communicate with learners and to monitor their activities. For the moment, the project leader's environment is very close to the learner's environment; however including some additional functionalities and specific rights. Thus, the project leader can modify the planning of a project, manages rights of turn taking during synchronous meeting. We are presently researching and investigating specific tools to assist the tutor in monitoring both individual and collective learner activities. To reach our objectives to refine the leader/tutor environment, an iterative design process is employed by implementing the SPLACH environment, interview and keep traces of how tutors use it, and then adapt and enrich the SPLACH environment accordingly. One of these tools is a system designed to assist the tutor in his monitoring tasks (George 2001).

Evaluation of SPLACH

One of our major concerns was to develop a computer environment, which can support projects in a large range of educational fields. In order to prove the reusability, SPLACH has been investigated in two different contexts: with junior high school students in the technology field and with adult students learning programming. In the following sections, we discuss some results focusing on the use of SPLACH. These results are based on observations, questionnaires and automatic data traces recorded by the computer system.

With Junior High School Students in Educational Robotics

Each year a robotics competition is organized for junior high school students in the department of the Sarthe (France). All teams taking part are given a list of specifications at the beginning of the school year; during the year the students work on designing robots in order to compete in the festival at the end of the school year. This festival provided an interesting situation to design the collective distance projects. The students on each team usually come from the same school. For our investigation, we created two teams made up of students from geographically remote schools. These teams of learners used our SPLACH environment from their classroom to work collectively on the robotics project. We assumed the role of project designer and project leader ourselves from our laboratory in order to better understand how it felt to supervise and monitor teams of learners at a distance. For these evaluation, we added specific tools from the educational robotics fields to SPLACH: a tool to view electronic course books that embed all notions introduced in the technological context, a tool to describe micro-robots [2] to computers which automatically generates elementary programs, and a tool to program and drive micro-robots. The Fig.3 shows screen shots of these different tools.

![Figure 3: Specific educational robotics tools integrated in the SPLACH environment](image)

The evaluation was conducted with fifteen students (aged 13/14) in three different schools. The list of specifications for this project, defined by the organizers of the robotics challenge, required the teams to design a robot which could carry out several functions (follow a black line, knock over a skittle, put a ball into a hole, etc...). The students defined the modules it would take to build a robot and then determined who was going to do what. Obviously, the modules were interrelated, which in turn promotes collective learning, since they depended on each other to bring the modules together as one robot, which would enter the competition.

[2] The robot used are Fischertechnik® micro-robots.
The evaluation lasted for about three months, with the students using the SPLACH environment for about two or three hours each week. Every Friday lunchtime, ninety minutes were set aside for synchronous meeting sessions with the teammates. Outside these sessions the teams could work on the project whenever they wanted to by communicating asynchronously via email or the discussion forum. Two weeks before the competition, the students met physically for the first time in order to assemble the different parts of the robots. On the day of the festival, one of our teams shared first place in the competition. The results of a post-questionnaire show how the learners felt the importance to work collectively, and that they found this type of collective work highly motivating. Moreover, the results of the questionnaire show that the learners perceived that they were part of a team throughout the project, which was also apparent during the competition. We can therefore say that our main educational goal, which was to create social cohesion and interdependence among distance learners, has been achieved. The learners had no particular difficulty to use SPLACH even if they were children. It was one of our concerns to make SPLACH so user-friendly that it would cater to a wide public of learners, including young ones.

With Adult Students Learning Programming

A second evaluation of SPLACH was carried out at the Tele-university of Quebec. Six adult students in a programming course used SPLACH during six weeks to work in teams, each student working from her/his own home. The list of specification of the projects corresponded to a practical work of their course. The main goal was to permit the students to work collectively on a program in Pascal, each student being responsible for specific functions of the program. A tutor at the Tele-university assumed the role of project leader.

We have integrated to SPLACH a specific tool to allow the learners to work in teams on a same computer program. This tool makes a link between SPLACH and the Delphi® environment. Thus the computer functions and procedures found in a source program written with Delphi® are automatically added into SPLACH. In this way learners share their programs. The Fig. 4 shows this tool during the display of a programming procedure in SPLACH. In the lower part of the screen, the learners can access the main program, their personal programs or their teammates programs.

Figure 4: Specific tools to program in team

Altogether, students connected to the SPLACH server for a total of 70 hours. Students’ answers to the questionnaire bring out the fact that they appreciated the possibility to communicate and to help each other. Furthermore, the students considered the synchronous phases to be necessary to the organization of the collective activity even if they place temporal constraints not always easy to solve. This type of project appears to help students better understand the necessary conditions to a good cooperation. They like the environment because it allows them to easily gather documents and programs together in the same place. Furthermore, they felt that the project leader had a crucial role, although some of them regretted that he was not more actively involved and more directive. Moreover, some of the students would like to take on the role of the project leader. It’s an option that we foresee for future investigations.
Outcomes From the Evaluations

For the two evaluations, the goal of the projects were reached: building and programming a robot for the junior high school students, writing a computer program for the students of the Tele-university. An observation of the students’ activities shows that final products have really been the result of collective work. These evaluations also made it possible to substantiate the validity of the SPLACH environment from both a pedagogical and technical point of view. This environment is capable to adequately supporting distance project-based learning. The students found it easy to use, most likely because it integrates all the tools necessary for collective work. We have also shown that the SPLACH environment can be used in different context.

Conclusions and Futures Directions

The SPLACH environment was developed to support project-based learning at a distance. It adapts its tools according to the actors: the project designer, the learner and the project leader. For a distance learning designer, SPLACH can be seen as a computer platform facilitating the setting-up of project based-learning in which you only have to integrate the tools pertinent to the subject-matter. If existing specific tools are developed in the java language, they could easily be integrated to SPLACH. In other cases, a link can be made in SPLACH to launch external specific tools. For learners, a strong integration of the collective work tools leads to make SPLACH accessible to a wide public of learners as the evaluations corroborated. It was noticed from our evaluations that the project leader/tutor had a much more active role compared to traditional tutoring of individual distance learning. The collective activity is more complex to supervise and monitor, which is more time consuming for the tutor. Thus, a future direction of our work lies in providing particular tutor tools to assist her/him in the supervising and monitoring of learners’ collective activities. In this way, we work on integrating a multi-agent system into SPLACH aiming at helping both the learners and the project leader.

Acknowledgements

The author would like to thank the France/Quebec cooperation commission for their support. It is realized inside the LEA project concerned by the tele-assistance in the context of practical work in technology. The LEA team is composed of researchers from the LIUM (France) and the LICEF (Quebec). The author wishes to express his gratitude to the schoolteachers, tutors and students for enabling him to carry out the evaluations in real-life situations. The author also wishes to thank Karin Lundgren-Cayrol for her helpful comments on an earlier version of this text.

Utilizing Electronic Portfolios in Teacher Education Programs
Constance Geier, Ed.D.
Northern State University, Aberdeen SD

The School of Education at Northern State University in Aberdeen, South Dakota has implemented the electronic portfolio as an assessment tool and as a means of integrating technology throughout teacher education. The electronic portfolio offers a unique opportunity to build preservice teachers' proficiency with technology as well as showcase their expertise in teaching.

The portfolio concept is very popular in education today—and for good reason. First, today's educators have embraced constructivism—the belief that teaching is an active and learner-centered process. This philosophy recognizes that students build their own understanding of the world by using what they already know to interpret new ideas and experiences. Constructivists emphasize not only what students know, but what they do.

Secondly, the growing interest among colleges of education in performance assessment makes a transcript of grades and a score on the National Teachers' Exam (NTE) seem inadequate indicators of competence. A wise person once said: "There is a lot of difference between naming the tools and building the house."

And thirdly, there is stiff competition for teaching jobs in most areas of the country. It is imperative that prospective teachers be able to demonstrate their teaching competence in concrete ways—to university faculty, to prospective employers, to policy makers at the state and national levels, to parents, the media and the general public.

Why electronic portfolios rather than the paper versions? Electronic portfolios emphasize process as well as product and are multi-sensory in nature, including images, sound, video, text, and multimedia products. It's more fun to see a great bulletin board than to read about it, and it's more effective to hear a university supervisor talking about a preservice teacher's strengths than to read a letter of recommendation. In addition, electronic portfolios facilitate the integration of technology throughout the teacher education program; they provide students with exposure to a wide variety of technology experiences—all in the context of teaching and learning.

The critical phases of portfolio development are collecting, selecting, and reflecting—but the process actually has many phases. Burke, Fogarty, and Belgrad (1994) proposed ten: projecting, collecting, selecting, interjecting, reflecting, inspecting, perfecting, connecting, injecting (and ejecting), and respecting.

As students think about what entries they will collect, how to select those that best convey their abilities, and how to present what they have learned, they are constantly reflecting. Reflective thinking (as defined by Dewey, 1933) is the ability to give serious and persistent consideration to a subject in order to act deliberately and intentionally rather than routinely and impulsively. If teacher educators want preservice teachers to move beyond non-reflective reliance on impulse, tradition, and authority, opportunities for reflection must be provided throughout the teacher education program.

After piloting the use of electronic portfolios with twelve teacher education students during the 1998-1999 academic year, the School of Education at NSU began implementing electronic portfolio components into teacher education methods courses. The model used for electronic portfolio implementation solicited proposals from faculty members interested in integrating electronic portfolio components into their methods classes. Faculty received monetary compensation for the creation and integration of electronic portfolio components into their courses.

Each student-created electronic portfolio is original; portfolio components are designed to address one or more of the ISTE National Educational Technology Standards (NETS) and performance indicators for teachers. In addition, students must address each of the five categories of the knowledge base for teacher education at NSU: Knowledge of Self as an Individual, Knowledge of Content, Knowledge of the...
Electronic portfolios have been a part of the teacher education programs at Northern State University for four years; current efforts have focused on assessment of the electronic portfolio process and product. Teacher education graduates are asked to complete a self-assessment survey of their technology expertise and their comfort level with technology integration. During their professional semester, preservice teachers showcase their electronic portfolios and receive feedback from university faculty members. Electronic portfolio components are then assessed to determine whether appropriate opportunities have been provided for students to meet the ISTE National Educational Technology Standards (NETS) and performance indicators for teachers as well as the required program outcomes for teacher education graduates of NSU.

This presentation will focus on data collected from the self-assessment surveys as well as the results of the electronic portfolio assessment. Specific components of original student-created electronic portfolios addressing one or more of the ISTE standards and meeting one or more program outcomes will be shared along with accompanying assessment tools, including a newly-developed holistic rubric.

Dr. Constance Geier is an Associate Professor of Education at Northern State University in Aberdeen, South Dakota. She has been at NSU since 1991 and has taught courses in Educational Psychology, Educational Assessment, and Educational Research. She currently serves as NSU's LOFTI Coordinator. LOFTI is a $10 million federal technology challenge grant administered by the United States Department of Education. LOFTI standards for Learning Organizations for Technology Integration, and NSU is one of numerous partners in the five-year grant.
Teaching Programmers/Designers Flash/ActionScript

Gregory P. Garvey
Department of Computer Science and Interactive Digital Design
Quinnipiac University
United States
greg.garvey@quinnipiac.edu

Abstract: This demonstration presents a constructivist approach to teaching web design skills, 2D animation, basic scripting and programming concepts using Macromedia Flash and ActionScript. The overall curriculum is discussed followed by an examination of two courses that focus on teaching Flash and ActionScript accompanied by demonstrations of tutorials and projects, which incorporate meaningful content provided by on campus institutions. The teaching approach is informed by theories of multiple intelligence and address different styles and rates of learning by featuring learner centered, hands-on tutorials, which emphasize learning by doing.

Background

In the fall 2001 Quinnipiac University introduced a new major in Interactive Digital Design to complement the major in Computer Science. Both programs are under one department in the College of Liberal Arts. The Computer Science Majors are provided with a foundation in Computer Science within the framework of a traditional Liberal Arts education that prepare graduates for success in a wide variety of Internet and computer related fields.

The Interactive Digital Design major provides students with in-depth hands-on experience in creating, designing and authoring original interactive media for CD-ROM, DVD, the World Wide Web, and desktop presentation. This major emphasizes artistic creativity, experimentation and technological competence grounded in a critical understanding of the arts, design and related areas of the humanities.

Approach

The program features a core set of requirements open to majors, minors and qualified non-majors. Because of this diverse clientele, the tutorials must address different styles and rates of learning. Teaching is informed by Howard Gardner (Gardner, 1985) theory of multiple intelligences and Robert Sternberg’s Triarchic Theory of Intelligence (Sternberg et al., 2000). Tutorial projects incorporate content based on university-affiliated institutions, which develop Sternberg’s triad of practical, creative and analytical skills. Demonstrations include sample projects created for the Albert Schweitzer Institute and the Service Learning Program at Quinnipiac, which is part of the national Campus Compact. Experience shows that the integration of this value rich content leads to a greater student engagement and commitment. Students enrolled in IDD 301 2D Animation thereby develop cognitive tools for working with image, text, motion, sound and interactivity guided by design principles. Project based learning is incremental trial and error i.e. learning by doing. IDD: 315 Scripting for Interactivity introduces advanced scripting including control structures, objects and classes, properties and methods, expressions and variables, conditionals, arrays, functions, handlers, smart movie clips, while using debugging and content management tools of FLASH.

Each new programming concept is always incorporated in a tutorial as part of a larger design problem. In turn the final goal is to instill an overall cyberliteracy such as advocated by Laura J. Gurak (Gurak, 2001). This instills recognition that: “on the internet, communication is a blend of oral, written, and visual information.” This cyberliteracy is matched an critical awareness that is fostered by working with real world content such as that provided by the Albert Schweitzer Institute as part of a true liberal arts education.

Reducing the Cognitive Load on Novice Programmers

Stuart Garner
School of Management Information Systems
Edith Cowan University
Western Australia
s.garner@ecu.edu.au

Abstract: Computer programming is a domain of knowledge that is generally considered difficult by students, many of whom experience low levels of achievement and become disillusioned. This paper suggests that cognitive load theory needs to be taken into account when designing instructional materials for this domain. The cognitive load that is experienced by a student can be considered to be made up of three types: intrinsic, extraneous, and germane. Computer programming has a high intrinsic load and it is therefore necessary to reduce the extraneous load as much as possible by using techniques such as the study of programming examples. Germane cognitive load can then be applied by removing certain parts of the solutions to the examples and then requiring students to complete these part-complete solutions thereby encouraging schema creation in longterm memory. A new software tool called CORT (Code Restructuring Tool) has been created which utilises this part-completion method.

Introduction

In education, certain subjects require problem solving skills and are considered by many students to be inherently difficult. An example of such a subject is software development and this requires students to be able to analyse problems and then design and implement solutions in a computer programming language. It has been observed that a large number of students achieve only low grades and become disillusioned with the subject, for example Perkins, Schwartz, & Simmons (1988) state that:

Students with a semester or more of instruction often display remarkable naivete about the language that they have been studying and often prove unable to manage dismayingly simple programming problems.

Also, King (1994) states:
Even after two years of study, many students had only a rudimentary understanding of programming.

One of the reasons for the above is that students experience a very high cognitive load during their learning and this paper proposes that cognitive load theory needs to be carefully taken into account in the design of learning materials and tools for such problem solving domains. The paper then describes a software tool called CORT (Code Restructuring Tool) that has been built by the author and used with novice programmers at a university in Australia.

Cognitive Load Theory

Cognitive load theory is built upon the idea that working memory is limited to around seven chunks of material (Miller, 1956) and that people can only deal with two or three elements simultaneously. The degree of interactivity between the elements also affects the capacity of working memory.

Chess playing can be considered a problem solving domain and research (Chase & Simon, 1973) showed that the main difference between novices and experts was the fact that the latter had thousands of board configurations, as many as 100000 (Simon & Gilmartin, 1973), stored in long-term memory within schemata. The consequence is that, unlike less-skilled players, experts do not have to spend as much time searching for good chess moves using their limited working memory. Similarly, research into problem solving (Carroll, 1994) confirmed that, compared to novices, experts have knowledge of an enormous number of problem states and their associated moves. Such states are within long-term memory and such research indicates that human problem solving comes from stored knowledge and not from complex reasoning within working memory. It is
suggested that humans are poor at complex reasoning unless most of the elements with which we reason are already in long-term memory, working memory being incapable of highly complex interactions using novel elements (Sweller, van Merrienboer, & Paas, 1998). This means that novices who are attempting a problem must engage in complex chains of reasoning using their working memory and in doing so it is likely that working memory will be overburdened. In other words the cognitive load on novices is too great.

Ways in which cognitive load can be reduced for novice problem solvers are therefore very important.

In the schema theory of model representation, a schema can be anything that can be treated as a single entity or element such as a mathematical formula or a particular programming algorithm. Schemata have the function of storing knowledge and reducing the burden on working memory.

Experts can process information relevant to their domain automatically, novices however having to process information consciously (Schneider & Shiffrin, 1977; Tindall-Ford, Chandler, & Sweller, 1996). An example of such automatic processing is that of the expert driver who can drive their car without apparently thinking, whereas a learner driver has to consciously think of several things at the same time such as depressing the clutch and shifting to a new gear, observing the road ahead, moving the steering wheel etc. Any instructional design for a domain has to therefore not only encourage the construction of sophisticated schemata but also encourage the automatic processing of those schemata. This is important because of the limited capacity of working memory that can only deal with a few schemata at the same time. The ease with which information can be processed in working memory is the main thrust of cognitive load theory.

Computer programming is a domain with a high intrinsic cognitive load and this needs to be recognised in any instructional design. The intrinsic cognitive load cannot be reduced, however something can be done about the extraneous cognitive load.

Intrinsic Cognitive Load

Intrinsic cognitive load is determined by the mental demands of the task (Chandler & Sweller, 1996). Some material has very low cognitive load and an example is the learning of the basic vocabulary of a foreign language. Each element or schema is independent from the others with no interactivity and subsequently the required mental processing, or intrinsic cognitive load, is low. Tasks that have low element interactivity can be learnt serially rather than simultaneously. Tasks with a high degree of element interactivity have a heavy intrinsic cognitive load and an example is the learning of the grammar of a foreign language as all the words in phrases need to be considered, that is processed, at once.

Extraneous Cognitive Load

Extraneous cognitive load is generated by the instructional format used in the teaching and learning process and poor design leads to a high extraneous cognitive load. If a high extraneous cognitive load is combined with a high intrinsic cognitive load then this can lead to working memory overload. This is often what happens with novice programmers when the instructional design is poor.

The important point is that when the intrinsic cognitive load of the material is high, then it is incumbent on the instructional designer to think very carefully and ensure that the extraneous cognitive load is as low as possible. A lot of research has been done in looking at ways of reducing extraneous cognitive load, for example (Chandler & Sweller, 1991; Kalyuga, Chandler, & Sweller, 1998; Marcus, Cooper, & Sweller, 1996; Sweller, 1994; Tindall-Ford et al., 1997). These include: integrating diagrams and text so as to reduce the “split-attention” effect; goal-free problem solving; and the use of worked examples in problem solving.

Germane Cognitive Load

More recently, the concept of germane cognitive load has been introduced into cognitive load theory (Sweller et al., 1998) It is thought that if the instructional design is such that the extraneous cognitive load is kept to a minimum, and the intrinsic cognitive load is not too high, then there may be some unused working
memory available. This could then be used by learners, with appropriate instructional design, to engage in conscious processing that helps in the construction of schemata in the particular domain of interest. This conscious processing is the germane cognitive load. An example is the use of part-complete solutions in the learning of problem solving (Paas, 1992; van Merrienboer, 1990; Van Merrienboer & De Croock, 1992). The studying of complete worked examples by students is seen as one way of reducing the extraneous cognitive load. When students have to complete an incomplete worked example then they have to “mindfully abstract” the schemata from the example in order to understand it. That is, they have to consciously process it and this increases the germane cognitive load. Figure 1 shows the relationship between the various cognitive loads in the domain of programming.

![Diagram showing the relationship between the various cognitive loads in the domain of programming.](image-url)

**Figure 1:** Cognitive load relationships in programming

**Use of Worked Examples and Part-Complete Solutions in the Teaching and Learning of Programming**

The “Reading” approach to the learning of programming makes use extensive of worked examples in an attempt to reduce the extraneous cognitive load on novices. A lot of the work in this area has been carried out by van Merrienboer and his colleagues (van Merrienboer, 1990a; van Merrienboer, 1990b; van Merrienboer & Paas, 1990c; van Merrienboer & De Croock, 1992; van Merrienboer, Krammer, & Maaswinkel, 1994). They argue that the traditional approach to the teaching and learning of programming is ineffective and that the “Reading” approach is a better one to follow. However, they also suggest that presenting worked examples to students is not sufficient as the students may not “abstract” the programming plans from them. Programming plans can be considered analogous to the chess of board configurations mentioned earlier. “Mindful” abstraction of plans is required by the voluntary investment of effort and the question then arises as to how we can get students to study the worked examples properly. In practice, students tend to rush through the examples, even if they have been asked to trace them in a debugger, as they often believe that they are only making progress in their learning when they are attempting to solve problems.

Such conscious processing by students places germane cognitive load upon them. One suggestion is that students should annotate worked examples with information about what they do or what they illustrate (Lieberman, 1986). Another suggestion is to use incomplete, well-structured and understandable program examples that require students to generate the missing code or “complete” the examples. This latter approach forces students to study the incomplete examples as it would not be possible for their completion without a thorough understanding of the examples’ workings. An important aspect is that the incomplete examples are carefully designed as they have to contain enough “clues” in the code to guide the students in their completion. In other words, the germane cognitive load must not be made too large. It is suggested that this method facilitates both automation, students having blueprints available for mapping to new problem situations, and schemata acquisition as they are forced to mindfully abstract these from the incomplete programs (van Merrienboer & Paas, 1990).
In one study, two groups of 28 and 29 high-school students from grades 10 to 12 participated in a ten lesson programming course using a subset of COMAL-80 (van Merrienboer, 1990b). One group, the "generation" group, followed a conventional approach to the learning of programming that emphasised the design and coding of new programs. The other group, the "completion" group, followed an approach that emphasised the modification and extension of existing programs. It was found that the completion group was better than the generation group in constructing new programs. It was found that the percentage of correctly coded lines was greater and that looping structures were more often combined with correct variable initialisation before a loop together with the correct use of counters and accumulators within the loop. It would appear that the completion strategy had indeed resulted in superior schemata formation for those students within that group. In addition, the completion group used superior comments in connection with the scope and goals of the programs, indicating that they had developed better high-level templates or schemata. It was noted in the study however that both groups were equal in their ability to interpret programs and that this might indicate that students in the completion group do not understand their acquired templates.

A side effect of the research was also noted. The drop-out rate from the completion group was found to be lower than for the generation group, particularly for female students with low prior knowledge. It was suggested that perhaps the generation of complete programs is perceived as a difficult and menacing task and that the completion strategy overcomes this difficulty.

CORT (Code Restructuring Tool)

A tool has been designed by the author that is based upon the above ideas of the completion of part-complete programming solutions. Three methods of using CORT have been identified that allow various degrees of germane cognitive load to be applied and the tool has been utilised with students at Edith Cowan University in Australia, student feedback being extremely positive.

CORT has been used within a software development unit in a Business degree course. This unit is an introductory unit to programming in Visual BASIC, the majority of students having no previous programming experience. The unit runs over a period of 14 weeks, the students having a two-hour lecture and a one-hour computer laboratory session in which they attempted various "CORT" problems. The students would then finish their problems if necessary in their own time.

A Typical "CORT" Computer Laboratory Session

At the beginning of a computer laboratory session, the students are given a hard copy of a problem statement that they have to try and solve using CORT. The students would then run the CORT program and load in the CORT file corresponding to that particular problem. Two windows display a part-complete solution to the problem together with possible lines to be used as shown in figure 2.

The part-complete solution on the right is then completed by moving certain lines from the left hand window. Lines can also be moved up or down, and indented or outdented in the right hand window. Some problems may have too many lines in the left hand window, some of those lines being incorrect. In addition, there is a simple editor to allow the amendment, addition, and deletion of lines of code.

When the solution has been completed, the code from the right-hand window is copied to the Windows clipboard. Visual BASIC is then run and a file is loaded which contains no programming code but does contain the necessary Visual BASIC interface for the problem under consideration. The CORT code is then pasted into Visual BASIC and the program tested. Use is made of the trace and debugging facilities of Visual BASIC, these facilities providing an insight to the workings of the notional machine.

If the program does not work, a student can switch back to CORT and make any necessary changes before retesting that code in Visual BASIC.

Methods of using CORT

Three methods of using CORT were identified and these different methods were varied throughout the unit so that different levels of germane cognitive load could be applied. The first method is to supply all the missing lines of code in the left-hand window without any extra lines. The second method also supplies all the missing
lines of code but also includes extra "distracter" lines of code that are not required to complete the program solution. Finally the third method is to supply only some of the lines of code in the left-hand window, students having to key-in some lines themselves.

Figure 2: CORT interface

Preliminary Feedback from Students

Data was collected on the use of CORT during semester 2, 2001. Preliminary results suggest the following.
- Students commented on the fact that CORT provides a starting point for solving a problem. Many suggested that they would not know how to go about tackling some of the problems if CORT was not provided.
- Method 2 of using CORT proved to be most popular. Method 1 was seen by students as being too easy while method 2 required students to think a great deal about the problem solution. Method 3 was not as popular as that required students to have knowledge of the exact syntax of statements.
- It was observed that students engaged in significant reflection and higher order thinking when using method 2.
- Students commented that they were encouraged and motivated by the fact that they could get their programs to work in a relatively short time frame.

Conclusions

This paper argues that cognitive load theory needs to be carefully taken into account when designing instructional materials for computer programming. Programming has a very high intrinsic cognitive load and therefore the extraneous cognitive load should be made as low as possible. However we still need to ensure that students "think" and are encouraged to create the necessary schemata in long term memory and this can be done by applying germane cognitive load upon them. One way of doing this is to carefully design solutions to problems that are only part complete and that require completion by students. This approach has been built into a new software tool called CORT (Code Restructuring Tool) (Garner, 2000) that reduces the extraneous cognitive load by supporting the completion approach to learning programming. Three methods of CORT have been identified and preliminary results suggest that method 2, in which all missing lines plus distracters are available in the left-hand window, has great potential for providing the necessary amount of germane cognitive load to help students develop the necessary programming schemata.

Abstract

In a Medical School the future cardiologist's education is made being considered theoretical aspects of the specialty and of the medical practice. In what it refers to the theoretical aspects of the teaching, an important resource is the discussion of scientific papers in cardiology. These papers describe real researches, approaching the used methodology, obtained results, statistical analysis and works related to the same. This work describes a support environment to the discussion of papers in cardiology, called CardioMeeting. That environment is integrated into an education meta-environment for cardiology, CardioEducar also described in this work.

1. Introduction

Within the medicine course, the cardiology teaching takes place in different moments. In the first years of the course, the student is exposed to the methods diagnoses. In the fifth and sixth year they participate in medical aid in the internship over different areas in a hospital.

Besides that, a fundamental moment in the training of the future cardiologist is the medical residence. After two years of residence in a medical clinic, the resident is linked into a unit of cardiology where they develop health care activities, receiving specific education in cardiology. This education and training feels through patients' care, and
the attendance of classes and of sessions where students, residents and cardiologists discuss patients' cases and current themes of the specialty. The Unit of Cardiology and Cardiovascular Surgery / Fundação Bahiana de Cardiologia (UCCV/FBC) of the Federal University of Bahia (UFBA) participates in the cardiologists' education through the Medical Residence, several undergraduate disciplines of the Medical School, and in the internship. Many classes are for discussion of scientific papers previously distributed to the students.

With the purpose of supporting these different aspects of cardiology training, we have launched a project - CardioEducar - whose purpose is to develop a learning environment based on the Internet. CardioEducar, an educational meta-environment, offers an integrated environment where professors, cardiologists, physicians and students have access to several educational environments. As a meta-environment CardioEducar comprises several working environments for cardiology education.

Within these environments of CardioEducar we have a set of environments we call Learning Environments that aim to support the different meetings where cardiologists, residents and medical students participate in order to teach and learn.

One of the most important aspects of medical students' education deals with reading and discussion of scientific papers. In our Medical School this education is performed through specific meetings with the following objectives: (i) to teach medical students how to read and to criticize cardiology papers; (ii) to teach the students the information they should look for as a justification (evidence) for their research and medical decisions; (iii) to show the students how to co-relate results from different works and to relate them to medical practice. This kind of meeting takes place every week at the University Hospital and it was ministered without technological support. The students were supposed to read the papers previously to a classroom meeting, to take notes and to prepare some questions for discussion. During the meeting, one of the students makes a summary of the paper and the professor leads the discussion and answers the queries. Usually, the professor relates the paper under discussion with other papers and researches results already discussed in previous meetings. However, there was no registration of the whole discussion and the students of subsequent groups cannot benefit from discussions already accomplished.

This was the motivation for CardioMeeting, an Internet based environment whose main goal is to support medical education on this specific meeting. In the following sections this environment will be described.

2. CardioMeeting

The main goal of the CardioMeeting system is to provide a technology support to the discussion session, since the planning of the discussion to the classroom meeting. It is composed of four main environments: the Authoring Environment, the Discussion Environment, the Meeting Environment and the Tutorial Environment (Figure 1).
The **Authoring Environment** supports a professor (the coordinator of a paper discussion meeting) in the organization of a discussion meeting. It offers facilities for introducing data of a single paper or a theme that involves more than one paper related to a subject. These data concerns in indicate the papers (by its reference) and to prepare some questions for discussion. The coordinator may also assign a student to use this environment to provide more details about the papers to other participants (for example, the abstract). Figure 2 shows a screen of the Authoring Environment.

**Figure 1:** The homepage of CardioMeeting with the four environments

**Figure 2:** Authoring Environment: Sessions’ Planning
The **Discussion Environment** monitors an asynchronous discussion among the students and the professor for a certain period of time as a preparation for the classroom meeting. This discussion may involve the questions posed by the professor, doubts, and debate about the limitations of the work presented in the paper, comments about the methodology and indication of related works. The discussions are asynchronous to provide more flexibility for the students to use the environment according to their possibilities and preferences. Figure 3 shows a screen of the Discussion Environment.

Figure 3: Preparation for Discussion Environment: methods and Methodologies

The **Meeting Environment** supports the classroom meeting, which aims to synthesize the discussion that took place during the preparation stage, and to reach a conclusion about the paper or the theme proposed. In this sense, this environment permits to register the final analysis of the discussion and also to retrieve information of past discussions. Figure 4 shows a screen of this environment.

Figure 4: Discussion Environment: Final Analysis of a paper
The Tutorial Environment organized in html pages supports medical students' education giving directions on how to read medical papers and is specifically concerned on topics related to the material and methods used in the research being described in a the paper.

3. Conclusion

CardioMeeting was developed by a multidisciplinary team of cardiologist, and computer science specialists, as part of a collaborative project (CardioEducar) sponsored by the Brazilian government. Other Learning Environments developed and integrated to the meta-environment CardioEducar are already in use with great acceptance (Gama et al., 1997), (Rocha et al., 2000), (Rabelo et al., 2001)

All the environments were implemented using ASP (Active Server Pages) as the web programming language. The cases are stored in a Microsoft SQL Server Database. CardioMeeting was developed according to a software process with an evolutionary approach, specifically defined for the CardioEducar project. A first prototype was built and after its evaluation by faculty members, cardiologists and students we have implemented the first operational version that is now in use in our University Hospital.

The utilization of the CardioMeeting showed us an increase of the participation by the students. The promotion of a computer-based discussion demonstrated more acceptances for some people than the one face-to-face. This aspect encouraged some of students to raise more questions before the classroom meeting. This environment also permitted some physicians of the institution to participate of the discussion, in case of they were not able to be present on the classroom meeting.

Acknowledgements

It is ironic that often the biggest problems computer information system students encounter in graduate school is not with their software development projects. This paper addresses one of the biggest problems that computer information system students encounter...how to work with other members of a group on a project. Research was conducted over eighteen months with two instructors, one from the computer information system department, and one from the instructional technology department of a public university located in the southwestern United States. This is an ethnographic research project, with qualitative methodology. The authors chronicled the events of each team and analyzed the events and results of each group studied throughout that period. The results of the study can contribute to further research on how collaborative teamwork can facilitate better understanding and comprehension of the requirements for graduates of computer information systems graduate programs.

The two instructors decided to monitor graduate students in the computer information systems capstone graduate projects. These students must complete a major software program development project in lieu of a masters’ thesis, and they must do so while working in teams, much like they will do in the realm of commerce after they graduate.

The instructional technology instructor served on each of the four teams over the eighteen-month period, acting as a mentor to a capstone group each semester, and participating in the dialogue and development processes of the project. Both instructors learned that, despite the programming and management information system classes taken by the students, the actual integration of what the students’ studied often did not relate to what they were doing in these “social” development team projects. The instructors observed that the computer information systems students (CIS) often entered the collaborative team environment with a preconception that their knowledge would be received without question, as a “top down” event. Seldom did students enter the group with an open-minded, receptive mind set. It quickly became clear to the students, however, that to survive the group and emerge with a product for the project, a shift would need to occur in the minds of the CIS students with respect to actually applying what they learned to the social context of software development teams. At the end of each semester, students would somberly admit that there was much more to working in software teams than simply developing software in the protected environment of university labs.
The two instructors would meet several times a month and compare notes as to how the students were progressing and whether they were working satisfactorily with other group members. In one instance, over a summer semester, the group actually fell apart due to the inability of the members to coordinate their schedules. In this instance all of the group members' efforts were frustrated because they were not able to meet together on an ongoing basis. As a result their project suffered and so did their grades. The instructional technology researcher chronicled the discussions and decision-making processes of each group, then, at the end of the semester, convened with the CIS instructor to assess what worked successfully versus what could be done better with the next crop of students the next semester.

What the researchers discovered was that: first, each group dynamic was truly unique and the products created were unique, even though the same assignment was given to a new group at the start of the new semester; second, the more flexible and willing the CIS students were to work with other team members often determined how much was accomplished on the project and how quickly it was done; third, when collaboration did not emanate from members in the team context, less work on the project was accomplished; when a CIS student had a positive attitude and was willing to be flexible about discussing how the programs could be created, it seemed that she/he enjoyed better rapport with the group and the group also seemed to accomplish more on the project.

By working together and demonstrating that collaboration worked between the two instructors from different departments, the students had an example of how people from different environments can come together and work toward a common goal. This point was missed at times by the students, but by the end of the semester when they were accountable for their grades, they quickly figured out how to work collaboratively, as best they could under the circumstances. The two instructors also presented a united front when reviewing the projects for completeness and for the decision of the students' final grades. The students emerged from the experience with knowledge gained from the collaborative process, both in their collaborations with their development team, and with the development team instructors.

Software engineering programs have utilized the collaborative team approach for years, but computer information systems programs are now beginning to understand the importance of collaborative modeling for their students. Collaboration in development teams could also offer insights to other academic disciplines, like Instructional Technology, because each team member brings a unique perspective as well as expertise to the team project.

Future studies of the role of collaboration and team-building in postsecondary environments, particularly in the computer science and instructional technology areas, could greatly contribute to the body of knowledge on mentoring and collaboration for computer information systems' studies.

Today, the Internet is a part of a new educational culture with its own unique characteristics. Online education is attempting to fill a niche in the changing nature of education around the globe specifically in the area of higher education. Consequently, many traditional educators are either considering or making the transition to the online medium. Educators are coming under increasing pressure to adapt their teaching to accommodate the new technologies.

This study focuses on a single, but arguably the most important area – teaching via the Internet. Towards this focus, faculty members from various universities and departments were interviewed to look at the many different ways the Internet is being used for teaching, and faculty experiences in that regard. The lessons they have learned over the years provide valuable insight into new, more effective ways of teaching students in the online environment. The term 'Online teaching' here means teaching and learning that takes place over a computer network of some kind (e.g. an Intranet or the Internet) in which interaction between people is an important form of support for the learning process (Goodyear, et. al. 2001).

This study is an investigation of the perceptions of higher education instructors about teaching courses via the Internet. Qualitative methodology was used to determine issues important from the perspective of the participants (Bogdan & Biklen 1992). Analysis was conducted using the grounded theory methodology, also referred to as constant-comparative method (Glaser & Strauss, 1967). Through this study, several themes emerged - Time, Instructional tools, and student-faculty relations. The findings and possible implications in teaching will be presented at the Conference.

Abstract: In this paper we introduce a Web-based tandem system which helps to establish language learning partnerships between people who prepare for the exam in bilingualism in South Tyrol. The system will be integrated as a module into the ELDIT language learning system which already includes a small text corpus and a learner's dictionary. The new module supports the formation of partnerships and the exchange of information including exercises between learning partners for the purpose of error correction and feedback. Adaptation technologies are applied in order to support autonomous use of the program.

Motivation

South Tyrol is a bilingual province located in the north-east of Italy with two official languages, German and Italian. Due to a rather strict geographical and social separation of the two ethnic groups, only a few people consider themselves truly bilingual [Cavagnoli & Nardin, 1999]. Passing the so-called examination of bilingualism, however, is a prerequisite for employment in the public sector.

Learning a language via tandem means that two learners with different native languages try to learn the language of their partner by having controlled conversations with each other. Such contacts and conversations can also occur via electronic media such as e-mail, chat, or video conferencing. These media offer new possibilities to overcome problems like spatial and temporal distances.

The eTandem System

To overcome some of the above mentioned problems and to facilitate language learning in South Tyrol, we are currently developing a Web-based tandem system, called eTandem. The eTandem system will be integrated into the ELDIT language learning system which already contains a learner's dictionary and a text corpus [Abel & Weber, 2000, Gamper & Knapp, 2002]. In this way, eTandem provides access to the preparation material for the exam in bilingualism and provides opportunities to establish language learning partnerships between the German and Italian population.

The eTandem system can be accessed via the following pages:

- Advertisement page: This page serves either to advertise interest in a learning partnership or to contact somebody else who already announced interest in a partnership. Furthermore, information about the preferred date of the exam or personal learning interests can be indicated.

- Text page: On this page the user can practice a text. Every word in a text unit is linked to the corresponding ELDIT dictionary entry. This facilitates to check unknown words or to lookup for words which the learner may need to answer the queries in the target language. Each text contains a couple of questions which the learner has to answer, producing in this way complete sentences in the target language. As long as no partnership is established, the texts can be saved as drafts and sent later.
• **Mail page:** This page provides a communication forum between learning partners. After working through a text unit, the learner can send the answers to the partner for correction. Similar, the messages from the learning partner arrive on this page. Furthermore, short messages such as comments on the work done or organisational aspects can be exchanged in this forum.

• **User profile page:** On this page each learner can inspect and change the parameter values set in the user model. Evaluations of adaptive systems revealed that it is extremely important that the user has control about the system. Therefore, we want to make the modeling and adaptation process as transparent as possible.

• **Help page:** This page explains the exam in bilingualism and the usage of the program. Depending on the learner’s familiarity with the use of computers the online help is more or less detailed. Moreover, for a novice a number of direct links to the corresponding help sections are provided.

Unlike other tandem systems, eTandem is intended to be used fully autonomously via the WWW. Therefore, a variety of users will access it. The eTandem system adopts adaptive technologies in order to cope with the problem of user diversity. A user model stores information about the users and his/her interaction with the system, which allows the system to adapt to the individual learner. When accessing eTandem for the first time, an introduction page will be shown and substituted by a link later on. Advertisements and the exam level are adapted to the individual learner, and a “What shall I do next?” suggests the best next step to be carried out. Adaptive features are also included in the other modules of ELDIT and are described in [Gamper & Knapp, 2002].

**Discussion**

Computer-assisted language learning is a widely explored research field. Language learning via e-mail conversations has been explored in several successful projects. Since 1994, universities and other educational institutions from many different countries work together in the “International Tandem Network” in order to help their students to learn languages via tandem, primarily via the Internet [Brammerts, 1994]. “Number2.com” is an Internet site which provides online preparation for college admission and placement tests. A coaching system is included. Teachers and parents can register as coaches. Their job is to provide encouragement and to help students to set goals. Coach and student can also work together on the tutorials and practice sessions [Crespi et al., 1995].

According to our opinion, the eTandem system will provide a great opportunity for the population in South Tyrol to learn and improve the second language. As computer-assisted language learning has been proven to be motivating for language learners, especially for young people, this could also be a contribution to overcome geographical and social separation of the two ethnic groups. The eTandem system is currently under development together with the other modules of ELDIT. A preliminary version of ELDIT can be accessed at http://www.eurac.edu/Eldit. A systematic evaluation of the overall system and in particular of the eTandem module remains future work.

Abstract: Based on the research of [Stil 1998] [Maurer 1992] [Lennon 1994] [Elliot 1995] [Colbourn 1995] [Reeves 1997] [Lugner 1997], the application of an expert system as an interactive multimedia knowledge module with explanation features named Virtual Tutor (VT) was developed. For students, the individual dialogue based session with the VT, provides the possibility to apply the knowledge acquired in combination with indirect assessment. The VT was further embedded in the Web-based on-line learning environment. The reported research merges qualities of an expert system with advantages of multimedia, thus creating a variety of innovative ways of knowledge mediation.

Based on the evaluation results the conclusion can be drawn that dialog based system meets more accurate the requirements of the students in case of solving problems. Problem solution can be found easier and faster than using conventional literature. The possibility of accessing additional information related to the subject domain and explanation on request, VT is an interesting and different tool for knowledge transfer.

Introduction

Higher education has entered a transition from the Teaching Paradigm to the Learning Paradigm. Emerging from this process are powerful new teaching styles founded on principles of active-learning and improved insights on the cognitive development of learning. As outlined in [Buckley 1999], learning environments that exploit interactive multimedia are of special interest. The educational potential of this technology closely parallels the pedagogical goals of the Learning Paradigm. According to [Buckley] a simple pedagogical set of features that can foster transition to the Learning Paradigm is as follows: (1.) Interactivity fosters active learning, (2) The sensory-rich nature of technology facilitates the engagement of additional powerful cognitive processes, and (3) Integration of assessment tools into the environment can provide students with feedback and encouragement etc.

"From a pedagogic point of view, learning requires "a deep understanding of the subject content" through a cognitive re-elaboration of the information" [Colbourn 95]. Inspired by the work of Mark&Greer 1995, Chan 1996, Youngblut 1994, Nunez concludes [Núñez 1999] as follows: "Knowledge-based learning environments have offered significant potential for fundamentally changing the educational process."

In general, classical Web-based tutoring systems rely on memory and do not take into account the cognitive information treatment process. In order to overcome this problem, the intelligent tutoring systems came into being, as described in [Han 1999]. The use of multimedia objects in educational systems can enhance their efficacy to a great extent in facilitating cognitive skills besides other components of domain competence as shown in research by Kinshuk [Kinshuk 1999].

Idea of the Virtual Tutor

The aim of the research presented in this paper was to apply an expert system as a knowledge module within the on-line learning environment. There are many benefits for the students within the on-line learning environment independent from the course content and style, like e.g. tools for asynchronous and synchronous communication and collaboration, search facility within a background library, a progress indicator monitoring the learning success etc. The application of ES makes it possible to use different knowledge representation and explanation approach. The individual session
with the VT provides also the possibility for students to apply the knowledge acquired in combination with indirect assessment.

With interactive sessions with the VT, various students' activities could be increased as follows: raising the learning motivation, research work, stimulating the creativity by carrying out analysis and synthesis, searching for solutions, interdisciplinary learning.

VT system requirements are as follows: (1) the interaction and the communication should be performed by a question-answer dialog, (2) the system has to explain why a particular question is asked (i.e. why a certain fact is questioned) and the influence of the fact on the problem solution, (3) the VT must be capable of explaining reasons for the suggestion of a solution or a particular ranking of possible solutions, (4) descriptions and illustrations of items concerning the problem domain have to be provided by hyperlinks connecting the multimedia information within the static and dynamic background library, (5) the system has to run at least under Netscape 4.x and MSIE 5.x, (6) the VT has to be designed and implemented considering the possibility of the easy change of the problem domain as well as easy enhancement within the same problem domain.

The Concept and the Architecture of the VT System

Following the requirements stated so far, we have decided to combine the properties of expert systems with the advantages of Web-based information transforming multimedia information structures. Because of this, as well as following also the ideas of platform independence and usage without installing the VT, the system was implemented in Java. The VT is built on JESS (Java Expert System Shell), a Java implementation based on Clips. [JESS] This makes it possible to provide the VT system as a Java applet within the GENTLE-WBT environment. It must be mentioned that the entire system (VT system, UI and the JESS system) has to be loaded by the client. To reduce network loads, a future implementation will be done by splitting the VT into a client-server architecture.

Within the following sections, the system and the working principle are discussed.

The Working Principle

The aims of the VT system within the course "Knowledge processing" are: (1) To provide Decision support of using proper AI techniques related to a particular problem. The first implementation takes into account expert systems, neuronal nets, fuzzy logic and neuro fuzzy. (2) An interactive system has to be provided. (3) The suggestion has to be explained by the system. (4) Additional descriptions and illustrations have to be provided by a static and dynamic background library of multimedia information.

To meet the aims stated above, the VT - in general expert systems - has to comprise three types of knowledge: Problem Domain Knowledge (PDK), the Description Knowledge (DK), and the Subject Domain Knowledge (SDK). Within the PDK the system has to know about various problem types that can be covered by the four AI systems, and thus to provide the proper questions (collect information about facts) for the user interaction. The DK is used to describe the results (suggestions of AI systems) and influences of facts on the particular problem. The SDK is responsible for reasoning and building suggestions. Furthermore, it controls the sequence of the questions related to already known facts[Pivec 1997].

The procedure of the working principle can be subdivided into three tasks (see also Figure 1): (1) Dialog between the user and the VT system. The student has to answer questions about the problem domain. (2) Internal representation of the problem. Related to the problem domain, an internal image of a particular problem is built by a set of attributes. For the first implementation the following properties are used to describe the AI problem domain: modularity, extensibility, mathematics model, expert knowledge, training sets, explanation, adaptive system, uncertainty, black box. The PDK and SDK components control the sequence of questions and change the internal representation. Weightiness of the attributes are changed (increase, equal or decrease) depending on the questions and the answers. That means that the properties are changed with respect to the facts questioned and the answers given by the students. (3) Suggestion of possible solutions. Based on the internal representation of the problem, the SDK determines a ranked output of the AI techniques. It is to be mentioned that it is easy to extend (e.g. enlarge the subject domain) or change the knowledge (e.g. to use the system for another course placed in another subject domain), because of the use of a knowledge-based system (expert system JESS). This makes it possible to change and maintains knowledge without changing the entire program.
The Architecture

The architecture of the VT system is illustrated in Figure 2. The JESS system contains three types of knowledge (PDK, DK, SDK) and manages the internal representation of the problem as well as processes the input and output stream of information. The parser within the output stream handles hyperlink information for the user interface (UI) of the applet. The hyperlinks are references to the static and the dynamic background library. For further work, it is planned that the pre-knowledge of the students is taken into account. This will make it possible to provide background information related to the current knowledge level of each particular student. A novice in AI will receive basic information, and an advanced student will get much deeper information. The UI represents the dialog between the students and the VT system.

As already stated, the VT system is integrated in the GENTLE-WBT [GENTLE] learning environment, as illustrated in Figure 3. The learning environment allows compiling courseware (lecture notes, exercises, etc.) and provides also diverse communication features (asynchronous discussion forum, chat, etc.). The decision was made to place the static background library into the GENTLE-WBT system. The static background library contains descriptions, definitions and illustrations concerning items of the AI techniques handled by the VT system. The information is prepared in multimedia modules using textual information, graphics, video files, and flash presentations. The later presentation form is used for an interactive information transfer.

Figure 3 also shows the interaction between the VT system and the lecture notes. For the first implementation of VT the existing lecture notes of “Knowledge processing” were applied. Hints at proper pieces of information refer to the VT system. Vice versa, explanations by the VT system also provide hyperlinks to subjects of AI techniques within the lecture notes. Students are enabled to work with the VT system and can get information or re-read topics of the lecture notes to get familiar with the relation and influences of a particular (given) problem.

The third part of referred information provided by the VT system is the dynamic background library. A huge amount of useful information is available on the Internet. The intention is to collect trustworthy information from university institutes, research centres, online libraries, company information, etc. related to the subject of the course. One of the advantages of including such a dynamic background library is that the students are supplied with up-to-date information. The xFIND (extended Framework for Information Discovery) system, an open source project developed also at the IICM, perfectly meets the requirements for such a dynamic background library. The dynamic background library has already been used in the course “Knowledge processing” for more than a year. The xFIND system is a highly scalable and distributed system for the management of online resources that consists of three components, the Gatherer, the Indexer and the Knowledge Broker. The system manages the content of Internet resources, and in addition a broad spectrum of meta information (xFIND quality metadata) about the resources. Thus, e.g. the topics, target audience, quality level, etc. of Web pages or entire structures of Web pages can be managed [xFIND]. The VT system requests information by a somewhat predefined dynamically compiled search query related to the topic or subject of interest. It is planned that the dynamic background library should provide different information related to the student overall performance. Such a feature has been already implemented in the xFIND system.

Evaluation of the System and Conclusions

The evaluation of the VT was carried out with students, as a part of the practical work within the course Knowledge processing at the Graz University of Technology. The students were divided into two evaluation groups: one group worked with a printed version of lecture notes, whereas the other group used VT to provide the solution to the presented problem. The group that worked with the VT had also access to the background library. The evaluation was carried out in parallel sessions.

The evaluation showed that the application of the VT is easy and the on-line help is sufficient. The most often applied system features were as follows: (1) - application of the explanation component, (2) - inquiring about rules. All students that worked with the VT solved the task correctly. Taking into the consideration the students' comments outlined later in this chapter, the conclusion can be drawn that when using the VT students have the possibility to interact with the knowledge in a different way as when using only the classical lecture notes. This makes it possible to provide different points of view of a problem domain and introduce more complex ways of reflection.
Figure 1: Working principle of the VT concept presented on the example of the AI domain of the course "Knowledge Processing". Students have to answer questions about facts, which describe the problem within the AI domain. The answers are used to build an internal knowledge representation. Based on the internal representation of the problem, the VT ranks suggestions of AI systems to be used for a particular problem.

Figure 2: The architecture of the VT system. The expert shell JESS manages the knowledge (PDK, DK, SDK, and IPR) of the system. The parser handles the hyperlink management referencing information from the static and dynamic background library. The applet represents the interface to the user.

Figure 3: System integration. The VT system is embedded in the GENTLE-WBT learning environment. It is rendered via the GENTLE-WBT Web gateway as a Java applet.

From students collected comments indicated that the group that worked with the lecture notes had time problems. They expressed that within the time given it was very difficult to find various parameters that were necessary to solve the task. In general, the comments reflected that because of the time limit, the knowledge processing was insufficient and relatively shallow.

Based on the evaluation carried out, the conclusions can be drawn as follows. Dialog based system meets more accurate the requirements of the students in case of solving problems. VT is an interesting and different way for knowledge transfer that provides help by problem solving. Problem solution can be found easier and faster than using conventional literature. VT provides explanation of solutions suggested and makes it possible to access additional information related to the subject domain. Besides conventional lecture, speeches and lecture notes, a VT-based subject domain presentation proved to be very helpful. To improve the knowledge transfer a range of exercises that have to be solved by the VT should be provided to students.

Designing Multimedia Presentations for the Learning Content

Guttormsen Schär, S., Krueger, H.
Institute of Hygiene and Applied Physiology,
Swiss Federal Institute of Technology, Zürich, Switzerland
e-mail: guttormsen@iha.bepr.ethz.ch

Abstract: This paper argues for changing design priorities in multimedia based e-learning design. Current multimedia research is media oriented, questioning which media to select for presenting information in general. The focus on media in this kind of research is converging at the same results: dynamic media are rarely reported more effective than static media. An important reason for the weak support for dynamic media could be that it often is implemented for unsuitable information contents. Multimedia design should start with a thorough analysis of the information content. We tested and found support for the following hypothesis in two experiments: information content and media should match on static and dynamic descriptions.

Introduction

Information presentation with multimedia is a challenge compared to traditional teaching and publishing methods. New information technology offers easy access to development tools for dynamic and visual ways of presenting information. Consequently, easy access to guidelines for how to employ dynamic media is important. Successful multimedia design does not result from the employment of dynamic media as such, but depends on a number of factors, of which effective media combinations, relationship between media and information content, individual characteristics of the learner and implementation and design of the presentations must be considered. This paper addresses particularly the employment of dynamic media (e.g. video, animations, voice) and the fit between media and information content. Static media (e.g. pictures, graphics, text) has a long tradition, hence recent research has focused on new dynamic presentation forms.

We hold that a central part of information presentation is to first analyse the information and then select the media that fit. In order to accomplish this we need descriptions of information, which are objective and topic independent. Objective descriptions must also be reliable, enabling different people to identify the same information class. Very few such information classifications exist for the e-learning context. Merrill (1983) suggests four useful information classes, which fit our criteria: facts, concepts, principles and processes.

Recent multimedia research gives remarkable little attention to the information content. Current multimedia research is media oriented, questioning first which media to select for presenting information in general, and eventual with which media combinations. Common co-research factors are various individual factors like ability, aptitude and experience, as well as design and didactical aspects. Experimental research in this context often employ similar design; information is presented with selected media, learning performance is tested and a conclusion related to success of the tested media is drawn. Information content is mostly not treated systematically. A discussion or meta-description of the presented information is almost entirely lacking. Various definitions of information contents are employed, which makes a systematic evaluation of the interaction between media and information content from the different studies literally impossible. A review analysing 25 studies revealed that the tested information contents or learning tasks belonged to seven different meta-categories (i.e. cognitive skill, short term recognition, procedural skill, concept understanding or learning, rule learning, fact memorisation, self assessment), of which all studies tested different example tasks (Park & Hopkins, 1993).

The focus on media in this kind of research seems to have reached a boundary, converging at the same results: few studies find dynamic media effective, mostly dynamic media are reported equal or less effective than static media. Hence, a new approach is necessary to evaluate how to employ dynamic media effectively.

Relevant research

We suggest starting multimedia design with a thorough analysis of the information content. The applied media should reflect the information characteristics. Both media and information content can be described in terms of
static and dynamic characteristics. The static and dynamic aspects of media are addressed when media are described as modalities of communication e.g. as visual, auditory, verbal or non-verbal coded information (Paechter 1996). In the media context, static vs. dynamic refers to whether or not we can perceive the information with a self-chosen speed. A representation is static when it enables us to decide how long the information shall be presented (e.g. text, picture). A representation is dynamic when the information flow proceeds automatically (e.g. voice, video). Also information can be described in terms of static and dynamic characteristics. Static information remains stable in its context e.g. states, descriptions, concepts, facts. Dynamic information is not stable over time, but refers to variable interactions between certain variables or factors, e.g. processes which can be described as a sequence of steps necessary to accomplish some goal, solve a particular class of problems, or produce a product.

We inferred that an important reason for the weak and varying support for dynamic media in research is that dynamic media often is implemented and tested for information contents for which it is not suited. Although dynamic media is often appreciated as a “nice” feature, a disharmony between information characteristics and media representation may hinder optimal learning. Studies, that tested various dynamic information contents confirm a bound between dynamic information and dynamic media. The tested information was defined as complex, dynamic and spatial, procedural texts (Large, 1994; Large, 1996), complex structural, functional, and procedural relationships among objects and events (Park, 1992), Newton’s law of motion (Rieber, 1990).

We tested the following hypothesis in two experiments (Guttormsen Schär, in review): Information content and media should match their respective static and dynamic descriptions. Our experiments also addressed the complex relationship between information, media representation and test of knowledge. Relevant results are:

- There is a close relation between information content and knowledge acquisition. Test of dynamic knowledge should reflect causal, procedural and eventual interactive aspects of the information. Tests of static knowledge should reflect the stable information aspects.
- It is difficult to acquire static information embedded in a dynamic context.
- There is a close relationship between information presentation and knowledge acquisition. Visual media supports visual knowledge. Verbal presentations relate to verbal knowledge.

Conclusion

Our results show that static and dynamic information qualities should guide media selection on an initial level. A simple key to multimedia design is to first select media according to basic static and dynamic information qualities. Further differentiated characteristics of the information content should guide the didactical media design and set the information in an appropriate learning context. An overview over multimedia in e-learning is given in Guttormsen Schär (2000).

Cognitive user profiles for adapting multimedia interfaces

Halima Habieb Mammar, Franck Tarpin Bernard
Laboratoire d'Interaction Collaborative Télé-enseignement Téléactivités (ICTT), INSA de Lyon, France
habieb@ictthp.insa-lyon.fr, tarpin@prhp.insa-lyon.fr

Abstract: An user does not achieve optimum performances if he uses pre-defined interfaces that misfit with his cognitive abilities. Our goal is to build cognitive profiles of users and adaptation techniques of HCI. We briefly present cognitive indicators and styles that are used in our filtering process of the output medias. We have chosen XML and ASP technologies to implement the system.

Introduction

In e-learning systems, each student is confronted to lessons and exercises which are relevant to his/her needs and preferences i.e. educational level, domain knowledge (expert or novice) but which do not take into account his/her abilities for assimilation, memorization, etc. The aim of our project is to build an adaptation technique of multimedia interfaces where cognitive abilities are considered. This dynamic process tries to estimate what combination of small media can compose the most suitable document for each user.

The context

In collaboration with SBT company, we work on an interactive web site for a supervised cognitive training: www.happyneuron.com (Tarpin-Bernard et al, 2001). During each training session (i.e. each connection), the user executes a set of exercises that the system suggests. Presented into a playful and cultural dimension, the exercises vary in difficulty's level, speed... in order to train the user (Habieb-Mammar et al, 2001). A database stores normalized data (means and standard deviations) for each variant of exercise and family of population distinguishing gender, level of education and age. The current statistics show that since the web site has been opened to the public, on may 2002, the number of performed exercises exceeds 750.000. Comparing the trainee’s results and the normalized data we progressively build his/her cognitive profile. Thanks to it, the system advises the elderly user in the choice of exercises.

In this context, we built an evaluation module composed of ten precise exercises that allows to quickly build a cognitive profile. Then, this profile, which is quite stable, can be used in very different context. Our first purpose is to elaborate an adaptive multimedia course explaining how the brain is working.

Cognitive styles

Cognitive styles refer to a person's habitual, prevalent, or preferred mode of perceiving, memorizing, learning, judging, decision-making, problem-solving (Dufresne, 1997). Individual differences about how people carry out tasks involving these functions may constitute a style if they appear to be: pervasive, which means that they emerge consistently in different contexts, independently of the particular features of situation; or stable, that is, they are always the same at different times. They are one of the most stable user characteristics overtime. They are consistent across a variety of situations, as opposed to user knowledge or experience that are more specific and evolving. Cognitive styles induce persons to adopt similar attitudes and behaviors in a variety of domains they concern. They are important in determining the most effective interface for a particular category of user, especially in the formative stages of an interaction (Fowler et al, 1985).

Cognitive user profile

The cognitive user profile is composed of numeric indicators representing cognitive abilities and styles:
- The cognitive indicators are dispatched into 5 sectors: memory, attention, executive functions, language and visual & spatial capacities. In detail, 25 indicators have been determined. We can mention several of them as an illustration: cultural memory, recent memory (verbal, visual or musical), working memory, lexical spelling, categorization, comprehension, planning, reasoning, form recognition, etc;
- The style indicators reveal some cognitive styles such as field dependence. These indicators are determined by a combination of cognitive indicators or through the comparison of the results obtained in several exercises. For example to determine whether the subject is field dependent or not, we use an indicator which measures the difference in performance after running the same exercise with two different images (the first with significant context and the second with non-significant context) then we adjust it with other cognitive indicators such as recent memory (verbal, visual or musical) and comprehension.

**Adaptation Process**

This user profile enables the selection of the outcomes modalities. The multimedia document is defined into an XML document. To illustrate the adaptation process, here is an example of a page dealing with the following subject: “The main parts of a language: the vocabulary and the syntax”. In the XML document, the page contains 2 elements. Each one could be presented according to different modalities:

![Figure 1: an XML document structure](image)

The problem is to find the “best” combination of media according to the willingness of the designer and the abilities of the reader. In this XML structure, the possible combinations are: (M1a ; M1b), (M1a ; M2b), (M2a, M3a ; M1b), etc. Thus, we can build a matrix whose lines correspond to compatibility criteria (e.g. capacity to manage of multimodality, respect of preferred modality, field-dependence...) and whose rows are the possible combinations of media. For each combination and each criteria, a compatibility factor is calculated using an arithmetic formula that combines the profile and the characteristics of the combination. The combination of media that obtains the biggest sum is considered as the most compatible. Hence the media are selected by enabling relevant tags before applying the stylesheet.

**Conclusion**

The first working track has been defined, experimentations and validation work are currently in progress especially to determine the compatibility factors. Our aim is to build a reliable user profile in order to exploit it not only in our site but in other coming applications. All this work has been possible by adopting multidisciplinary approach (computer sciences, cognitive psychology and education sciences).

Supporting Online Video-based Correction for Language Learning through Markup-based Video Editing

Yoshiaki Hada, Hiroaki Ogata, Yoneo Yano
Department of Information Science and Intelligent Systems
Tokushima University
Japan
{hada, ogata, yano}@is.tokushima-u.ac.jp

Abstract: This paper focuses on an online video-based correction system for language learning. The prototype system using the proposed model supports learning between a native English teacher and a non-native learner using a videoconference system. It extends the videoconference system so that it can record the conversation of a learning scene. If a teacher edits the video to include explanations, the video can become very useful as teaching material. However, in ordinal video-editing systems, it is difficult to show edited parts. Therefore, this paper proposes a video correction system and focuses on the online video-editing model.

Introduction

With fast development of the Internet, people around the world have more chances to communicate directly with CMC (Computer Mediated Communication) tools, such as e-mail, chat and bulletin board systems. By applying the CMC tools to language learning, it is possible for learners to communicate with native speakers in foreign languages. In fact, many approaches, which may lead to improved exchanges among different cultures and language learning with the CMC tools, have been proposed. Hanson et al. (1998) used the CMC tools for improving international collaboration and comprehension among university learners around the world. The experiment showed that a learner's ability to comprehend and express themselves in foreign languages was highly improved. It also pointed out direct communication with native speakers was very important for foreign language learning. An approach that emphasizes foreign language study through communication is known as the communicative approach (Johnson & Morrow, 1981). In this approach, grammatical rules and vocabularies are of secondary importance. Recently, the communicative approach has attracted much interest in CALL (Computer Assisted Language Learning).

From a technical point of view, the high-speed and broadband network has realized rich, smooth and synchronous communication and collaboration using not only text but also audio and video materials (LeeTiernan et al, 2001). For example, in an English conversation school in Japan, Japanese learners attempt to master English with a distant teacher (native speaker) using a videoconference system. The interactive video makes learning more effective (Dalton, 1990). What seems to be lacking, however, is reuse of the conversational video for language learning by reviewing and editing the video of the past lesson.

This paper proposes an online video-editing model for language learning, which allows the teacher and the learner to revise and edit their conversational video. If the videoconference system records their conversation into video files, the teacher can edit the videos using a video-editing tool. However, it may be very difficult for the learner to understand the teacher's task in the original video because the ordinal tools create quite a different video from the original one. Therefore, we propose a markup-based video-editing system called Viclle (Video-based Communicative Language Learning Support System) through the proposed model, which provides a similar environment to a real one where texts are corrected using red-pen on paper. Using this system, a learner can correct their conversational video, e.g., a teacher inserts a new video segment and annotations with correction marks. Using this system, it becomes easier to understand the teacher's correction comments. The features of Viclle are as follows:

1. A teacher can correct a video recorded by the videoconference system in Viclle.
The system uses VCML (Video-based Correction Markup Language) to describe the contents of the video correction.

A learner can see what the teacher has just corrected. This is based on WISIWYS (What I See Is What You See).

A learner can study by interacting with this system based on the correction marks.

The revised/explained video can be generated from an original video and a VCML document.

This paper is organized as following. First, related work is introduced. After that, a video correction and an online video-editing model are described. In the next section, a VCML is used to describe the video correction and the implementation system is shown. Finally, concluding remarks are given.

Related Work

Recently, wide ranges of authoring systems have been developed, which allow both text and media annotations. Among them, a multimedia annotation environment for young children using Java has been developed (Bouras, et al., 2000). It is used to provide children with the opportunity to reflect upon and annotate episodes from their everyday life. This system can lead to arguments with many learners. However, it has no functions to learn with the inserted annotations.

The approach used in the project of ACTS082 called DIANE (Benz, et al, 1997) recorded an arbitrary application output of the basic content of a multimedia document and to annotate it with all kinds of media available to the user. This system defines the annotation framework, however, the target for usage is not defined clearly. Therefore, it can cope with the ordinal video but cannot deal with two videos recorded by a videoconference system. It has no players to show these synchronously.

The classroom 2000 (Abowd, et al, 1996) project focused on teaching material. There is a hypothesis; tools to aid in the capture and subsequent access of classroom information will enhance both the learning and teaching experience. Therefore, the teacher can make teaching materials with various media and show it to the learner. The learner can annotate on the teaching material. However, the learner cannot study with his/her own video.

Lieberman et al (1994) have developed a system to use video as a tool for procedural knowledge representation. However, this system is not suited to language learning because it can only annotate still pictures extracted from the original video by drawing.

Language Learning using Video Correction

Video Correction

Conventionally, texts have been corrected using a red pen to highlight errors. Thus, rectified contents are made clear. According to such a traditional correction manner, an online markup-based collaborative writing support system, called CoCoA (Communicative Correction Assisting System) (Ogata et al, 1997) and CoCoA-J (CoCoA for Java) (Ogata et al, 2000) has been developed, which is very similar to the real correction environment with a pen and paper. This system has been used for language learning, and it can automatically generate the original text and the revised one from the corrected text. However, it cannot deal with multimedia contents such as video and audio. Therefore, it cannot correct a video like a text, exactly.

In order to rectify a video, one should focus on each of the smallest units. A text consists of many characters. The correction of a text operates on a character. Similarly, a video consists of many frames. It can operate like a text if a frame is treated like a character. [Figure 1] shows text correction and video correction. The correction of a text in (A) shows deletion and insertion for characters. Video correction in (B) shows them for frames.

![Figure 1: Comparison between correction of a text and video correction.](image-url)
Online video-editing model

Several editing systems aid teachers when reviewing and correcting learners' drafts. Farkas & Poltrock (1995) classified an online text-editing model that considered four models; the silent editing model, the comment model, the edit trace model, and the traditional markup model. In the silent editing model, the teacher overwrites and corrects the learner's document. In the comment model, annotations are inserted in the original document. In the edit trace model, the teacher works in the manner of an author, deleting, adding, and moving text. The computer can compare an editor's new version with an original one. It allows learner to view the draft that contains teacher's changes. Microsoft Word accepts this model. The traditional markup model employs correction marks to the computer screen, for example, deletion, insertion, and move. According to this classification, this paper proposes an online video-editing model as follows: (See [Figure 2])

(A) **The silent model:** After correcting the wrong parts of an original video with a general video-editing tool, the teacher creates a new video file. This is the simplest model, however, it is very difficult for the learner to check the teacher's work. This model is destructive because the teacher cannot readily recover the original video once he/she has made a revised video.

(B) **The comment model:** This model employs pop-up notes, temporary footnotes, hidden text, and special symbols placed within the original video. A system based on this model is developed with SMIL. It often takes a considerable amount of time for teachers and learners to obtain a revised video from comments on the original video.

(C) **The Mark-up model:** This adapts the traditional marks used with pen and paper to video editing on the computer screen. The symbols are both familiar and intuitive for teachers and learners: for example, deletion, insertion, and move. For instance, MATE (Hardock et al, 1993) that is a text-based collaborative writing tool, allows teacher to use both digital ink and voice commands toward pen and voice computing. In this model, both learners and teachers can interpret the teacher's modification with markings much more readily than in the other models. Moreover, they can easily derive both the original video and the revised one from a marked-up video.

Many systems employ a traditional mark-up that allows multiple users to mark-up an electronic document as if they were marking up a printed copy of the document. However, no studies have ever tried to adapt a markup model into a video-editing system. Therefore, this paper proposes a video mark-up model for supporting language learning. In addition, a correcting system has also been developed.

![Figure 2: Taxonomy of online video editing models.](image)

Learning process using Viclle

In order to learn a video through video correction, the video to be revised by a teacher is needed. Then, the teacher can correct it and the learner can study with it. The learning flow shown as [Figure 3] is as follows.

1. **Recording with a videoconference system:** A teacher gives lessons in speaking a language. The videoconference system in Viclle records a video of both the teacher and the learner. The learner and the teacher share the files via network. The video is used as a basal video for later operations.
(2) Correcting video: The teacher corrects the recorded video with Viclle Editor. The instructor makes the data for correction and rectifies the video with it. The teacher sends the VCML file (made by Viclle-Editor) to the learner after correcting. The VCML file shows only the contents of the correction but the video is shared in (1) so the teacher does not need to resend the original video.

(3) Learning by correction: The learner studies using the corrected video with Viclle-Viewer. According to the VCML file and the learner's process, Viclle-Viewer plays the contents. When learning, the student reviews and repeats places that are different to understand on the corrected video.

(4) Entering questions: If the learner has some problems and questions, s/he can describe them. In addition, if there is a question from the teacher, s/he can answer it. After that, the Viclle-Viewer generates a VCML file and sends it to the teacher. The VCML file contains the learner's question and feedback. The data relates the correction to the original VCML with a link.

(5) Grasping learner’s feedback: The teacher grasps the learner’s feedback from the VCML file with the Viclle-Editor and refers to that work for the next time. The Viclle-Editor shows the feedback for each correction.

The above is repeated when learning. The learner and the teacher repeat the learning process and solve the learner's problem. As a result, the learner may improve his/her communicative skill.

![Learning process using Viclle](image)

**VCML: Markup Language for Video Correction**

Video-based Correction Markup Language (VCML) is proposed to describe video correction. In addition, it can represent the learner's condition after studying. This markup language is based on XML. XML is a markup language used to exchange the corrected contents on network. Therefore, a teacher and a learner can exchange the correction only with VCML because the original video is linked by VCML. Some of the advantages of VCML are as follows:

1. It does not edit the original video.
2. It uses the correction marks shown as [Table 1].
3. It becomes a revised video by applying the tags of revised corrections.
4. It becomes the explained video by applying the tags of explained corrections.
5. It is possible to represent the condition of the learner's studying.
6. It is independent of the kinds of computer and software.
7. It is possible to send and receive by e-mail because of the text format.

**Table 1: VCML tags for video correction.**
Implementation

Viclle has been developed on Windows 2000. The development language is Java SDK1.3.1. Java Media Framework (JMF) 2.1.1a is used as a framework to deal with media, JAXP (Java API for XML Parsing) is used as a XML Parser, RELAX (Regular Language description for XML) to analyze XML documents, and Relaxer as a parser of RELAX are also used.

A snapshot of Viclle-Editor and its pop-up windows is shown in [Figure 4]. In the (A)Correction Editor, a teacher can edit the original video with correction marks. The videos for the correction and the operation buttons are shown on it. When the teacher wants to correct the original video, s/he can rectify by choosing the correction mark on the (D)Correction Palette. The correction mark is inserted by clicking the palette. An example that inserts replace correction is shown. When the replace button is clicked, the (E)Correction Dialog appears. Then, the user selects the media type; text, audio, video, picture or link. In this case, the user selects video as the media and inputs the text to the comment box. After that, the correction of replace is completed. Similarly, the user can insert other corrections. In order to confirm or select the correction frame, the frames of the original video are shown in the (B)Timeline. The display method can be altered by the (C)Timeline Controller. In order to affirm the correction condition, the (F)Correction Status Bar is used. The inserted corrections are shown by the marks on the bar. In order to change the contents for playback, the (G)Play Mode is used. According to the attribute of correction marks, the playback contents can be changed.

Conclusions

This paper proposed an online video-based correction model for language learning. No studies have ever tried to adapt a markup model into a video-editing system. The prototype called Viclle can correct videos recorded by the videoconference system. In addition, VCML is proposed to exchange corrected contents and learner's condition. A video was used as a tool for commenting or giving lessons. However, as the video correction uses the markup model, it can discover information required by a learner in real time. Thus, a video through video correction can be used as teaching materials. Although Viclle was used for language learning in this paper, the video correction is independent of the domain. For instance, it can use sports training for the form; acquire gestures in different cultures like that between Japanese and Americans. In future work, a VCML document will be used to retrieve video databases that are stored VCML documents. The data can be used as error databases. Another point under consideration is the examination of a speech recognition system to help the correction work and train learner's pronunciation or intonation.

Keeping it Simple: The Case for E-Mail

Gila Haimovic
The Open University of Israel
Israel
gilaha@openu.ac.il

Abstract: The Open University of Israel (OUI) is a distance education institution which offers over 250 computer-mediated-courses through the Internet. All OUI students must pass an English reading comprehension exemption exam or take the University's English reading comprehension courses. Because reading instruction differs from content instruction, different considerations need to affect how best to utilize the computer when planning CMC delivered reading courses. The distance courses in English reading comprehension are transmitted via e-mail rather than the Internet. The purpose of this paper is to recommend this "primitive" option, and to explain why it suits courses of this kind. There is a tendency to move on to ever-more impressive modern technologies, and constantly seek new ones. To avoid falling into the trap that Gabi Salomon referred to as the "technological tail wiggling the educational dog", we decided on the e-mail option.

The Open University of Israel (OUI) is a distance education institution which caters to students of all ages who wish to earn an academic degree, in Israel or abroad. There are no entrance requirements, but students must live up to the University's stringent course demands, and all must pass an English reading comprehension exemption exam or take the University's English reading comprehension courses. Though the Open University offers over 250 computer-mediated-courses through the Internet, the distance courses in English reading comprehension are transmitted via e-mail. The purpose of this paper is to recommend this "primitive" option, and to explain why it suits courses of this kind.

The OUI Study Method

The OUI's teaching method is not space- or time-dependent as it is not based on a central campus where lecturers and students gather, or on an established and uniform schedule [1]. Students enroll in specific courses rather than in a faculty or department. They select the courses in their program of study from a varied and wide-ranging selection. The individual program may include a diverse array of disciplines (which in other universities belong to separate departments or faculties), or may be based on a more focused disciplinary format which resembles, to some extent, single-discipline or dual-discipline programs of study in other institutions.

Students' rate of progress is not measured in units of time (years or semesters), but rather in the number of accumulated credits. The individual rate of progress is determined by the students themselves – based on the amount of time available to them. The only constraining time-frame is the semester, as the duration of most courses is one semester of 15 weeks, and the students are required to meet the requirements of the course during the semester in which they are enrolled.

The OUI offers close to 500 courses based on scholarly or scientific works, consisting of one or more volumes written by renowned specialists in their field and produced especially for OUI students. The coursebooks are adapted to self-study: they are usually divided into units, each of which deals with a specific topic to be studied within a fixed period of time. Guiding questions are integrated into the material, as are exercises and self-assessment questions. Each course includes face-to-face components: group tutorial sessions, laboratory work or study excursions. While participation in these sessions is usually not mandatory, it is highly
Technology at the Open University

The main reason for integrating technologies, and the Internet in particular, into OUI courses, was to provide a virtual campus as a substitute for a real campus, to compensate students for what they miss when learning at a distance. A second objective was to take advantage of additional educational resources, beyond what the university provides. These include all public domain educational resources and digital library services, which enables students to access bibliographic and other databanks, electronic journals, computerized encyclopedias, as well as the computerized catalog of the university libraries network in Israel, from their homes. Another aim was to compensate for the lack of face-to-face tutorials for students whose nearest study center is far from their homes, or who are unable to attend tutorial sessions for various personal reasons, by providing virtual tutorials through electronic communication.

The Center for Information Technology in Distance Education (Shoham) was established in 1995 to help the Open University enter world-wide academic activity in the field of information technology in teaching and education. The major focus of the Center's activities is on research and development of teaching methods based on state-of-the-art information technologies and incorporating them into OUI courses.

Telem, a department within Shoham, specializes in computer-mediated communication (CMC). It has developed an interactive on-line learning environment on the Internet, which is part of the teaching/learning process and serves both students and faculty. Today close to 250 CMC courses are offered, with state-of-the-art technologies incorporated into course development and teaching procedures.

Interactive learning: The computerized teaching/learning environment provides for one-on-one and group interaction among all participants in the course: students, instructors course coordinators and guest lecturers. Every CMC course has its own HTML and Java-based Web site that provides interactive learning materials through electronic asynchronous communication including discussion forums, e-mail, and materials that students can download. The sites can be accessed by students in Israel or abroad through the Internet. All course sites are graphically and functionally similar, and linked to administrative information drawn directly from the OUI's central database: the course schedule and description, the course tutors and the list of students. The academic aspect of the sites includes Hebrew-based applications that were specially developed to enable the course coordinator to easily and independently update the data, without the need for any knowledge of Web programming. With this platform available and widely used at the OUI, the question arises as to why the English reading comprehension courses do not take advantage of it.

English Reading Comprehension Courses at the Open University

Reading comprehension skills in English are necessary for all students for whom English is a foreign language. Without the ability to read in English, students find that sources needed for much of their academic studies, especially in advanced courses, are not accessible to them. As a result, all Israeli universities require a minimum level of reading comprehension in English and students cannot be awarded a degree without passing an exemption exam or taking English reading comprehension courses. Since only 10% of students entering the...
university come with an exemption in English, the reading comprehension courses are among the most highly populated, if not the most popular, at the OUI.

The Open University offers a series of courses in English reading comprehension for academic purposes on five levels: A (advanced); B, C (intermediate); and D, E (beginning). The courses are offered in three study formats: intensive (a semester-long course comprising 14 weekly face-to-face meetings), regular (a semester-long course comprising 7-8 bi-weekly face-to-face meetings), and computer-mediated (a semester-long course which includes 1-3 face-to-face meetings and 9 e-mail sessions, of which 7 are compulsory). Of the three formats, only the latter is a distance education format.

Most university courses are, by nature, content courses. In contrast, learning a language is a process of communication and goes well beyond learning lists of words and practicing grammar exercises. Because the classroom is a more natural environment for language use and social interaction, language courses are traditionally taught in a face-to-face (f2f) format. If we consider reading as a mode of language use, and distance education as a mode of language instruction, distance education for this particular mode of language use seems particularly appropriate. Indeed, we encounter striking parallels: the reader (when reading in "real life") and the learner (when learning to read) both function in isolation when interacting with a text. In both cases, discourse is enacted at a distance, a disassociated first person (the author or the instructor) is actively present, and no reciprocity is manifest, within the interactive context [2]. One could, therefore, argue that reading instruction and distance education are particularly well-suited. It would therefore seem logical to use the available platform for teaching reading comprehension. But because reading instruction differs from content instruction, different considerations need to affect how best to utilize the computer when planning CMC delivered reading courses.

The Telem course sites are designed for content instruction, and are intended to afford additional interaction among the participants and to provide technology-based learning aids that increase the effectiveness of and enjoyment from the learning process. Learning materials are based on multimedia and hypertext, and include animations, simulations, multiple-choice exams with immediate feedback; and access to databases on the Internet. These aspects are less relevant when transmitting an existing reading comprehension course via computer. Traditionally, reading comprehension programs rely entirely on pre-defined and pre-produced teaching/learning materials in which the selection and organization of the reading texts and the tasks are determined by the syllabus-writer. In a f2f teaching/learning context, the instructor, in selecting what to teach, turns the abstract syllabus into what s/he considers to be the most appropriate means to activate the learning process. Thus it is the instructor who controls and promotes the learning. In a CMC reading course, while the instructor is responsible for dividing the syllabus into sessions, arranging deadlines for task completion/submission, and making decisions for assessment and evaluation, once the course gets started, the participants take over [3]. In order to explain the choice of technology, it is necessary to briefly describe the course.

The E-Mail Format

The following description is of a B-level e-mail mediated reading course which has been implemented for the last five semesters at the Open University. The objective of the course is for students to reach the level of proficiency expected in the parallel f2f B-level course (intensive or regular formats). The students sit for the same mid-term and final examinations taken by students registered for the course in all formats.

Participants: In order to make the course manageable for the tutor, the number of participants in a group is limited to 20.

Materials: The teaching materials, which are pre-prepared and handed out to the students, comprise the following:

- A collection of reading passages consisting of articles selected on the basis of topic interest and level of difficulty, the same texts used by the rest of the students.
- Workbooks dealing with nine texts, arranged in modules according to test organization patterns (comparison/contrast, description, cause and result, argument, research) including approximately 20 questions to guide the reading process and relevant teaching points (reading strategies and linguistic features). The workbooks are similar, but not identical to the regular materials.
A "Resource Center" which brings together all the major teaching points dealt with in all modules as a handy reference.

[2] I am grateful to Dr. Esther Klein-Wohl of the Open University of Israel for pointing out this parallel.

[3] This concept was proposed by Dr. Anita Pincas of the Institute of Education, University of London.

Process: The initial f2f meeting provides the students with the opportunity to get to know each other, to familiarize themselves with the structure of the course and to understand what their responsibilities are. This meeting serves as a "kick off" point for the course and its main focus is to deal with students' queries and technical problems, as well as an introduction to pre-reading activities. The students can attend two additional f2f meetings by joining regular groups near to their homes: one is held a week before the midterm examination, and another is held before the final examination. These serve to prepare the students for the exams by explaining the format of the exam and supplying a practice examination.

The rest of the course consists of asynchronous e-mail sessions. Prior to each e-mail session, students are sent a list of the questions which they are assigned. Each student is assigned 8-9 of the 20 questions which relate either to pre-reading or to close reading, as well as post-reading questions for all students. The date of submission is mandated in advance as a specific day of each week and the questions are sent out one week in advance. The weekly tasks demand active learner engagement rather than passive participation in classroom sessions. The tutor's feedback, which provides the correct answers as well as specific comments regarding language features, useful reading strategies and general and individual feedback relating to students' cognitive and metacognitive awareness, is sent out to all students within three or four days of the deadline for submission, and serves as additional English-language reading material.

Our students have reacted extremely positively to the course, and their achievements have consistently been as good as, or better than those of their peers in f2f groups. Their feedback (provided on an anonymous questionnaire filled out by all students at the end of each course) has invariably emphasized the one-on-one teaching and the close contact they enjoy with the teacher, thanks to the e-mail communication.

Why E-Mail?

In recent years, scholars in various content fields have been grappling with the question of appropriate formats for CMC. Perhaps surprisingly, among the scholars who recommend the simple e-mail format, rather than what Margaret Anderson (1997) calls "new and 'glitzy' technology", are faculty who specialize in Engineering and even in Computer Information Systems [4]. This indicates that the choice of e-mail is not necessarily related to students' assumed computer skills, nor to the technological options available, but rather to the specific needs of the course and its pedagogical context.

As we have shown, our distance education reading courses also do not utilize all the multimedia aspects of what can today be called "traditional Internet teaching" as exemplified by the Telem platform. In terms of pedagogy, our reading comprehension students are given the reading texts on paper, and not through the computer, because reading, and especially reading comprehension skills, are dependent in large part on back-and-forth reading, marking the text, and note-taking. Reading from paper is still considered easier than reading from a screen [5]. We also need to consider the purpose of this course. Beyond the formal requirement of English language proficiency, our goal is to enable students to read and understand the required course readings that they are assigned, some of which may be in English. These readings are usually provided to students in a printed booklet. Thus, in "real life" - for their studies - students will be reading on paper.

In terms of technical aspects, the platform utilized by Telem (Opus) makes it difficult to mix English and Hebrew within a single message, and students often answer reading comprehension questions in their L1. Another problem relates specifically to the Telem platform. After connecting to the Internet, students need to go to their course site, enter a password, and, often, wait. They then need to go into the weekly forum to find the assignment, print it out, leave the computer to do the assignment, and then repeat the process to post their assignment. Having posted their assignment, they need to check the forum to see when the feedback is posted,
and repeat the process to get the feedback. Thus students need to remember to go into the course site at least

[4] Interesting papers in this context are by Margaret Anderson ("An Internet-Based Asynchronous Distance Education Course") and Donna Ehrhart ("Interaction Through Electronic Mail") in the context of CIT '97, Learning with Technologies, May 27-30, 1997 (Brockport, SUNY) and Julie Sharp's paper, "E-teaching Simply with E-mail" presented at the 30th ASEE/IEEE Frontiers in Education conference, October 18-21, 2000 (Kansas City, MO).

three times a week. Moreover, there are often announcements which relate to administrative aspects of the course which are often urgent messages, and students have no way of knowing that these have been posted unless they go to the course site daily.

In contrast, when the course is transmitted via e-mail, merely by opening their e-mail, which they do anyway, students receive assignments, announcements and feedback. They can post their answers in a combination of English and L1 within the same e-mail message, or send them as attachments in Word or any other word processor. Because there is no need to remember to check the site, students can be sure that they are up-to-date and have not missed anything. The simplicity of e-mail works in both directions: If the student has a problem, s/he can send a "help" message to the instructor by e-mail, and be assured of an immediate response. The price students need to pay, in terms of time on task (or, more precisely, time around task) and dealing with what is often an unwieldy system, is too high for a course that does not utilize the advantages of the course sites available at the OUI. To avoid falling into the trap that Gabi Salomon referred to as the "technological tail wagging the educational dog,"[6] we decided (to continue with the dog metaphor) that in some cases, a mutt is better than a certified pure-bred, even if less elegant.

Technology in distance education is constantly improving and becoming more user friendly and flexible. There is a tendency to move on to ever-more impressive modern technologies, and constantly seek new options. But our objective is to teach, and we have to be careful not to lose the baby because of the bathwater. Sometimes the simplest, least sophisticated technology makes more sense than state-of-the-art.

Acknowledgements

Dr. Esther Klein-Wohl, Head of the English Unit at the Open University of Israel, introduced me to this mode of teaching, and forced me (kicking and screaming) to teach this course. In retrospect, I'm grateful to her. I am also indebted to the Research Authority of the Open University which enabled me to present this paper.
Museum Education in an Age of Wireless Communication

Abstract: This paper describes the beginning designs for a museum education expansion project. Museums have not only been at the forefront of protecting artifacts, they have been educational initiators, encouraging humans to value and learn from artifacts through exhibits and educational programs. The objective of this project is to advance the meaning of museum education with innovative uses of communication technologies. Web-based artifact databases and handheld communication devices are introduced as promising vehicles for the collaborative construction of modern museums, existing beyond the walls of buildings that house artifacts.

Introduction

Museum educators, like many people, are eager to experiment with the latest technology. Soon after museums started having websites, ‘virtual’ exhibits began to appear. The virtual exhibit like its on-site counterpart allows a curator or web designer to interpret the contents of the museum to engage and educate the virtually visiting public. Also like their on-site counterparts, virtual exhibits reach their audience with mixed degrees of success.

Beverly Sheppard of the Institute for Museum and Library Services, describing the strengths of museums, observes that communities and families trust museums as resources, that they act as stewards for collections and ideas, and that they “offer authentic, first-hand encounters with the objects and information they collect” (Sheppard, 2001). Trust, stewardship, and authenticity can be seen as central qualities of museums, qualities as important to the museum learner as the subject-specific knowledge presented by museums.

Unfortunately, web based exhibits have difficulty expressing these very qualities of museums. The difficulty of knowing what to trust on-line has been discussed since its popularization and though some well-known museums might be trusted web resources, smaller museums do not necessarily share in this trust. Web presentation of authenticity also becomes complicated because of the many problems of representing physical objects in a digital media. Clearly, interaction with an artifact in a museum is an “authentic” experience but the authenticity of interacting with a virtual artifact is more problematic. Similarly, despite some efforts to show stewardship on-line it is not clear how well these behind-the-scenes exhibits translate to an appreciation of the stewardship conducted in museums or the question of each individual’s responsibility as stewards to objects in their own environment.1

The developing tools of wireless communication offer an opportunity to address these qualities of trustworthiness, stewardship, and authenticity. Instead of providing virtual access to distant objects, handheld computers and wireless networks can bring virtual museums’ interpretive powers to the authentic objects as they exist in our surroundings. These technologies can be used to help visitors organize their existing knowledge and to deliver the expertise of the museum to learners studying in their own homes and communities. Mobile computing can also be used to facilitate truly interactive educational experiences in and out of the museum. Despite advocates’ push for the use of constructivist techniques in museums, only a handful of authors have explored the connection of...

---

1 For example, see the “Conservation Time” section of “Tempus Fugit: Time Flies” << http://www.nelson-atkins.org/empusfugit/default2.htm) created for the Nelson-Atkins Museum of Art.
constructivist theory to museum use of technology. While web exhibits and gallery kiosks provide interactivity separately from the artifacts, mobile technology offers an opportunity to integrate the advantages of instructional computing directly into the gallery visit or out-of-museum activity.

Goals

In this project we redefine the virtual exhibition as an interactive experience of visitors with real objects using mobile communications technology to deliver, organize, and record jointly constructed knowledge (Hewitt & Scardamalia, 1996). Wireless communications through their flexibility and portability offer the opportunity to make the authentic interaction with artifacts part of a complex situated learning experience (Brown, Collins, & Duguid, 1989). We will unite concepts from museum education and educational technology with the strengths of museums to improve learning in exhibitions.

Program Design

Development of the project will involve a test school and museum working within a single exhibition. The design will include two different sections. First, a database driven website developed in coordination with the museum will facilitate collection and organization of content including text, images, and other media. Students planning a visit to the museum will use the site as a locus for self-directed study where they will gather information provided by the museum, linked web resources, and off-line resources based on their own research agenda.

The second module delivers information gathered by the students to a handheld computer, allowing access to their existing research. Transmitters within the museum would feed the computers' location appropriate information as the visitor traverses the exhibit. Additional tools, such as a digital camera to allow students to photograph details of artifacts or a color wheel to record student observations about color and form, will make the handheld into a data-gathering device. Information gathered during the exhibit would be uploaded to the central database to be made available once the student returns to school for collaborative projects.

Future Directions

The structure of the project will easily adapt to use in any exhibition or subject area. Further development will be necessary to extend the project for home use. Development of the communications aspect of the project is central to the project's vision of fostering shared meaning development between visitors and institutions.

Ultimately, the project will create a series of tools that can be made available to any institution interested in using mobile connectivity interactively within a museum. The tools developed in this project would help museums to teach their core functionality. These qualities of museums: reliable (trustworthy) research, stewardship over cultural and natural objects, authenticity of experience describe a manner of considering the world. Traditionally museums hope to teach us to look more carefully at objects, think more deeply about meaning, and approach our surroundings with a sense of wonder. By helping us put these ideas into practice, mobile communication technology helps us to appreciate more fully not only the artifacts in museums but also the objects in our lives.

Rgilpin@mail.cis.com

The Problem

The playing field in our nation’s public schools is not level and East Carolina University and Newport Elementary are changing that by launching a collaborative project to ensure that students in one second grade class have the technology needed, at home and at school, to master expected North Carolina Standard Course of Study content. The main research question is: how strong is the correlation between achievement gaps and technology gaps in a second grade class in Newport, North Carolina?

The literature is replete with information about the “digital divide.” Government reports have measured this divide for the past half-decade. But, by using a conservative definition, it reports a technological “stabilization.”

The Study

Researchers are measuring ameliorative factors designed to even the technological playing field in the classroom and the home. Each student has been given a Hewlett-Packard Jornada Pocket PC, equipped with electronic reader, software for word processing, spreadsheet application, email, Internet access capability, a calculator and scheduling/tasking packages for homework, classwork, and communication with parents.

Each is being quantitatively tested for knowledge of the technology and content related to the North Carolina Standard Course of Study. Data has been gathered and is presently being analyzed. Preliminary results are available and are presented in the next section.

Preliminary Results

Preliminary results indicate a tendency for handheld technology and the appropriate software to improve the performance of “at risk” students, especially in the areas of reading, writing, and the practical use of technology.

The digital divide is muted by the use of technology that students can take home with them and parents are generally supportive of the initiative.

Future Studies

Quantitative studies are needed to measure more specifically the impact of technology on students and the digital divide. Studies focusing on subjects such as reading or writing only might shed more light on what works and what doesn’t.

Case studies with a larger N, e.g., an entire district, different grade levels, etc. would bolster the literature.
Evaluating Online Instruction: Adapting a Training Model to E-Learning in Higher Education

Abstract: In this paper, we present our model for the evaluation of postsecondary online distance education courses and programs. To better address the unique nature and audience for these courses and programs, and the related institutional needs for assessing their success or failure, we focus on a model from corporate training that provides a comprehensive, multi-level evaluation of a distance course or program. This model is based on Kirkpatrick's (1975) levels of evaluation. We provide a general description of how this model can be implemented via online means to provide the assessment information required by postsecondary institutions.

Background

Over the past decade, online instruction has become a popular delivery option in many institutions of higher education (Green, 1997). One criticism leveled against conventional "student evaluations of teaching" suggests that when used alone, these provide limited information about student comfort without addressing significant factors such as student learning and ability to transfer that learning to real-world situations (Trout, 2000). Moreover, many evaluation systems for online learning emphasize usability and reliability of the technology over the value of the instruction to the students (Anglin & Morrison, 2000). Finally, the unique nature of E-learning suggests that traditional course and program evaluation may be particularly deficient in providing necessary data that can help drive further development and support of effective online instruction (Clark, 2000).

The needs driving the evaluation of E-learning in postsecondary education coincide with the classical reasons for evaluating any type of learning experience as well as expand on them. As with any evaluation of conventional instruction, instructors, administrators and other stakeholders in online learning want to know the value of their course and program offerings in terms of student satisfaction and student learning. This includes:

- Student satisfaction with the learning process (interactions with course/program materials, instructor and other students)
- Appropriate level, pace, depth and breadth of instruction
- Accomplishment of intended instructional objectives
- Areas in need of further instructional and pedagogical development

Although most university evaluation systems do not address transferability of learning to any significant degree, since students taking distance education courses are often out in the workplace, and facing real-world demands from...
clients and supervisors, it is especially important that E-learning assessment activities address whether the learning that takes place is useful to the students. Information collected about this process might include whether:

- The content of the learning provides a basis of knowledge that can be built upon in later instructional situations
- The learning can be transferred to enhance performance in real-world settings

In addition to these basic assessment needs for instructors, other stakeholders in the online learning process (administrators, technical support, designers, etc.) also hope to measure these facts about the technologies used:

- Performance of technologies used
- Usability of the technologies
- Reliability of the technologies
- Compatibility of the technologies with each other and existing student technologies

Because E-learning is generally a new and unproven method of instructional delivery that faces bias against its efficacy, cost efficiency, and quality from those in traditional academia (Ashworth, 1996; Cordes, 1998), it faces additional institutional demands for accountability, such as:

- The costs and benefits of installing and maintaining the technology infrastructure required for distance education.
- Concerns about the effect of distance education efforts to the institutional reputation
- The need to collect data to assist in future institutional decision-making

The Significance of Kirkpatrick’s Model to Online Instruction

In general, a rigorous online evaluation system should measure the success of the content, process, and delivery of online instruction in terms of the individual student, the program and/or institution, and/or the field in general. It should also be able to address the efficacy of its chosen pedagogy and technology. This paper seeks to adapt a model for the evaluation of E-learning from the field of training and development that takes into account a number of different aspects of the online learning process. This four-level model of evaluation, developed by Don Kirkpatrick (1975) is currently utilized by 67% of businesses that evaluate their training (ASTD, 1997). However, while there have been a few efforts to apply Kirkpatrick’s levels to evaluate distance education in a higher education setting (Essex & Cagiltay, 2001; Hack & Tarouco, 2000), this practice is still far from commonplace.

Once adapted to higher education needs and perspectives, Kirkpatrick’s evaluation model can be used to address the many layers of questions that exist about E-learning. Specifically, Kirkpatrick’s model consists of 4 levels, each one more extensive in its purview of instructional effectiveness than the one preceding it and each stage relying on achievements gained in the one preceding it for success. Therefore, it is a cumulative model that can be used to provide in-depth information about the value of an online course or program. Within each of the four levels described below, a systematic method of evaluation is integrated into the process that specifies the goals, objectives, criteria, and methods of assessment.

The Proposed Evaluation Model

Level I: Student Satisfaction

Identify Goals

As the course was being developed, instructors and developers should have identified the goals associated with attaining student satisfaction with the course or program in terms of both instructional design and the delivery technology. These goals are fairly generalized, such as making sure the course is attractive and accessible to students, and that students feel comfortable and competent with the course requirements. Ideally, this is done as part
of the initial course design process, but if these goals were not previously explicitly identified, the evaluation team will need to work with the course designers to extract them before the evaluation process begins.

Identify Objectives

Objectives need to be based on the overall goals of the course, which are transformed into objectives through specific and concrete definition. The developers of an online course evaluation should measure student satisfaction based on the objectives regarding the instructional materials, the instructional strategies, and the types of interactions provided by the course. In terms of delivery technology, evaluation measures should look at specific objectives in terms of the ability of the hardware, software, and networking to meet student expectations and needs. Again, if these objectives were not previously explicitly identified, the evaluation team will need to work with the course designers to extract them before the evaluation process begins.

Develop Performance Criteria

In the design phase, developers and instructors of online courses need to determine appropriate criteria for measuring the success (student satisfaction) of the instruction, and these criteria need to be based on the course goals and objectives previously decided upon. Furthermore, Clark (2000) points out that it is important to separate instructional technology from delivery technology when evaluating online courses. Some examples of performance criteria for instructional technology are: whether the course met student goals; if the level of instruction was appropriate to the student audience; if the pace was appropriate; if the course covered an appropriate range and depth of content; and if the student-student and student-instructor interactions in the course were considered to be helpful by students to the learning process. Criteria for delivery technology might include whether it was compatible with student equipment and existing institutional systems, and its reliability, usability, and speed.

Specify Data Collection Method

Evaluation at Kirkpatrick Level 1 can be done on either a summative (end-of-term) or formative (midterm) basis, or both. The most common method of collecting Level 1 data is through a survey instrument, usually administered as a summative student course evaluation that asks student opinions on whether the course fulfilled their objectives. Document analysis is also a popular method of evaluation with online courses, since the unique nature of an E-course is that a record of all discussions, assignments and group work is maintained. Other statistics, such as when, how often, and how long students access various aspects of the course, are also available in server log documents. There are also options to collect formative data that can be used during the course of the instruction to guide changes in course delivery and design. Focus groups provide students a forum in which to build on each other’s impressions of the course, and these can be implemented in secure online forums, where students can provide open and honest feedback that is later summarized anonymously for the instructor. Individual student interviews, while more time-consuming, can allow for deeper exploration of student attitudes and experiences with the course. Observations of the course by a faculty colleague or instructional consultant (attained by allowing them access to the course discussion forums and other documents and communication) can also reveal much about student engagement, levels of interaction, and general conduct of the course.

Level 2: Student Learning

Identify Goals of the Instructional Effort

Cross & Angelo (1993) identify five basic areas of higher education from which instructional goals are drawn. They are: higher order thinking skills (problem solving, analysis, synthesis); basic success skills (reading, writing, listening, speaking); field dependent knowledge and skills (methods, materials, tools); academic perspectives and values (objectivity, rigor, collaboration); and personal development attitudes and skills (responsibility, leadership, commitment). Theoretically, the student learning goals for an online course do not differ from those of a traditional course. However, competency with the technology itself always, whether implicitly or explicitly, comprises part of the online instructional process and the basic requirements for success in an online course.
Identify Objectives of the Instructional Effort

Some objectives related to higher order thinking skills might be: identifying the important elements of a problem; understanding the relationship between the elements; and determining what changes in which elements need to be made to solve a problem. Basic success skills objectives might include: understanding what is important and what is secondary in written information; articulating ideas in written format; listening to others' opinions and ideas; and articulating ideas in verbal interactions and presentations. Objectives relating to field-dependent knowledge may encompass: understanding which methods are appropriate and their uses in the field; identifying appropriate materials and their characteristics; and selecting the best tools for the task(s) and knowing how to utilize them. Objectives developed under academic perspectives and values might be: learning how to approach intellectual problems with objectivity; understanding the thoroughness required for rigor; describing and defining practices that lead to teamwork and accomplishing collaborative goals. Personal development attitudes and skills objectives might include: responsibility to one's work within the discipline; leadership in the field; and commitment to one's own values.

Develop Performance Criteria

Defining performance criteria for assessing student learning is normally part of any instructional module or course, and leads the evaluation of student learning. Specifically, criteria generally fall into two categories of student performance (demonstrating learning): those that pertain to understanding of content; and those that pertain to the mastery of a process.

Specify or Review Existing Assessment Methods

Except for evaluation of the student's mastery of technology, this level of evaluation may borrow heavily from established course materials and evaluation instruments; e.g., examinations, written assignments, projects, and portfolios. These evaluations for the E-course can then be analyzed in exactly the same way as they are in traditional, on-campus courses, such as providing average student scores and grade percentages for individual assignments to grade point averages for the course. Student mastery with the technology can be tested directly, such as by giving them technology-related tasks to perform, or inferred by their success with the assignments in general. If grades are not an issue, mastery learning techniques will provide instructors with the number of modules or instruments completed at a given proficiency level (which should ideally be at or near 100%).

Level 3: Transfer of Learning

Identify Goals of Transfer Learning

The goals of Level 3 evaluation are twofold. First of all, learning in an academic setting is often considered to be sequential and progressive. That is, basic knowledge and understanding must be acquired before students may "advance" to higher order thinking and problem solving. This is the philosophy behind offering some courses in sequence, and requiring that the preceding course be successfully completed before moving on to the next level. Secondly, the goal of much higher education is that student learning will be transferred to real-life situations/problems (such as internships, student teaching, service learning projects, professional tasks, etc.). Whether E-learning focuses on the professional development needs of those already in the field, or are a part of university programs in professional education, successful transfer of learning is usually the ultimate goal of the educational process. Thus, they often encompass the goals of both pre-service professional training and the further development of professionals in the field. Transfer of learning, though, is often difficult to evaluate, since it must be evaluated after the learning process takes place, and in a setting other than the real or virtual classroom. Universities are not accustomed to tracking student learning post instruction, except for programs with comprehensive or qualifying exams or summative portfolios. However, since transfer of learning is so important, any rigorous assessment program must include this aspect in its design.

Identify objectives
The objectives of transfer learning are diverse and depend heavily on the field of study, but in general the objectives will address students' ability to access specific skills and relevant knowledge post instruction, and their knowledge about when and how to use these skills and relevant knowledge for real-world problems and tasks.

**Develop Performance Criteria**

Specific performance criteria for transfer learning will depend heavily upon the field of study and/or the professional field involved, and the level at which the students work in that field. Professional fields often determine the criteria that their members must meet through granting licenses and certification. Academic fields typically measure performance through instruction, research and publication. Subprofessional performance criteria in both of these fields often approximate professional tasks, but at a lower level of mastery.

**Specify Methods to Evaluate Transfer Learning**

In both academic and professional settings, the transferability of learning can be assessed using simulated, authentic scenarios or case studies in which the students' problem-solving skills are put to test. In order to approach real-life situations, cases must be complex, ill-defined (Savery & Duffy, 1996) and require the use of higher-order thinking skills on the part of the students. To further authenticate the process, when the task would, in the real-world, be a collaborative effort, students can be required to work in teams so that the skills of communication, negotiation, and compromise are also implicated in the solution. In these scenarios or cases, roles can either be initially defined for the students or can evolve naturally from the process. Another option for assessing transfer learning, if the students are employed or interning in a real-world professional/academic environment, is that the students may be observed in real-life situations by supervisors, by colleagues, and by clients (students). Another option would involve the students submitting a video or audiotape of a job-related performance for evaluation.

**Level 4: Return on Investment or Business/Academic Impact**

**Identify Goals**

Whereas in a corporate training program the return on investment (ROI) of any online training effort is measured in terms of whether or not the cost of the training is more or less than the additional profit gained through performance improvement based on the training, academic programs define success in different ways. While the financial aspect still exists for the academic world, because most students hope to be in a better financial position after a course of study than before, there may be other indicators of success for students that they count into their calculations of ROI, such as increased job satisfaction, lower stress, etc. In any case, deciding whether a course "was worth it," is often a very personal kind of ROI calculation, and difficult to quantify. Looking at ROI from an institutional perspective, colleges and universities often look to intermediary indices, only some of which indirectly refer to the financial health of the organization. Specifically, academic institutions and programs often use academic reputation, program rankings, and accreditation status as indicators of success. Although the reputation is somewhat ephemeral, high program ranking established by a reputable organization and accreditation through appropriate organizations are attributes that institutions of higher education that offer E-learning are not willing to sacrifice. Other indicators of program success are the success of graduates of online programs as well as increasing popularity with the E-learning program for students.

**Identify Objectives**

Calculating objectives related to ROI from an individual student perspective can be, as stated above, a very personal process, involving an estimation of how much the learning from a given course or program improves the life of the learner in terms of fulfilling monetary, career and personal goals. From the institutional perspective, objectives relating to academic or program reputation may also be difficult to decide upon, since much of reputation is established through word-of-mouth and on other informal bases. School and/or program rankings, however, generally occur at predictable intervals through identifiable evaluative agencies. Therefore, objectives can be set which relate to these specific evaluative events. In addition, objectives can be set related to a positive change in the type and level of positions attained by graduates of the program or institution, and/or positive changes in institution/program enrollment rates.
Develop Criteria for Positive Changes

Again, students will determine their own individual criteria for assessing the ROI relative to a given course or program of study. The threshold for which the student decides that the course or program was “worth it” may be difficult to quantify, but most students will have an implicit sense of it. From the institutional perspective, given the imprecise nature of measuring a concept such as institutional reputation, criteria for assessing an institution’s or program’s reputation may merely focus on the documentation of a stakeholder’s opinions regarding positive changes. Positions attained by graduates of a program can be evaluated along the lines of perceived status, entry salaries, and/or numbers hired within a certain period of time. Rankings and enrollment rates, however, can reveal quantitative changes, in which positive changes can be tracked and documented. Care must be taken to ensure that perceived positive change is not the result of other, external factors such as changes in the nature of the field, changes in professional demands, changes in the availability of resources, or changes in other policies or regulations.

Develop Evaluation Methods

Evaluating student assessment of ROI may simply consist of asking them, in a survey or interview format, whether they regard the benefits of the course of study to have been greater than the associated costs. Since the objectives of each student and the criteria for measuring these objectives are likely to be so idiosyncratic, it would be difficult or perhaps impossible to get at a more objective assessment. From the institutional side, evaluation methods for determining the impact of an online program on an institution or program can be accomplished through: inspection of published ratings/rankings; the hiring rates of graduates; the level of positions obtained by the graduates; the accreditation and licensing status of graduates; the accreditation status of the program, and enrollment rates. These measures all provide data that can be used to indicate program success. Data may also be collected on the status of graduates through surveys, interviews, and focus groups with them.

Conclusion

The major advantage of the Kirkpatrick model of evaluation is that it fosters a thorough assessment of the instructional process by viewing the process systematically, through four different lenses. Most college and university efforts to evaluate E-learning are not done systematically and fall short of their goals, either by emphasizing student satisfaction for the process over the actual learning achievements or lack thereof, by concentrating on positive or negative aspects of the technology while overlooking the learning process altogether, and/or by ignoring whether or not the learning will transfer to the real world environments that the learner will face. The Kirkpatrick model can also be used to integrate evaluation on the local scale with a more systematic and administrative look at institutional and programmatic influences. This new evaluation method helps put into perspective data that can inform future university decisions about their technology infrastructure, the professional development of faculty involved in online learning, and the prospective role of E-learning in university programs.

sTeam- Providing Primary Media Functions for Web-Based Computer-Supported Cooperative Learning

Thorsten Hampel
Computer Science and Society,
Heinz Nixdorf Institut
Fürstenallee 11, 33102 Paderborn, Germany,
E-Mail: hampel@upb.de

Abstract:
The WWW has developed as the de facto standard for computer based learning. However, as a server-centered approach it confines readers and learners to passive non-sequential reading. Authoring and web-publishing systems aim at supporting the authors' design process. Consequently, learners' activities are confined to selecting and reading (downloading documents) with almost no possibilities to structure and arrange their learning spaces nor do that in a cooperative manner.

This paper presents a learner-centered - completely web-based - approach through virtual knowledge rooms. Based on this concept, the goal of the presented work is firstly to develop a theoretical framework to explain the design potentials of technology-supported learning processes (distinguishing individual and cooperative primary media functions). Secondly, a technical framework (cf. www.opensteam.org) should be developed allowing us to study different technical configurations within the traditional university setting. Considering the systems design the concept of virtual knowledge rooms is to combine event-based technology of virtual worlds with the classical document management functions in a client-server framework. Knowledge rooms and learning materials such as documents or multimedia elements are represented as a fully object oriented model of objects, attributes and access rights. We do not focus on interactive systems managing individual access rights to knowledge bases, but rather on cooperative management and structuring of distributed knowledge bases.

Introduction

Discussions about the role of technology in teaching and learning center on two basic paradigms. Firstly on hypermedia systems that aim to support individual learning processes, here special emphasis is being placed on new didactic qualities, attributed to the interactive combination of different media types such as text, graphics, audio, video, etc. The second paradigm embodies the notion of "delivering education" that is networking technology being used to distribute and access study materials as well as to establish communication channels between students and teachers. Although the idea of utilizing net services has strong collaborative connotations, the main argument in favor of networking is the temporal and spatial independence it offers and, consequently, the independence from close collaboration with others.

Now, students can learn individually at their own pace and at a location chosen by themselves.

However, many studies evaluating the role of technology in learning processes have yielded conflicting results, indicating that there is no general, clear-cut connection between the effort required to produce high-quality multimedia educational materials and improvements in the learning process. The problem is to attribute certain benefits to a single variable – say, the specific technology used. Mostly, the results are a combination of different variables such as didactic style, educational strategy, technology deployment, appropriate selection of content and the personal qualities of teachers and students. (see [Hesse 1997] and [Keil-Slawik et al. 1996]). Thus, the widely accepted idea that learning can be improved by the individualization of learning processes using hypermedia and networking technology is not generally borne by scientific research.
Instead of using technology to individualize learning processes, we have chosen the opposite approach – namely, using technology to support cooperative learning processes within the framework of traditional university education. Rather than trying to do away with the need for physical presence in the learning situation, we seek to support social processes in which students and teachers meet for a specific time at different places. Apart from practical considerations, theoretical research reveals that, ultimately, the social embedding of learning is a crucial factor for success. Furthermore, our approach is based on the general assumption that technology can only solve technological problems, didactic problems requiring didactic solutions. Hence, teaching activities cannot be replaced by technological functions, and the embedding of technology into teaching and learning activities must be studied carefully.

Media Functions

Media are generally viewed in terms of communication, based in most cases on the classical transmitter/ receiver or producer/ consumer model. The integration of different media types such as text, image and sound (multimedia) in combination with the fusion of transmission channels and services (Internet), make it necessary to extend our concept of media. Media are no longer simply means of communication; they are – and have always been – both means of expression/ cognition and means of organization. Without media our cultural achievements are inconceivable. Complex social processes based on the division of labor are just as reliant on media as they are on science and education. Media, for their part, require technology to create an objective, mostly symbolic world. To determine the potential and possibilities offered by new media, we must first remind ourselves of what constitutes, in technical terms, the benefits they provide.

Keil-Slawik and Selke at first distinguish three classes of media functions, called primary, secondary and tertiary media functions. They closely examine the relevance of technology in human learning processes. Primary media functions describe fundamental functions to place artifacts in the perceptual space of a person (a group of persons). Secondary media functions extend them taking the learning process itself into account, thus they refer to applicable didactic models. Tertiary media functions consider methods of self-adapting and artificial intelligence, that means, now the medium itself is subject matter (see [Keil-Slawik & Selke 1998] and [Hampel 2001]).

The next important step is to differentiate between primary individual media functions and primary cooperative media functions. Concerning the primary cooperative media functions the primary individual media functions such as Creating, Deleting, Arranging and Linking are seen in the context of the cooperative learning process. Consequently, the primary cooperative media functions are realized through the options of Transmitting, Accessing and Synchronizing. To sum up, we distinguish four primary individual media functions and three primary cooperative media functions as follows:

Primary individual media functions:

- **Creating, Deleting** - Media serve to create or delete a perceptual space. Concerning the first allowing conception and reality to be correlated by action and the relevant conclusions to be drawn. Scientific instruments, experimental apparatus, models and simulation programs are just as much instances of artifacts that perform this function as are symbolic descriptions, diagrams, images, formalisms and visualizations of large data sets.
- **Arranging** - To attain new insights it is necessary to correlate different documents. Problem solving and learning invariably involve identifying differences and concurrence, combining different types of descriptions
and representations or weighing statements from different sources against one another. To support these processes, the artifacts to be correlated must be brought into the field of perception, simultaneously if possible. Here, logical connections should be represented, if possible, by spatial connections as well, to enable them to be swiftly identified and processed.

- **Linking** - Arrangements embodying an important connection should be preserved after the act of arranging. In this way, they do not need to be regenerated at a later point in order to continue working with them. Suitable links, for example, enable users—ideally in a single step—to refer to all documents that are of relevance for the respective meaning context.

### Primary cooperative media functions

- **Transfer** - The transfer of media between learners. Cultural learning achievements are social processes. Reducing learning to the individual processing of a document, e.g., means failing to realize that the same document has already been used, assessed and passed on in a specific social teaching/learning situation. The primary cooperative media function "Transfer" is meant to describe the exchange of media between two persons or between one person and an object, which arranges an exchange to a person.

- **Accessing** - Giving access rights to shared material, cooperative use of individual primary media functions: With the media function "Transfer" we explicitly address one person, whereas the media function of Accessing describes the access as a process which is not influenced by others, such as the creator. An illustrative example provides the filing of a document in a virtual room. Depending on the access rights to the concerning document it is possible to access it by "reading" and "writing". Another example is the use of a Shared Whiteboard, which offers the possibility to access materials of another person or to access materials from different learning places.

- **Synchronizing** - Conveying shared views on shared objects, coupling, awareness: We can identify the media function of Synchronizing in physical acts of updating presentations. On the one hand these acts are about creating shared views on documents and the report about changes in these documents and on the other hand the awareness of cooperation partners. Primary individual media functions in a cooperative structure require shared views of the partners on their materials.

The rationalization potential of new media lies in the implementation and integration of these primary media functions, concerning the more effective handling of the physical artifacts in terms of the mentioned basic areas of functionality. Here, the new media offer a wealth of new forms for the effective generating, transferring, giving access to, arranging and linking semiotic artifacts, ranging from the integration of different types of media to net-based services and search facilities.

To this extent, learning-supportive infrastructures, like the sTeam-system make use of all materials at any location where learning takes place.

### Architecture

The developed basic architecture combines two different approaches. On the one hand the development of document based CSCW/CSCL-Systems (mostly office motivated) and on the other hand the event-based architecture of MUDs and MOOs. As a result we have a flexible structure of cooperative virtual knowledge spaces which is strongly related to the WWW, but furthermore develops new methods of managing documents and other materials.

Interactions among users and between users and documents are realized as interactions between cooperating shared objects. Shared objects are persistent and are oriented towards a room structure (room metaphor). Access rights control the instance of new objects and the interaction between objects. These interactions may take place between objects in client and server.

The complex design of the basic architecture originates in the need for a scalable and easy to maintain architecture which can easily be suited to exiting and future standards. Design patterns describe recurring patterns in an object-orientated software engineering.
The designed basic architecture is subdivided in a sTeam-server, an external Web Server, a relational database and several clients. The sTeam-server coordinates the administration of users and groups, provides for the room-structure with its containing objects, organizes the communication between users and realizes the synchronization of the presented contents between the different clients. The Roxen Web Server is used as a gateway to access different Web browsers of sTeam. The relational database guarantees the persistence of the various objects (see [Hampel & Keil-Slawik 2001]).

Core server

The sTeam-core server provides for the necessary mechanisms which guarantee the reciprocal perception and the cooperative use of knowledge structures. As runtime environment, the open source LPC interpreter Pike is employed. Aside from a good performance Pike is equipped with a wide code base and a great number of existing libraries. The native Pike libraries are supplemented by a connection to different open source libraries which are implemented in the programming language C for performance reasons.

The concept of cooperative knowledge spaces demands a special administration of objects, users and different events. Thus the chosen architecture follows an entirely object-oriented design. Objects own different attributes and sometimes in the case of document types a content. Interactions between objects are guaranteed by remote method calls or events. The runtime environment is composed of further modules for the implementation of various protocols. NNTP, POP3, IRC, LDAP and COAL are directly supported. By applying NNTP the annotations of documents are presented as news. POP3 is employed to integrate news that are transmitted within the sTeam platform into the usual working environment. The chat channels connected to rooms are released by the IRC protocol. Finally LDAP permits the access to the user administration within the learning environment of the institution where the system is employed. This way within a certain university students could get access to the cooperative learning environment by using their general identification and password. The communication between server and clients is guaranteed by the implementation of a specific communication layer, the Client Object Access Layer CAOL. Currently COAL-API is implemented for the programming languages Java, C++ and Pike. The COAL-/Java-API allows the login/logout of a client and the subscription and the reception of events from the server, furthermore method calls and the transfer (up-, down-load) of objects. The object structure of the server is reproduced in an analogue way on the client side. For each server object type a corresponding class exists in the COAL/Java-API. Instances of these classes correspond to real objects on the server but they do not contain data and contents of the object. A replication of objects does only reveal a part of the viewed or needed objects. Thus through the generated proxy-objects server objects may be accessed by direct method calls (e.g. in the case of attribute changes).

For different reasons the Web server is separated from the core architecture. We employ the open source Roxen Web server (cf. www.roxen.com). In this way protocols which are implemented within Roxen (e.g. the HTTP-protocol coded by the Secure Socket Layer (SSL) can be immediately used. Beside of the very robust implementation of the HTTP
and the FTP protocols the gain in security seems to be an important aspect for the acceptance of the system. The database responds to the generic SQL interface of the programming language Pike. At the present time the free database MySQL is accessed. Through an abstraction layer, referring to papers from Ambler about the mapping of object structures on relational databases, (see [Ambler 2000]), the entire object administration is separated from the database logic. Thus the independence from the really employed database technology is guaranteed.

Evaluation

Designing technology only based on hypothesis calls for empirical confirmation in order to have evidence of the usability of the own results. Therefore we carried out the lecture “Grundlagen der Informatik für Lehramter” (“Basics of computer science for prospective teachers”). Our evaluation concentrates on the use of virtual knowledge spaces as a structuring and learning platform for cooperative knowledge management. As such it provides the students with diverse possibilities to work in cooperation with others as well as to work for themselves. Technically, we speak of a collection of documents directly assigned to a synchronous communication channel. It is possible for the students to attach comments to all of the documents. The used configuration allows the students to insert documents, to annotate, to copy and to create new links. Furthermore they could create new rooms and link already existing rooms with new exits. The setting for the mentioned lecture is characterized by three groups of virtual rooms. These are private areas of the students, assigned areas for the different learning groups and one central area containing all of the course materials.

The main goal of this setting was to prompt the students to search for additional material, which could be presented to the other students. Comments and annotations, which are connected to the documents should help the students discuss the content of the course with each other and with the lecturer throughout the semester. Thus, the contents of the lecture can be structured in an according way and new insights may be drawn from the different personal styles of structuring information.

Based on observations during the first weeks the students rather annotated any material, thus a new area called “Speakers Corner” was created. The goal was to focus on the possibilities for discussions in only one special area. Furthermore two students were asked weekly to select five slides of a presentation which in their opinion represented main aspects of the lecture. To discuss these slides, the students should as well annotate why they had especially selected the chosen ones. Now all the other students were asked to comment on the selection, to present further arguments or to show other possibilities.

Solutions to the weekly exercises were given as annotations to the respective documents if possible. If the answers were more extensive, another way was to create new documents or even new rooms. It was very interesting to see that the students agreed on publishing their results. Thus it was easier to discuss the results and refer to other solutions. As a first surprising outcome of this experiment, it was observed that the possibilities to structure the learning environment newly were not used as much as we thought it would. Such a lack in the use of provided technical possibilities can be traced back to several aspects, which in the following have to be examined more closely.

One possible hypothesis is that the method of creating new exits, etc. is too complicated (thesis I). Another explanation might be that the students realize only slowly, which new
competencies they have while working with the system (thesis II). We have to examine how far this problem is a principal one, that means, how far hierarchical structures are internalized so that the students do not deviate from them (thesis III). One point to confirm the correctness of thesis I is the observation, that students only used annotations where they were forced to do so.

To sum up, the six month practical use may be assessed positively. The concept of cooperative virtual knowledge spaces has mastered its first practical application period.

Conclusions
Virtual knowledge spaces are a new approach towards the extension of traditional hypertext systems in their way of structuring documents with event-based cooperative approaches. At the same time, cooperative knowledge spaces create new design conflicts which have to be handled in a systematical and well-founded way to gain from their inherent creative potential. The main goal of our research is to acquire the necessary knowledge and to develop a theoretical foundation. Therefore we need a basic architecture, which allows us to realize a variety of virtual knowledge spaces with a small amount of time and energy. During the last years we have succeeded in developing such architecture. Another important prerequisite are theoretical concepts which allow us to distinguish between technical and non-technical aspects and furthermore to examine the correlation between them.

To experience the potentials of virtual knowledge spaces the system has been practically tested in a traditional learning situation.

Using Scripting to Increase the Impact of Highly Interactive Learning Objects

Frank Hanisch
WSI/GRIS University of Tübingen, Germany
hanisch@gris.uni-tuebingen.de

Abstract: This brief contribution describes how to employ a scripting interface for proper embedding of highly interactive learning objects (Java Applets) into Web-based courseware. We start with a short overview of our current toolkit of reusable software components that allow the development of a greater pool of virtual experiments. We illustrate how we overcome their isolation by scripting from other learning objects, e.g. from course text, illustrations, or exercises. Further we discuss how to build up a community that may create and modify scripts online by using online wizards. As proof-of-concept we demonstrate applications in the field of Scientific Visualization.

Introduction

Process-oriented learning environments enforce active self-learning and therefore include constructive concepts that are embodied as interactive learning objects. Today, Java applets allow for intuitive, bidirectional interaction together with high-level visualization that may be seamlessly embedded into a Web-based courseware. In 1998 we demonstrated how to reduce the immense costs that affords the development of a large pool of virtual experiments by creating a toolkit of reusable software components (Klein & Hanisch 1998). Since then, many other projects focused on developing component repositories for learning objects (Laleuf & Spalter 2001).

Unfortunately, actual profit of resulting courseware is reduced by poorly implemented interlinking of learning objects. In particular, interactive learning objects appear isolated: they neither can be modified sufficiently (e.g. by choosing parameters or enhancing functionality) nor be interlinked properly with their context (e.g. by synchronizing with a guided tour). We therefore supplied our virtual experiments with a scripting interface. Scripting enables authors and learners to steer interactive learning objects by textual commands defined within other learning objects (Christian 2000).

To enable community members to take part in the development of our courseware, we set up online wizards. Single learning objects may be modified, annotated, or rated. We deal with non-interactive and interactive elements, e.g. we implemented prototypes that enable authors to modify an experiment’s set of scripts.

Software Components

Our component-based architecture consists of geometry objects, renderers, constraints, scene graph components, and GUI elements. Renderers encapsulate an object’s visual appearance. They may hold arbitrary properties to describe their visual appearance (e.g. colors, line strength, strokes). Similar, constraints separate an object’s construction (e.g. orthogonal lines) and update dependencies automatically. A plug-in architecture assures extensibility. The object itself (point, mesh, etc.) contains only primitive functionality together with a transformation cache. Adapters synchronize objects with GUI elements (e.g. a scalar with a slider) automatically. Using a hierarchical scene graph we result in default interaction behavior and visualization for all our experiments. Scene graph nodes contain a geometry object together with a matching renderer and an interaction sub-tree that provides the desired interaction behavior for our geometry object. The set of scene graph actions (rendering, picking, dragging, etc.) is extensible.

Scripting Interface

The experiments’ base component is equipped with a scripting interface. Scripts may import user-defined classes, instantiate objects, and call their methods. They also might be bound to GUI elements. Scripts are defined and documented by programmers, or, using online wizards, by community members. A well-defined state machine manages all data input steps and provides facilities for authorization, default values, undo, and preview (Figure 1). After verification of an editorial board, the given input is integrated into the script database. This entails other challenges. How to ensure bug-free and generally applicable scripts? Or, by what degree should we tolerate scripting if participants work collaboratively? Our answer is: simply do the same as for non-interactive content. Require authors to test their scripts at preview step. Evaluate and enhance scripts like any other learning object - gather access statistics, utilize a rating system, and equip scripts with forum, help, and annotation facilities.

Applications

Figure 1 illustrates how scripting may help us to overcome an interactive learning object’s isolation. The current course text describes the definition and basic properties of a vector field. We embed scripts to match the experiment’s vector field to the illustrations (which show a symmetric, radial, and potential field). The scripts will insert particles into our scene graph, or adapt the GUI and add text fields for a function parser. The learner may continue to work with his experiment. Other chapters contain scripts to exchange renderers for popular visualization techniques (arrow plot, colorization, streamlines, LIC).

Acknowledgements

We wish to thank our institute’s member Michael Hauth for implementing the Runge-Kutta integrator, as well as our student researchers Sven Gottwald and Christian Holzer for developing our scripting interface and online wizards.

Abstract: This paper is a report on the findings obtained from evaluating the planning and implementation of an online symposium addressing the issues of continuing professional development. The participants included educators, researchers, and training specialists in Canada. The symposium was part of an Office of Learning Technologies (OLT) funded project. The symposium was delivered through a blended learning model delivered via asynchronous and synchronous technologies. The symposium’s goal was to gather and disseminate knowledge regarding the process of implementing learning technology initiatives in the workplace. It also evaluated the use of a blended learning model for professional development. Overall, the symposium achieved its goals using a blended learning model, however, the synchronous virtual classroom environment worked more effectively in group collaboration and discussion compared to the asynchronous learning environment. Recommendations are summarized for planning and implementing an online blended learning model.

Introduction

While researchers claim that the majority of adult learners are satisfied with learning in computer-mediated contexts, there are still students that do not appreciate this type of learning or find it extremely challenging because of the lack of human elements like visual/verbal cues in Internet based forums (Holt, Kleiber, Swenson, Rees, and Milton, 1998). Therefore, there is a constant need for distance educators to evaluate the experience of adult learners in the context of interactive computer mediated communication (Sorg and McElhiney, 2000). One of the functions of this project is to examine the effectiveness of using a blended learning solution, including both synchronous and asynchronous delivery tools for collaboration, interactivity, and dissemination of information.

Several researchers and practitioners have noted the benefits and disadvantages of using synchronous online conferencing for instructional purposes. Perceived disadvantages of text-based synchronous online communication include a lack of focus and reflection in students’ comments (Honeycutt, 2000). Other limitations noted in the literature are that students are constantly challenged because visual and verbal cues are not present during the text-based discussion (Sorg and McElhiney, 2000).

However, these disadvantages seem to be outweighed by the several benefits associated with text-based synchronous online communication. Such benefits include increased student participation, liberation of minorities, and facilitation of small group discussions (Bump, 1990). Sorg and McElhiney (2000) concluded that by using text-based synchronous environments students gain a sense of empowerment, a feeling of belonging to a group, and construct their own knowledge.

While useful, the previous studies are limited to synchronous online conferencing that is text-based. Recent studies have started examining the effects of synchronous online learning environments or virtual classrooms that use video and audio (Voice-over-Internet Protocol) for communication. In a study that used synchronous online instruction with one-way video and two-way audio, Hofmann (2000) observed that the technologies became transparent in the learning process, and the focus became the content rather than the medium. This is an indicator of a successful technology based program. According to Appelt and Mambrey (1999) synchronous virtual learning environments seemed to increase the quantity and quality of interaction among students, and between students and teachers, subsequently establishing a network of communication and collaboration among students and teachers. The importance of collaboration in learning is evident, as it is tied to knowledge construction (Jonassen, 1996).

These virtual learning environments may be even more effective if a combination of synchronous and asynchronous learning is utilized, which is referred to as blended learning. Blended learning “focuses on optimizing achievement of learning objectives by applying an appropriate combination of learning technologies for the learners, context, and skills taught” (Singh and Reed, 2001). Charr-Chellman and Duchastel (2001) claim that the ideal online course may include web-based textual materials such as study guides, discussion forums, both synchronous (real-time) and asynchronous (delayed), e-mail, and voice/audio communication, which could be audio/video conferencing over the Internet or traditional telephony. These elements would be used depending on the context and content of instruction. An advantage of using asynchronous interchange is that students can participate in a flexible manner at their own time (Charr-Chellman and Duchastel, 2001) for thoughtful analysis and critical reflection (Bhattacharya, 1999). On the other hand, the benefits of using synchronous exchanges include “a more direct sense of collegial interaction, immediate resolution to questions posed, and possibly a strong contribution to team building” (Charr-Chellman and Duchastel, 2001, p.7). Blended learning would take advantage of the benefits of both synchronous and asynchronous instruction.

The Rensselaer 80/20 Model (Lister, Dunckel, Scalzo, Jennings, and Wilson, 1999) proposes the use of blended learning. Based on this model Rensselaer Polytechnic Institute created undergraduate courses that were 80% asynchronous, including streamed on-demand video and audio or other resources accessed on the Web, and 20% synchronous. A technology used for the synchronous component was an interactive distance system called LearnLine, which emulates the “proven techniques of interactive teaching that are so effective in the face-to-face classroom” (Lister et. al, 1999, p.2). Lister et. al (1999) conclude that while the asynchronous component is invaluable as long as it is instructionally sound, the synchronous interaction is an integral part of the distance learning course, which helps keep students on track with course deadlines, allows students to receive immediate feedback, builds a team and community spirit among students, and improves retention rates.

Beyond Learning Technologies: An Online Symposium was part of an Office of Learning Technologies (OLT)-funded research project entitled Evaluating Learning Technologies Initiatives (ELTI) in Continuing Professional Development. The Beyond Learning Technologies online symposium was organized and hosted by the TELUS Centre for Professional Development and the Institute of Professional Development at the University of Alberta. The symposium was organized and hosted by the TELUS Centre for Professional Development and the Institute of Professional Development at the University of Alberta. The symposium was delivered through a blended learning model delivered via asynchronous and synchronous technologies. The symposium’s goal was to gather and disseminate knowledge regarding the process of implementing learning technology initiatives in the workplace. It also evaluated the use of a blended learning model for professional development. Overall, the symposium achieved its goals using a blended learning model.
University of Alberta, in collaboration with the ELTI research team. Participants in this symposium included educators and researchers from various universities across Canada and training specialists from the federal government and private industry.

The main purpose of the online symposium was to disseminate the findings of the ELTI project associated with implementing learning technologies initiatives and generate comments and feedback from the participants on these findings. Since innovative learning technologies initiatives were used for the symposium, including both synchronous and asynchronous delivery tools, the planning and implementation of these technologies was evaluated and recommendations are provided for professionals in the field.

The symposium took place completely online and consisted of an asynchronous (delayed) and synchronous (live, real-time) component.

The delivery tool used for the synchronous component was CentraOne. This is a Web-enabled virtual classroom environment using Voice-Over-Internet Protocol technology. Each of the synchronous sessions was 1.5 hours in duration. The content for the sessions was provided by the ELTI research team and was modified by TELUS Centre eLearning team to ensure that instructional design principles were followed and that the content was appropriate for synchronous online delivery.

For the asynchronous part of the symposium, an online course was created in Web Course Tools (WebCT), which contained case studies, executive summaries, links to resources, a draft of the final report, and an asynchronous discussion board.

The primary methods used in evaluating the Beyond Learning Technologies online symposium involved evaluation surveys, the recordings from the synchronous online sessions, and the archived asynchronous discussions.

As a secondary method the tracking system from within WebCT was also used to collect information on which participants logged on to the WebCT course and how many pages were accessed within the course.

Findings

Overall the symposium seemed to be successful as it achieved its primary goals, which were to disseminate knowledge about the Evaluating Learning Technologies Initiatives in the Workplace project and to gather feedback from participants on the questions examined in the project. It also achieved its second goal, which was to implement and evaluate the use of a blended delivery model, which is an innovative learning technology in itself, where by both synchronous and asynchronous online delivery modes were implemented for this symposium.

Specifically, the participants seemed very enthusiastic about the synchronous online sessions. Several participants noted that they enjoyed the interactivity and the opportunity to have a discussion with colleagues in different geographical locations, using the Internet, without having to travel. Additional positive comments were made related to the facilitation of the event, ease of use, effectiveness of the tool, and the collaborative human interaction amongst the participants. Negative comments centered on microphone volume levels, which were not consistent across users.

The asynchronous part of the symposium, a course built in WebCT did not seem be as successful. While participants used it to access the resources associated with the symposium (case studies, executive summaries, links etc.), the use of the asynchronous discussion forums were underutilized.

Recommendations

The success of a blended learning model using Web-enabled communication technologies depends on planning and implementing key procedures during the lifecycle of the project.

General Instructional Design Recommendations

- Identify the audience (participant)
- Identify the learning objectives and outcomes
- Identify discussion topics and evaluation methodology
- Choose the appropriate amount of time needed for synchronous and asynchronous instruction
- Choose the appropriate tools within each learning environment to best convey the learning concepts
- Develop electronic curriculum which is instructionally sound and suited for online delivery
- Develop discussion and survey questions to encourage participants to interact and collaborate

Recommendations for a Blended Learning Model (including synchronous and asynchronous online instruction):

- Ensure that participants meet minimum computer hardware requirements, which is critical for remote participant connectivity and for reducing participant frustration.
- E-mail logon credentials to the remote participants as well as timelines and dates.
- Provide an orientation of each learning environment to participants.
- Provide access to technical support for the participants to help those who experience difficulty in getting properly connected to both learning environments, during the events.
- Encourage participants to log in one half-hour prior to the commencement of the event. This facilitates establishing a comfort level for the participants. Microphone and speaker volumes can be adjusted appropriately.
- Complete a dry-run session prior to the actual synchronous live event to ensure the presenters are well prepared and comfortable with the Graphic User Interface.
- Integrate the use of synchronous and asynchronous components of the course so they are interdependent rather than independent. For example, answering questions in the asynchronous component successfully will require that you have attended the synchronous component of the course.
- Evaluate the participants’ learning experience.

Tagging the didactic functionality of learning objects

Per Skafte Hansen, IMM, DTU, psh@imm.dtu.dk
Stig Brostroem, LRC, DTU, sb@dtv.dk

Introduction: We recently undertook to implement and package a number of short presentations on a CD-ROM, as a supplement to other material for a course in numerical analysis. The items vary in terms of size, natural viewing media and intended use; and the purpose of our work, other than the didactical one, is to monitor the resource requirements for the production and wrapping of such material.

This seemingly straightforward task brought us into direct confrontation with issues concerned with the concept of learning objects (http://works.opencontent.org/writings2.pl) and their future usability.

Background: The CD-ROM in question will eventually contain fixed texts (surveys, exercises etc.), modifiable texts (a report layout, the framework for a do-it-yourself manual, etc.), code examples, animations with optional voice-overs, and video-recorded miniature lectures. To make the whole effort useful and at least to some extent reusable, we ventured into marking up ("tagging") each item as a learning object. The difficulties encountered in this process hinge on the fact that the standards (consult http://www.imspoint.org/specifications.html) for learning object content packaging, whether finalized or drafted, are biased towards bibliographical usages and pay insufficient attention to the needs of the author, the teacher and the learner. In particular, we wanted to address, as equally important:

Subject: Within the subject of numerical analysis (our present example), there are sub-subjects such as one-dimensional interpolation, with sub-sub-subjects such as the proof of the structure of the error term in polynomial interpolation, and the "sub-vs. sub-sub"-relations are difficult to state in the tags

Didactic function: An interactive self-assessment is in quite another category than a video-recorded proof of a theorem, yet the current standards do not allow for this kind of distinction

Granularity: A whole alternative exam for a course is too large to be one learning object, a single graph too small, an exercise in programming a graph-drawing function suitable

Note, that adequately monitoring granularity is the responsibility of the author, not of the tagging tools; but it will be of importance for what follows.

Recommendations: There is a need for extending the type declaration to have it describe the didactic function of the object. A crude approximation to what is meant may look as follows:

Simple fact(s) may be such things as definitions, measurements, precise names
Relations may be rules, formulas, laws, observable causal connections
Operations may be experiments, algorithms, typical design manipulations, exercises and self-tests
Insights may be explanations, proofs, rationales of (best) practices
Stimuli of innovation are such open-ended items as project (exercise) proposals

(The five italicised categories used are part of a general paradigm currently under development by the first author and should only be considered a starting point in the present context).

The type declaration idea might in fact allow for composite types, as in procedural programming. The simplest version, a fixed-depth, fixed-span type declaration of depth D corresponds to the addition of D tags, each with a pre-defined table, table of tables etc., of allowed values, after the above manner.
The structure into which a user (teacher) will fit the individual component cannot and should not be standardized: the whole of such a structure will form a course or the equivalent, and to name an example — the position of a learning object in the time-line of the course and in the logical flow in a final exercise may be very different, top-down vs. bottom-up composition being but one such disparity.

Yet, engineering disciplines abound with components-in-connection, as exemplified by circuits and networks, process plants, in fact the general idea of dynamical analogies and system design. — One may safely argue that the very notion of a “component” requires a network for the component to sit in. Also, one must avoid the situations of a learning object author blindly composing what he believes someone else may need, or the user receiving the result without knowing whether or not it is of any use in an overall arrangement unknown to the original author. We therefore most strongly recommend that learning objects and some mechanism for their assembly be considered dual and of equal importance in standardization initiatives. An idea of what we have in mind is illustrated in the following diagrams:

Figure text: The left listing, easily re cast for a graphical user interface, gives a choice of subjects for a course in elementary numerical analysis, one topic highlighted; the middle diagram indicates the learning objects as components-in-a-network, one selected; and the right table the inner structure of this specific learning object, with a few tag declarations (in bold).

To allow for composition with, and use of, such networks, meta-tags might assist by providing information concerning e.g. the pre-requisites of the learning object at hand. Such information requires standardization pertaining to the teaching and use of the subject items and may thus eventually be unacceptable outside the realm of the curriculum of a given university. Also, the tagging process, already time-consuming, will become truly demanding of intellectual effort whenever a new subject area is entered.

Still, learning objects are to be “launched” by authors, but searched for and employed by teachers and consumed by students. We expect to see authoring, searching and viewing tools merge in the near future and wish to point out that the choices of identical or symmetric display and operations lie with the tool designers, not with the designers of the mark-up standards. But as we envisage a future in which learning objects are aplenty and computer networking full-grown, we must require of the learning objects themselves, and hence of their tag structures, that they support a specialized search. Otherwise, the well-known “app. 1,001,300 hits” — message will soon preclude the use and hence the benefits of learning objects. This is why questions of object size interweave with the technical issues: you can only find what you are looking for if it is suitably tagged; and you can only carry the burden of “tagging”, if each item is of an appropriate size. Otherwise, you either have too many to look after, or quite few, but each too complex to describe in the simple manner required by the mark-up procedure.

Brief conclusion: While the ideas and concepts behind learning objects are sound and natural, especially to engineering educators, aspects of their design and use are still un- or underdeveloped. From a components-in-a-network point of view, the most important issues are: a didactically based typing of the learning objects themselves; the entire design superstructure into which the learning objects must be fitted; and the symmetry of the interfaces, as seen by each pair of the triad: author, teacher, learner.
Exploring Student Performance on a Multimedia Exam Program (Vexam): the relationship between item formats and item difficulty levels

Yung-Wei Hao
School of Education
University of Texas-Austin, USA
hao@mail.utexas.edu

Abstract: This research study aims to explore the influence of multimedia and text formats on student performance in the multimedia exams. The focus group is the 390 students who took an online, self-paced undergraduate course in Department of Anthropology at the University of Texas at Austin in fall 2001. Vexam was the assessment tool for the class. The test items, created by Vexam, were multiple-choice items and consisted of text, movie clips, and/or pictures; they were categorized in the two groups, multimedia and text only. The research question is whether there is a significant relationship between the use of multimedia and text only formats and item difficulty levels in the exams. An exploratory research study and result will be presented.

Introduction

With information technology designs becoming more user friendly, and the cost of multimedia decreasing, multimedia technology provides the education field with additional degrees of freedom, enabling the exploration of alternatives to traditional education (Vogel & Klassen, 2001). In order to relieve pressure on teaching staff caused by increasing enrollments, more institutions are investigating computerized testing as a tool for formal assessment. (Stephens, Bull, & Wade, 1998; Zakrzewski & Bull, 1998).

The computer screen offers numerous options for overcoming the disadvantages of uninteresting and unvaried format (Byrnes, Forehand, Rice, Garrison, Griffin, McFadden, & Stepp-Bolling, 1991). By incorporating multimedia, some assessment tasks can be made more relevant. Item stimuli can be made dynamic by having video, audio, and animation (Bennett, 1999). Multimedia testing environments can be more authentic, because they can be contextualized with multiple media elements, and the text can be combined to present the tests with items resembling real-life tasks.

However, simply adding an illustration next to a word does not make the situation better (Gyselinck, 1996). Especially in testing, whether the type of presentation can influence student performance, it is not yet known and needs further research. More investigation is needed to establish whether people can be confused or distracted by multimedia when the items are easier. The purpose of this study is to gain deeper insight into the effects of use of multimedia and text only on student performance in the multimedia exam.

The Study

The study focuses on whether using multimedia can help people answer questions correctly. The item difficulty level is used to interpret the students' performance. The item difficulty level is defined as the number selecting correct answer divided by the total number taking the test (Kubiszyn & Borich, 1999). By analyzing the difficulty level of test items, the study investigated whether there was significant relationship between item formats and item difficulty levels (the students' performance). The research questions were raised for this study as follows.

- Is there a relationship between the use of multimedia and text-only and the item difficulty level (the students' performance)? If the answer is yes, what relationship is it?

The 390 students took the online, self-paced course and took the multimedia exams weekly. Vexam, a multimedia exam program and not a computer-adaptive testing program, was the assessment tool for the class. The 585 test items were retrieved from the 10 exams students took during the semester. The item formats consisted of text, movie clips, and/or pictures. For those items whose item discrimination index is less than 0
were taken away. Only the items with positive discrimination index are worth analyzing. Thereafter, all the rest of the test items with positive discrimination index in 10 exams were categorized by their item difficulty levels (from 1 to 9) and by their item formats (multimedia and text only). By comparing different types of item formats with different item difficulty levels in the exams, the study tested whether there was significant relationship between item formats and item difficulty levels.

Findings

According to the result of the study, item formats have a significant relationship with item difficulty levels. Namely, different item formats have a significant relationship with the proportion of people who got the item correct. On the other hand, there is no significant difference between the multimedia format and the text format in each item difficulty level.

Conclusion

The results of the study showed that the use of different item formats had a significant relationship with the students’ performance. Also, in each item difficulty level the text format and the multimedia format do not have significant differences. This is a work-in-progress. Further research will investigate the reliability of the research results and students’ behavior and perspectives on taking the multimedia exams. Educators should be careful when using multimedia elements in testing, since item formats have a significant influence on students’ performance. There still lacks a standard methodology for developing computerized testing (Drasgow and Olson-Buchanan, 1999). More innovative research is needed to explore when and how multimedia can cause the effects, which can influence student performance.

Designing Simulations for complex skill development

Barry Harper and Rob Wright
Faculty of Education, University of Wollongong
Wollongong, Australia

Abstract: Theoretical approaches to instructional design for skill development in complex domains lags behind the changing nature of education and training reflected in the application of contemporary views of learning. In particular, employing novel pedagogical approaches for advanced skill development has not been extensively investigated. The development of an application of guided simulation incorporating reflection tools to train naval officers in pilotage has been undertaken to illustrate this process. The skills and knowledge which are part of the conceptual framework that learners need to acquire to be pilots have been analyzed and the design incorporates a variety of instructional strategies that are well suited to supporting outcomes driven learning.

Introduction

The possibilities afforded by new multimedia technology, combined with contemporary ideas about learning, have opened up new design opportunities for educational simulations. In particular, the use of sophisticated multimedia environments has made the design of experiential simulations, in which the learner plays an authentic role carrying out complex tasks, a much more tractable design task.

However, theoretical approaches to instructional design for skill development in complex domains has lagged behind the changing nature of education and training reflected in the application of contemporary views of learning. As theories of learning have developed and educationists have gained more experience in the use of computer based technology, there has been a shift of emphasis from the behaviourist paradigm, and through what Atkins (1993) has called the weak artificial intelligence approach, to a constructivist view. This shift of emphasis has not been extensively investigated for advanced skill development with some notable exceptions such as the ADAPTIT project (Pass, et al, 1999). This view of design has influenced the development of an application of guided simulation incorporating reflection tools to train naval officers in Pilotage. The skills and knowledge which are part of the conceptual framework that learners need to acquire to be pilots have been analysed and the design incorporates a variety of instructional strategies that are well suited to supporting complex cognitive skill development.

Contemporary Theories of Learning

Many writers have stressed the need for open-ended exploratory authentic learning environments in which learners can develop personally meaningful and transferable knowledge and understanding. The lead provided by these writers has resulted in the proposing of guidelines and criteria for the development of software based on a constructivist view of learning (eg. Savery and Duffy 1995; Duffy and Cunningham 1996; Grabinger 1996; Squires 1996; Hamafin and Land 1997; Grabinger, Dunlap and Duffield 1997). Harper, Squires and McDougall (2000) have proposed a recurrent theme of these guidelines is that learning should be authentic. They have noted that a review of the literature points to three seminal concepts, which originate from the notion of authenticity: credibility, complexity and ownership.

For learners to feel that an environment offers credible opportunities for learning, especially when skill development is paramount, they need to be able to explore the behaviour of the systems, which are the focus of their learning. One way to do this is through working with simulations of the systems to be mastered. The environment should provide the learner with intrinsic feedback, which represents the effects of the learner’s action on the system and mechanisms to experiment with ideas, try out different solutions to problems and reflect on those solutions.

Grabinger and Dunlap (1995) emphasise that learners should be presented with complex environments that represent interesting and motivating tasks, rather than contrived sterile problems. Only in complex,
rich environments will learners have the opportunity to construct and reconstruct concepts in idiosyncratic and personally meaningful ways. However, learners may need help in coping with the skills to be developed in complex domains. Strategies, which have proved useful in helping learners, include scaffolding (Krajcik et al. 1998), anchoring (Cognition and Technology Group at Vanderbilt 1990), and problem-based environments (Tobin and Dawson 1992; Grabinger, Dunlap and Duffield 1997). Additionally, metacognition, in which learners reflect on their own cognition to improve their learning, has been advocated by a number of writers, eg. Scardamalia et al. (1989) and Papert (1980). It is claimed that by a conscious personal appraisal of cognitive processes, an individual can improve his or her capacity to learn (Hoban, 2000).

The Simulation Paradigm

Simulations as learning environments have had a long history of use in education and training and have been based on a variety of theoretical views of learning. Initial claims for the educational benefits of using simulations tended to emphasise pragmatic solutions to classroom problems. Processes, which take a long, time, eg. population growth or genetic change, or which happen very quickly, eg. changes in impulsive force during a collision, are possibilities for simulation. Difficult, dangerous or expensive processes are also candidates for simulation, eg. experiments with radioactive materials.

The key feature of an educational or training simulation is that it makes use of a model to represent a process, event or phenomenon, which has some learning significance. The learner is able to interact with this representation and the simulation provides intrinsic feedback that the learner can interpret as the basis for further interaction. The underlying model may be mathematical leading to the generation of numerical results, rule-based with the intention of providing feedback on subjective input, or even context-based in that the learner is placed in a context that simulates a real situation.

A broader view of simulation can be taken if an 'in context' environment is considered as a simulation. In this form, the simulation is designed to place the user in a professionally-relevant context where they can investigate an issue and solve a problem, without necessarily receiving the intrinsic feedback characteristic of the more mathematically or rule-based simulations. While working with such models, the user often comes to see the simulation as a 'real world' in its own right (Crookall et al., 1987). Gredler has described such simulations as experiential and proposes they aim to establish a particular psychological reality and place learners in defined roles within the reality. He describes the essential components of an experiential simulation as '(1) a scenario of a complex task or problem that unfolds in part in response to learner actions, (2) a serious role taken by the learner in which he or she executes the responsibilities of the position, (3) multiple plausible paths through the experience, and (4) learner control of decision making' (1996, p. 523). Role playing simulations of environmental planning are classic examples of experiential simulations. Such models can be considered as representing real-world systems as either an "in-place-of" or a "bring-to-life" format.

Regardless of the type or format of the simulation, the overriding purpose for simulating systems remains to provide a learning environment that supports the learner to develop mental models about a process or the interrelationships of variables. Simulations can help learners achieve these objectives by providing a substitute experience for those processes and systems, which by reason of cost, scale, time or risk would not normally be accessible.

Complex Cognitive Skill Development

In many areas of training, where learners are to achieve a high level of efficiency in complex tasks, achievement of complex cognitive skills is a key goal. The term complex cognitive skills can be thought of as complex, in the sense that they comprise a set of constituent skills and at least some of these constituent skills involve conscious processing and cognitive, in that the majority of constituent skills are in the cognitive domain. Merrienboer, (1997) has developed an instructional design model, the 4C/ID model, which has influenced the design process which lead to development of the application described in this paper. The model is based on the view that in development of complex cognitive skills, learners should practice simple-to-complex versions of either the whole complex cognitive skill or meaningful clusters of constituent skills and that complex cognitive skills have both automated and cognitive components.
Pilotage Training

The skill of piloting a ship into an anchorage is a complex cognitive one, which involves not only a constant process of decision-making, based on data and crew input, but also management of multiple inputs in real time.

The training of navy personnel on the piloting of ships has had a history of making use of sophisticated simulators, but initial training has tended to be based on more traditional classroom experiences. With an aim of developing a more efficient training process, drawing from our experience and research with simulation, a PC based simulation has been developed, based on contemporary views of learning. Our instructional design strategies for this package are based on authentic experiences, a problem solving context and discovery (de Jong & van Joolingen, 1998) and reflection (Schon, 1983; Schon, 1987).

The development of an understanding of Pilotage is the key goal of this package. The skills and knowledge which are part of the conceptual framework that learners need to acquire to be pilots have been analysed and incorporated into instructional strategies that are well suited to supporting outcomes driven learning, and yet place learners in an environment which, in Gredler's terms, can be considered to be experiential.

The package makes use of learner-interaction in a visual context that is consistent with being a pilot on a combat ship. The strategies used to develop the high levels of skill necessary consist of:

- Lesson materials, containing support elements for concept development and review as well as a set of reference materials commonly used when planning and executing pilotage
- Guided simulation where the learner makes decisions within a simulated environment and can then consider the consequences of their decision, and
- Use of constituent skills which build to complex cognitive skill sets which are necessary to solve the task
- Reflection where the learner can review their experience and reflect on their success (Figure 1).

![Figure 1 A view of the introductory tutorial window](image-url)
A set of lesson-style tutorials was developed to expose trainees to a logically sequenced set of pilotage theory concepts. Essential 'lessons' are available for trainees to use to increase their understanding within this area. Where the lesson concept is complex or difficult it is supported with animated sequences relationship models or diagrams. Each lesson also contains a review module where the key concepts of the lesson are presented for review using a question and answer approach. Once an initial sub-set of the tutorial concepts has been worked through by the beginning trainees they can commence the simulation. The content remains easily accessible when a trainee needs to review or check a concept relevant to the complex skills demonstrated when working on the simulation environment.

The Simulation provides a pseudo-realistic environment modelled on the visual cues, pilotage processes and control tools found on a typical naval vessel. The experience of using the simulator gives the trainee the opportunity to plan, observe, and make decisions that directly impact upon the movement of the vessel with realistic outcomes such as being able to maintain a planned course to varying degrees from successfully reaching your destination through to running aground. The key interface elements of the simulation are: A chart that details a fictitious island group with the information needed for planning a pilotage track through the area, tools to 'mark-up' the chart for a planned pilotage run, data such as depth soundings and navigational aid such as beacons, landmarks and buoys. In visual pilotage mode, a 3-dimensional view from the bridge of the ship is derived from the chart as well as incorporating extra data such as tidal streams and currents (Figure 2). The trainee is able to manoeuvre the ship using speed and course adjustment controls, monitor the ship's progress via tools such as the depth sounder, wind-direction and wind-strength display, stopwatch, ship's clock, propeller revolutions, heading and speed readouts. As well as interacting with these controls, the trainee is able to take bearings on objects within the 3D visual environment, which can be panned, to starboard or port. This enables the monitoring of the ship's progress relative to the planned pilotage route.

![Figure 2 Visual Pilotage mode showing the chart, a 3D-engine display and reflection tool.](image)

The simulation can also be run in a blind-pilotage mode. In this instance instead of a 3-dimensional view of the experience, the trainee is provided with a radar view typical of that used in situations of limited or no visibility. The manoeuvring controls remain constant between modes.

Reporting progress to the ship's commander is achieved through a set of interfaces that allow the trainee to focus on single or multiple facets of pilotage such as monitoring a headmark, determining gyro error, fixing the position of the ship etc. These actions are recorded in the ship's log, designed to support learner
reflection. The simulation can be operated within a practice or assessment mode. Within the practice mode, prompts triggered by the actions and sequence of actions of the trainee are provided to supply intelligent feedback on their progress. In this mode the trainee is also able to 'record' and 'playback' their pilotage run from a user-determined point in time. In assessment mode the trainee enters an environment absent of these support and review mechanisms, with a complete record of the run recorded for assessment by an instructor, or self-assessment by the learner.

The reflective process is facilitated through the use of a number of key features. Whilst the trainee is working within the simulator, practising their pilotage skills, their current actions are recorded in such a manner that enables them to review their past actions in two forms. The first is a list version of the key events that have occurred displayed within a floating log device window. The second is a visual 're-run' that reproduces their actions just as they occurred and displays them within the 3D visual environment. The provision of a 'snail-trail' that is visible within the chart module when the ship's movement is paused or stopped in practice mode gives a visual trail that shows the history of the ship's movements in the current simulation run. There is also the provision to 'save' pilotage chart and run sequences. These are small enough to be easily emailed to instructors for use in review procedures. A notes device which allows trainees to collect text, images or animations as well as store pilotage run files, provides a mechanism to assist them in making sense of the training environment through establishing and storing links to material of interest and annotating their experiences with their own language. The combination of these tools of reflection provides a substantial means of capturing, reviewing and assessing the performance of the trainee.

Conclusions and Research Agenda

The package offers a wealth of research opportunities, particularly in investigation of the use of simulation and reflection tools to develop complex cognitive skills. Initially the package will be used with the Singapore and Australian Navy with an evaluation process informing researchers about the effectiveness of the approach. An initial investigation of the usefulness of the package will be undertaken through user testing and expert review. The package will then be introduced to defence personnel in both countries, with a comparison of the traditional classroom outcomes against outcomes when using the package. Outcomes measures will be based on authentic assessment on board vessels modelled in the package. This will be a starting point for more detailed research on the specific tools built into the package.

Abstract:

An instructional application consists of a set of resources and activities that implement interacting, interrelated and structured experiences oriented towards achieving specific educational objectives. Computer-based instructional applications have to be faced as any other development activity following a well defined process. With this purpose some design methods for computer-based instructional applications have been proposed. However most of them are focused on "on-line" courseware structures which are quite rigid as far as they have serious shortcomings to deal with courses structured in multiple ways. Moreover, these methods usually lack a specific mechanism to model instructional concepts and strategies. This work proposes a design framework to develop multi-structured instructional applications combining a didactic model with a software engineering approach to deal with educational and technical requirements. The underlying model extends knowledge structures, such as those involved in the Merrill's Transaction Instruction Theory, adding them didactic information. It also considers the functional aspects of these structures. An XML-based notation is proposed to represent such structures and their management.

1. Introduction

An instructional application can be defined as a set of resources and activities which implement interacting, interrelated, structured experiences that are designed to achieve specific educational objectives. Instructional applications are usually structured by means of static patterns which are based on a sequence of book-like electronic pages. They are designed using courseware methodologies that focus on presentation and navigation issues but lack a didactic basis. The resultant products are mostly "pretty-printing" on-line courses but didactic aspects are hardly considered. The current work proposes a design framework which is independent from computer-based delivery technologies and it allows the representation of multiple didactic structures from an instructional point of view. Such a framework requires a model to deal, on one hand, with instructional design topics and, on the other hand, with the design of computer-based applications.

Instructional design can be defined as the discipline that connects descriptive theories with instructional practice. Among the different instructional theories proposed in the literature, we will assume the Instructional Transaction Theory (Merrill 1996) since it makes possible to figure out the relationships between educational and technical components. Merrill's mental models consist of two major components: knowledge structures (schema) and processes for using this knowledge (mental operations). The Merrill's hypothesis states that adequate instruction would require multiple types of knowledge structures to be identified and made explicit to the learner. Thus, the Instructional Transaction theory provides a powerful tool to structure the knowledge about a given topic and to define the procedures for accessing it. In the framework proposed in this paper, Merrill's model is extended to add didactic information to knowledge objects and structures. A Didactic model is built using the previous entities as the basis and assigning them attributes whose values suggest how they can be used or even adapted in a specific learning or teaching scenario.

On the other hand, the proposed framework deals with the design of educational computer-based applications. Most of the existing methodologies are addressed to author courseware using formats such as HTML documents. They seem adequate for presenting and accessing information in a open environment like the Web but lack a data structuring capability. Another option is using proprietary multimedia authoring tools like Authorware™ or
Tooolbook™ that provide a more powerful data model but they bound the reuse and exchange of content module (Wiest, 2001). In this sense, an important effort has been made to organize and to manage educational data using metadata (Duval 2001). However, standard metadata proposals mainly aim at the reuse and exchange of learning material and they are not directly involved in the context of instructional application design. In the current work, notational systems based on metadata are used to represent instructional and didactic entities. The proposal consists of defining an XML-based notation which specifies the Merrill's Instructional Transaction Theory entities and their extension introduced in our Didactic model. Such notation will allow an instructor to define his own didactic structures which can be built from a common repository of instructional objects.

The remainder of the paper is organized as follows. Second section revises some related works. Third section introduces the design framework proposed in the current work. Such framework is based on a didactic model whose structural components are presented in fourth section. Fifth section complements this model with its functional view. An application example is described in section 6. Finally, section 7 presents some remarking conclusions.

2. Related work

There are several technology-based educational initiatives that propose a separation between didactic aspects and content related issues. In this context, the Multibook project (Steinacker et al. 1999) considers two domain spaces: the Concept Space and the Media Brick Space. The first one contains a network of knowledge topics which are connected via semantic relations. The second one contains information units of various multimedia formats. Media Brick elements are linked to the Concept entities and instructional mechanisms such as "example", "deepen" or "explain" are setup between these elements. A similar approach is proposed in LMML (Süß et al 2000) which differentiates Pedagogical and Instructional properties from the Module and Content objects. However, only strategy attributes with possible constant values “beh” (behaviouristic) or “con” (constructivistic) can be specified. Other proposals such as the Targeteam project (Teege 2000) or the Palo language (Rodriguez et al 1999) are also constrained to relations or mechanisms such as motivation, illustration, exercise or explanation without an additional didactic value.

In metadata contexts, there are Educational Modeling Languages (EML) which allow the specification of many kinds of educational data. These data can be implemented using notations which take advantage of standard proposals on one hand, or particular and specific proposals on the other hand. The first option is used in the Multibook project to define the Media Brick elements from IEEE Learning Objects or the Chameleon project and its TeachML (Wehner 2001) notation that is based on IMS standards. These standard formats are useful for exchanging them in different learning contexts but their didactic attributes are very restrictive. In the second category, there are formats such as LMML that defines instructional ContentObjects which contain media units such as tables, lists, images or text. The problem is that these units are strongly coupled with instructional objects and it prevents to assign them with different media objects. Similar problems are found on other EML proposals such as Targeteam contents, EML learning objects (Koper 2001) or Palo elements.

3. Design of Instructional Applications

Figure 1 shows the global architecture in the proposed instructional application design framework. The upper level deals with Instructional Design Theory which manages entities such as "knowledge objects", "knowledge structures" and "transaction shells". According to Merrill, a knowledge object is defined as "a precise way to describe the content to be taught". Knowledge objects can be combined into knowledge structures. Knowledge structures are external representations of knowledge that are parallel with mental models that in turn are internal (cognitive) representations of models. Transaction shells consist of rules for selecting and sequencing knowledge objects. The entities defined in the Merrill's model are the basis for the next level (Instructional Design Modeling). This central level is characterized by a Didactic Model whose components extend the previous entities with didactic information. They are divided in two categories that represent the structural and functional model, respectively. Structural model is composed by instructional objects, derived from knowledge objects, and didactic structures which extend knowledge structures. Functional model is based on instructional tasks and learning scenarios. An EML notation is being designed to specify both structural and functional components. Next section will describe them in depth. The lower two levels deal with the computational implementation of instructional applications. The first one is based on a hypermedia model to represent the instructional entities and their relationships in an formal and abstract notation (Buendia et al 2001). The second level is related to the technology involved in the delivery of instructional applications using an e-learning environment.
4. Structural model

This section focuses on the structural components of the Didactic Model proposed in this paper. The simplest element of the current model is the Instructional Object (IO) which is used to manage Merrill’s knowledge objects from a learning point of view. Instructional Transaction Theory describes knowledge in terms of three types of knowledge objects: entities, activities and processes. When an entity, activity or process is addressed in a learning context, there are multiple aspects that differ depending on the learning conditions around the knowledge object. The main goal of IO elements is to represent such aspects. If the learning target is an entity, IOs such as definitions, statements or examples can be used to describe it. Activity knowledge items can be characterized using IOs such as exercises, questions, analogies, hints and so on, and finally, processes are also qualified with simulations, feedback elements, or animations.

IOs are not only isolated information units such as definitions or exercises but they are also concerned with the way these units are used in a learning context. For instance, an entity definition is assigned with a difficulty level, a statement declares a property value assigning it a relevance index and an example displays the entity with a specific portrayal (text, audio, image, and so on). Therefore, IOs must consider the multiple possibilities for a knowledge object to be learned in order to deal with different learning styles and needs.

The model presented in this paper provides a flexible framework to incorporate multiple kinds of didactic information which can be added to IOs. The instructor has to decide the different difficulty or abstraction levels assigned to each object, its relevance in a certain learning context or the portrayal that requires a given user profile. This design process is highly related to the features of a subject domain and it becomes a manual and laborious process. Tools as metadata notations have been used to support this process.

In this work, there is a simple XML notation proposal and the definition of IOs is adapted according to the subject domain. This means that they can be defined on top of other entities such as Merrill’s knowledge objects or IEEE learning objects, extending them with didactic elements as those referred in Figure 2. In this example, a Description IO is used to teach the “magnetic disk structure” (knowledge object). The “ObjectDescription” shows that an image representation has been selected in the current teaching context. Didactic parameters as the portrayal configuration or the abstraction type indicate how this image is displayed and the level of abstraction it represents. EML notations usually also include information about the organization of the educational contents in different structures. In some cases like the Multibook project this information is mixed with the own instructional objects. In our model, there is a strong separation between both types of information.

Instructional objects are organized using Didactic Structures (DS) which can be managed as independent entities. These entities are addressed to capture the didactic relationships between those objects. There are two kinds of didactic relationships in the current model: explicit and implicit. Explicit relationships link IOs using a specific action, for instance, “an example illustrates a concept definition” or “a question evaluates an explanation”. Implicit relationships are derived from the way knowledge items are organized.
In this case, we are interested in knowledge structures coming from the Instructional Transaction Theory which are used in the current work to model DSs. Merrill mentions different types of knowledge structures such as lists, taxonomies, dependencies, algorithms and causal nets. A DS can be built on top of one or more knowledge structures. For instance, the description of a magnetic disk in a computer system can be based on identifying its components and assigning them a portrayal configuration. It can also include an algorithm representation to show the access to a specific component (e.g. a cylinder). The DS connections with other model entities are represented on Figure 3. It shows a simplified UML diagram which specifies that DSs are entities aggregated from instructional objects (IO) and knowledge structures (KS). Both IO and KS entities are based on knowledge objects (KO) which are composed by elements such as Identify, Portrayal and Properties. DS entities also extend the basic information coming from IO and KS, using didactic attributes such as the portrayal selection.

The current work is closer to the IMSDL proposal (Silverhorn & Gaede 1999) which defines instructional strategies, responsible for structuring the information units to be learned but independent from the subject domain. However, these structures are addressed mainly for courseware. Nevertheless, we do not know any proposal focused on generating structure templates which can be applied in specific didactic contexts in a reusable and modular way. We are developing XML Schemas to represent a wide range of didactic structures from basic knowledge structures.

5. Functional model

The functional model describes the entities that allow a user (student or instructor) to interact with DSs. DS entities are the nexus with the other structural elements. Figure 4 shows a simplified UML diagram that represents the main functional entities and their relationships with the remainder entities. These entities are learning scenarios and instructional tasks, respectively. Learning scenarios (LS) are defined as the set of terms and conditions that characterize the user learning. Each individual user or group of them is assigned with one or more LSs. Instructors have to configure the LS entities, assigning features such as learning modes, timing schedules, instructional methods and learning goals. Each LS aggregates one or more Instructional Tasks (IT). They are defined as the operations a user has to perform to achieve a specific learning goal. IT entities model the functions associated to the didactic structure interface. They can access to one or more didactic structures and a certain DS can be attached to multiple ITs.
ITs are related to the Merrill's concept of "transaction shell" which consists of rules for selecting and sequencing knowledge objects. In the current model, IT entities do not access directly to IOs which are encapsulated into the didactic structures. This feature eases the design process because the instructor deals with IOs in a more abstract way. For instance, in a dependency DS, the IO components are all considered as chain elements without differentiating them. An IT like Explain specifies the navigational operations through the branches of the Dependency structure. A navigational operation can consist in the selection of a given branch and it could depend on learning modes such as "learning by examples", "by doing" or by "exploration and experimentation". In the first case, the Explain task is based on revising Example IOs while the other cases involve the working with Activity IOs. One of the main instructor responsibilities is to define the ITs attached to each DS. This definition is also a manual and laborious task and an EML notation is being developed to assist the instructor in this process.

6. Application example.

In this section, an example is used to show the application of the proposed Didactic model. The example consists of a Didactic Guide called "Learning XML basics" which is based on a Dependency structure. Figure 5 shows a diagram of top-down dependency. The root node represents the main learning goal described as "Learning XML". The descendent node has assigned a Definition IO which intends to answer the "What is XML" question. The didactic relationship between the Goal and Definition IOs is an IsBasedOn relationship type and it means that the knowledge about the XML notion (current node) is required to meet the goal defined in the previous node. From the current node, there are several branches which represent extensions (IsExtendedBy relationships) of the current definition node. These branches store requirements in order to understand the previous node and each one has assigned a specific competency (difficulty) level. According to this assignment, a different IT can be attached to each branch. These competency levels are based on the learning modes cited previously. Learning by examples can involve identifying instances of a concept, e.g. an XML document (left branch) or a DTD document (central branch). Moreover, each XML document example can be assigned with a certain difficulty level which is used as parameter by the IT. It causes that the structure branches can be navigated-accessed in different ways. A Predict IT can check a specific process, e.g. the validation of an input XML document using a DTD syntax. This validation process is based on an Activity IO which is related to a previous Example object by means of an IsCheckedBy didactic relationship. In a higher level learning mode, the Predict task could include additional activities such as the DTD configuration.

7. Conclusions

A design framework has been proposed for developing instructional applications beyond the rigid courseware structures that underlie the typical Web-based courses. The proposed framework is based on a didactic model which provides a gateway between instructional theories and concepts, and hypermedia and Web application engineering. This model considers two issues: a structural view based on instructional objects and didactic structures, and a functional view that manages the previous entities using instructional tasks and learning scenarios. The didactic model is supported by an XML-based notation which eases its translation to computing environments.
This notation has been applied to represent taxonomy-like didactic structures. It provides the possibility to organize available educational resources in a way closer to the instructor teaching requirements. We have also planned to extend the XML-based specification to other didactic structures based on dependencies and algorithms. Further works include their usage in specific learning contexts such as Electric and Information Engineering areas. We are also developing a tool to allow the access to these structures in a Web-based environment.

Videoconferencing: A Tool For Collaboration And Professional Development

Katherine L. Hayden, Ed. D. & Joan H. Hanor, Ph.D.
California State University San Marcos

Introduction

With the expanding infrastructure for telecommunications in the world today, new applications for communications are emerging in society. To assure success in the workplace of tomorrow, it will be necessary for students to have collaboration and communication skills that utilize technology tools (Schlechty, 1997). As a communicative technology, videoconferencing offers the potential to provide students relevant skills, connect distant or remote learners, and induce change. Teachers and administrators must receive training in the design and application of appropriate uses of videoconferencing to support effective, efficient, and meaningful learning. Videoconferencing has been used in higher education and businesses for several years and now is spreading to K-12 environments. "Educators tend to use new technologies within the context of their perceptions of instructional strategies" (Hayden, 1999).

The instructionist teacher views the characteristic of videoconferencing that allows connection to a distant expert, as an opportunity for a remote lecture. On the other hand, the constructivist teacher views this same characteristic as an opportunity for students to ask questions and clarify meanings. Educational reform efforts suggest that constructivist teaching strategies and learning environments should be explored for student activities and assessments (Brooks & Brooks, 1993; Sandholtz, Ringstaff & Dwyer, 1997). In order to prepare teachers and schools for best practices using videoconferencing technology, constructivist instructional strategies need to be matched with new technologies (Hayden, 1999).

This paper will report the findings from a study (Hayden, 1999) that investigated the "best practices" for videoconferencing. The paper will describe the strategies that were applied from the research to an educational technology professional development program for teachers and administrators in California.

Research on Videoconferencing

Description of study

A study completed in 1999 (Hayden) used the Delphi process in order to facilitate a panel of experts in projecting their experiences with education, technology, and videoconferencing in order to identify important characteristics and critical support strategies necessary for videoconferencing in constructivist K-12 environments. The panel's recommendations provide a guide for technology trainers and professional development planners in implementing effective teacher training and support. As one participant in the Delphi study stated:

I have been more conscious about what I've organized for teachers (VC project development) and in teacher trainings. I have stressed more active participation among the students. This has been very helpful for me; I have referred to the information/results from this survey several times in trainings. Teachers' ears seem to perk up when you have data to support your philosophies and different examples to give (Hayden, 1999).

Characteristics of Videoconferencing

Twenty characteristics of videoconferencing that support constructivist learning emerged in the study completed by Hayden (1999). These twenty characteristics are categorized into four themes in Table 1: (a) connections, (b) questioning, (c) learning, and (d) interaction. Within this list of twenty characteristics, ten characteristics of videoconferencing were rated higher than the other ten. By organizing the top ten characteristics by theme area, learning experiences using videoconferencing to support constructivist
learning could be planned. Table 1 shows how a videoconferencing project can incorporate all ten of the top videoconferencing characteristics.

Table 1: Planning An Activity Using The Top Ten Characteristics Of Videoconferencing That Support Constructivist Learning Environments (Hayden, 1999)

**Talking head.** The theme of remote lecture, sometimes referred to as “talking head”, has been a common format for videoconferencing sessions. New technologies are usually implemented first in the old paradigm. In the case of videoconferencing, the classroom lecture can be viewed by remote learners at different locations. The problem with the “talking head” model is that participants are often not engaged because they are not physically connected with the presenter by being in the same room. It is difficult for the presenter to see all of the remote participants and he/she may not be aware that viewers are losing interest in the session. The linking of videoconferencing and constructivist strategies tend to avoid the “talking head” model and participants become more engaged as they actively participate in the session.

**Shared electronic documents.** One way of engaging participants in a videoconference is to display shared documents and images to reinforce concepts and address multiple learning modalities. The characteristic of “students creating a shared electronic document using synchronous connections” was ranked 19th in the twenty-item list of videoconferencing characteristics. One suggestion made by an expert in the Delphi study was for “more accounting for the various media that are used in VC, i.e. elmo, video tape, computer, whiteboard, etc. All of these can enhance the potential for constructivist uses of VC.”

**Support Strategies**

The three-round Delphi process identified critical strategies that support videoconferencing in constructivist environments. The top ten strategies for supporting videoconferencing are categorized into six themes: (a) people, (b) access, (c) hardware and software resources, (d) materials, (e) staff development, and (f) cost/budget (see Table 2).
From Desktop to Web:  
Standalone CBT to Web-based Instructional Application

Scott Heath, Research Department 
Bonfils Blood Center, USA  
scott@qm.bbmbc.org

Daniel R. Ambruso, MD  
Bonfils Blood Center and University of Colorado School of Medicine, USA  
Daniel.Ambruso@UCHSC.edu

Abstract: The need to convert our stand-alone computer-based learning modules to a form that would be independent of any single location or brand of computer became clear to us several years ago. We were also interested in improving the availability of our software. The growth and standardization of the World Wide Web provided us with a format offering color, graphics, animation, and hypertext. Distribution problems would be eased, and the distance education possibilities were also an advantage of this approach. This presentation focuses on how the initial choice of an interactive, hypertext format was central to our repurposing effort.

Education as the first motive

Bonfils Blood Center’s Transfusion Medicine Education Program was created to address the lack of familiarity of many medical practitioners with transfusion issues (Simon, 1985). We wanted to provide medical students with application-level experience of practical procedures or principles (clinical correlates) involving topics already identified as important in the field. Cases were chosen that involved many of those procedures or principles. These cases were grouped into thematically related modules, which were part of the regular course of medical studies. Given the extensive medical curriculum and the already busy schedule of the medical student, we felt a learner-centered, computer-based approach would be best. We have developed over twenty cases, grouped into four modules, in our first dozen years.

Active Learning

The instructional advisors to this program, from the University of Colorado at Denver’s School of Education and University of Colorado School of Medicine, felt strongly that a learner-centered, active learning design would be most appropriate (Jonassen, Ambruso, Olesen, 1992). We had to provide experiences leading to competency in a complex, ill-structured domain. We hoped to avoid the usual oversimplified presentation that often leads to "inert knowledge" (Whitehead, 1929). We decided on an approach combining elements of cognitive flexibility theory, case-based learning, and instructional simulation (Heath, Ambruso 1996).

Hypertext

The obvious form for our educational experiences was hypertext (linked, interactive, random-access information). However, by the time we started working on our fourth set of instructional cases, it was obvious that the Internet itself had far outpaced the neglected HyperCard product as an implementation of the hypertext concept. We decided to try to replicate our first module as a series of HTML documents (Internet "pages"). The result proved very popular with students and faculty. Internet-based versions of two other modules were produced, and a third conversion is underway using DHTML and other advanced web technologies.

Opportunities for Updating, Refining

When a case or module is rewritten as World Wide Web pages, it can also be revised. The new version can reflect the latest advances in both the field of transfusion medicine and ("below the hood") in the newly available capabilities of the Internet.
Adding Color

The use of color in the standalone CBT versions was limited. No need was seen for color when these programs were originally written. Furthermore, the colorization schemes that became available for HyperCard were awkward and prone to technical difficulties. In the Internet environment, color has always been an inherent part of all visual elements, at least in the Netscape and Explorer programs. We hope that the presence of color and other appropriate graphic design elements may serve to enhance the learner's experience.

Client-side Data

One challenge of any Internet-based instructional system is the lack of an obvious way to store information for later use. Security issues require browser makers to prevent any Internet page from gaining direct access to the computer's permanent storage. The 'cookie' method allows limited creation of small amounts of data on a computer, but many people turn this feature off.

Global Variables

Instead of using local files for learner data that our programs may need, we store information in variables associated with the opening page, which remains open but hidden once the current page is opened in front of it. Alternatively, we use a 'frame' portion of the visible window to store information used by subsequent 'frame' portions of the same window.

For example, the students enter their names, which appear at various points in the program and on the completion report that is sent to us automatically when the student completes the program. Another example is the laboratory test orders placed at one point in the program, which must be acknowledged, and the results given, at a later point in the program. Both the student name and their orders must be stored in such a way as to be available to the routines that send us their report or that show them their earlier decisions or test results.

Data Management

Combining JavaScript variables, DOM element addressing, and Cascading Style Sheet controls, we have created a client-side database management system that would not have been possible with the technology available when this program began.

Conversion Process

We considered the following factors when we decided to convert our CBT to web-based instruction:

Does my CBT need to be converted to web-based instruction?

- Hypertext is suited to Internet
- Cross-platform operability (need to use any computer)
- Availability of graphic elements (color, animation)
- Ease of distribution, maintenance

What challenges face such a conversion?

- Different results on different platforms, browsers, versions...
- New capabilities not evenly implemented across browsers
- An Internet application does not have full disk access

What are some possibilities

- Client-side data management
- Animation
- Wide distribution

Designing high quality learning environments: Reflections on some successes and failures

John G Hedberg
Faculty of Education, University of Wollongong, Australia
john_hedberg@uow.edu.au

Over the past decade, there have been many changes in the tools we use to design, the ways information can be represented and the underpinning theories which drive educational experiences. This presentation will focus on several examples of software design that have been pedagogically successful and have demonstrated what is possible in software design and online learning. Contrasts will be made with some examples of the current push into e-learning and how best to structure learning environments to ensure student participation and high quality learning outcomes especially when students come from differing backgrounds and cultural traditions.

“A poor tradesman blames his tools”

Over the past decade there have been several major developments which have helped the growth of interactive multimedia and more recently the concept of e-learning. The task for designers has been challenging and this paper reviews several projects, many of which broke new ground and won international awards. Along the way the reality of creating innovative products which represent good practice and seek to model modern educational principles has been driven by several factors not the least being the tools which have been used and the visual representations of the knowledge domain of each product. This paper will describe several projects and critique their design ideas and their execution.

Significant efforts have been made to develop and implement alternative frameworks for learning often based on a class of theories collectively referred to as constructivism. Fundamentally, constructivism asserts that we learn through a continual process of constructing, interpreting, and modifying our own representations of reality based on our own experiences. Indeed many books enumerate a long list of ideas about how these principles might be applied to the design of learning environments, but how to place the ideas strategically into the learning experience is often omitted (see for example, Khan, 2001; and Mills, Lawless and Merrill, 2001). Often the advice is very broad and covers all aspects of pedagogical design from methods to integrate new technologies to potential assessment strategies. The integration of technologies, which may allow the representation of ideas in many different media forms, provide opportunities for the designer or instructor to customise instruction and place learners in open-ended, student-centred, rich tasks.

This paper explores what has been effective and what, while superficially might be seen as an effective product or set of ideas, might not have been as successful as first expected. It will generalise some of the lessons that might be drawn from the decade of effort to ensure that the learning environments:

1. fostered judgement and learner responsibility.
2. supported critical inquiry and creative approaches to problem-solving
3. created engagement through the effective combination of learning task, visual representation and authentic assessment of the product goals.

Principles assumptions and quality
Like past revolutions in education, e-learning will go the way of previous technologies unless there are changes to the design framework used as the starting point. Savery & Duffy (1995) described four principles that should be applied to modern technology-based learning environments based on constructivist views. These were:

1. Learning is an active and engaged process. “Learners are actively engaged in working at tasks and activities that are authentic to the environment in which they would be used.” (Savery & Duffy, 1995, p.37).
2. Learning is a process of constructing knowledge. Learners need structures and challenges from which to develop their understanding of ideas and of the world.

3. Learners function at a metacognitive level. Learning is focused on thinking skills rather than working on the "right answer the teacher wants". Students generate their own strategies for defining the problem and working out a solution. Student can gain wisdom through reflection.

4. Learning involves "social negotiation". Students are able to challenge their thoughts, beliefs, perceptions and existing knowledge by collaborating with other students thus assisting their cognitive development process.

In a recent paper, David Boud and Mike Prosser (2002) have also attempted to specify the characteristics of high quality learning outcomes. They suggest that the four major areas of concentration in a high-quality learning environment should be:

1. How do learning activities support learner engagement? (This reasons for the learner wishing to become involved with the learning tasks and the way the tasks require them to reflect or employ their previous interests and understandings)

2. How does this learning activity acknowledge the learning context? (In the case of e-learning there are unique characteristics such as the unique position of the learner in a real context and how the assessment matches the real world skills that are seen as easily transferred from the learning context to professional practice)

3. How does the learning activity seek to challenge learners? (Novices need supportive structures, experts require information to fill in the missing blanks in an existing knowledge structure, too much ambiguity can turn a student away, too little and they become bored. Students might need support to extend the information provided as part of a problem-solving scenario)

4. How does the learning activity provide practice? (As with most effective learning contexts the matches between assessment, learning tasks, and the transfer tasks might align and model performance. To ensure that it occurs, the feedback must support the ongoing development of the learning)

In addition, in the e-learning context the choices of technology infrastructure and its deployment are crucial to support the effective learning outcomes. So the above lists describe the goals for constructivist design and high quality outcomes, but the choice of tools and the range of pedagogical options that the tools themselves either constrain or facilitate will also contribute to the learning outcomes. David Jonassen (2000) has provided recent guidance about the importance of the design of learning tasks by suggesting a range of problem types that vary in the degree of structure and the linkage they have to authentic real world tasks. Providing structure and support for the more ill-structured task is the real challenge for the designer working in a constructivist framework.

Design intentions for digital media

With an understanding of the shortcomings of much of the commercially generated available learning packages, a combination of ideas taken from constructivist learning environments, situated learning and problem-based learning in rich information landscapes can be used to form the basis for effective design. Hedberg et al (1994) proposed that learning outcomes in digital environments depend on starting points such as; the learning environment, the learner's view of the purpose of the task; and the motivation of the learner.

The process of learning involves the construction of meanings by the learner from what is said, demonstrated or experienced. Thus the role of the teacher is one of facilitating the development of understanding by selecting appropriate experiences and then allowing students to reflect on these experiences. Often constructivist learning situations suddenly throw students on their own management resources and many fend poorly in the high cognitive complexity of the learning environment. Cognitive support tools and the explicit acknowledgment of the double agenda of metacognitive self-management and learning can help. The scaffolding and coaching of the cognitive apprenticeship model offers another solution, a strategy which many design teams have explored with a great deal of success.

Several multimedia design models have been developed which illustrate the combination of complex learning environments and which also give students their own real control over their learning environment. If one of the primary goals of e-learning is to stimulate active involvement, then educators and instructional designers need to better understand the symbiosis between the visual interface and the design of the learning tasks in promoting and sustaining learner engagement. Engaged learners are intrinsically motivated to perform. They direct their
efforts to understanding the tasks and challenges in a learning context; and they strive to construct knowledge and derive meaning from their prior experience and available resources. Well designed visual interfaces can help stimulate learner engagement or, conversely, disengage learners if they are poorly designed. Poor design can place high cognitive demands upon the learner that can reduce interest and divert attention away from the primary learning tasks. While not described in detail here, the combination of visual clarity of knowledge representation and manipulation and the sensitivity to outcomes of the learning task is which create challenge and engagement is a measure of the design success (Metros and Hedberg, 2002).

Instructional designers continue to wrestle with the challenge of affording a new generation of visually savvy learners with engaging online experiences. In her seminal book Computers as Theatre, Laurel (1993) suggested ways to use the notion of theatre, not simply as a metaphor, but as a way to conceptualize human-computer interactions. Laurel defines this type of engagement as, “what happens when we are able to give ourselves over to a representational action, comfortably and ambiguously. We gain a plethora of new possibilities for action and a kind of emotional guarantee” (p115). What Laurel is referring to is Flow State. Csikszentmihalyi (1996) coined the term to describe the state of total engagement. Users attain Flow State when they have no conscious awareness of the passage of time. Flow State occurs when users enjoy a sense of playfulness, a feeling of being in control, a period of concentration when attention is highly focused, an interlude of enjoyment of an activity for its own sake, a distorted sense of time, and a rewarding match between the challenge at hand and one's personal skills. The emphasis on motivating tasks situated within well-designed and engaging interactions provides the instructional designer greater surety that the final experience will be effective.

Creating a framework for review

Step 1: Information Design and Project Space Definition
At the beginning of any project it is necessary to compile information on learners' needs and describe the parameters of the project space. The purpose of this initial stage is to begin a holistic structuring of the information and to model it so that it will eventually form the basis of an organizing visual metaphor. Isolating the key attributes within a learning experience is not trivial. Three questions need to be answered by the client and designers.

1. **What is the topic (content) of this project?**
2. **Who are the intended users of this knowledge domain?** The content might be the same for different groups, but learners may want to “view, use or manipulate” the content in different ways.
3. **Why is this project/course being undertaken or developed?** The client’s original stated objective almost always needs revisions to better identify and describe the underlying purpose.

Step 2: Interaction Design
Effective interaction design that matches users' cognitive expectations ensures they are motivated and engaged. Simply the use of interactive technologies does not necessarily ensure that meaningful interactions will occur, rather The challenge is to create interactions that are easily manipulated at the users' technology skill level. Norman (1988) provides guidelines for constructing interactions.

1. **Visibility:** The user can tell the state of the device and the alternatives for action through observation.
2. **An effective conceptual model:** There should be consistency in how program functions “work” leading to a coherent conceptual user model.
3. **Effective mapping:** There are clear relationships between actions and results, controls and their effects, and between system state and what is visible.
4. **Feedback:** There must be continuous feedback about the results of actions. Novice designers often fail to realize that almost every action creates some perturbation. For feedback to be effective, designers should employ a variety of feedback that link to specific learning outcomes.

In addition to Norman’s guidelines, there are alternative techniques for reducing the cognitive load on a learner’s working memory to enhance interaction design.

1. **Use visual conventions borrowed from the real world.**
2. **Apply consistent visual metaphors.**
3. **Recognize the role of the learner as actor.** The user is participating in a dialogue that is unfolding, often in real-time (Laurel, 1993; Hedberg & Sims, 2001).
In several products, we provide access to the data in the same way as individuals would access, manipulate and explore resources in the real world. While there still must be supportive scaffolds and structures, the choices the learners make under this model are similar to those they make as “experts” in a knowledge domain. The only difference is that the tasks have supportive elements that describe decisions in context (Lave & Wenger, 1991). Visual metaphors and information structures must provide information-rich presentations, especially when the structures are extensible and can be unfolded, as the learners need more or less support and scaffolding to complete their chosen learning tasks.

**Step 3: Presentation and Interface Design**

The third step transforms the design concepts derived in the first two steps into a visual presentation structure, which represents concepts, conveying order, classifying information, clarifying meaning, directing focus, stimulating interest, facilitating interactions, confirming choices, supporting recall, directing navigation, creating ambience and otherwise engaging the learner. In many products, we choose visual metaphors of commonly-used places to serve as the context in which decisions about the learning tasks take place. Thus we used a field research centre for the ecological set of problems, a classroom with small groups placed around it to model groupwork for teaching K-2 mathematics.

**Issues that have influenced the journey**

While the above design intentions and process has been following to a greater or lesser extent, the following key aspects that have influenced the “judged effectiveness” of each project and have formed the basis of comparison:

- **Technological advances** — major advances in the past ten years have made a difference. Especially the advent of QuickTime in late 1991, the widespread availability of World Wide Web, and the use of browsers to drive cross platform products from 1994.
- **Visual Design** — mirroring the technology developments, several graphical design tools have improved and developed in the decade. Photoshop enables visual design overlays with their “layers”
- **Design of Learning Tasks** — the visual representation and the tools for constructing environments have been instrumental in achieving the growth in complex learning tasks and how they have been implemented in software.
- **Authentic assessment options** — as digital media became easier to integrate within products, the possibilities of presenting authentic environments where the assessment tasks were realistic and authentic became greater.
- **Clarity of team goals and ease of operation** — there are several options about how a team functions, as projects grew bigger the size of the team also increased but the relationships between client and designers, and the others contributing to the final product can have a critical bearing on the clarity of the representation of the knowledge space and the symbiotic relationship between the learning task and the visual representation of the task through the interface.
- **Degree of control of design team versus client demands for particular outcomes**. The client can support options to ensure new and creative implementation of their ideas. If this occurs then the project can push the boundaries, create new representations and more challenging tasks.
- **Implementation support in the field** — a project may have the best of intentions but it may not have support which makes it viable to generate high use by the intended audience. Also the increasing combination of CD-ROMs and web sites designed to maximise the feedback and interactivity can ensure that the products have the equivalent of “after sales service”.

**Examples of effective Symbiosis**

The complete list of examples is provided at [http://www.emlab.uow.edu.au/](http://www.emlab.uow.edu.au/). However simple illustrations of the review can be drawn from the CD entitled “123 Count with me,” which illustrates the application of the model (Figure 1). The CD introduces basic mathematical concepts to K-2 teachers and shows them how they might use an innovative instructional strategy to group students and introduce basic mathematical concepts. If a comparison is made between the two different approaches to a similar task (Figures 1 and 2), it can be seen that the poor representation of Figure 2 (and the fact that it varies with cursor movement) can be very difficult for an audience which does not hold sophisticated interface conventions. The comparison can be made over a range of factors which are outlined in the next section. (Other examples will be demonstrated in the presentation. These will be based on several products, including: Stagestruck, Exploring the Nardoo, aspire, Pilotage and Count me in too.)
Ensuring successful outcomes

There are many factors that might be judged as creating successes and when they are lacking producing less successful products. However in this paper, I will concentrate on a few:

*Implementing the design concept.* An idea at the concept stage may not necessarily translate into a good visual representation as the project develops. For instance, in developing materials to teach teachers how to implement a math program then the visual representation of those ideas has to correspond with the original concepts and intentions. Comparing the two figures (1 and 2) above which illustrate two forms of the same idea. Figure 1 was judged more comprehensible by the client. While in Figure 1, the major focus was to introduce mathematical understandings to an audience of remotely located teachers, for Figure 2, the emphasis was on explaining the nature of the mathematical framework and the visual elements became more focussed on decoration rather than functionality.

*Representing information so that it can be accessed and manipulated.* In the same example, in providing a list of options the use of the directory metaphor has been employed. In the early stage of design of 123 count with me, we identified three organizing areas in which the related elements of information could be clustered and which provide meaningful structures for a teacher using a classroom metaphor.

*Implementing constructive and problem-based activities.* In many learning environments, learners can manipulate the elements which form the basis of their construction. Again in the above example, several capabilities have been provided which simplify some of the teacher/user tasks. There is a subtlety and a strategy to the design of activities which will lead to active use and engagement. The choice of problem (Jonassen, 2000) and the subtle development of activities that move from social to task focus suggest the direction of challenge for the designer. Jonassen (2000) has demonstrated how his initial theory of problem design can be translated into challenging tasks. Often this will mean that initially task a designed as series of discreet assignments, a rethink can create a series of linked tasks and challenges, and when these are woven into an ongoing scenario in which the student builds their skills as they go through the activities sequence then powerful learning outcomes can be produced.

**Conclusion**

Effective e-learning environments build upon solid foundations of learner needs and outcomes, metaphorically crafted cognitive processes, and instructional strategies communicated through effective visual interfaces that intrigue, challenge and engage the learner. Crafting of such projects requires an approach in which the instructional designer, technologist, graphic designer, educator and student collaborate to ensure that the end result is usable, functional and visually communicative and attractive. This can be accomplished by employing
reasonable yet innovative conventions; such as organizing visual metaphors that scaffold access to the underpinning knowledge; choosing tasks that support the desired level of challenge and engagement. As interactive technologies become the staple communication vehicle for virtual worlds, effective interactive instructional design based on constructivist principles will ensure that the learner’s focus on the learning task rather than simply operating the software. The choice of authoring tools can also greatly affect the way information may be structured and manipulated. Popular authoring tools may actually reduce the interactivity and information representations that are possible (Hedberg & Sims, 2001). Achieving success means that there is coherence between task, its visual representation and the project functionality. So the choice of tool, the selection of task and the importance of an engaging learning experience need to be undertaken with insight. And for e-learning, while some tools might facilitate the physical process of putting educational materials online and creating learner access, they may also never address the educational outcomes for high quality learning.

References

StageStruck. (1998) Sydney: National Institute for Dramatic Art. Project Director, Amanda Morris, Multimedia Producer, John Hedberg; Instructional Design, John Hedberg and Rob Wright (CD-ROM produced as part of the Australia on CD program, funded through the Department of Communication, Information Technology and the Arts, Canberra.)
Summary of key projects and their focus

Following the success of the earlier package, this package is being designed to assess the performance of those teachers who are seeking accreditation as “experts” in the use and application of the 123 K-2 mathematics program. It consists of a CD-ROM and links with a central site that will mark each authentic assessment.

The primary focus of the ‘123 Count With Me’ CD-ROM project is to provide professional development to primary school teachers in small, remote schools who do not have easy access to district consultancy support. The project is based on the content of the Curriculum program “Count me in Too”, which is a numeracy program aimed at K-2. This numeracy program increases teachers’ understandings about how children can be assisted to progress through the early components of the Mathematics syllabus in relation to Number.

The aim of this project is to provide a tool for teachers that helps them to implement the Creative Arts K-6 syllabus. The CD-ROM illustrates and explicates the syllabus and CSD resources, demonstrating the syllabus in practice. Practice and methodology is shown through a range of visual and text modes. The CD-ROM allows teachers to explore all aspects of the syllabus, in a way that suits them as adult learners. The structure and content contained within the resource will support investigation by individual teachers working alone or in groups working under the guidance of a curriculum officer.

Pilotage Courseware (2001). Client: IMPART Corporation, RAN and SAF

The Royal Singapore Navy and Royal Australian Navy requested the submission of a creative solution to increase the level of success that trainee Officers of the Watch currently enjoy and the level of access they have to a flexible, practical training environment. Trainee Officers are provided with the basic background theory of pilotage, and a means of practicing the application of this knowledge and developing associated skills. This occurs in a simulated ‘real life’ environment that is consistent with being a pilot on a combat ship. In effect this provides an effective training environment whilst avoiding the usual risks and costs associated with conducting such practice in the real world.

aspire –Olympic Resource Kit for Australian Schools (1999). Clients: SOCOG; AOC; Collaborators: Dept of Education and Training; Curriculum Corporation

aspire is an educational kit developed for the 2000 Olympic Games comprises, a CD-ROM, booklet, posters and video and was distributed to schools Australia wide in 1999. The aim of the kit is to foster enthusiastic engagement in the Olympic experience and a belief in the Olympic spirit. It sought to raise interest in the Sydney 2000 Olympic Games and promote the richness and cultural diversity of Australian life and national identity. The target audience was wide K-12.

StageStruck was developed with the assistance of the Federal Government’s Australia on CD Program. StageStruck was designed for students to experience the world of the performing arts as well as showcasing the diversity of Australian Performers and Performing Arts Companies. StageStruck provides a highly interactive environment where students are able to explore each of the elements associated with designing and directing a performance whilst creating their own. Awards have been numerous and include: In 1998, EMMA Gold Award- best overall; BAFTA Interactive Treatment award in the United Kingdom. In 1999, New York Festivals International Interactive Multimedia competition - Gold Medal in the Education section; AIMIA Award - Best Arts/Cultural Title or Site and in 2000 it won the Milia d’Or Awards for the Education & Training Category.

This is a program based on an inland water catchment, which can be investigated through four time zones and four locations in each time zone. Each time zone has a particular theme that transposes the four locations and each location will have an embedded investigation in the form of a scenario. Users can move readily from location to location in each time zone and from zone to zone. Students will be able to interrogate data and personalise results. The user investigation is supported by help facilities and guides as well as simulations and games designed to support solutions to problems. In 1998 it won an EMMA Award (European Multi-Media Association) and one of best five new educational products for 1997 by the American Software Publishers Association.

A simulated lake environment on CD ROM. Students can investigate various ecosystems of the lake, make physical, chemical and biological measurements, collect information about individual animal and plant species in and around the lake, and see and hear news reports, expert views and local opinions on a variety of issues relating to the lake and its ecology. Inquiry and problem-solving techniques have been embedded in the package through case studies of ecological scenarios presented to the user via media reports of problems posed directly to the user.
Abstract
This paper describes the evaluation of high quality learning designs which are being selected for possible redevelopment in a National Project funded by the Australian University Teaching Committee (AUTC). The project focuses on "Information and Communication Technologies (ICTs) and Their Role in Flexible Learning" and is evaluating over 50 projects with a view to developing a range of software tools, templates and/or guidelines based on those that are deemed to be effective ICT-based learning projects. The approach is unique in that it tries to pinpoint the key attributes of ICT-based projects that make them suitable for application in other contexts and in other knowledge domains.

Introduction
There tends to be general consensus among experts that the forms of learning environments most effective for meaningful learning in higher education are those that are based on the contemporary theories of learning which support knowledge construction through learner-centred settings (e.g. Duffy & Cunningham, 1996; Bostock, 1998). These perspectives about learning are challenging conventional teaching approaches. For example, Cunningham et al. (1998) state:

The growing acceptance of new educational philosophies and practices, such as constructivism and action learning during the 1980s, have challenged the valence of the didactic lecture/tutorial/textbook model common in higher education, promoted the notions of the academic role as 'a guide on the side' rather than 'the sage on stage', and conceived of the student role as one of independent self-directed learner. (p. 25)

The growing awareness of effective and meaningful teaching and learning plus the recent developments in ICT has led to synergies emerging between the use of ICT and the adoption of powerful learning strategies. The Web is one technology that shows particular promise for supporting meaningful learning through its remarkable functionality, support for flexible delivery modes and capacity to link and connect those involved in the learning process (e.g. Levin, 1999). The possibilities exist for rich learning based on this technology, but for the most part, pedagogically sound and exciting Web courseware tools have yet to be developed to take advantage of such opportunities.

One of the key issues is that the pace of change of emerging Web technologies is so rapid that pedagogical models may be needed to help create Web tools from a learner-centred perspective. Salomon (1998) has supported this concern and has noted that for the first time in history, technologies are outpacing pedagogical and psychological rationale. However, a body of literature is starting to report on innovative tools, with strong pedagogical underpinning. Bonk (1998) has reported on interactive tools for on-line portfolio feedback, profile commenting, and Web link rating. Oliver and McLoughlin (1999) are building tools for on-line debate, reflection, concept mapping and student surveying and discussion. Wills, Ip & Bunnett (2000) are building engines for online role plays. As a way of describing the range of options that might contribute to a learning design in such contexts Figure 1 shows the combination of elements that might be considered in such an endeavour.

In this project, the terms "learning designs", "high quality learning experiences", and "flexible learning" are defined as follows: Learning designs: refer to a variety of designs that support student learning experiences. Learning designs may be at the level of a whole subject, subject component or learning resource. High quality
Learning experiences: refer to experiences resulting from an environment, which encourages students to seek understanding rather than memorisation (only for the purposes of assessment), and which encourage the development of lifelong learning skills. Flexible learning refers to an educational approach that meets the diverse needs of students. The project is to focus on how ICT can be used to design flexible opportunities for students.

Figure 1: Elements of learning designs for online learning

Current settings hold fewer impediments to ICT uptake than have been present in the past. Universities within Australia have moved swiftly in recent years to develop the necessary infrastructure to support ICT as a delivery medium and most universities now boast a solid ICT infrastructure aimed at supporting teaching and learning programs. The uptake of ICT as a delivery medium has been supported by professional development programs and activities aiming to develop the ICT literacy of staff plus clearinghouses and Web sites for dissemination of information about ICT in teaching. Funding has been applied by government sources to support the development of university teaching and learning and many organisations now exist that support and promote quality teaching as a scholarly pursuit. Among the major impediments that still stand are the lack of quality teaching and learning models and appropriate instructional material and software for teachers to apply.

This project aims to provide some relief to these impediments by identifying and creating quality resources for generic and mainstream application and by providing appropriate support and resources that will guide and encourage their use. Projects of this type should result in a coming decade that witnesses a growth in pedagogically based learning technologies.

Aims of this project

The aim of this project is to assist university instructors to create high quality flexible learning experiences for students by providing a range of generic resources/tools/templates/guidelines that draw upon successful flexible learning projects that utilise ICT and which may be generalised beyond the scope of the individual project. Successful ICT-based learning projects are those that facilitate high quality learning experiences for students. A study conducted by Alexander and McKenzie (1998) highlighted that one contributing factor towards a successful learning outcome for an ICT-based learning project was the learning design employed. Thus, this project has followed the process:

1. Identification of a range of learning designs that have been demonstrated to contribute to high quality learning experiences and which can be applied generically;
2. Design and subsequent development of a series of re-usable software, templates and/or guidelines for the learning designs previously identified; and
3. Dissemination of good practice for the use of or implementation of the software, templates and/or guidelines in new contexts.

Crucial to the success of this project was the development of an evaluation instrument referred to by the project as an Evaluation and Redevelopment Framework (ERF), with a twofold purpose:

1. To facilitate the identification of learning designs that foster high quality learning experiences; and
2. to provide a mechanism to determine whether such learning activity designs have the potential for re-development in a more generic form.

Project structure
The project began in November 2000 and is structured against four milestones:

2. Milestone Two (November 2001): Identification and documentation of learning designs that foster high quality learning experiences and that have the potential for redevelopment in a more generic form.
3. Milestone Three (June 2002): Development of a selected number of learning designs in a generic form to at least prototype stage.
4. Milestone Four (December 2002): Completion of the development of learning designs in a more generic form and finalisation of a web site that will store the project’s developed resources.

Development of the Evaluation and Redevelopment Framework
Characterising High Quality Learning
A major project activity has been the critique of what constitutes “high quality learning”. Professor Boud and Associate Professor Prosser were commissioned, as two leading thinkers about learning in higher education in Australia, to develop a paper on high quality learning. Their ideas together with feedback from the project team led to the development of a set of “Key Principles for High Quality Student Learning in Higher Education—from a Learning Perspective” (Boud & Prosser, 2001). The key principles describe four main characteristics that underpin high quality learning in the higher education context. The principles are elaborated through a series of questions that provide a lens through which learning environments can be explored. The four principles are holistic in that they incorporate both learning outcomes and learning processes and are based upon an experience-based learner-centred view of learning. The four principles are outlined below in the form of descriptions of high quality learning activities.

High quality learning activities:
1. Engage learners through:
   - Building on their learning intents generally and their particular expectations of the activity in question;
   - Acknowledging and taking account of their prior experience, both their knowledge and experience of situations which might impinge on the present ones;
   - Mobilising their will and desire and developing some kind of emotional engagement with the task in hand;
   - Providing them with a sense of agency with respect to the activity or significant parts of it; and
   - Recognising that learning is a social act and involves other learners for at least part of the activity.

2. Acknowledge context through:
   - Involvement with problems in context;
   - Recognising the context of the learner (who may see themselves as decontextualised);
   - Maintaining an awareness of the cultural assumptions and stereotyping which may be incorporated in the context;
   - Situating learning tasks within disciplinary or professional or practical knowledge as appropriate;
   - Taking account of the site of application of what is to be learned (this poses different challenges when the learner is currently engaged in the site of application and when they are not);
   - Appreciating the knowledge demands on students and equipping them to deal with them; and
   - Ensuring that there is a clear alignment between the activities in which students will be engaged and the ways in which they will be assessed.
3. **Challenge learners through:**
- Prompting them to seek and discern variation in the knowledge and experiences in which they are involved;
- Questioning the assumptions they bring to the activity and the assumptions they develop through it;
- Encouraging them to see what is provided as a means to wider ends and go beyond what is provided; and
- Creating situations in which they are required to take responsibility for their own learning and to shape the activity to their own ends.

4. **Involve practice through:**
- Demonstrating what has been learned for themselves and for others;
- Gaining feedback at strategic points in learning, but also recognising that finding ways of gaining feedback for one self other than that provided is also important;
- Reflecting on and making sense of their experiences. Continuous exposure to new activities without integration and consolidation within the learner’s framework is not conducive to good learning; and
- Developing confidence in performance from practice.

**Developing the evaluation instrumentation**

Whilst the above principles formed the basis of the evaluation framework, the following issues were raised by the reviewers that they should be incorporated into the instrument:

- How technology is embedded in a learning design and how its use supports or hinders the learning experience.
- The issues of scalability, transferability, and technology affordances.
- To determine suitability of redevelopment of a learning design, the evaluation should provide a mechanism to glean the critical design features from a learning design and consider how these design features could be implemented in a more generic form.
- To place the review framework within a staged process which might inform the project through a series of critical decision points.

The first complete version of the evaluation instrument was devised by the Core Team and Research Team after the first workshop. This version was formatively evaluated in the second workshop (scheduled one month after the first). The Research Team also examined existing evaluative instruments to determine whether these could inform and/or be incorporated into the project’s evaluation framework.

Since the second workshop (held at the end of April 2001) the evaluation framework has undergone further review and formative evaluation. Feedback from the Project Review Panel and International Reference Group has been considered and via discussions with the Core Team, Research Team and Steering Committee, a revised version of the evaluation framework has been developed. A challenge for the project has been how to elucidate the key and/or unique elements of the learning design that enable the facilitation of a high quality learning experience for students. The strategy thus adopted is to request a description of the learning design by the designer(s) in a contextualised form in terms of the following:

- The learning activities (and their sequence) that students are required to do.
- The resources that are required to support the activities.
- The support mechanisms that characterise the learning design, eg., role of the instructor, establishment of collaborative teams, etc.

In addition, all resources utilised by the students along with any evaluation data or findings have also been submitted. The evaluation review framework was implemented in two phases. The purpose, process and outcome for each phase are outlined in table 1.

The instrument is to be completed individually by two evaluators. The evaluators are to reach consensus and submit one completed Evaluation Form.</td>
<td>• Judgement of the potential of the learning design to foster high quality learning. • Generic description of the learning design. • Judgement of the learning design’s suitability for redevelopment in a more generic form.</td>
</tr>
</tbody>
</table>

The current stage of the project

The current stage of the project is applying the framework to a number of Learning Design exemplars. The outcome from this activity is intended to provide:

1. Documentation of Learning Designs identified as having potential for redevelopment in a more generic form; and
2. A formative evaluation of the framework and its operationalisation to a level of “robustness” deemed adequate by the project team.

In this stage we have:

- Identified over 50 potential ICT-based learning exemplars for examination. 28 examples will undergo full evaluation. Some strategies employed to compile the list of exemplars included: nominations made from the project team, review of past CUTSD (Committee for University Teaching and Staff Development) projects; and a review of relevant literature sources.
- Established approximately 30 Evaluation Teams. Evaluation Teams comprise pairs of national and international experts in the use of information and communication technologies for teaching and learning in Higher Education. Nominations have been made by the Project Core Team and by participants who attended a national flexible learning conference in July 2001.

From the feedback received it appears that many of the learning designs the core team identified for evaluation are suitable for redevelopment but the expense may not warrant it. Preliminary analysis of the evaluations returned to date raises the following questions for the core team to consider:

- Do we have a large enough range of types of learning designs?
- Is the evaluation framework adequate to enable reviewers’ analysis of the generic attributes of any learning design?
- Are reviewers capable of distinguishing between the task of software evaluation and this task of evaluating the underpinning learning design?
- Are reviewers evaluating a particular implementation of a learning design for redevelopment or are they taking into account other implementations of that particular learning design?
- Do we have an adequate definition of learning design and has it been communicated to the evaluators?
- Is the evaluation process able to cover levels of granularity in learning designs? Should the tasks, resources and supports in the learning design also be evaluated?
- Can learning designs really be context-free?
• Will the essence of a learning design always be translatable into a software product or would it instead be better to write guidelines for good design?

In order to ensure the range of learning designs reviewed is not limited in representation of a broad range of pedagogical approaches, the project team explored the development of a Learning Design classification framework. An analysis of the learning design exemplars collected to produce a grounded learning design categorisation plus a review of categorisations of learning designs in the literature will be presented at the conference. The project Web site aims to inform people of the progress and provide access to the resources and materials as they have been developed. (http://www.learningdesigns.uow.edu.au)

Student Modeling in Computer-Assisted Language Learning

Trude Heift, Janine Toole
Linguistics Department, Simon Fraser University, Burnaby, B.C., Canada
{heift, toole@sfu.ca}

Abstract: This paper provides an overview of Student Modeling techniques that have been employed in Intelligent Language Tutoring Systems (ILTSs) over the past decade. We further discuss the Student Model of our ESL Tutor, an ILTS for English as a Second Language. The Student Model is based on student subject matter performance and provides feedback and remedial exercises suited to learner expertise. We further report on a study in which we determined the extent to which our Student Model addresses the need for an individualized language learning environment.

1. Introduction

Individualized language instruction has long been recognized as a significant advantage of Computer-Assisted Language Learning (CALL) over more traditional workbook tasks. A "one size fits all" approach is not appropriate for a learning environment. Students learn at their own pace and often, work for their own purposes. Learners also vary with respect to prior language experience, aptitude, and/or learning styles and strategies. According to the Individual Differences Theory as described by Oxford (1995), if learners learn differently, then they likely benefit from individualized instruction.

Despite the need for an individualized learning environment, Student Modeling has not been a strong focus of CALL. One likely reason is that in order for a computer program to adapt itself to different learner needs, the system needs a dynamic model of the strengths and weaknesses of the learner (McCalla & Greer, 1992). Even when it comes to Intelligent Language Tutoring Systems (ILTSs), only a few have employed Student Models to individualize the learning environment. According to Holland & Kaplan (1995), this is likely due to the challenging task of representing the domain knowledge itself, the module which contains facts and information about the language being taught. If the grammar is not accurate and complete, even a precise Student Model cannot compensate. For instance, Holland (1994) states that a system which does not detect ambiguous errors accurately will obscure a Student Model.

There are a number of modeling techniques that can be implemented in a computer program. The system can model subject matter performance, students' learning strategies and/or cognitive styles. ILTSs primarily model subject matter performance, that is, students' surface errors. While such a Student Model might not be complete, it assists in individualizing the language learning process and "is sufficient to model the student to the level of detail necessary for the teaching decisions we are able to make" (Elsom-Cook, 1993: 238).

In this paper, we describe the Student Model of the ESL Tutor, our Web-based ILTS for English as a Second Language (ESL). The ESL Tutor analyzes sentences from the student and detects grammatical and other errors. The feedback modules of the system correlate the detailed output of the linguistic analysis with an error-specific feedback message. The Student Model is based on student subject matter performance. It provides feedback and remediation suited to learner expertise.

In the following section, we provide examples of CALL systems that employ Student Models and discuss their distinct emphasis. In section 3, we describe the architecture of the Student Model of the ESL Tutor. Section 4 reports on a study in which we determined the extent to which our Student Model addresses the need for an individualized language learning environment. Concluding comments can be found in section 5.

2. Student Modeling and Intelligent Language Tutoring Systems

In analyzing Student Models, McCalla (1992) makes a distinction between implicit and explicit Student Modeling which is particularly useful in classifying the Student Models in ILTSs.
An implicit Student Model is static, in the sense that the Student Model is reflected in the design decisions inherent to the system and derived from a designer's point of view. For instance, in an ILTS the native language of the learner can be encoded as a bug model that includes frequently made errors and ultimately diagnoses them.

In contrast, an explicit Student Model is dynamic. It is a representation of the learner which is used to drive instructional decisions. For ILTSs, for instance, the Student Model can assist in guiding the student through remedial exercises or it can adjust instructional feedback suited to the level of the learner. In either case, the decisions are based on the previous performance history of the learner. The following discussion will provide examples of ILTSs which have implemented implicit and explicit Student Models.

2.1 Implicit Student Models

Implicit Student Modeling has been applied to ILTSs to diagnose errors. For example, in Catt & Hirst's (1990) system Scripsi the native language of the student represents the learner model. It is used to model the learner's interlanguage. With regard to Student Modeling, the pitfall of such an implementation is that it is a static conception. The system's view of the learner cannot change across interactions with the system. It has no impact on instructional decisions and provides only a gross individualization of the learning process when ideally, a Student Model is dynamic (Holt et al., 1994).

In a more individualized example, Bull (1994) developed a system that teaches clitic pronoun placement in European Portuguese. The Student Model is based on the system's and the student's belief measures, language learning strategies, and language awareness.

The system’s belief measure is comprised of the proportion of incorrect/correct uses of the rule; the students provide the data for the student’s belief measure, being required to state their confidence in their answer when entering sentences. Learners also identify their preferred learning strategies when using the program. According to Bull (1994), language awareness is achieved by allowing the student access to all information held in the system. The information, however, is not used to drive the instructional process. A number of studies have also shown that students tend to not take advantage of the option to access additional information. For example, Cobb & Stevens (1996) found that in their reading program learners' use of self-accessible help was virtually non-existent, in spite of their previously having tried it in a practice session, and also having doubled their reading performance as compared to either a no help or dictionary help option in the practice session.

2.2. Explicit Student Models

In developing an explicit Student Model one typically starts by making some initial assumptions based on pretests or stereotypical postulations about the learner. For example, initially every student could be assessed as an intermediate. During the instructional process, the Student Model adjusts to student's behaviour moving to a novice or expert profile, as appropriate. This technique is used in explicit Student Models to make instructional decisions.

Explicit Student Modeling has been used in a number of ILTSs, primarily in the form of tracking. Tracking can be as simple as calculating percentages of correct answers or more sophisticatedly, identifying particular errors which occurred in the student's input. The information is then used to alter the instructional process, either in the form of further language tasks or feedback.

Explicit Student Modeling is found in the system The Fawlty Article Tutor (Kurup, Greer & McCalla, 1992) which teaches correct article use in English. The system presents the student with scenarios whereby the student must select the correct article form and the appropriate rule. The tutor keeps an error count and selects the scenarios on the basis of the performance of the student; thus the path through the program is individualized by altering the instructional process according to prior performance of the student.

Bailin (1988, 1990) in his system Verbcon/Diagnosis also employs the tracking method. Diagnosis provides practice in using English verb forms in written texts. All verbs are presented in their infinitival form challenging the student to provide the appropriate verb form. The system tracks the most frequent error occurrence and the context in which the error occurred. The information is used to provide informative feedback based on contrasting correct and ungrammatical uses of tenses. In addition, Diagnosis suggests exercises to help with the remediation process.

In the following section we describe the ESL Tutor and discuss the modeling technique used.
3. The ESL Tutor

The goal of the ILTS we have developed for ESL is to provide meaningful and interactive vocabulary and grammar practice for second language learners. The ESL Tutor analyzes sentences from the student and detects grammatical and other errors. The feedback modules of the system correlate the detailed output of the linguistic analysis with an error-specific feedback message.

In the ESL Tutor, feedback is individualized through an adaptive, explicit Student Model, which monitors a user's performance over time across different grammatical constructs. This record of strengths and weaknesses is used to tailor feedback messages to learner expertise within a framework of guided discovery learning: a beginner student will receive the most explicit feedback while the instructional messages for the expert will merely hint at the error. The feedback aimed at the beginner will also contain less technical terminology than that for the intermediate and expert. For example, Figure (1) shows a feedback message for an intermediate student, which indicates incorrect subject-verb agreement.

In contrast to Figure (1), the feedback message for the beginner learner will provide less linguistic terminology and state that The verb IS is not correct here. For the advanced learner, the feedback will provide less of a clue and simply display There is an agreement error in this sentence.

In the following section we discuss the technique employed in the Student Model of the ESL Tutor.

3.1. The Student Model of the ESL Tutor

The Student Model of the ESL Tutor dynamically evolves based on the student's performance. The information in the model is used for two main functions: modulation of instructional feedback and assessment and remediation.

The Student Model keeps track of an individual student's performance on a variety of grammar skills; from subject-verb agreement to passives to count/mass nouns. A student has a score for each grammar skill. This score ranges from 0 - n, where we have set n to 30. The score increases when the student provides evidence of a successful use of that grammar skill, and decreases when the student provides evidence of an unsuccessful use of that grammar skill. The amount by which a student's score increases or decreases can vary depending on the current value of the score. Initially, we set all scores to an intermediate level.

For the purposes of modulating instructional feedback, we identify 3 categories of scores. Scores from 0-10 are assigned to the novice category, 11-20 to the intermediate category, and 21-30 to the expert category.
When a student makes an error on a particular grammar skill, the message they receive depends on their score for that skill. If they are ranked as novice, they will receive a more informative message than if they are ranked as an expert. Since the score for each grammar skill is independent of the score for the other grammar skills, a student may be expert at subject-verb agreement, but novice at forming the passive - and receive the appropriate message.

The score information is also used for a variety of remediation and assessment tasks. By comparing the Student Model at the beginning and end of a session, we can provide a summary of the mistakes that a student made during that session. In our current system, these are summarized into general categories such as "Verb Tenses", "Pronouns", etc. These groups are set by means of a parameter file. Similarly, we can also identify the grammar skills where the student was correct and provide a "positive" of what the student did right. At present we show a list of the errors at the end of each exercise set.

Further, one can also examine the Student Model overall and identify the current strengths and weaknesses of the student. We identify the strengths of a student as the five highest scoring grammar skills that have a score greater than 15 (half of the total scale). We identify the weaknesses of a student as the 5 lowest scoring grammar skills that have a score less than 15. Students can access this information.

Finally, the Student Model information can also be used to provide exercises to the student which focus on their areas of weaknesses. Instead of repeating the same exercise which the student made the mistake on, the ESL Tutor has the capacity to identify examples which require the same grammar skill. This avoids the problem of the student rote learning the solution to a particular example, without actually learning the general solution. We have not yet implemented this functionality in the ESL Tutor.

4. Evaluation

The Student Model of the ESL Tutor is based on our German system (Heift & Nicholson, 2001) which has been tested extensively. In one of the studies, we determined the extent to which the Student Model addresses the need for an individualized language learning environment. 33 students participated in the study and a total of 1352 sentences were considered for analysis.

When analyzing the data with respect to individualized instruction, we were interested in the types of errors that occurred during practice and their distribution with respect to the three learner levels: beginner, intermediate and advanced.

The error breakdown in Table (1) shows that students were most often at the intermediate level, which is not surprising since each student is initially placed at the intermediate level. Nonetheless, approximately one third, or 30%, of the time, students either required more elaborate feedback suited to the beginner learner, or, in the case of the advanced learner, less detailed feedback was sufficient to correct the errors. Moreover, and although not illustrated in Table (1), ten students or 30.3% of all participants received remedial exercises for at least one of the six chapters.

</tbody>
</table>

Table 1: Break-down of Grammar Errors
The data further indicate that most errors occurred with direct objects (21.5%) and subject-verb agreement (20.6%). However, these were the most frequent constructions contained in the 120 exercises of this study. For instance, only chapters 5 and 6 (40 exercises in total) focus on the present perfect and modals. These constructions are not contained in any of the previous chapters, thus there is less opportunity for errors with these grammar topics than, for example, subject-verb agreement.

It is interesting, however, to consider the number of grammar errors made by each learner level. From a learning perspective, the data in Table (1) indicate three distinct groups:

1. those grammar topics where the error distribution for the beginner and advanced levels is fairly balanced (missing words, extra words, word order, auxiliaries, verb complements),
2. those grammar points where students are far more often at the beginner than the advanced level (direct and indirect objects, accusative, dative, two-way prepositions), and
3. those grammatical constructions where students are far more often at the advanced than the beginner level (subject-verb agreement, subjects).

The data of our Student Model also allow us to gain insight into students' performance on a particular grammar skill over time. For example, Figure (2) illustrates the performance on direct objects by four students who were randomly selected from our data set. The x-axis displays the five chapters that contain direct object constructions and the y-axis shows the scores which correspond to the three learner levels. The graphs indicate that one of the students stayed at the intermediate level throughout practice. In contrast, the remaining three students shifted from the intermediate to the advanced level. The data confirm that while there is variation across learners each student also changes performance levels as s/he progresses through the course.

The data support the need for an individualized system which makes subtle distinctions between learners and error types. Our Student Model has a number of advantages. It takes into account students' past performance, and by adjusting the score value to be incremented or decremented, it is adaptable to a particular grammatical constraint in an exercise or the pedagogy of a particular instructor. For example, a language instructor might rate some errors more salient than others in a given exercise. In such an instance, the increment/decrement of some grammar constraints can be tuned to change their sensitivity.

The main strength of our Student Model, however, is that a single erroneous message will not drastically change the overall assessment of the student. The Student Model indicates precisely which grammatical violations occurred, allowing for a fine-grained assessment of student competency. In consequence, a student can be at a different level for each given grammar constraint reflecting her performance of each particular grammatical skill. This subtlety of evaluation is desirable in a language teaching environment because as the student progresses through a language course a single measure is not sufficient to capture the knowledge attained and to distinguish among learners. The Student Model aids in directing each student toward error-specific and individualized remediation.
5. Conclusion

In this paper we provided examples of Student Models that have been employed in CALL over the past decade. We introduced our ESL Tutor, an ILTS that provides error-specific and individualized feedback. The Student Model of the ESL Tutor is based on learner performance history and makes system decisions accordingly.

A study in which we evaluated the extent to which our Student Model addresses the need for an individualized language learning environment emphasizes the importance of an adaptive language learning system that considers user diversity. Approximately one third, or 30%, of the time, students either required more elaborate feedback suited to the beginner learner, or, in the case of the advanced learner, less detailed feedback was sufficient to correct the errors. The data further confirm that while there is variation across learners individual students also change performance levels as they progress through a course.

Our study also provided some interesting insights into the error typology of different learner levels. Due to the constrained environment of the exercises of our system where students select from a given pool of vocabulary and grammatical structures, errors in omission, insertion and word order were less frequent than other grammar errors. Fewer errors occurred overall and thus the error distribution with respect to beginner and advanced levels was fairly balanced. We are currently establishing a similar error typology for our ESL Tutor.

Abstract. This article describes the New Learning Environments in the Work of the Teacher (NET) development project in the Province of Lapland for university-level teaching methods NET is organized by the Centre for Media Pedagogy and funded by the European Union’s European Social Fund (ESF). Its objective is to improve and support the use of information and communications technology (ICT) in the work of university-level teachers and the teaching support staff. The article presents the content, some assessment principles, and the effectiveness of the NET study programme (15 cr.) developed during the project. The study programme will be realized twice in 2001–2002. The research into effectiveness of the study programme will examine the methodological and ontological commitments of empowerment-evaluation. Self-direction will be examined later in relation to meaningful learning, methods of guidance and to the more extensive, regional effectiveness of training.

1. Introduction

New Learning Environments in the Work of the Teacher (NET) is a development project for university-level teaching methods in the Province of Lapland. It is organized by the Centre for Media Pedagogy at the University of Lapland and realized through funding by the European Union’s European Social Fund (see Ruokamo, Syrjakari & Karppinen.) The project is the result of cooperation between university-level educational institutions and the Provincial Government of Lapland and it is being realized in the years 2000–2002. The goal of the project is to:

1. support the professional development of teaching and the teaching support staff at
the university-level using client-oriented multi-disciplinary courses by focusing on
the use of information and communication technology,
2. develop the content and methods of training and development services in order to
serve working life, and
3. stabilize the cooperation of the institutions of higher education in the development
of the area.

The 15-credit (NET) study programme, which corresponds to the first objective of the project, supports the preparedness of university-level teachers and teaching support staff to benefit from information and communications technology in their work. Its purpose is also to increase awareness of open learning environments, their related perspectives on learning and pedagogical trends. The study programme is organized twice in the years 2001–2002 and the research of effectiveness is closely related to both courses. In this article, empowerment-evaluation is taken as a perspective of the research of effectiveness. Its functionality as a method of assessing effectiveness will be examined in relation to both the course students and the objective of the project. Empowerment-evaluation is related closely to the concept of self-direction. The aim is to consider the development of the participants’ self-direction during the study programme and later to examine whether self-direction can have a wider regional effectiveness and how assessment by itself can be effective.
2. New Learning Environments and Self-Direction

Learning environments are comprehensive environments of operation that are formed from many different factors: environment, students, teachers, different perspectives of learning and forms of action, sources of learning, and the tools and objectives in using them [http://www.uta.fi/ttv/verkkotutor/oppymp.htm]. Thus, a learning environment is much more than a physical space. New learning environments are often connected to the use of developed technology in teaching. However, new technology can also be used in a traditional learning environment. Challenges and obligations, which in themselves are not bonded to new technology any more than they are to older technology, are often connected to a new learning environment. An attempt is made in new learning environments to create natural forms of working in which a student can direct events in the direction of his or her personal objectives and assessment. Often, a virtual learning environment, an open learning environment, and a network-based learning environment are used as a parallel or replaceable concept of the new learning environments (Manninen & Pesonen 1997). With the concept of an open learning environment, student centricity and flexibility form the basis of the learning experience. Openness can mean, for example, emphasizing the goal-orientation of the individual and individual self-direction. (Kivimäki 2000.)

Working in a network forces a student to be active and to make choices, in other words to be self-directed. A student also influences how he or she works in the environment, at what speed, and at what depth he or she wants to become familiar with certain contents on his or her computer (Kivimäki 2000). Self-direction and autonomy is not only a question of technical control; rather, it is also a question of the student's internal expansion of knowledge. Instead of self-direction, Garland (1994) uses the concept of personal control. The personal control of learning requires that a student aspires toward study in a critical manner and, for example, aims when studying to separate essential knowledge from the immaterial or believable theory from the unbelievable. Often, this type of activity does not happen automatically, nor do the skills of an adult student always give the readiness to act in a self-directed manner. The role of a tutor becomes emphasized in studies within new learning environments. Lehtinen and Jokinen (1999) describe the change in the roles between a guide and a student towards that of self-direction as presented in Figure 1.

3. Empowerment in Order to Strengthen Self-Direction and Effectiveness

The effectiveness of training can be studied from many perspectives. In addition, its focus and the role of the researcher influence the formation of the research process. These dimensions are outlined in Figure 2.
The methodological and ontological commitments of assessment research are defined according to the focus of assessment, the role of the researcher, and the nature of the knowledge. The point of emphasis for assessment can be either in the result or in the process. The role of the researcher can change from the external observation of a process to that of an internally operating therapist. Moreover, the nature of knowledge can change from one objective reality to the relative relativism of subjective knowledge and to the pluralism of knowledge. In the development project New Learning Environments in the Work of the Teacher for university-level teaching methods, project planners work in the role of both tutor and researcher. Thus, the position of the researcher suits the role of empowerment/confirmer. An attempt is made through process-formed assessment to develop the training project and the study programme. The central task of process evaluation is how well the material collected during the process is used in guiding the project and in specifying its objectives (Seppänen–Järvelä 1999). The challenge is to be able clearly to bring forth the informative material obtained through experience, its basic observations and findings. It will help the work of development, learning, and reflectivity and thus improvement. The core of empowerment is participation and participating. Conquest includes the two related sides of empowerment: change in the individual’s self-determination, in other words in the ego, and participation through changes taking place in the environment. It strengthens the functionality of the subject. (Antikainen 1996, 253–254.)

The meaning of the concept of empowerment in relation to professional adult education differs slightly from the above. A study programme should provide its participants with such tools, that in their work (and life) they are able to activate, motivate, and solve their problems by themselves. The afore-mentioned claim is based on the humanistic concept of a person, which believes, among other things, in the following strengths and opportunities for individual development.

1. The subject principle: a human is a conscious being that can affect his or her thinking and action; he or she is not a passive object in which information can be accumulated.
2. The development principle: a human is not naturally a subject; rather, he or she develops gradually as an increasingly knowledgeable actor and thinker.
3. The action principle: development takes place through human action.
4. The societal principle: development always takes place in some societal and cultural environment. (Toiskallio 1994, 20–22.)

Therefore, empowerment–evaluation offers the opportunity for the work of development; in addition, it notes the relationship between the individual and the environment through the activity of an individual’s development of activation and self-direction (see Heikkilä 2001).

4. New Learning Environments in the Work of the Teacher— the Realization and Content of Training

The NET training provides the preparedness to benefit from new learning environments and to renew one’s pedagogical practices and skills in information and communications technology (ICT). As part of their
practice during the course, the participants develop network-based training modules, web-based learning materials, and the beneficial tools for building knowledge in the learning environment, the use of which is assessed during the course.

The NET study programme is intended for university-level teachers and teaching support staff in the Province of Lapland. It has 130 participants from the University of Lapland, the Rovaniemi and Kemi-Tornio Polytechnics, and class teacher students specializing in media education.

Training includes contact teaching in Rovaniemi, video-conferencing to distant localities, and collaborative working. It takes advantage of environments based on information networks. In addition, support training is organised to further the development and realization of network courses and web-based learning materials.

The training offered in the New Learning Environments in the Work of the Teacher (NET) project provides a 15-credit study programme organized twice during 2001 and 2002. The NET I course was and is being realized from January 2001 – February 2002 and NET II from November 2001 – December 2002. The training includes the following courses:
1. Orientation to Studies,
2. Learning Environments and Network Pedagogy (3 cr.),
3. The Planning and Realization of Network-Based Studies (4 cr.),
4. Copyright, Data Privacy, and Data Protection (1 cr.),
5. Information and Communication Technology (ICT) in Learning (1 cr.),
6. Interaction in a Network (3 cr.), and
7. Assessing the Learning Process and Learning Environments (3 cr.).

The study programme is in accordance with the study requirements at the Faculty of Education at the University of Lapland.

The first NET course began in January 2001 with the participation of 74 university-level teachers and teaching support staff from the University of Lapland, the Rovaniemi Polytechnic, and the Kemi-Tornio Polytechnic. This first course group acted as the focus for the experiment and development of the study programme. Its contents were mainly considered satisfactory; however, some parts were seen as problematic. The lack of clear and objective-oriented tutoring was one of the more significant problems. Insufficient attention was paid to the relationship of interaction among the student group and to benefiting from group strength and shared expertise. These factors can in turn affect the preparation of the final work on time and the realization of the objectives of the course. The NET I course came to an end in February 2002.

The second NET course began in November 2001. The first experience gained in the course was that at the beginning, insufficient attention was paid to group strength (face-to-face presentation), to taking into possession and working in the learning environment, and to rules. Moreover, time was used separately for guiding personal curricula and the principles of goal-oriented learning. The Sonera eXperience Training environment was used as the network environment for NET I. Discendum Optima was chosen as the network-based environment for NET II. The Discendum Optima environment enables better non-hierarchic and interactive activity in a network than the Sonera eXperience Training environment does. Of the training contents, thematic discussion channels are built into the environment, where the aim is to promote learning, shared expertise and experience. The concept of shared expertise refers to a process during which several people share intelligent resources related to knowledge, plans, and objectives in order to achieve something that an individual person is unable to realize on his or her own (Brown et al. 1993; Oatley 1990). The students in NET II will graduate by the end of 2002, when information about the achievement of their goals will have been obtained.

5. Conclusions

This article has examined the New Learning Environments in the Work of the Teacher (NET) development project in the Province of Lapland for university-level teaching methods – its contents, objectives, and some assessment principles. The goal has been to present a model based on empowerment-evaluation, which is one means of performing effective and planned assessment. Post-assessment is insufficient; rather, pre-assessment and guided assessment are also needed. As a central concept, self-direction rises to the fore in empowerment-evaluation, which increases the meaningfulness of learning and the effectiveness of training. Self-direction is often related to network-based education, to new and open learning environments, in that it is in these that study demands some form of self-direction from a student. Its internalization is not, however, self-
evident for the adult student; rather, its development requires the development of guiding processes. On the one hand, the learning occurring in new learning environments in itself can encourage self-direction; on the other hand, simply being along on a network course does not automatically bring about self-direction. This research will examine self-direction in relation to methods of guidance and in relation to achieving the objectives of the project by answering the following questions: 1) Does NET strengthen and confirm the self direction of the participants in the study programme? 2) What were the significance and procedures of guidance in the process? 3) Can self-direction have a more extensive, regional influence?

Based on the assessment of the NET course, an advanced study programme will be developed that, instead of being based on teaching methods related to new learning environments, will provide more systematic information on teaching methods related to new learning environments and to the opportunities offered by digital media in open learning environments. In addition, the pedagogical models and principles occurring within network-based education are developed and assessed in the national HelLa project, which is a cooperative project of the Universities of Lapland and Helsinki (see Ruokamo, Tella, Vahtivuori, Tuovinen & Tissari). We are able to utilize the principles of assessment developed by the HelLa project in analysing results of this study programme, and will present results of effectiveness research when both NET study programmes have ended.

Abstract: In order to take a part in a particular Web-based training session learners need to work with a number of tools reflecting a particular training strategy. By operating these tools learners access different training objects contained in that training session. Such training objects contain relevant information for their current training task. Nowadays, modern WBT systems support dozens of different, sometimes rather complex tools and provide access to thousands of training objects. In this paper we analyze the problems of user interface that can become a rather complex one in training sessions conducted in such systems. In order to overcome such problems we provide a simple general user interface solution for these WBT systems. Further we provide an evaluation of the responses from users we gathered in applying that solution in a number of Web-based training sessions. This evaluation showed us that there is much more potential in our solution than we believed at the first resulting in the evolution of our user interface solution to a simple knowledge delivery tool. Such tool might be used to conduct training sessions that contain always the most up-to-date and the most relevant training objects residing in the system.

1. Introduction

Technically, WBT systems (Gaines et al., 1997) consist of a large repository of training objects and a number of tools to manipulate these training objects. Usually, these tools support operations such as creating, deleting, accessing, or updating of training objects (Dietinger et al., 1997).

According to the variety of types of training objects supported by a particular WBT system, or in other words according to the number of tools and functionality that such tools support we may distinguish between (Helic et al., 2000):

- Standard WBT systems
- Advanced WBT systems.

Standard WBT systems support only basic training objects, such as learning unit, learning course or discussion forum. Tools provided by such systems include authoring tools, publishing tools, navigation tools, simple search tools, etc. Usually, such tools are rather primitive with a simple basic functionality and a comprehensive user interface. On the other hand, advanced WBT systems support a wide range of different training objects. For instance, these training objects include learning goals, mentoring sessions, brainstorming sessions, knowledge cards, knowledge profiles, etc. Structurally these objects may be rather complex. For instance, a knowledge card is an instance of so-called semantic network, which is a rather complex structure. Obviously, tools provided by advanced WBT systems are by far, more numerous,
provide a richer functionality and more complex than tools provided by standard WBT systems. Consequently, these tools have a rather complex user interface.

From the users' point of view WBT systems offer possibilities to take part in different training sessions. Usually, a training session is considered to consist of a so-called training strategy and a number of training objects (Helic et al., 2001a). Training strategy reflects a particular way of working through the subset of training objects to achieve a particular training goal (Helic et al., 2001b). Actually, a training strategy is a collection of tools combined in a certain way and reflecting a particular training methodology. For instance, consider the training strategy known as Web-based learning. This training strategy is a collection of tools that provide functionality needed to access and navigate through different learning units and learning courses (Andrews et al., 1995). Web-based learning might be considered as the basic training strategy supported by all WBT systems. Another example of a training strategy would be so called Web-based tutoring. This strategy is a rather advanced training strategy supported by an advanced WBT system called WBT-Master. Web-based tutoring prescribes working with a set of special WBT-Master tools. These tools allow users to navigate through a sequence of so-called learning actions and training objects associated to such learning actions in order to achieve a particular learning goal.

Obviously, advanced training strategies supported by means of advanced WBT systems might consist of a rather large number of tools (Helic et al., 2001a; Helic et al., 2001b). Considering that such tools have rather complex user interface themselves any collection of these tools would have a rather complex user interface as well. Thus, users of advanced WBT systems might be confronted with a serious problem of a complex, inscrutable user interface. Also taking into account that more advanced training strategies might include training objects of many different types, thus resulting in an increased number of different tools needed to implement such a training strategy, the user interface problem is becoming even larger. Evidently, if we want to be able to conduct training session by means of advanced training strategies we need to solve the increasing user interface problem on a larger scale. Hence, not only do we need to simplify the user interface of a particular tool but we need also a more general user interface solution that is able to reflect all peculiarities of any training strategy and provide a single access point to each of tools needed to implement a particular training strategy. Apparently, such solution needs to be highly configurable, customizable user interface solution.

WBT-Master provides such general user interface solution in the form of so called Personal Desktop.

2. Personal Desktop

Conceptually, a personal desktop is just a set of folders containing references to designated training objects and WBT-Master tools. Tools from a particular folder reflect a particular training strategy, whereas the training objects from that folder contain information relevant for achieving a certain training goal.

![Figure 1: Content of a personal desktop folder](image-url)
He/she creates a personal desktop folder containing different WBT-Master tools and a number of training objects residing on the server. Once when the personal desktop folder has been created he may share that folder with the learners' group, thus allowing them to participate in his/her training session. Obviously, by accessing the created personal desktop folder learners have access to designated training objects by means of the implemented strategy. However, learners are not any more confronted with arbitrary tools or training objects provided by the system. Rather they are supposed to access only few relevant training objects and that by means of tools reflecting the desired training strategy.

Figure 2: working with training objects from a personal desktop folder

This concept greatly facilitates the fact that a typical user works with just a few tools and training objects offered by the system. In other words, this special customization mechanism is used to adjust the rich system functionality to personal needs of a particular learner or a group of learners. Hence, a tutor or an author may decide on preferable user interface for such group of learners and on training objects, which are needed to accomplish a particular training task. Another important aspect of the personal desktop concept is collaboration facilities, which are provided by so-called shared folders and internal messaging system. For example, a learner group may share a certain folder to put all contributions of the group members into it. In this way, the contributions may be easily accessed by group members and discussed by attaching messages to such contributions.

Figure 3: Exchanging messages with a personal desktop folder
3. Working with Personal Desktop

Generally, first experiments with personal desktop show a great acceptance of this concept by users.

Authors very much appreciated a possibility to define all requisites of a particular training session, i.e., all tools that are needed to implement a particular training strategy, as well as all relevant training objects as members of a folder. In this way they were not supposed to know all peculiarities of the system in order to combine the system tools into a coherent training strategy. For instance, they were not supposed to know how to attach a discussion forum to a learning course to provide learners with a board to discuss topics from that learning course, but rather they just put that learning course and a discussion forum into a personal desktop folder and the above-mentioned relationship between these objects was automatically established by the system.

On the other hand, tutors liked the messaging functionality of a personal desktop folder the most. This functionality allowed them to keep the communication between members of a particular learner group within the scope of a particular training session. Also, possibility to reuse (for instance, in the form of FAQ) the results of such communication was quite well accepted by tutors.

Finally, learners appreciated the simplicity of user interface as offered by such training sessions very much. Not any more did they need to find their way through dozens of system tools and large number of training objects. Rather they just worked with a few tools and relevant training objects combined into a simple navigable list.

However, there exist some disadvantages of this concept as well. The most important shortcoming of such an approach can be stated as follows. A particular training strategy, i.e., a particular collection of tools that implements that training strategy might be seen as a rather static entity. That means that a particular training strategy is likely not to change in the course of the time. For instance, consider the above-mentioned Web-based learning training strategy. This strategy consists always from say a number of learning courses and a discussion forum attached to these courses. What really changes in training sessions is training objects. Actually, training objects might be seen as a very dynamic entity. Not only that in different training sessions training objects are completely different but also in one and the same training session training objects are likely to change. For instance, some training objects might become obsolete, newly updated versions of training objects might be created, etc.

These results led us to the conclusion that we need to extend the concept of personal desktop and redesign it in a way that it becomes robust to such changes. Thus, we decided to incorporate a mechanism that would be able to automatically select training objects that are the most relevant and the most up-to-date training objects. Only such training objects should become members of a particular personal desktop folder. Obviously, such mechanism must be able to "reason" about training objects and decide whether a particular training object is relevant to a particular training session, i.e., does it match certain criteria posed by that training session.

4. Personal Desktop as knowledge delivery tool

WBT-Master supports semantic data structures, which can be used to create different semantic overviews of training objects residing in the system (Helic et al., 2001a). These structures include so-called knowledge cards and knowledge domains.

A knowledge card is a description of particular concept (i.e. semantic entity). For example, a semantic entity "Database technology" may be seen as a knowledge card. Practically speaking, each knowledge card may provide access to a number of associated training objects. For example, a course on "Relational Data Model" may be associated with the knowledge card "Relational Data Model", some other training objects may be associated with the same knowledge card. Knowledge cards may be interrelated into a semantic network using different types of relationships: "is a part of", "is a kind of", "synonym for", etc. For example, the knowledge card "Relational Data Model" may be related as "is a part of" to the knowledge card "Database Technology." The knowledge card "World Wide Web" may be related as "is a kind of" to the knowledge card "Hypermedia Systems." The knowledge card "Web Base Training" may be related as "is a synonym for" to the knowledge card "Computer Supported Collaborative Learning".

The infer mechanism essentially utilizes the other important property of the semantic network - a possibility to infer training objects using semantic relationships. Whenever users access a knowledge card,
the system automatically infers all training objects, which are associated with this particular knowledge card and with knowledge cards related to this one. This mechanism greatly facilitates the initial access to the most relevant training objects.

On the other hand, a knowledge domain is a collection of training objects, which are structured using a predefined template called the knowledge domain schema. A knowledge domain schema may be seen as a definition of semantic categories and all possible semantic relationships between them. Thus, a knowledge domain contains training objects, which might be seen as instances of a particular semantic category interrelated by means of semantic relationships with training objects that are instances of related semantic categories. Basically, we may use this mechanism to express facts such as: the document "C" (an instance of say "Module" category) is related to the document "A" (an instance of say "Author" category) by means of the "Author Modules" semantic relationship. Similarly, the document "C" is related to the document "B" (an instance of say "Project") by the means of the "Project Modules" semantic relationship, etc.

Now, users may browse and search knowledge domains by means of the terms defined by the knowledge domain schema. For instance, users accessing an instance of the "Author" category automatically get a link to an index of all instances of related categories, i.e., a link to all "Author Modules" appears on the screen. Similarly, knowledge domain might be used to execute semantic queries, i.e., to search for all "Modules" that are related to a certain "Project" training object, etc.

The extension of the personal desktop concept treats knowledge cards and knowledge domains as training objects that might be added to a personal desktop folder.

Figure 4: Adding a knowledge card to a personal desktop folder

By adding a knowledge card as a training object in a personal desktop folder we achieve the following. Whenever users access a knowledge card from a personal desktop folder the system automatically infers all related and to that particular concept relevant training objects.

Figure 5: Accessing a knowledge card from a personal desktop folder
If a new training object is associated with this knowledge card, the system automatically captures that change by inferring the newly added training object the next time we access the personal desktop folder. Thus, this mechanism is a rather robust one to changes in the underlying repository of training objects. On the other hand, by adding a knowledge domain to a personal desktop folder users are provided with possibility of browsing semantic overviews of training objects residing in the system. Again, if a new training object is added to such an overview, the system automatically updates the overview the next time when we access it. Thus, changes in the system's repository of training objects are captured again. Hence, by incorporating these two simple knowledge-processing mechanisms into the concept of personal desktop we were able to enhance personal desktop from a general user interface solution to a simple knowledge delivery tool.

5. Conclusion

Generally, first experiments with the Personal Desktop system demonstrate a rather good functionality and acceptance by users. Learners like the situation where they are not confronted with too much system tools or irrelevant training objects but rather with just few important tools and training objects. On the other hand, tutors and authors very much appreciate the fact that they were able to completely control their training sessions and especially corresponding training strategy. They can be sure that their learners are confronted with only those tools that are the essential part of the implemented training strategy. Moreover, the extension of the concept of a simple user interface tool to a knowledge delivery tool leads to the conclusion that learners are not only confronted with the relevant system tools but also with the most relevant and up-to-date training objects that are needed for a successful training sessions.

Playing Video Games and Cognitive Effects: Teenagers' Thinking Skills and Strategies

Lyn Henderson
School of Eduction, James Cook University, Townsville. Australia 4811
Email: lynette.henderson@jcu.edu.au

Abstract: The study examines a dominant aspect of youth culture: playing video computer games. The study is interested in the recreational video game as a means of informal cognitive education. Centered within an information processing theory and introspection methodological framework, the study investigates via stimulated recall methods the thinking skills and strategies used by two teenagers when playing an action-adventure video computer game. The players used a wide range of cognitive processes that are valued in schools such as: metacognition, prediction, justification, inductive and deductive reasoning, strategy planning, and parallel processing.

Surveys (eg., Australian Bureau Statistics, 2000; DigiPlay.org.uk, 2001; Hall, 2000) have replica findings revealing that, although video games are predominantly a male youth pastime (approx. 80% boys 9-14 years), female youth are increasingly playing (approx. 60% girls 11-14 years); both play daily for periods ranging from 30 minutes to five and a half hours. Recreational video games are one of the most dynamic influential forces shaping youth culture.

There is a remarkably limited research literature concerning the cognitive effects of video game playing (eg., the special edition, Journal of Applied Developmental Psychology, 15, 1994; Camioni, Ercolani, Perrucchini, & Greenfield, 1990; Pillay, Brownlee, & Wills, 1999). This is perhaps because recreational video games are popularly seen as trivial without educational worth and something from which educators must rescue children and distance themselves. Yet cognitive processes are broader than those taught and tested in school. As part of our informal education, playing games has been identified as an important facilitator of cognitive development. This study is interested in the recreational video game as a means of informal cognitive education. The exploration of the cognitive processes utilised by teenagers while developing video game literacy will be of theoretical and practical interest to teachers, researchers, and the interactive multimedia industry. Overall, the project aimed to understand one key question: Do recreational video games, a dominant aspect of teenage culture, provide a context that encourage valued cognitive processes? To this end, the study investigated (identified, categorised, and analysed) the thinking skills, processes, and strategies utilised by young teenagers when playing recreational (as opposed to school-based educational) video games.

This was an empirical qualitative study based in an information processing theory, mediating processes paradigm, and introspection methodological framework. This paper reports data from two 13 year old volunteers, one male and one female (self-identified as Tony and Eyore, respectively), who had been playing for over two years. Final Fantasy IX, an adventure/action game, was chosen by the students and approved by their parents as it contains some low level violence but no "blood and gore". The data were collected through videotaped individual stimulated recall interviews at the beginning of the game and up to the same screen in the game. The stimulated recall technique is designed to probe the players’ reasons behind their actions and interpretations of the results of the action as well as to reveal the range and types of thinking skills, strategies, and processes utilised within the context of their use. Hence, these interviews occurred when playing the game which, together, took approximately one hour. Participants were not allowed to read the instruction help booklet before commencing the game.

</table>
Eighteen types of thinking skills were utilised during the students' first encounter with the game. Higher order thinking skills were utilised by both students, for example: predicting what may happen and hypothesising “if ... then ...” consequences of actions and events; evaluating the game, graphics, characters, and their own gameplay; justifying, rationalising, and explaining their actions and what was happening in the game; and metacognising their awareness of what they knew and did not understand and suggesting ways to troubleshoot their lack of comprehension. Some types of thinking skills were unevenly engaged in by the students: comparing this game with other games; confirming the accuracy of their strategies, predictions, and ideas; judging, particularly issues of morality in the game and expressing thoughts about their affective feelings such as frustration (more so Eyore) and empathy for what the characters were experiencing (more so Tony).

Inductive and deductive reasoning were utilised a pleasing number of times. However, trial and error, a legitimate problem solving approach though not the most efficient (Martinez, 1998), was the major strategy because they were “learning how this game worked” (Tony's Interview). Nor was it surprising that equipping their characters for fighting came a close second during the short session.

In terms of overall processes, the players had to work out how the symbols, icons, images, and control buttons acted individually and in unison. They had to attend simultaneously and selectively to a number of different pieces and types of information displayed on various parts of one screen and from one screen to the next; that is, they had to further develop their skills of parallel processing (Greenfield, et al., 1994). They had to figure out the rules of the game. Indeed, what the data shows is that they were engaged in a process of transforming and manipulating their mental models of previous games and gameplaying with this game and its quite different gameplay.

Even with such a short playing time as this research episode, the data reveal that playing Final Fantasy IX provided a valuable informal educative experience. They engaged in cognitive skills, strategies, and processes that are valued in schools. They demonstrated that playing this game involved complex cognitive processes.

Abstract: The purpose of this brief paper is to invite additional project partners into our research. We believe that an international, rather than country specific, survey of the various issues involved in playing recreational video/computer games will help characterize this important aspect of youth culture on a global basis. It will also help inform parents, teachers, governments, the media, and video/computer game designers, including educational and edutainment instructional computer game designers.

Recreational video/computer games are a significant cultural artifact of youth culture and are a multi-billion dollar industry. “Video/computer games”, is a generic term encompassing four types of games: (a) video games that use a CD or cassette console with attached control devices connected to a TV monitor; (b) computer games that are played on the computer using a CD-ROM or the Internet; (c) “gameboys” that are small hand-held rectangular devices that have the display screen in the top half and the control buttons in the lower half; and (d) arcade games that are played in public shops or arcades. The pervasiveness of these cultural play artifacts with their “scintillating pulsating surfaces that are dynamically seductive”, invite exploratory play while shaping the users’ lives (Turkle, 1997). This pervasiveness has led to a corresponding rise in the emotional debate regarding the consequences of video/computer game playing.

There have been a number of surveys establishing children’s, teenagers’, and young adults’ gender usage patterns, game preferences, and/or opinions on issues of violence and addiction (e.g. Australian Bureau of Statistics, 2000; Centre for Research on Innovation and Competition, 2002; Downes, 2000; Drotner, 2001; Media Analysis Laboratory, 1998; Griffiths, 1997; & Walsh, 2001). However, these surveys and studies have limitations that our international multi-focussed survey would help overcome. For instance:

- previous surveys, except for Drotner’s European survey based on 1998 data, have been country specific;
- they sometimes target different age groups, making international comparison incomplete;
- they do not target all types of recreational video games: computer CD-ROM games, Internet games, arcade games, and “gameboy” games;
- many of their questions are not the same, making international comparison incomplete;
- they usually do not target identity-status issues;
- they do not target the participants’ perceptions of educational versus recreational video/computer games; and
- they do not target English literacy, video/computer game genre literacy, and identity issues with respect to the Web and print computer gaming magazines.

We have commenced research that involves a comparison of various issues concerning video/computer game playing by 13 and 14 year old youth in Australia, Israel, England, and, in a minor way, China. This age-group was chosen because it has been identified in some surveys to be the age when teenagers lose interest in
video/computer game playing and this age group is consequently often ignored in the wider literature. (Yet our survey reveals that the 13/14 year olds all play one or more types of video/computer games.) The research comprises a 28 item questionnaire that was designed to help identify various aspects of computer/video gaming for this age group. The questionnaire obtains gender, age, and ethnicity profile data. While some items contain multiple parts with fixed choices within those parts, others (including a drawing) are open-ended thereby allowing the students to delineate the issues relevant to them. (Surveys usually opt for closed categorical-mode entries for ease of coding and correlation.)

The broad issues targeted in our survey concerning video games, computer CD-ROM games, computer Internet games, arcade games, and “gameboy” games include:

- usage patterns (what types are played, and for how long, when, where and with whom with each game type); use of Internet game playing is particularly targeted;
- reasons for playing each type they play;
- reasons why they quit a particular game playing session;
- role of video/computer games in their recreational lives;
- game genres played and preferred, and reasons why;
- identity-status construction and positioning (of themselves, of and by their peers, by the games, and by the gaming print media); this area is also linked to gender and violent/non-violent issues;
- perceptions of effects of games on themselves and others;
- concerns associated with video/computer games;
- characteristics that make a good video/computer game;
- video/computer game literacy;
- comparison of educational vs recreational computer games. (Our data highlights the relevance of identity-status factors in this comparison.)

At present, we are processing some 584 completed questionnaires from the participating countries. Categories and correlations have been delineated and a database is being constructed. We expect this analysis to enable us to obtain a global characterization of this growing digital gaming culture, and to shed light on its role in the youths’ lives internationally.

Students Composing Music in a Cognitive Apprenticeship
Interdisciplinary Online Curriculum:
An Analysis of Systemic Issues in the MUSYC-IT Program

Lyn Henderson, Frank York, and Donna Rigano
School of Education, James Cook University,
Townsville, Australia. 4811
Email: lynette.Henderson@jcu.edu.au and frank.york@jcu.edu.au

Abstract: Music Uniting Schools, Youth, and Communities through Information Technologies (MUSYC-IT) is an innovative multidisciplinary program offered to Grade 5-8 students in Schools of Distance Education and small rural schools. Students conduct an oral history interview, reinterpret this as a lyric, compose a melody to that lyric using computer software in a cognitive apprenticeship model through mentoring by experts via the Internet. The paper analyses 764 emails to identify the issues involved. The findings reveal four major themes: information technologies; intersystemic development; implementation and delivery; and student learning and outcomes. Technological glitches, variability in mentors, commitment of participants, maintenance of the status quo were major issues. Most students completed their song and presented it publicly; principals, parents, and students request it be continued.

In Australia, there is unequal access to music studies for rural and remote students. Where offered, music is limited as it is theoretical or extra-curricular. Music Uniting Schools, Youth, and Communities through Information Technologies (MUSYC-IT) is significant in that it addresses rural youth identity, place, computer technologies, and music in a way not previously approached in Australian curriculum or, we believe, internationally. Compare the face to face PACERS Small Schools Cooperative which employs a professional musician (Anderson, 1999) and the Harvard’s SongSmith classroom based program (Walters, Meyvaar, & Scripp, 1990). The e-mentoring approach adopted by Canada’s Composers in Electronic Residence (http://www.edu.yorku.ca/CIERmain.html) and the USA’s Vermont MIDI Project (http://www.vtmidi.org) are both extension programs supplementing classroom teaching (also see: MacKenzie, 1998; Ruippo, 1999).

MUSYC-IT is the music program for our students, whether learning in their own homes through the Schools of Distance Education (SDE) or in a classroom at a small rural school. Students of various ages (10-13 years), grade levels (5-8), and abilities participated individually and collaboratively, contributing at their own level within a cognitive apprenticeship model (Brown, Collins, & Duguid, 1989). The students conducted oral history interviews with community people thereby validating local identity and community within an increasingly globalised world. Students then reinterpreted the content of the interview as a lyric, composed a melody using PrintMusic software, and were coached during the process through guided scaffolding by expert mentors, particularly the nationally acclaimed composer and lyricist mentors, via the Internet (cf. Schlager, Poirier, Beans, 1996). The students were learning something of what is involved in being a professional historian, lyricist, and composer.

The three year project is an agent for educational change. This study is part of a larger research project that attempts to identify social and educational issues concerning intersystemic development, delivery, implementation, and outcome factors involving a computer-mediated interdisciplinary curriculum in SDE and small rural classroom context. As the research literature reveals, information technology innovation in schools is difficult with variable implementation success (eg., Riley, 2000; Rogers, 1995). The first year or phase of this project was no exception. The specific aim of the paper is to identify the systemic issues concerning the implementation and delivery factors in the first year with respect to the online email communications between the participants of the program.

Methodology

The procedure employed in this analysis utilized an interpretive perspective (Erickson, 1986). This interpretative approach advocates the portrayal of the idiosyncratic and the particular as legitimate in
themselves (Walker, 1986; Wignall, 1998). Pseudonyms or role descriptions are used throughout this report. Ethical dilemmas associated with the use of confidential information were addressed by providing drafts to participants who could be identified in the text. Modifications and suggestions were incorporated at their request. The setting of the study involved a number of different sites. James Cook University was the location of the two university project directors and researchers. Two types of school sites were involved: One was the four SDE whose students are on grazing properties isolated from regular schools or travelling (one of MUSYC-IT students was in England with her family). Each of the students enrolled through the SDE had their own site that was, in fact, their own home. The second school type was a rural multi-grade classroom, half of whose students undertook the program under the guidance of a classroom teacher. Finally, both the lyricist and composer mentored from their homes as occasionally did the project directors. The participants involved the following:

Research and development project directors (1 male; 1 female) conceptualized and coordinated the program, designed and developed course materials and the Website, mentored, wrote grant applications, and oversaw the data collection by two research assistants.

Students: One self-selected cohort involved 11 Grade 6-8, SDE students (3 male and 8 female) who had some rudimentary knowledge of music and worked under the guidance of a home tutor, usually their mother. The second cohort involved 13 (8 male and 5 female) Grade 5-7 students selected by the teaching-principal on the basis of their ability to work unsupervised.

Mentors: Four subject specific mentors (3 males; 1 female) provided expertise to the students; and one parent acted as the IT troubleshooting mentor.

Home Tutors & Teachers: 12 home tutors (one had 2 children enrolled) and 1 teaching-principal for Term 3 and 1 classroom teacher for Term 4 with the rural multi-aged/grade cohort. Most home tutors and both teachers had no or little music knowledge; and

Administrators: Two SDE female coordinators (one left at the beginning of Term 3). Theirs was an administrative role that did not involve mentoring and was extra to any regular teaching duties; 2 principals.

Data Results and Analysis

Specifically, this paper reports an analysis of the email documentation connected with the overall project. There were 764 emails between the participants during 2001 (additional ones were inadvertently deleted or not sent to the project directors). The data were firstly categorized according to the source of the documentation. The constant comparative method provided a theoretical construct from which to operate (Dye, Schatz, Rosenberg, & Coleman, 2000; Glaser & Strauss, 1967). Each category was coded with a set of interpretive codes that emerged from the data and from discussions between the researchers. These coding categories were combined into main themes about the processes and issues involved in the implementation of the curriculum. This text is an interpretive representation of those themes and aims to describe and characterize the factors involved in the implementation of the online curriculum.

The intensive and exhaustive analysis of the data yielded many significant insights into the processes and issues involved in the development, delivery, and implementation of the online curriculum. Four major themes presented in Table 1 elaborate these insights in an attempt to qualitatively describe what the participants were talking about as the program was implemented. Evaluative conclusions about the implementation of the program are drawn and implications for future implementation are discussed.

Table 1: Major Themes from Email Analysis

**Theme 1: Information Technologies**

This theme deals with the issues and processes involved in getting the IT operational for the students enrolled in the program, as summarised in Table 1: Internet issues, software, and hardware. Handling of the Internet issues was lengthy. There were issues such as the schools' and university’s firewalls, Web site, Internet access, and security that needed quick resolution. There was an underestimation of the amount of time required for these issues to be addressed by the different stakeholders with messages becoming increasingly more urgent. The failure of the Website to be up and running at this stage caused much frustration for both students and administrators alike. The delay meant that multiple mailings of files and attachments were necessary. Once the Website was working students were able to access the site at their own convenience.

The initial stages of the course involved correspondence that reflected further frustrations concerning uncertainty in the accuracy of email addresses because of changed email accounts, the rural school’s firewall, and the families of distance education students having two email accounts to handle various sized email files. In one case, these email problems, exacerbated by low bandwidth technology, resulted in two students withdrawing within the first 3 weeks of MUSYC-IT.
A significant issue involved the selection, ordering, and distribution of the relevant music software required for the program. After much discussion about, and trialing of, the most appropriate software to be used, there was a problem with the supply of this particular product. Decisions for alternative software had to be quickly made and actioned. Unfortunately, once the software arrived, installation of the PrintMusic two CD pack—the original program on one CD with the upgrade on the other—was variable as some worked and some did not. Conveniently for MUSYC-IT, a parent from the rural school volunteered to be the troubleshooter for software, email, downloading plug-ins, and hardware problems. Utilisation of community resources cannot be overlooked as an invaluable factor when dealing with IT and school change.

**Theme 2: Intersystemic Development**

This theme involved the intersystemic issues of planning, grant applications, and media publicity, as summarised in Table 1. Crucial issues involved the scope and cohort size of the project.

To help avoid a top-down imposition of MUSYC-IT on teachers and students, negotiation and consultation with the SDE, parents, and students commenced in December 2000 for implementation from July through to mid-December 2001, with a student involvement of up to three hours per week. Initially, it was thought that 20-30 students from Grades 7-10 would enrol in MUSYC-IT as a core interdisciplinary subject. This did not eventuate. Some reasons had to do with the maintenance of stasis and custodianship of the status quo (Southcott, 2000), as, when it came to the crunch, there was opposition to changing the SDE segmented curriculum. Other reasons had to do with the initial SDE coordinator's workload aggravated by being new to distance education and the level of appointment, and being a self-acclaimed neophyte with technology. Another possible reason is that there were no obvious status or career rewards, incentives, or recognition for teachers to support innovative change through MUSYC-IT (Ely, 1999).

An alternative to a core subject was implemented. MUSYC-IT was offered as an elective with students exempted from some activities and assessment to ensure that the students' total workload was not increased. Lack of clear communication about the latter was late and inadequate, helping to cause small SDE enrolments. In fact, this negotiated and agreed upon strategy was not operationalised for two Grade 8 students in one SDE district, and it was the reason for their failure to complete, and hence postpone till 2002, the lyric and melody. As it eventuated, having 11 SDE students geographically dispersed throughout half of Queensland with different bandwidth Internet access and one in England and 13 in a rural classroom proved a worthwhile "pilot" cohort for ascertaining the viability of MUSYC-IT under both conditions.

The various issues and balance of power involved with this area of intersystemic innovation in schools intrigued the project leaders. The literature helped us understand that the principal was adopting the role approved by Fullan (1992) and supported by Glickman (1991), arguing that too much store is placed in the leader as solution compared to the leader as enabler of solutions.

Funding applications for both research and development, particularly the latter, commenced well before the setting up of the project, and still continue. Collaboration with one of the administrator participants, the principal of the coordinating SDE, was pivotal in acquiring funding for the composer-educator mentor, the purchase of the PrintMusic software, and the music camp. Without this grant, the project would have been postponed. The assistance of the lyricist-mentor helped obtain an Arts Queensland grant for his involvement in MUSYCIT. The project leaders underestimated the time taken in submitting numerous grant applications, five of which were successful.

In requesting assistance from industry partners, the research project was hoping to offset costs involved in purchasing the necessary equipment to run the course. Requests for hardware support were not successful because industry were hoping to reach wider audiences and receive more in return for their support than simply recognition. Telstra CountryWide's support for free Internet access for 30 accounts, a designated secure Website and a Website domain name for six months demonstrated a significant level of support. It was especially welcomed by the families involved in MUSYC-IT.

Besides developing their own curriculum resources, the project directors became clients for four final year B.Ed. students in a core IT course: the students created and acted in three iMovies that formed part of their course assessment and that will be utilised as resources for next year’s MUSYC-IT intake. Three of the students also critiqued the music curriculum tutorials and worksheets and suggested extension material using PrintMusic software. This unforeseen outcome of MUSYC-IT capitalised on widening the scope of IT diffusion to JCU graduating students.
Theme 3: Implementation, Delivery, & Research

This theme describes the processes and issues involved in operationalising the program and conducting research (see Table 1).

The project directors committed an enormous amount of time to the project in terms of receiving information, attending formal and informal implementation meetings both at the university and at the coordinating SDE (2 hour drive) and rural school (1 hour drive), devising enrolment applications both in hard copy and an email version, distributing these via the SDE coordinator, processing enrolments, inducting the mentors, organising and running the music camp, providing feedback, troubleshooting, and conducting research. Email correspondence between project leaders was heavy during periods when either one of the project leaders was away. Email correspondence was open, frequent, prompt, and with the intent of keeping the leaders up to date with current developments pertaining to the whole project. The time commitment during the early part of Term 3 of the coordinator of the SDE to help solve the technical and enrolment glitches that delayed the start of the program by a week was a positive factor in the implementation of the project.

The project leaders also attempted to organize a teleconference in the initial stages of the program. This required that a range of times for all participants be offered and then narrowed to a common time. Unfortunately, because of some unforeseen circumstances, the teleconference did not eventuate. The purpose was that students, home-tutors, teachers, SDE coordinators, the rural school principal, and mentors would hear each other's voices, troubleshoot any major problems, and feel a greater sense of collegiality in this new venture of teaching and learning music. From the email exchanges, this sense of collegiality between students did not eventuate for all participants. Perhaps a teleconference would have helped.

Theme 4: Student Learning and Outcomes

This theme is concerned with the learning outcomes experienced by the students themselves. It involves the quality of interactions between students and mentors, their responses to the various tasks of the program, and the degree of satisfaction with their final product. The types of issues and processes discussed include working in pairs/groups, how to conduct interviews, and providing feedback to mentors.

Once the IT problems were overcome and the students were able to work through their worksheets with the music-educator mentor's guidance, there was a much more positive note to the email correspondences: "Whilst I am writing I just want to say how much I am enjoying doing this course. Sometimes I find some of the words a little hard to understand and it has been a little bit complicated with the few problems we've had. Now, though, I think it's great to see the music on the computer and I look forward to doing activities in the future" (Email correspondence 27/08/2001 from A to music curriculum mentor).

Students appeared eager to conduct interviews and were able to identify elements about their interviewee's story. However there was some confusion about how the SDE students were to work online in pairs for this activity. Group work for SDE students appears to be a challenge and, although suggestions on how this activity could be carried out were provided, they were obviously inadequate for some students.

The lyricist-mentor undertook a very prominent mentoring role and his concern for student progress was obvious. Rather than sit back and wait for student outcomes, he often was proactive in ensuring that communications were working and that students were making adequate progress on their lyrics. Some of the email messages from the lyricist mentor, rather than contain attachments, contained the information for students in the body of the message. Sometimes the messages were up to five pages long. Depending on the preferences of the mail programs used to receive mail, these messages may have had untidy formatting. Whether these email postings were somewhat overwhelming for students is something that will be explored further in the participant interviews. Students were appreciative of his mentoring; for instance: "Please find attached The Value of Time. All of your suggestions were wonderful—they made me look more deeper [sic] into what I was trying to accomplish. I'm a lot happier with the song now that you've helped and I agree— it's worth changing the things that don't quite fit, even if you really like them... You've been brilliant and I really am grateful for the easy ways you have explained things to me" (Email 29/09/2001 from S to lyricist mentor cc. to the project directors). As the students were nearing the completion of their lyrics, there was evidence that they had established clear and effective lines of communication with their lyricist-mentor.

Unfortunately just as the melody composition stage of the project was commencing, the composer-mentor withdrew from the program and a replacement mentor had to be found. The new composer-educator
appeared to find mentoring via email more problematic than did the lyricist mentor. He was also not as prompt with replies as students would have liked. This figured in the non-completion of some of the students melodies. It also suggests that the project directors should have provided formal induction into online mentoring.

There were very few correspondences from rural school students. This comparative dearth of email correspondence from the students, who all had their own email accounts, reflects the fact that the teacher-led class spent time face-to-face jointly brainstorming the various mentors’ emails, activity tasks, composing the lyric, and working with PrintMusic. There were fewer problems with hardware and software at this site because the IT mentor-troubleshooter was a parent. Overall, this seemed to result in fewer frustrations or need to email the mentors quite so frequently as did the students who were studying in an individualized setting.

The music camp and presentation of their songs was a success. Both principals, the mentors, and most parents and students asked that MUSYC-IT be offered at both first and second year levels in 2002. As one Grade 6 student summarised: “Gliches in the program are only to be expected as it is new and innovative. These will be overcome next year. MUSYC-IT helps you grow as a student. I really enjoyed it.”

**Implications**

- It is not only technical resources that count in technological diffusion and school change but also the time and energy demanded of people to plan, share, observe, and take action (Boyd, 1992).
- More lead-up time is necessary to avoid technical gliches interfering with the mentoring and learning, and thereby lessening frustrations.
- Maintaining a designated IT troubleshooter is important; the project directors thought they had it covered inhouse at both JCU and the SDE. Not surprisingly, hindsight proved that such IT personnel prioritised their commitments to their organisation before assisting a project.
- Mentoring online needs induction workshops for some to be the expert efficiently and effectively.
- Developing effective guidance for collaboration online needs implementation.
- Obviously having a designated project coordinator would ensure a smoother running of MUSYC-IT.

Abstract: This paper describes a hypertext system to support novice Java programmers to improve their understanding of software design issues. The system provides the usual hypertext support such as cross-referencing and formatted display of source code. In addition it implements a number of object-oriented metrics and it detects and remediates typical misconceptions of novice programmers.

Introduction

For many years we have been involved in teaching a first programming course to students of physics, mathematics and informatics. Three years ago we have switched from Pascal to Java as a first programming language.

Our experience thus far has shown that despite the fact that Java is relatively clean conceptually (at least compared to C or C++), many students struggle to learn the syntax and concepts of Java and gain enough experience with programming to be able to reason about program design. An important aspect of the course are individual programming assignments, in which students have two to three weeks to design and implement a program which is then discussed individually with a teaching assistant. These discussions are invaluable for detecting and remediating the student's misconceptions about programs and program design practice. The following is a typical conversation that might take place between a teaching assistant and a student:

TA: What are these instance variables i and j in the class Matrix?
Student: Those are the loop index variables I use for various methods, like the ones for adding and multiplying matrices.
TA: But why are those declared as instance variables? Surely i and j are not actual properties of a matrix.
Student: Yes. I originally had declared those variables locally in each method, but I figured that I could make the program shorter and simpler if I moved the declarations to the object's scope.
TA: Isn't that dangerous? It is quite difficult for me to check whether these methods will work correctly. And suppose one method called the other and both used the same index variable, or that multiple threads called these methods simultaneously. That would mix things up.
Student: Yes, I suppose so.

This conversation reveals a number of implicit assumptions and misconceptions that the student has about what it means to design classes and programs. The student moved the declarations to the object level because he is aware that simplicity and elegance of programs is highly valued in program design culture. But this particular simplification is rooted in a misguided notion that simplicity is achieved by having less code.

From the student's point of view the program is perfectly understandable, and the experience of having the teaching assistant tell him that it is not is quite sobering. Students generally do not think about the possibility of others reading and using their code, and what that implies for the way their program should be designed. Their only immediate concern is (1) that their program compiles, and (2) that it works. Their thought processes are organized to achieve those goals, in that order. Many of these misconceptions
are situated at a meta-cognitive level (Schoenfeld, 1992). They are not learned explicitly from books and lecturing, but are acquired implicitly by participating in a community of design practice.

We do not believe that direct interaction sessions can be replaced by technology alone. But what we can do is make them more effective by removing the most common misconceptions earlier in the process so that the interactive sessions can focus on other, more important issues. Our aim is therefore to design a tool, which will help students detect such common misconceptions and advise them on how to improve their work while doing it. To motivate students to actually use it, it must be conceived as a generally helpful programming tool rather than a teaching tool. Students are not aware of their misconceptions and therefore will not be inclined to actively look for them. For this reason, we will embed it in a more general hypertext documentation tool.

Design Approach

To design the system, we have followed the following approach:

1. Create a feature model (see e.g. (Czarnecki & Eisenecker, 2000)) of the features found in the many similar tools that exist on the market today. These include tools such as LINT, object-oriented software metrics (Chidamber & Kemerer, 1994), and HTML cross-referencing tools such as javadoc\(^1\) and javasrc\(^2\).

2. Use XML to represent Java programs at different levels of detail. For Java interfaces and code we selected JavaML (Badros, 2000) and for Java byte-code we have developed our own XML syntax called BCML (byte code mark-up language).

3. All other configuration and state information is also maintained in the form of XML. The syntax of this XML reflects the feature model developed earlier.

4. XSLT (XML transformation language (Clark, 1999)) is used for laying out source code, calculating metrics and detecting misconceptions.

By studying the programs that students had submitted in previous assignments, we were able to identify a number of misconceptions (currently some 20) that we believe cause students to write badly designed code. For each of these misconceptions we then looked for symptoms (and sometimes counter-indications) in code. For symptoms that can feasibly be detected automatically, we then select the representation (currently JavaML and BCML) which is best suited for detecting it. Finally, an XSLT template is written that matches a particular symptom and generates a suggestion for improving the design. Table 1 shows one example of such a misconception.

<table>

<tr>
<td>The number of classes (excluding subclasses) that access or update its member variables a superclass or nested class of that class</td>
</tr>
</tbody>
</table>

Table 1: An example misconception.

The suggestions for improvement generated are general natural language statements. It is not our intention to attempt to improve code automatically. Focus of the project is not on formal specification or verification techniques, but rather on a heuristic approach.

\(^1\)http://java.sun.com/j2se/javadoc/

\(^2\)http://home.austin.rr.com/kjohnston/javasrc.htm
System Architecture

To keep a system like this maintainable and extensible we have decided to take a very strict attitude towards simplicity and architectural integrity.

- The architecture should not depend on the language used (Java) nor on its specific XML representation (JavaML). The use of XML and stylesheets allow some form of independence from programming languages and representations.
- The system architecture should be independent of the specific insights about misconceptions. It should be straightforward to add support for new misconceptions and to add new measures to detect them.
- The number of available views (e.g. class, package, inheritance diagram, index, ...) and their structure should be completely configurable, so that developers can compose and add new views without modifying existing code and users can select a view dynamically.

These principles lead to a surprisingly simple but powerful architectural design. Figure 1 shows a sketch of the system’s architecture. When a request is received by the servlet, it loads a configuration file containing a description of the structure of each view. This config.xml file contains parameters that are placeholders for information provided by the request, such as the URL, session parameters and HTTP cookies. The system then processes the resulting XML file with the master style sheet which in turn will call upon a parser to generate XML from Java source code or byte codes and applies the appropriate templates on the resulting XML.

![Figure 1: Sketch of the system architecture and component interactions.](image)

The resulting architecture is very simple in that the servlet is not even aware that it reads Java. It only deals only with HTTP, and simply calls the XSLT engine to process the configuration file. All of the particulars of locating Java files, parsing them and transforming them are local to the stylesheets.
Current Status and Future Work

The current implementation provides an interface that is very similar to Sun's Javadoc. It provides package, class, usage, tree, and index pages. The difference is that the class view provides the ability to view source code for each method as well, with a feature to show the type and declaration of each variable that is referenced (illustrated in Figure 2), and one to highlight each usage of a particular variable.

![Field Index](image1)

**Source code:**

```java
package test;
public class test.SimpleTest extends java.lang.Object
{
    public static int W;
    public static void main( java.lang.String[] args )
    {
        for ( i = 0; i < 10; i++ )
        {
            System.out.println( i );
            if ( i > 5 ) i = 10;
        }
    }
}
```

![Source code](image2)

**Figure 2:** The source code view of a class. This view has a number of useful features, such as: syntax highlighting, the ability to expand and collapse code sections, cross-links from variable references to their declaration. When the cursor is moved over a variable declaration, all its uses are highlighted and when the cursor is moved over a variable reference, its declared type is shown. Note that this class shows three misconceptions: there is a public variable, this variable is used as a control variable for the for-loop, and the control variable is updated in the body of the for-loop.

In addition, a 'metrics' and 'misconceptions' view are provided. The metrics page displays a number of standard object-oriented metrics as defined by (Chidamber & Kemerer, 1994). The other shows a number of misconceptions, as is illustrated in Figure 3.
Misconceptions for test.SimpleTest

Public Instantiation Variables
Number: 1
list:
  • public int i
  Since this variable is only accessed from within this class, it is better to

Control of loop variables

for-loop control variables is modified in for-body $i$ in method main

Scope of local variables
Unused arguments
The argument args of the method/constructor main can be removed because it is never

Source code:

Figure 3: The misconceptions view, showing how the system has detected four possible problems with the code of Figure 2. It has detected that there is a public variable which could be made private; the loop control variable is an instance variable, and it is updated inside the body of the loop. The last section indicates that the argument to the 'main' method is never used (although in this case, the argument is required for another reason).

Currently we are developing measures for detecting more complex misconceptions specific to object-oriented design. The system has also been extended to that students can easily use the service remotely. This requires that their Java files can automatically be transferred to the server for processing. To allow this, the student currently has to run a small server program that allows the server to access files from his or her class path.

We intend to make the system available to students as a tool for doing preliminary self-evaluation of their assignments before handing them in.

You Are Entering a World of Sight and Sound: The Effects of Self-Generated Images on Music Ear-Training as a Possible Alternate Teaching Approach for Music Education Within a Web-Based Environment

George J. Henik
Educational Communication and Technology Program
New York University

ed.ss.webmaster@nyu.edu or georgehenik@yahoo.com

Abstract:
17 volunteers were administered an online drawing environment where they generated images as a response to musical intervals, then tested on their recall of these musical intervals while using their images as cues. A paired t-test comparing pre to post treatment showed a significant effect in the online treatment ($t(16) = 2.759, p = .014$). A series of multiple regressions also yielded a significant model ($F(4, 12) = 4.284, p = .022$) with $r^2 = .588$. The findings are explained with respect to dual coding theory (Clark & Paivio, 1991; Paivio, 1971, 1990) and the generative theory of reading comprehension (Wittrock, 1990).

When examining research into web-based learning environments, the most noticeable omissions occur in music education. One of the largest obstacles to designing effective online music applications has been hardware, i.e., computers that were being used for instruction were not capable of effectively reproducing authentic sound. Though this has changed over the last six years, there is little research on how to effectively use computers to teach music. In attempting to design instructional software that seeks to teach any aspect of music (performance, composition, history, or theory), it is imperative to understand how learners process music and how this can inform effective design of musical educational media.

This pilot study is investigating some possible connections between aural, visual, and verbal information in musical ear training tasks and more specifically, the learning of musical intervals (distance between two notes). By making a connection between these modalities, a more effective method for designing music education software may be possible.

Theoretical Foundation

The research involving educational implications of musical auditory processing with respect to images is scarce. Many studies look at the relationships between verbal and visual information (Mayer, 1997, 1999; Mayer & Sims, 1994; Moreno & Mayer, 2000) or between verbal and nonverbal information (Clark & Paivio, 1991). Datteri (2000) investigated the influences of music on the perception of apparent motion in stick figures and action terms, and through Gestalt audiovisual principles concluded there may be a deeper semantic system connecting the visual and auditory modalities.

Clark, Stamm, Susman, and Weitz (1974) examined recall of sounds that could be labeled versus those that could not be easily labeled. They concluded that dual coding theory (Clark & Paivio, 1991; Paivio, 1971, 1990) could be expanded to auditory information in the form of sounds as well. Additionally Lipscomb and Kendall (1994) examined the interaction between music soundtracks and film, suggesting that a model of motion picture perception must focus on the "source of meaning within both the auditory and visual modalities" (p. 88) and is therefore "individual-specific" (p. 91). In another study that examined the effects of verbal labels on music recognition, Hiraoka and Umemoto (1981) used 19th and 20th Century classical excerpts to examine how verbal labels affect the memory recall of musical passages. They concluded that the subjects who made their own imagery seemed to use it as a retrieval cue that resulted in higher recognition scores.

Thus, there may be a dual coding process in learning that exists within the auditory modality, and that by having a user generate meaning or images, a stronger connection can be made. Wittrock's generative theory of reading comprehension (1990) discusses the importance of generative meaning through reading. Could this process be similar to verbal information with regards to language?

There are several well-established theories about processing music with respect to language. The assumption that music is processed in the same way as language is far from clear, and it actually appears that there are two different systems that exist within the auditory modality, one for verbal information and one for auditory information (Sloboda, 1985).

Even if there are two different systems that exist, perhaps there are similarities in the way information is processed. Therefore, if a user were able to generate an image based on a music interval, then a stronger connection may be made between the visual and aural modalities that might result in the user learning the intervals more effectively.

Methods

Research Questions: Based on the previous suppositions, a number of research questions arises:
1. What are the effects of user-generated images on interval recognition tasks?
2. What is the relationship between user-generated images for interval recognition and a) prior music knowledge, b) prior drawing knowledge, c) music interest and d) drawing interest?
Sample: The sample consisted of 17 graduate students. While most had a limited musical background there was a mixed background in graphic design.

Materials and Procedures: The experiment involved a web-based drawing program developed in Macromedia’s Flash 5.0. The participants were able to generate images based on musical intervals that were saved in a database and later used to test their interval recognition. Participants were given pre and post-tests. Other variables that were explored were prior music and drawing experience, as well as attitudes towards music and drawing through online questionnaires.

Results

In order to answer the first question a paired t-test was conducted. This showed a significant increase in scores from the pre to post-test ($t(16) = 2.759, p = .014$). Further analysis was performed to determine if a particular interval was recognized more often than the other intervals. The pre and post-test scores from each of the three intervals used in the study (Major 3rd, Tritone, and Perfect 4th) were then analyzed using paired t-tests. Significant differences were observed between the pre and post-tests only for the Perfect 4th ($t(16) = 2.634, p = .018$). In order to answer the second question a multiple regression was conducted using responses from the questionnaire to rate prior music and drawing knowledge and interest as the independent variables, and their answers from the post-test as the dependent measure. This overall model was found to be significant ($F(4, 12) = 4.284, p = .022$) with $r^2 = .588$. The only variable that contributed significantly to the model was the music background score ($t = .574, p = .039$).

Conclusions

There are several possible conclusions that can be drawn from these results. Since the Perfect 4th was the last interval presented in the study, it makes sense that it was identified significantly more than the other intervals. The results from the multiple regression indicate that having a music background may be more important than having a background or interest in drawing. In any case, the pilot study shows that the web can be used as an effective multimedia learning aid. In terms of dual coding theory, the connections between an abstract user-generated picture, abstract auditory information, and abstract verbal information may have increased the cognitive load experienced by some learners. The participants were still able to significantly improve their skills despite this, so perhaps the act of “generating” was still effective though not conscious.

The results from this study may not necessarily be attributed to the act of drawing as normal music ear-training involves the same type of rote memorization. The fact that only the last interval was significantly recalled enforces this. Since the music labels were a problem for some subjects, further research should be conducted using those students who have a stronger background in music, as well as including interface changes that might help lower the extraneous cognitive load of the treatment.

Abstract: This paper presents an overview of Pixed which is a Web-based Adaptive Educational System. The design of Pixed is based on the use of annotated notional networks to represent the user's point of view on the domain model in order to provide an interactive help based on re-using experience.

We first explain how the annotated notional network representation, together with several annotation systems, provides help to learners and to teachers. Then we introduce the automatic re-use of experiences which constitutes the other keystone of Pixed.

Keywords: Web-based Adaptive Educational Systems, Constructivism, Adaptive Hypermedia, Case-Based Reasoning.

1. Introduction

Internet success, as well as the Software companies' interest for the "educational market" pushed universities towards the web-based teaching. This unavoidable evolution modifies the teacher's role who must help learners to build their knowledge rather than being a "knowledge transmitter".

Currently, teachers do not have powerful tools helping them in using this new workspace. Most online courses are only numerical transcriptions of paper versions, and commercial training environments on the Web (WebCT [Href2], LearningSpace [Href3]) counterfeit traditional modes of teaching. This way of teaching, inspired by the programmed instruction [Ski58], is unsuited to the learner's needs [Laf96].

2. Related works

To compensate the physical absence of the teacher and to decrease the hypermedia's induced difficulties (cognitive overload [Rou98], confusion [Cas96]), research systems such as "ELM-ART II" [Web97] or "AHA!" [Deb01] try to adapt teaching material (navigation in the course and presentation of documents) to the learner, facilitating his task. Like these systems, Pixed\(^1\) provides the learner with some help thanks to Adaptive Hypermedia [Bru01].

In the previously quoted systems, the teacher describes a course which will be transmitted in a form adapted to the learner. The knowledge thus belongs to the teacher and the system is only a media. In a close way of the Nestor navigator [Ek199], Pixed is based on a constructivist model [Phi95] where the learner builds his knowledge representation actively by annotating and choosing documents.

Pixed also differs from the others Adaptive Hypermedia systems by re-using the system's experience. By system's experience we point out elements (traces) of training that the system records during its use. These elements, added to a basic user model, will constitute the skeleton of the cases used in a Case-Based Reasoning (CBR) engine [Aam94]. The integration of the CBR paradigm aims to help the adaptation process and to help the building of the domain model.

---

\(^1\) Projet d'Intégration de l'Expérience en Enseignement à Distance
3. How Pixed helps

Among all the hypermedia adaptation techniques pointed out by Peter Brusilovsky [Bru96], we chose to focus our search on curriculum sequencing and adaptive navigation (3.1.) because it is on these points that we think that the projections in terms of assistance to training are the most significant. However Pixed's documents have annotation skills (3.3.) which allow the system to adapt the document presentation to the learner (3.2.).

3.1. Help learners to find their path

Pixed proposes a path in the hyperspace of the course adapted to the learner model. This model fills a part of the PAPI specifications [Pap00], and integrates an ANN (annotated notional network) [Her98]. Figure 1 presents an example of ANN. This type of network can be resume as an impoverished form of semantic network where the relations are strongly related to didactic skills.

![figure 1: An ANN example](image)

Concretely Pixed uses ANN to propose 3 helping level:

- **The linear path mode**: a document sequence generated from the learner model [Her99] is provided to learner. The system thus chooses notions, the presentation sequence of these notions and relevant documents. This mode is the closest to traditional teaching where the curriculum of the course is decided in advance by the teacher as well as the list of the associated documents.
- **The assisted mode**: the learner gets a documents sequence (with crossings possibilities) as well as a map of the corresponding hyperspace. This map only represents the notions semantically close to the notions located on the path proposed in the preceding mode. The learner can consult documents explaining notions in direct relationship with those necessary for understanding the goal notion (according to the model).
- **The free path mode**: in this mode, an hyperspace map is the only navigation means. The learner is free to navigate among all the course notions, and for each notion he can choose among the associated documents. However, the system offers him some advice (icons colors) on the estimated relevance of the notions according to his goal, like on the relevance of each document compared to the selected notion.

Thus the learner can choose to be more or less helped by switching his navigation mode.

3.2. Adapt the content to the learner

There are two ways of contents adaptation in Pixed:

- When for a given notion there are several relevant documents, Pixed can select which one to present to the learner. For that, Pixed takes account of the recommendations of the teachers (annotations), of the learner model and of the system experience.
- When an HTML document is selected, Pixed carries out a second adaptation by masking some parts of the document. For that, Pixed takes into account the teacher's annotations and of the learner model. The masked parts can however be consulted by learner with a click on the context beacons which announce more information.

One of Pixed's originality is that the adaptive presentation is not only based on the learner model but is also a function of the system's experience (4.) and of the document annotations (3.3.). Thus teachers and learners take part in the adaptation process.
3.3. Offer annotation tools to users

In Pixed, learners and teacher can annotate any whole document on the server, or just a parts of HTML documents. This in order to guide the adaptation but also to provide a tool allowing teachers to communicate between them and with learners. Thus we hope to stimulate a dialogue around the domain's ANN.

3.3.1. Annotating a whole document

Teachers can annotate a whole document in two ways : by attaching it to a notion and by attaching a textual description to it. The interest note can be used by the system when it has to make a document choice or simply to make it available. The textual annotation being intended for a learner wishing to choose a document among those that can be consulted, or to teachers who wish to re-use a document of this course in another course.

3.3.2. Annotating a part of a document

To annotate a document’s part, teachers and learners have three tools:

- The first enables them to colour parts of the text while specifying for whom (beginner, intermediary, expert) these parts are useful. These annotations will allow the system to mask parts which seem unsuited according to the learner's model.
- The second tool allows an attachment of parts of a document to notions. Teachers and learners can specify the explained notions and the necessary notions in order to understand these parts. The goal of this annotation is to guide the availability and the choice of documents.
- The last tool enables them to attach textual annotations inside the document. They can highlight the part which they want to annotate with a mouse click, then a contextual dialog box appears with annotations possibilities (figure 2). These annotations will be added to the document in the shape of small icons "notes" in the text of the displayed document.

All these annotations can be kept private or shared with other users.

---

**Figure 2:** While reading an HTML document, the learner opens a contextual dialog box to annotate a word.
3.4. Help teachers to build a domain model

Pixed separates structure and contents of the course while proposing a much greater freedom in the edition of this structure. The hyper-textual structure does not physically exist, it is generated from an ANN built by teachers. Each teacher has his own representation which he can share with the other users. As course documents don't have hyper-textual links between them, they are added and described by the teacher (3.5.). One way of describing is to link them with notions. Pixed provides a graphical interface allowing teachers to edit and publish their ANN.

The creation and the maintenance of this model constitute an additional task for teachers, but we think that this extra work is beneficial in the long run: the domain model is represented explicitly by what will support the sharing and the re-use of modelings and documents between teachers.

3.5. Facilitating the addition of interactive documents

Teachers can deposit and remove documents in the format of their choice with a description (author, date...). They can specify which main notions are explained in a document and can also give a list of notions necessary in order to understand this document. The system provides a help to teachers by pre-setting the necessary notions for understanding according to the domain's ANN. Teachers remain free to follow these recommendations by adding or removing notions of this list.

This document availability method can seem a constraint for teachers, but it allows a rapid exploitation of these documents. However Pixed leaves the possibility to the teachers of adding documents to the course without connecting them to an ANN. The document will thus not be usable in the state, but it will become so as soon as a teacher annotates it.

Pixed also offers a tool for the interactive creation of multiple-choice question set. Teachers can set them on the server like other documents, and the system can use them in the evaluation of a pupil's knowledge.

4. Integration of the system’s experience

The second keystone of Pixed is the re-use of the system’s experience. In this part, we’ll try to explain what we call experience and how it can improve help for users.

4.1. What experience are we re-using?

The experience of the system is composed of the training-episode's trace, that the system records during its use, stored as cases. A case is a triplet made up of an initial learner model, of his trace of navigation and of the final state of his model.

4.2. Why reusing the experience?

4.2.1. The experience improve adaptive navigation

The use of the experience for the navigation assistance such as we conceive it can be summarized as follows: the system creates a case from new learning, then it searches in the base for similar cases. This similarity (Tversky type [Tve77]) is function of the particular distances between identical notions, of the annotations and of the final goal-notion.

The system extract the path from the adapted case obtained, then it eventually increases this path and annotates it according to the annotations of learners which were used to work out the similar cases. This adapted course is proposed to the learner which is evaluated at the end of the course. The system then learns this new case by memorizing it.

At the end of the training, Pixed also preserves the re-use trace (elaborate case + similar cases + stored case). This trace will increase one second base which allow the system to refine its measurements of similarities.
4.2.2. The experience improve adaptive presentation

When the system must choose between several documents, it integrates the experience in the evaluation of the relevance of each document. Thus a document which will have been consulted much in similar cases of training succeeds and little in cases of failed training will be favored.

When an HTML document is selected, Pixed can unmask the parts of the document that were selected in similar cases of training successes. These cases can also be used to add some annotations.

4.2.3. The experience helps the maintenance of the ANN and of the document database

The first use of the system experience is to inform teachers about the use of their course as an improved log file. So they are helped in maintaining the document database.

Modifications of relations weightings can also be proposed on a statistical principle: if a badly known notion seems more penalizing to reach the goal, the system proposes an increase in the threshold of the relation of associated precedence. The experience constitutes a significant help here, because it is very difficult for a teacher to estimate the thresholds and contributions of the relations.

Pixed helps teachers by proposing changes of their model for a better explanation of learners' successes or learners' failures. For example, if a notion announced by a teacher as preceding to a training is never consulted by learners without harming their training, Pixed will propose to teachers to call into question this relationship.

By observing the successes of learners having followed the courses proposed by the system, Pixed will be able to propose to the teacher some new links which he would not have provided in his model.

![Figure 3: The use of the experience in Pixed](image)

5. Discussion

New methods of teaching must come with new educational technologies. Pixed, by separating structure and contents of the course, improves the hypertext use and also explore a new way of teaching.

We believe that this course creation methodology is adapted to training hypermedia environments and that a shared experience makes the users feel helped in their tasks.

The actual stage of our research tasks is a phase of a test with a great number of users in order to validate our approach on a greater scale.

Abstract: Our activities in co-teaching an engineering design course across the Atlantic, i.e., at Carnegie Mellon University (CMU), USA and at Delft University of Technology (DUT), the Netherlands, at the same time, required the use of information and communication tools for communication and collaboration purposes between students and between instructors and students. In this paper we analyze the overseas communication and collaboration processes among students and instructors, and their implications for learning. We have used a theoretical framework for 'collaborative learning' and for 'stimulating active participation' for analyzing our observations and for translating our results to a broader theoretical framework. In practice, it meant that we experimented among other variables with group compositions and with instructor role descriptions. We concluded that many of the techniques mentioned in literature did enhance collaboration and learning between students, but that intense communication with overseas instructors is still a major stumbling block.

1 Introduction

The availability of various information and communication technology tools (ICT) has enticed many experiments that are aimed at evaluating the use of ICT tools in university courses. Our activities in co-teaching an engineering design course across the Atlantic, i.e., at Carnegie Mellon University (CMU), USA and at Delft University of Technology (DUT), the Netherlands, at the same time, also required the use of ICT tools for communication and collaboration purposes between students and between instructors and students.

In earlier papers (Herder et al., 2002; Subrahmanian et al., 2001) we have reported on the use and effectiveness of tools like video conferencing and video taped lectures in the course. In this year's edition of the course we have focused on communication between students and instructors and on the role(s) of the instructors on both sides of the Atlantic. The experiments in this course are part of a large project executed at DUT, in which various instructors research the functional use of ICT in their courses (Brakels et al., 2002).

The main objective of the course "Engineering Design Problem Formulation" is to teach the process of engineering design problem formulation and the role of mathematical and other modeling techniques to aid in that formulation. The pedagogical objective is to get the students to understand that articulating the right problem, based on a process of negotiation and clear representation of the problem among the stakeholders and the design team, is more important than being able to solve perfectly the wrong problem (Subrahmanian et al., 2001). The reason for involving students from the USA as well as from the Netherlands was that by doing so, we were able to use a "constructivist approach" to learning: showing the students that knowledge is not developed in isolation but within a social and cultural context (Brown and Duguid, 2000; Fetherston, 2001).

First, we ask groups of students to formulate a number of small design problems, to become familiar with the use of the basic framework of goals, tests, design spaces and starting points and with the use of mathematics as a language for articulating and unambiguously representing a problem. The groups are mixed groups in the sense that they include students from DUT as well as from CMU. Once they are reasonably familiar with this way to recast problems, we step up to larger group-based assignments. They are asked to read and report on books from a list we provide in the area of engineering and design. The students were to analyze the design exemplars in the books and characterize them by using the four-part description we present to aid in formulating design problems. The final, large assignments include design problems, such as design of a transportation system for Pittsburgh and the design of a water/sewage system for a new housing development near Amsterdam.

In this paper we analyze the communication and collaboration processes among students and instructors. The next section will describe the theoretical framework that we will use to analyze our results. During the course, we have experimented among other variables with group compositions and with instructor role
descriptions, which will be described in the next section. The results describe our experiences with on-line
participation and on-line learning, based upon a survey we held among the students after the course and based
upon our observations during the course.

2 Research Model and Approach
2.1 Introduction to the Course as an Electronic Conference

The course described in this paper required on-line communication because of distance (USA and
Europe) and time difference (six hours) between the two groups of students and instructors. Based upon our
experiences from running last year's course (Herder et al.; 2002, Subrahmanian et al., 2001), in which our efforts
focused on the technicalities of the use of ICT tools in teaching, we decided this year to focus on the
collaboration and communication aspects between the groups and instructors. In particular, we ran the different
elements of the course in different ways.

The course required students to work on formulation problems together by discussing the problems,
posing questions to each other, critiquing and commenting each other's work, sharing the workload and
decreasing the project's run time by 'leap-frogging', i.e., half of the group works while the other half of the group
is out-of-office - the second half continues the work when the first half is out-of-office, etc. All communications,
reports, comments and the like were to be posted in the web-based document management system LIRE' (n-dim
group, 2001) so that all information would be retrievable for anyone at any time. This type of on-line
collaboration and interaction is often referred to as a computer mediated conference (CMC).

Salmon (2000) developed a five-stage model for on-line learning and moderation of electronic
conferences, which we will use in this paper as our research framework. The consecutive stages defined by
Salmon are: (1) Access and Motivation, (2) Socialization, (3) Information Exchange, (4) Knowledge Con-
struction, and (5) Development and Reflection.

For each of these steps it is important to focus on the technical issues, the mutual learning issues and the
E-moderating issues. The technical issues have been described in our papers mentioned earlier, and we refer to
those papers for the conclusions. This paper focuses on the other two issues in the five stage model, i.e., the
learning issues (student - student interaction) and the E-moderating issues (student - instructor interaction). Steps
three and four from the five stage model will be worked out in detail in this paper. Table 1 shows some brief
previous results and implementations for the steps and issues that are not being discussed elaborately in this
paper: the technical issues for all steps are summarized in the second column, and the learning and e-moderating
issues are summarized in the two right hand side columns for steps one, two and five.

Table 1. Application of the five stages (Salmon, 2000) to the course (bold typeset is discussed in this paper).

Salmon (2000) provides some advice relevant to each of the five stages. Other authors, however, provided
more in-depth advice on how to stimulate collaborative learning and active participation. In particular, we have
used the techniques proposed by Hiltz (1994) to stimulate active participation and collaborative learning. These
techniques are briefly summarized in the next two sections.
2.2 Collaborative Learning

The ultimate goal of taking a course is to gain knowledge or learn new skills. Particularly in a course where group work is key, collaborative learning is probably dominant over traditional one-to-many learning from instructors. In order to get students to (collaboratively) learn the skills and knowledge they are required to learn, it is imperative that some techniques are being applied that support and encourage collaborative learning and student to student interaction. We have turned to Hiltz (1994) for a number of concrete collaborative learning formats and assignments. The ones that we used in the course are: students as teachers, writing groups, group or team projects, and team building.

2.3 Stimulating Active Participation

Any conference or discussion requires a moderator who is able to stimulate participants to actively participate in the discussions. For computer mediated conferences the issue is even more significant, as the moderator and participants are not in direct contact with each other. Hiltz (1994) suggests a number of techniques that may stimulate participants to engage into electronic conferences, some of which we have applied in parts of our course. The techniques used in the course in the instructor-student communications are "require regular participation," "instructors present conflicting opinions," "responding and weaving by instructors," "explicitly request responses," and "role playing."

2.4 Research Variables and Approach

Our experiences in running the course last year indicated that we needed to provide the students from the outset with some basic instructions about how to communicate effectively with people at a distance and with a time lag. Instead of letting each group 'invent the communication wheel' all over again, we pointed them toward the various opportunities besides emailing, such as chatting, telephoning or even video-conferencing.

Table 2 shows the techniques we applied in the various stages of the course. For the first small assignment in the course, we dropped the students in at the deep end of the pool with respect to getting the overseas cooperation to work. We provided them with basic technical support and with conventional instructor support. As the course progressed, instructions and structure became increasingly unambiguous by applying more and more techniques for collaborative learning (student-student communication) and active participation (student-instructor communication).

The following sections describe our specific implementations and experiences with the various techniques. The impacts on the learning and collaboration process have been measured by distributing a survey after the course and by evaluating the course with the students in a face-to-face meeting. Our personal observations were used with caution as a third source of information.
3 Collaborative Learning

The course was taught simultaneously at both locations by two instructors at each side during fall 2001. We were able to re-use the schedule and material (lectures, handouts) that we developed in fall 2000 when we ran the first experiment of this course. A total number of 24 students participated in the course (6 at DUT and 18 at CMU). The students were instructed about the basics on cross Atlantic cooperation in the first class, comprising communication tools and etiquette. The survey indicated that the methods for communication were reasonably clear at the start of the course, as indicated in figure 1. It shows the number of students that agreed or disagreed on the statements in the survey, using scores on a 1 (disagree) - 5 (agree) scale.

Cross-Atlantic collaboration was initiated for the first assignment by doing group work - groups based on personality tests of the students (Meyers-Briggs test, 2001) that spanned the two participating universities - and by forming writing groups, i.e., letting the students critique each other’s intermediary work and reports. Some students indicated that they felt disconnected from the students at the other side of the Atlantic because they only knew each other from electronic communications. Other students divided the group work such that they had to communicate with each other as little as possible. Only towards the deadline of the first assignment, the students reformed into writing groups to critique each other’s work.

In order to enhance the communication and collaboration in the groups we asked the students to form the groups for the second assignment themselves, resulting in better team building (Hiltz, 1994). All groups managed to cooperate more intensely on the book reports, and in most cases the reports were reviewed and critiqued by all group members. For the third assignment the groups were reshuffled again and we explicitly asked the students to present new or complex aspects of their work on the assignment in class to the other students. In addition, they were asked to pose questions to the other students. The students became teachers, which further enhanced collaborative learning in and between the groups.

Figure 1. Communication tools in the course.

Figure 2. The usefulness, intensity and efficiency of local collaboration as compared to international collaboration.

Figure 3. Students' opinions on international collaboration for future courses.
The students were asked to rate the usefulness, intensity and efficiency of the overseas collaboration compared to the collaboration with local group members. As expected from theory and observations, the results in figure 2 indeed show that local collaboration was more useful, intense and efficient. Figure 3 shows that, despite the difficulties of international collaboration shown in figure 2, the students would still rather intensify the international collaboration than cancel it.

The students were found to spend an average of 2.5 hours per week in emailing with each other, in addition to over 1 hour per week of on-line chatting and over 1 hour per week of using LIRE. The telephone and the video clips available were used only a couple of minutes per week on average.

4 Stimulating Active Participation

The first student assignment comprised two small formulation problems. The instructors were given no specific roles other than to quickly answer questions and to teach a number of regular classes. The group assignments were mandatory and any results were to be posted into LIRE, thereby requiring participation. Students tended to consult their local instructor primarily and left the coordination of instructors' advice and responses to the instructors. Topics that appeared to be relevant for all the students were discussed or communicated plenary by the instructors to all students (responding and weaving).

For the third assignment we decided to boost active participation by applying a number of extra techniques. The instructors were given specific roles with particular objectives that would conflict with other instructors' objectives. More specifically, the students were the project contractors, one instructor was given the role of project commissioner for the design problem, while the second instructor Overseas played the role of one of the stakeholders with possibly conflicting objectives. For example, we added an environmental lobbyist as a stakeholder to the design of a disposal method for an oil rig (commissioned by a fictitious oil company). Finally, we required the students to send weekly progress reports to the overseas instructors. By explicitly requesting responses, we expected that instructor-student interaction and active participation would be enhanced even further. However, the students never managed to send a progress report to any instructor, indicating that our response request did not fit their specific activities or needs. We did observe that more frequent contacts occurred between instructors (local as well as overseas) and students in the final assignment compared to the first two assignments.

![International instructor-student communication](image1)

**Figure 4.** The possibility, necessity and preference with respect to communication with the international instructor.

![The role of the instructors](image2)

**Figure 5.** Preference of students on the roles of instructors in the large assignment.

The results shown in figures 4 and 5, confirmed our hypothesis of international instructor-student communication: although the international communication is necessary and feasible, the students still prefer to communicate with a local instructor. This confirms results obtained by Walkington and Maroulis (2001), who
found that social presence and meaningful relationships between instructors and students are crucial for sound pedagogy, but are very hard to achieve in CMC activities. Although the role playing technique may have had the effect we aimed at, i.e., more intense communications between the two sides of the Atlantic, the opinion of the students about the role playing in the final assignment is indistinct, rendering that technique debatable for application in a cross Atlantic design course.

5 Conclusions

We have used the framework developed by Salmon (2000) to identify two important areas for improving the cross Atlantic design course, taught for the second year in an international setting. A number of techniques for these two areas, i.e., stimulating active participation and collaborative learning, were taken from Hiltz (1994) and were gradually incorporated into the course.

We found that the techniques for collaborative learning in a CMC environment contributed to a smoother learning process, although they did not take away fully the stumbling blocks for international cooperation. Students indicated that an intensification of international collaboration was desirable, if and only if this would be supported by appropriate communication tools, aimed at the contents of the work, but also on the social interaction between the students.

Techniques that we used to enhance active participation, mainly techniques applied by instructors, were found to be successful, except for the role playing technique. Our rationale for assigning roles to instructors was that we expected it to form an incentive for boosting communication between students and instructors from overseas. Students, however, preferred to talk to their "own" instructors, after which they relayed the messages to their overseas colleague students if necessary. Communication between the students was nevertheless increased which may have enhanced collaborative learning.

General comments from the students after the course have been encouraging. Most students indicated that they found the international course an interesting experiment. We should, however, increase their access to communication means that allow more social interaction than email and CMC alone. Many of the techniques we only gradually incorporated into the course this year, will be used from the beginning of the course next year.

Hinze, Bischoff & Blakowski: Jigsaw Method in the Context of CSCL

Dipl. paed. Udo Hinze
FH Stralsund

Prof. Dr. Michael Bischoff
FH Luebeck

Prof. Dr. Gerold Blakowski
FH Stralsund

Abstract: Group techniques and methods show great promise with respect to the learn effect, in Computer Supported Collaborative Learning (CSCL). These should result from the perspective of cognitive elaboration, the construction of shared knowledge and the possibility of multiple perspectives. However, the previous results of this research were not very extensive. Therefore we started a jigsaw in CSCL in the context of the federal flagship project, "Virtual University of Applied Sciences for Technology, Computer Sciences and Business Administration" (VFH). During the course of 'Environment oriented Management' (EoM) we tested the different assumptions and suppositions regarding the effect of the jigsaw method. In the case study we focused the evaluation on the degree of collaboration and the influence of the group method. The result was that jigsaw proved to be an efficient method to intensify collaboration in CSCL. To archive this certain conditions have to be consider. Aspects like group cohesion, individual competence, and awareness, have a significant influence on the result of the jigsaw.

1 Introduction

Teamwork is strongly associated with high degree of effectiveness and efficiency. The apparent evidence toward the superiority of cooperative vs. individual work is also transferred to the area of learning. It is widely accepted that, "cooperative learning is supporting the success in learning in general" [PfWe00, pp.140]. As plausible as this statement appears, you can also state that: "you can decide neither theoretically nor empirically which social form of learning and working is better" [ReMa99, p.4]. Both negative and positive effects within the area of Computer Supported Collaborative Learning (CSCL) can be proven empirically in a relatively effective manner.

A way to stress the positive aspects and to minimize the negative ones is to use group work techniques.

In the context of the course "Environment oriented Management" (EoM), which was conceived and produced for use within the federal flagship project "Virtual University of Applied Sciences" (VFH), a group work technique called jigsaw was implemented.

The cooperative task to complete was structured using this method. A jigsaw uses a redundant group structure: main groups and expert groups. The group task can only be completed with the knowledge acquired in the expert groups, and thus with the intensive cooperation of all team members.

2 CSCL – arguments and implications

As positive impacts and arguments speaking for CSCL, three positions are taken into consideration. These positions are particularly scrutinized for their feasibility and their implications regarding the use of the jigsaw method.

2.1 Cognitive Elaboration

The possibility of cognitive elaboration in cooperative settings is valued positively and used as a main argument for the necessity of CSCL in the psychology of learning. In general one can assume that new information can be linked with the existing schemes only after it has been restructured an elaborated. One of the most effective
processes of elaboration is the explanation of the learning matters from one's own point of view. Therefore teaching is the most effective way of learning. This fact is conceptualised as the perspective of cognitive elaboration [e.g. Slav93].

But the explanation of the learning matter relates only slightly, or has no impact at all on the learning success of the recipient [Webb91]. The advantages lie rather clearly on the person who gives the explanations. Thus, a structure needs to be created which makes explanation possible for all group members—indeed from group status and individual competence. Within this context the main starting point is the creation of the task. If designed as a jigsaw, one can assume that explanatory processes, independent from the status, are to be stimulated.

2.2 Multiple contexts and perspectives

Relevant for CSCL are the demands on the learning settings and the task formulated by instructional research. Significant matters include: authentic and situation-based learning settings, social and multiple contexts and multiple perspectives.

Within the framework of multiple perspectives, a learning situation is created so that the learner possesses the various possible perspectives of the task. During cooperating the group members are supposed to take the perception of the other group members. Thus, alternatives can be identified and rated. As one can see, the learning goal is much more than just the acquisition of factual knowledge.

Multiple perspectives should exist in cooperative settings, however a contention with divergent positions is not inevitably necessary. Group members can, for example, ignore existing diverging opinions. Dealing with multiple perspectives should thus be anchored within the learning task as well. The jigsaw should be an effective way not only to make multiple perspectives possible, but also to present it as necessary for solving the learning task.

2.3 Construction of shared knowledge

A further reason for the use of CSCL is propagated in the situated learning approach. Within this context learning is conceived as an active, self co-ordinated, situated and constructive process.

Additionally, learning is primarily considered as shared knowledge construction [e.g. DeDu99]. Cognition and the acquisition of knowledge are socially divided activities and thus refered to the use of co-operative learning scenarios like CSCL.

Indeed, the social context is necessary, however, it is an insufficient basis for the construction of shared knowledge. Intense interaction and the construction of shared knowledge must be specifically promoted. Using the jigsaw could be one possibility for that purpose.

3 Jigsaw Process

Jigsaw is one method which makes the interdependence of group members possible, promotes interaction and cognitive elaboration, takes into consideration the principle of the multiple perspectives and contexts as well as the construction of common knowledge. In the following the course EoM will be used as an example (see Fig.1) to present the different phases of the jigsaw process [Clar85, Clar94].

After the introduction of the topic, the learning materials were divided into sections (phase 1) and the learners were divided into interest groups, which independently compiled a section of the material (phase 2). Thereby different parts of the material are covered by different interest groups. In the module EoM, the theme ecological tax was processed by three different interest groups, which each had another emphasis as well as a divergent view on the problem. The basic positions were sketched up in advance.

The first task was to identify with the position alleged for the group and to collect arguments and pieces of information to support it. From these considerations, according to the theme of ecological tax as well as from the view of the respective group, a position paper should be prepared, in which the point of view of the group is written up along with background information.
To produce multiple perspectives the participants should likewise consider how the other groups could argue their perspectives and include this in their discussions. An essential aspect was the construction of shared knowledge through intense interaction within the group. Additionally, cognitive elaboration was necessary in those areas were the focus was on bringing together the divergent opinions for the respective position paper.

In the third phase new groups were formed based on the chance principle. The scenario was an expert conference initiated by the government. At these „meetings“ in which the different points of view on ecological tax were discussed, agents of all interest groups participated. For that purpose the participants had to acquaint themselves with the position papers of the other interest groups. After that the pros and cons of the individual positions were analyzed and discussed. At the end of the discussion, each group had to find a consensus and outline a course of action for the future. In a written summary the consensus found, as well as the course of action along with the underlying arguments were to be presented.

The third phase particularly intensively included the three implications mentioned above. Here, taking multiple perspectives was imperative. To prepare a common consensus paper, the participants had to take the other positions and try to understand their argumentation. Here the cognitive elaboration became more important than in phase 2. The participants had to explicitly explain the arguments for their positions in the groups. The main point is that the possibility to give an explanation is not bound to the status and/or to the competence of the participants. To achieve an adequate result, all participants had to take in turns both the role of the teacher and the role of the learner. All these processes required intense interaction and led to the construction of common knowledge.

The fourth phase included the evaluation and reflection of the results. For that purpose the consensus papers of the „expert meetings“ were made accessible to all course participants. The participants were to read the consensus papers of the other expert groups and to give their opinion to the produced results. Additionally, they were asked to reflect on the group work itself, as well as on the jointly compiled results.

4 Evaluation

The empirical foundation of cooperative learning methods is largely fragmentary in Germany. Systematic comparison investigations to the employment possibilities and effectiveness controls are not widely available [Gies01]. Still more deficits can be seen in the research situation with respect to the employment of the jigsaw method in the area of CSCL. According to Friedrich, a.o. [FrHe99, p.126], "the suitability of this (...) can first of all only be assumed".

Inasmuch as the module „EoM“ has been introduced in a small scale up to now, first locally in the pilot mode of the VFH, the evaluation refers more to the current status. The primary goal of the formative evaluation was to draw qualitative statements, which refer concretely to improvement possibilities. The main question was how deep the degree of collaboration was and how the degree of collaboration was influenced by the group method.

4.1 Results

Thus, the main question was whether the group cooperation can be considered as sufficient. The majority of the participants (53%) answered this question negatively and a lower value was reached. Therefore it seems that the expectations for the concept were not realized. On the other hand, there were also explicit positive statements like, "The group dynamic inspired me" and the "Shared responsibility for the result". There were seen as an advantage. It was also mentioned, that the, "creation of the consensus paper as a conclusion [...] made a lot of fun". Considering all these facts the concept of the division of work was rated positively. This is supported by statements like, "the result crystallizes out by putting all these different pieces together. Everybody helped to put the pieces of the puzzle together and the picture got its shape from various views". This statement emphasized the main features of the jigsaw method like cognitive elaboration and construction of shared knowledge.

How can this contradiction be explained? First of all, the result regarding the cooperation in the groups must be seen in a relative terms. Here different aspects play a role. One the one hand, the degree of collaboration in virtual groups is considered to be relatively low. Lack of cooperation is also dependent on the deficits in the computer mediated communication. The evaluation of the other CSCL projects within the framework of the VFH pilot phase produced results that generally stated that the cooperation was perceived by the majority, in part or even by the entire group, as not close enough. Thus the value in the EoM module is comparatively high.

Basically, there was a lack of awareness, i.e. of the mutual perception and based on this of the group cohesion. The production of awareness, tersely defined as „knowing what is going on" [Ends95, p. 36] is a problem that has social effects and also refers to the responsibilities of the members and groups. In pure virtual group work, basic social information is often missing. This information usually gained in the presence phase at the beginning of the course which has at least the implicit goal of getting to know one another. Providing this information likewise on a homepage or a „wanted poster" still remains not to be an optimum solution. For example there was the reference: "I would like to know more precisely who the other persons are. But I don’t like this to do through homepages. I surely won’t like to present myself completely in the www."

After all, it remains difficult to find optimal solutions to quickly create a confident atmosphere and intense group cohesion that is purely computer based. One aspect are the students references that the lacking social cohesion can possibly be met in advance with a, "virtual getting-to-know-game". Another possibility to make getting to know each other informally possible would be ‘by providing different chats about different themes at the beginning of the course’. But all together it can be noted that the students of the pilot phase of the VFH did not or just hardly knew each other prior to the group work. There were no informal contacts like the ones they developed during a longer regular course of study at a virtual professional school. This aspect was also emphasised by the participants: "One should get the chance to get to know the coursemates better (thus on-line over a longer time period). To my mind the social aspect plays (even under the criticism of the "loneliness" in front of the monitor) a substantial role". However here the opinions differ. The statement that one of the central advantages of CSCL is that: "Due to the lacking social contacts one does not become distracted from the actual group work" shows that the expectations for group work are quite different. Thus it remains to see whether and how the problems appears in the regular teaching of the VFH.

A further complementary aspect that led to a partial negative view of the co-operation, was the lack of time. Processes, for example the discussion about the common knowledge background - the so-called “grounding” [CIBr93] which contribute to a smooth co-operation, require a larger time framework especially for virtual groups where they take place through computer mediated communication (cmc). The lacking grounding was also stated particularly regarding the cmc: "I think that several clear formulations (e.g. 'I do not consider this as
practicable).

The personal verbal expression, which in Emails is usually transferred more casually than it should be the case in formal letters, is experienced as stronger. Clear statements are often experienced as provocative and responded accordingly. Thus, unfortunately, a front quickly develops.

The time aspect is especially important for groups, because the phase of optimal performances, begins relatively late. Accordingly, the "short time frame provided" and the "time pressure" were mentioned as difficult aspects.

In conclusion one can say that, "in this virtual learning atmosphere - although there is a set of communication aids available, it is quite more difficult to find a consensus than in a real course where you can meet personally for one or two hours". The intended processes of negotiation require intensive interaction, therefore they need an adequate time framework.

Another aspect that showed up rather indirectly was the partial overtax of the participants with self-controlled learning. The participants have considered the autonomy, provided while dealing with the task, rather to be a lack of guidance than a chance for self-controlled learning. Therefore the lack of "concrete clues" was criticized. The need for strong guidance becomes clear in the following statement: "Everyone was working on the first draft-deleting paragraphs, adding new notes with different colours and asking and/or answering questions within the same document. Thus the document became very meaningful, however it was no longer clearly arranged. I would have liked it better if there had been a concrete rule for everybody which states that, first of all, everyone has to provide his/her own version/approach in which the results of his/her own internet-research are presented". Here the adjustments to the learning process as before appeared to be as structured and rather receptive process. Unfortunately, the self-controlled learning forms are usually less accepted than it would be didactically desirable. In particular it was shown that the positive effects of the jigsaw, in this concrete case of the shared knowledge construction, were existent but were also not always perceived as helpful.

### 4.2 Conclusion

All in all the result is an ambivalent picture. The jigsaw method is not only feasible on-line but also as a meaningful learning method. The advantages such as perspective change, intensive interaction with items of cognitive elaboration and co-construction of knowledge were clearly recognizable. These advantages were mainly assumed as positive by the students.

A principal requirement for successful CSCL is accurate scheduling and precise formulation of the task. In addition it is also useful to offer enough material and sources for background information.

Another condition for the effective realization of the jigsaw is the consideration of the basic conditions. Like each good learning method the jigsaw is not successful by itself. Three basic conditions played a substantial role in the case study.

One focal point were the group cohesion and the social awareness as central items of the procedure. These can be threatened in different ways. On the one hand, one could execute a presence phase before the CSCL that helps to overcome the communication barriers and thus relieve the group identification.

On the other hand, with purely virtual group work it should be considered how implemented awareness supporting tools can facilitate the social, spontaneous and informal interaction and thus improve the cohesion in the group.

In addition to form groups and to perform the relatively complex task a larger time framework is required for communication, co-operation and co-ordination.

A final aspect, which should be considered likewise more specifically for the realisation of jigsaw, includes the individual capabilities and competences of the learners. Experience and knowledge of the students taking courses in further education are very heterogeneous. Collaborative learning also covers processes of self-controlled and self-organized learning. These abilities are differently distributed. There are different learning types for which CSCL is well suited however there are other for which is less suited. Finally it can be considered to implement a graded tutoring and structuring quasi "on demand".

Therefore the jigsaw is a very good method to initiate positive processes of collaborative learning in the CSCL. This also showed up in the case study. As it is the case for all complex learning forms, the organization and counterbalancing of the multiple basic conditions and factors, remain an iterative process of optimization. This offers further opportunities for empirical research, which may concern the concrete learning success needed.

The New Four R’s: Reading, Writing, Arithmetic and the Internet—Teaching Teachers to develop Web-Based Units of Instruction.

Jeannine St. Pierre Hirtle Ed.D.
The University of Texas at Arlington
USA
jhirtle@uta.edu

Abstract
The New Four R’s: Reading, Writing, Arithmetic and the Internet—Teaching Teachers to develop Web-Based Units of Instruction is a case study examining an online secondary methods of instruction course for post baccalaureates which requires students to develop web-based unit plans. The authors posit that in order for teachers to effectively teach with technology, it must be integrated into their teacher preparation course work by modeling effective technology integration into their teaching and assignments.

Introduction
Educators will be charged with preparing students to be successful citizens and members of a society that is rapidly being transformed by technology. All of the major fields in the world of work such as engineering, medicine, transportation, manufacturing, and entertainment, the government and the military have embraced technology in order to stay current—so must education (The Milken Foundation, 2001). Yet education preparation programs are being charged with not adequately preparing preservice teachers with adequate technological and pedagogical skills to prepare students to usefully implement technology.

A study of teacher education programs initiated by the Milken Exchange on Educational Technology and carried out by ISTE suggested that “these programs should increase teachers’ exposure to appropriate technology if they are to aptly prepare them for today’s classrooms” (Moursund, 1998). As a professor, in a web-based distance education program, I work with students who have degrees and are seeking certification in teacher education through distance education. These nontraditional students are teaching on emergency certification or working in other jobs preparing to transition into teaching. Within these same classes, I also worked with students who have varying degrees of experience as teachers and are pursuing graduate degrees in education.

I chose as our text of study How People Learn: Brain, Mind, Experience, and School (Bransford, et al 2000), which is a compendium of research on people learn and subsequently how educators can teach to build upon what then know about how people learn. Bransford et al posit that there are four critical ingredients to learning environments, and those are that they must be: learner-centered, knowledge-centered, assessment-centered, and community-centered.

As I approached the design of Advanced Methods of Instruction, one of the foundation courses in teacher certification, I looked at the elements traditionally taught as part of the course: how to develop a syllabus, how to develop goals how to write objectives, how to plan units of study, and how to write daily lesson plans. I asked myself how I could take these elements and apply them pragmatically to a twenty-first century classroom? I took as a basic element of a twenty-first century classroom, access and connection to the Internet, and asked my students to develop web-based unit plans which would incorporate the four elements of an optimal learning environment. It was important to be that these be value added—that there be some purpose for them to be web-based which would enhance the learning environment.

Methodology
I chose to examine the following sources for data: my syllabus, online lessons, student responses on threaded message boards and student e-mail which referenced this assignment. In addition we examined the web-based unit plans. And finally we analyzed student assessments of their own work to ascertain how they
saw themselves fulfilling the requirements of the assignment. Then we triangulated the data by comparing the results of the analysis with each other and the two students from the case studies. The questions that guided my inquiry were: How did I as an educator of pre and in service teachers use technology to model the four elements of an optimal learning environment—learner, knowledge, assessment, and community centeredness—while charging the students with the assignment of integrating technology into their own curriculum design? Did the web-based student unit plans use technology to incorporate the four elements of optimal learning? Were the web-based student unit plans value added?

The research design for this study is an action research project which I examine two case studies chosen. Four different kinds of data were analyzed (document review, threaded message boards, e-mails, web-based unit plans and interviews). This writing is an intermediate look at the study.

Data Analysis and Discussion

A detailed discussion of the data analysis can be obtained my e-mailing the author of this paper.

Conclusions and Implications:

As a result of this study, I found that I was able to integrate traditional elements of the unit planning into a technology-enhanced curriculum after modeling technology integration in my own lessons with students, and through requiring students to participate in technology-enhanced lessons, as well as charging them to create a technology-enhanced lesson plan. I found several student developed “model” technology-enhanced unit plans, but also, had many that fell short of the mark, by just putting a unit plan which required little or no technology on the Internet. I chose two case studies from the “model” unit plans to indicate what optimally could be done. The only conclusion I can draw as to why students did not utilize technology is hypothetical at this point and not data driven. In speaking informally with students, I found it seems that students could not conceptualize that classrooms they teach in would have access to basic technology such as the Internet, or would have computer in the classroom or nearby accessible for student use. And in my own thinking, I think that students without a lot of schema for lesson planning, and/or with limited technology backgrounds could do just enough to accomplish a traditional lesson plan posted on their web page. I also found that while I felt I explicitly taught and modeled with technology integration the four elements of learning—student-centered, knowledge-centered, assessment-centered, and community-centered and required students to have that focus in their lessons, many fell short of that mark and relied, again on traditional lesson planning without the four elements of learning and minimal technology integration.

When a professor in a teacher preparation course models the integration of technology as well as requires students to integrate technology into their course work, these preservice or inservice teachers can do this successfully. But in order to make technology an integral part of curriculum, it must be modeled in teacher education classes. Based on the findings of this study, I suggest that traditional components of curriculum, unit, and lesson design can be incorporated in a technology-enriched assignment. Enhancing curriculum with technology does not have to be the responsibility of the technology educators. Rather, it can and in some cases should become the responsibility of teacher education professors and curriculum.

The Design and Development of an Electronic Performance Support System for University Professors in the Field of Biomedical Science and Biotechnology in Taiwan

Li-An Ho  
Department of Educational Technology  
Tamkang University  
Taiwan, R.O.C.  
lianho@mail.tku.edu.tw

Abstract: This project plans to design and develop an electronic aid in collaboration with a national university (NU) in Taiwan. Using the concept of knowledge management and computer-mediated learning theories and strategies, this electronic system takes the form of electronic performance support system, which aims to provide university professors a framework for 1) effective administration of data involving teaching, 2) better organization and management of the subject matter knowledge and information, 3) successful adoption and application of technological means to transform a traditional classroom teaching method, 4) opening multiple channels of communication between teachers and students, and 5) amplifying students' motivation of learning.

Background Introduction

As society moves into the information age, changes must be made in the educational process to ensure that students will have the skills they need in the changing workplace. Soon after Electronic Performance Support Systems (EPSS) gained recognition in the corporate setting, many educational professionals and researchers began exploring the potential advantages of adopting computer technologies in different learning environments. As Scales (1994) points out, there are two trends in the educational reform movement that prepare students to keep up with the changes in the society. They are integrating electronic technology in the classroom and using EPSS as a tool for promoting training and support in education and in the workplace.

Thus EPSS gradually becomes visible and applicable for instructional purposes is an inevitable trend. However, I found that it has not been recognized and correctly implemented at most universities in Taiwan. This project sought potential partnership in universities where an EPSS could help professors utilize existing resources and improve instructional effects for greater teaching and learning outcome.

Project Description

This new system aims to provide a framework to facilitate both teaching and learning. This electronic framework is presented through an electronic performance support system (EPSS). The system is expected to raise the recognition of the use of EPSS in educational settings, and to introduce a new perspective of teaching, learning, and instructions. The goal of this project is to design and develop an electronic aid in collaboration with professors at the department of Applied Chemistry at National University (UN, pseudonym) in Taiwan. By adopting the concept of knowledge management and those theories and strategies of computer-mediated learning, this new EPSS will provide professors effective tools and means to: 1) effectively administrate data involving teaching, 2) effectively organize and manage subject matter knowledge or content information for anticipated learning outcome, 3) successfully adopt and effectively employ technological means to transform the traditional classroom teaching/learning format to a new computer-facilitated instructional environment, 4)
increase the number of communication channels between teachers and students, and 5) amplify students' motivation of learning by using electronic means.

This EPSS has been constructed based on the needs of the professors and students at the Department of Applied Chemistry at NU. The new system has been integrated with functions, information and knowledge structure, and instructional activities to supplement their regular teaching and learning routines. The new system was expected to incorporate a Web function so that the distance and scheduling barriers, which often occur in the context, could be overcome between professors and students.

The new system incorporates two sub-systems: one for the professors and the other for the students (Fig. 1: system functional framework). Both professors and students will need authorizations to log onto their designated menu pages. For professors, the Recourse Center, so far, has three functions: a posting board of the departmental information, a grade template for student data, and a public forum for daily conversations. The Student Menu page contains seven components. They are: 1) a news board for posting most recent course update, 2) a course syllabus containing course information and schedule, 3) problem-based learning section allowing professors to post questions or project requirement for stimulating students' thinking, 4) course material based on course calendar, 5) a discussion forum promoting out-of-class communications among all parties, 6) online tests, and 7) a system functional descriptions served as system's online help. Up to date this new EPSS is still under construction. The system framework might be changed based on users' feedback generated through the iterative design-evaluation-analysis cycle.

The National SMETE Digital Library for Teachers: Realizing a New Paradigm

Ellen S. Hoffman  
College of Education Eastern Michigan University  
United States  
ehoffman@online.emich.edu

Marcia A. Mardis  
Merit Network, Inc. at the University of Michigan  
United States  
mardis@merit.edu

Abstract: The emerging National Science Math Engineering and Technology (SMET) Education Digital Library, which is being constructed by a variety of educational institutions, is an "online network of learning environments and resources for SMET education at all levels" (NSF, 2000). It is envisioned as a premier portal to a rich array of current and future high-quality educational content and services, and a forum where resource users may become resource providers. Technical, social, and economic issues involved in developing the library are reviewed, with emphasis on implications for teacher education and instructional support.

Introduction

The National Science, Mathematics, Engineering, and Technology Education Digital Library (NSDL) is an educational vision with initial funding from the National Science Foundation (NSF)—a vision that is different from any existing library today. Projects led by universities, K-12 entities, professional associations, government agencies, non-profit organizations, and corporations are part of the Library’s realization. The NSDL will be the culmination of over a decade of research and collaboration among librarians, technologists, and educators in the public and private sectors (Wattenberg, 1998).

Recommendations for a national digital library for science, mathematics, engineering, and technology education (SMETE) have focused on the need to define and interconnect user communities, establish collections and services, and develop tools that focus on learning and teaching needs.

The Internet Paradox: Is More Less?

High-quality content can be difficult and time consuming to locate on the Internet despite the increase in sites that attempt to provide searchable, usable materials for teachers and students. Digital library development must go beyond simply providing selected links on specific topics. Critical barriers for digital libraries today are as much human issues as technological ones. Even when good collections are developed, getting them known and used remains problematic in this age of Internet information overload (Zia, 2001).

The NSDL has the potential to encourage and support inquiry-driven, collaborative learning while incorporating distributed architecture to provide stability, reliability, and smooth interoperability. The NSDL has the possibility of allowing pre-service and in-service teachers to bring innovative tools and practices into their classroom in a supported and effective manner.

To some degree, the Library’s debut is premised on the concept that given the right funding and organizational structure, technical solutions are either in existence but not yet well placed for optimal use and interoperability or can be developed within known frameworks in a relatively short timeframe.
A Virtual Library Vision

A prime consideration in building digital libraries is meeting users’ unique needs. Therefore, the NSDL will have to provide value-added services that enhance the user experience; users must have a compelling reason to visit the Library rather than to use public search engines.

The NSDL intends to support pre-service and practicing teachers through its commitment to assuring resource quality, supporting contextual learning, fostering critical literacy skills, acknowledging access inequities, and advancing scientific understanding with many resources and services beyond traditional books and journals, including non-textual sources, lesson plans, curriculum guidelines, and tutorials.

While NSDL's focus is on SMET education content, services, infrastructure, and community, the tools and techniques that are developed and tested in this program will apply to other virtual library development. The NSF effort is seen as a prototype that can lead to further deployment in fields. In addition, NSF is developing international linkages that have the potential to create global resources for SMET education.

Progress and Achievements

The NSDL efforts began with projects focused on development and deployment. Projects are grouped into four tracks: Core Integration, Collections, Services, and Targeted Research. Universities and professional societies lead most efforts. All projects represent more than one institution and many have K-12 linkages. Project abstracts and links to project sites can be found at http://www.nsdl.nsf.gov/.

Key organizational concepts that guide NSDL progress are its distributed nature, the need for active governance that involves all stakeholders, a variable collections structure that includes those following prescribed requirements, harvested through targeted selection, and gathered with smart agents. The NSDL also prioritizes the development of a technical infrastructure that will support multiple portals for entry, and the use of multiple metadata standards to meet the diverse needs of the different disciplines and users.

Future Challenges and Considerations

Traditional roles for librarians and teachers are blurring, and the skills of each are expanding. Certainly, then, there are implications for pre-service preparation and continued professional development. To maximize its effective, the NSDL will need to go beyond an awareness campaign.

New learning resources bring opportunities to reuse and repurpose digital learning objects. New media types, such as digitized audio and video collections and data sets, are also becoming available. Recognizing the opportunities in this area, NSF and the Institute for Museum and Library Services (IMLS), have begun to explore ways in which library and museum holdings may contribute to new curricular materials (Zia, 2001).

Finally, evaluation in its many forms will be increasingly important as the NSDL continues to grow. The NSF intends for the NSDL to be a community-building resource for students and teachers; significant involvement of the country’s teachers and librarians will be vital to achieving a strong program and a thriving community.

Abstract: This paper presents the structure of a system that supports interactively teaching on multimedia material. The system has many advantages with respect to existing systems: it is not proprietary, and allows portable data on many operating systems. It supports communication over networks, both synchronous and asynchronous. It allows students to deposit information and comments into the system itself. It has strong support for reusability of the teaching material. It also permits navigation in the material at the metalevel of topic maps. A critical review on what has been done and what still has to be done is also carried out.

1. Introduction

The development of Computer Based Learning systems has a long history, which dates back to the late fifties [Cro59]. At first, such systems were command-line or menu based, and allowed limited interaction to the user. Users were allowed to read some text material, and automatic tests could be performed on the progress of learning. Such systems were very limited in scope and had little advantage with respect to traditionally learning based on books.

With the development of graphical user interfaces (Mac, Windows, Amiga,...) and the rise of authoring tools like hypercard [Goo87], the presentation of learning material got more complex, allowing the insertion of pictures, animations, video and audio elements and interactive elements to the teaching material. The more variety in the possibilities of the systems, the more complex the system became, and therefore the more expensive to develop.

Today, the wide availability of internet connection and multimedia capable computers has brought into computer based teaching software yet another new level of complexity. Both teachers and pupils can work on the material independently from location, in a synchronous or asynchronous way, and can communicate online whenever problems arise. Not only, but the distribution of content to a wider audience and the possibility of distributed real time collaboration raise new questions, both from the computer science point of view, due to the necessary management of large amounts of text and multimedia material, as well as for the effectiveness of inter-human communication over networks. Moreover, the amount of information present on the network makes it difficult to organize, maintain and search through the material.

Together with the University of Applied Sciences in Bielefeld, the University of Bielefeld, the School of Film and Television (HFF) Konrad Wolf in Potsdam and the School of Arts in Berlin (HdK), the Bauhaus-University Weimar has decided to offer a study course in Media enrolling online students. Moreover, also "regular" students of all five institutions should be allowed to use the material for their study courses.

The main goal of the project is to develop a system, a framework for teaching and for content material. The material is stored in the framework itself, permitting students of the faculties involved to learn material at the undergraduate level using the computer. As a first step, traditional physical presence based teaching will be expanded by allowing students to use the system. Once completed, the system will support the use of computers in three different scenarios:

- By a tutor in a lecture, live in the classroom

---

ERIC
• By a student, synchronously or asynchronously, at home and complementary to presence based teaching
• By a student in distant education, as sole connection means to the curriculum

It is well known that one third of the knowledge built during University studies is derived from exchange of information among classmates. The system allows therefore students to make annotations on texts, to integrate and develop new material, and provides control mechanisms for allowing such student generated content to be fed back into the teaching system itself.

To facilitate searching in the material, and to support alternative navigation paths through the material, a meta layer based on topic maps [Be99] is laid above the basic contents. The user will be able to navigate through the abstract mesh of the material freely, almost following its quest for information. Extended usage of topic maps is still at its infancy, and looks a promising technology since it allows a flexibility which is barely available when crawling through the material itself.

The Bauhaus-University Weimar has already developed interactive courseware for Civil Engineering, [HofSch01, HofSch00]. The new system bases on the strengths of the previous system called Mambo, which was a test bed for the use of multimedia in distant education. Focus is now set not only on reusability of content, which improves the cost factor, but more on user centered design of the framework, especially when it comes to Computer supported collaborative working (CSCW). Also new are the integration of topic maps, CSCW and communication elements through the system.

2. Description of the System

2.1 Main systems features

Based on an overview of state of the art learning platforms in the second half of 2000 [Com01,Com01a], no XML-based, cross media publishing capable system was then available, which would have allowed to add the features needed for the goals listed in the last section. As a result, it was decided to implement such a system around existing, commercial content management systems, allowing to concentrate on the features missed and at the same time aim for professional features like scalability and security (locking, roll-back, and so on). The use and application of open standards wherever possible permits content portability to other systems.

Figure 1 shows a schematic structure of the systems architecture and functionality. The system is built around two commercial software systems residing on a server (centre of Fig. 1) and extended using self developed or adapted software.

Next we describe the elements and their functionality of the system with the help of three use cases – content creator, teacher and student.

2.2 Content creator role

The left side of Figure 1 shows the authoring clients, where content creators (authors and media producers) access the content stored and managed on the servers. The check in/out process is simple – the users check out text or binaries using an editor or a media client, which locks access to these elements for other users.
These clients are connected via TCP/IP and authorized through an LDAP system to access the Server, on which two management systems are responsible for the content. The Content Management System (CMS) used is “Sorman CMS”[Sor01]. Its role is to take care of all XML-based content (text, tables, equations, and the structure of the content). The second system used is an Asset Management System (AMS), which is used to store raw data (binary data, such as pictures, video sequences, animations and audio data). We chose to use “Cumulus 5 Enterprise Edition” by Canto[Can01] for this task.

Content is created either by teachers with experience in the production of multimedia material or by professionals, which work as contractors for the teachers. Together, they develop the media units to be implemented, thus meeting both didactical and technical requirements.

All primary content has to be created adhering to existing standards and well-documented file formats as far as possible. For text and structuring this means XML, for the binaries proprietary formats are avoided as much as possible. This is supported by the need of client side operating system independency – many of the proprietary file formats cannot be viewed or played on machines using Linux or Solaris as operating system.

2.3 Teacher role

In case of a new course to be created, a teacher usually does most of the writing and mark-up of text himself. This is different for multimedia production, where expert media professionals have to support the teacher both by suggesting the media which are going to be used for the purpose as well as by checking the compatibility of the teacher’s desires with the
specifications concerning usability and reusability. This includes applied technologies (file formats etc.) as well as font size, colour schemes, line widths etc. ensuring usability with different output devices.

As more and more material is stored in the system, it will become possible to reuse text or media elements from other users. We believe that this is the only economically feasible way of handling the use of computers in education, since otherwise the production cost of quality material is too high. All material set in the system gets semi-automatically indexed during insertion. Metadata is then added to the data inserted. Thus, the topic map of the new material can be generated in an easy way.

2.4 Student role

Basically, student work is divided into three different fields: learning with course material, communication and creation of new content.

The learning with course materials is done via a client computer, from where the student logs into the system and participates in courses he has signed up for. The planned structure of the courses will make it possible to have the student pass simple tests before he can access further material, if desired by the teacher. Additionally, obligatory participation in chats, discussions or simple tests can be added to the curriculum of a course.

In cases where people are performing goal oriented searches in the system and are not following the course, topic maps can be used for navigation. Topic maps are abstract meshes of “entities” which one might think of as terms, concepts or objects, and meaningful connections between them. These topic maps do not contain learning material themselves, but can link to them using “occurrence” links pointing towards the object. One can imagine topic maps to be a meta layer above the course material. Once a student has problems understanding the meaning of the courseware he is following, he is allowed to leave the course structure “upwards” to the topic map and reorient himself there by locating his position within the map. He might then go to another connected topic and from there back to the course material to continue “grazing” on the material.

Communication is needed at different levels, depending on the teaching methods being used. Tutoring via e-mail is provided throughout all courses, as well as discussion forums and chat lines, and videoconferencing.

Also, means are provided for inserting the new material generated by communication into the system. Students are also encouraged to insert homework, or seminar work, or comments into the system itself. The first purpose of this practice is to allow the student to present his results in front of others, to discuss them and finally to improve his knowledge and share it with others. Some of the student material can be used by the teachers themselves, once it has been screened by an expert ensuring its quality. This allows a more rapid growth of the material than it would be possible when done only by the teachers.

2.5 Integrating commercial software

The two commercial systems employed are responsible for managing text, binary data, and topic maps. They provide the following advantages:

- Both systems come with built in mechanisms protecting users from inadvertently deleting data by providing so called “roll back” functionality, which, like an undo function, allows to go back to an earlier state of the work. Furthermore, both systems proved to scale to a larger number of concurrent users working on content at the same time, which is important for daily use in a University.
Both systems are accessible on a programming level to adapt them to additional needs. Existing APIs provide functionality which can be used to “glue” other, self-developed programs to them.

Experience [HofSch00] has shown that two main workflows can be differentiated, one concerning text and ordering of content, the other concerning the creation of binaries like pictures, animations, films, or interactive programs. The separation of these workflows is sometimes difficult, as most authors are not used to outsource the production of binaries, but can be supported by dedicated management systems. Especially with binaries, it is necessary to have good support for describing, searching and viewing to reduce production time and cost.

These systems serve as a query-able backend and repository for the data generated by the teachers and the students.

3. **Conclusions and future work**

We have presented a system structure for a system that supports teaching interactively with multimedia material. The system has many advantages with respect to existing systems: it is not proprietary, and allows portable data on many operating systems. It supports communication over networks, both synchronous and asynchronous. It allows students to store information and comments into the system itself. It has strong support for reusability of the teaching material. It also permits navigation in the material at the meta level of topic maps.

The current implementation state is the following: the CMS and AMS are running and provide the basic functionality of the system. The development of a first prototype for the underlying multimedia data types has been finished. The first document type definition has been drafted. The first integrated prototype will undergo a first evaluation at the end of February 2002. Courseware is being developed while regular courses are taking place: an analysis of the teaching methods in the different course types is being done.

It proved a real challenge to develop a common language between extremes such as engineering, the humanities (specifically cultural studies) and fine arts. Studying media involves competences from the arts, from the humanities, from economy and from technology. Especially when it comes to teaching methods and ways to formalize different approaches, often different worlds collide. Obviously, people from such different fields of work have quite different understandings of science, work, and especially teaching. Such differences pop up at each step in the conception phase, and it is sometimes a big challenge to find a common ground.

This explains why it is far less easy to modularise learning material as it has been thought from an engineering background. Complex topics of cultural studies are usually taught in seminars, and base on a strong personal interaction between the teacher and the pupil. Reproducing this situation in a virtual e-learning environment is a challenge, both from the technical as well as from the communication point of view.

Also non trivial is the task of having teachers producing material which is usable by the system. The material itself is often not clearly modularised, nor is it tagged with the name of one or more concepts, so that the creation of the topic maps has often to be done by hand through indexing the material delivered, and modules are inconsistent within the system. This could be solved through issuing guidelines for the creation of the material.

Publication of content stored in the management systems is from a technical point of view not as difficult as it has been a few years ago. We plan to connect a cocoon-engine [Apa01] to the content management system, which will do rule based conversions suitable for both screen and paper publication. Further publication to other output devices should be no problem, as long as suitable media for the device is available and marked up accordingly.
The question of user management is one which seems more technical than anything else. We hope to find this assumption confirmed as we develop the part of the system responsible for that. We will look in rather fine detail into the problems arising from questions like user-defined annotations to text, as we believe to find some technical surprises there.

The navigation using topic maps has been mentioned above. A first prototype is being developed allowing for 3D-interaction with topic maps, to allow both users and creators of topic maps better interaction with the system in three-dimensional virtual spaces.

Support of specifications is needed when describing the content in metadata and grouping content to learning material. Currently it is evaluated in how far full support of specs like EML, IMS, LOM and SCORM is feasible and useful, or if such a specification should be adapted to specific needs like CanCore did [Can01a]—especially as at the time of this writing the project group is trying to develop a first, prototype, document type definition.

In the field of communication many things like e-mail, chat, newsgroups, blackboards and the like have been in use for quite some time. An overview of current, mainly open source solutions will be evaluated for incorporation into the system. Other means like whiteboard sharing and video conferencing will be looked at at a later stage of the project.

Acknowledgements:

This project is funded by the Bundesministerium für Bildung und Forschung (Federal Ministry of Education and Research) in the programme NMB (Neue Medien in der Bildung, new media in education). The financial and logistic support of the programme is gratefully acknowledged.

Much of this work could not have been done without the help and support from Thore Schmidt-Tjarksen, Marko Meister, Christoph Lincke, Annett Zobel and Matthias Hupfer. Thanx!

Abstract: This short paper discusses the unique ways in which educational media technology can help meet the instructional needs of ESL (English as a Second Language) students in the regular content area classrooms. One of the most promising pedagogical approaches for working with ESL students in the regular classroom is called Sheltered Content Instruction, but finding the appropriate materials for the regular classroom teacher to use in reaching the goals of this approach can be difficult. However, with some simple blending of the Internet and media technologies already in place in most content area classrooms, this challenge can be reduced. This paper discusses the theoretical potential of using Internet and media technology to meet the goals of Sheltered Content Instruction and demonstrates the practical viability of this merger by briefly describing a step-by-step construction of a Sheltered Content Instruction Electronic Learning Module.

Background: ESL Sheltered Content Instruction

Currently there is a rapid rise in the numbers of ESL students in American schools. The ESL research community is working to develop teaching methods that can assist in the difficult task of teaching content area academic knowledge to students having limited English proficiency. One of the most promising pedagogical approaches for working with ESL students in the regular classroom is called Sheltered Content Instruction. The focus of Sheltered Content Instruction is to teach academic, or content area subject matter to ESL students using more comprehensible or “sheltered” English in the spoken and written forms (Eschevarria & Graves, 1998). This involves consistently providing context clues such as gestures and visual aids, along with reading-level appropriate learning materials, and, ideally, other interactive stimuli to
guide ESL students through their content learning. This type of approach is designed to be utilized in the regular classroom by content area teachers who have received some training in teaching ESL students, and who have the resources available to provide the sort of scaffolding needed to meet the goals of Sheltered Content Instruction. Finding the appropriate materials for the regular classroom teacher to use in reaching the goals of this approach can be difficult. However, with some simple blending of the Internet and media technologies already in place in most content area classrooms, this challenge can be reduced.

**Technology Use**

Technology use in ESL instruction is developing (c.f. Feyten, et al., 2002). The fluidity of student learning needs from one ESL learner to another should make the use of computer technology to target learning activities to specific learning needs a common solution. However, in conducting a search for web sites, it becomes evident that the Internet does not typically have technology applications recommended on specific Sheltered Content Instruction sites. In addition, sites that present detailed information about Sheltered Content Instruction do not have recommended sites that teachers could use. Consequently, the opportunity to integrate technology into the ESL classroom in a Sheltered Content Instruction context poses certain obstacles. The focus of this paper is to explain how it is possible to blend the concepts of Sheltered Content Instruction with readily available technology so that content area teachers with ESL students can develop appropriate and interesting learning materials that accomplish intended ESL student learning outcomes.

Specifically, aligning web-based content area reading materials with student readability levels is one technique that teachers need to be able to do as quickly as possible. Copying text and putting it in a Word document allows a teacher to quickly assess the readability level. Once the text is in a Word document, it can be chunked into shorter narratives and organized with multimedia. Readability can then be adjusted by using synonyms to make text and passages more available by lowering or raising the language to a student’s reading level. The shorter blocks of text also can be presented through text-to-speech software and allow students to focus on the content without tripping over words that take so long to decode that reading comprehension is diminished. Once there is familiarity with these approaches, a more ambitious use of technology is the development of specific learning modules on the web, or with a CD, or using a PDA that beams students’ work from one appliance to another for review and comment. These technologies present the information to be learned through a student or teacher presentation that is age appropriate, motivating, and educationally sound.

**Sheltered Content Instruction Electronic Learning Module (SCIELM)**

A sample SCIELM could be developed by a regular content area teacher using the following steps: 1) identify the content reading assignment that the majority of the class will complete; 2) search the Internet for similar content material online that is written at a more appropriate reading level for the ESL student(s); 3) copy and paste the text into a Word document and run grammar check to determine the reading level of the text; 4) substitute words and phrases as necessary for further alignment with ESL student abilities; 5) add graphics or other multimedia as available; 6) assign readings. Additionally, this sort of SCIELM could very effectively be developed within a Virtual Learning Circle environment (Thomas & Hofmeister, 2002) which would allow for continued asynchronous academic interaction regarding the textual material.

Web-Based Surveys: A Comparison to Paper-Based Surveys.

The use of web-based surveys in educational research is growing in popularity every year (Solomon, 2001). As familiarity with technology increases, survey methodologist and researchers alike will find developing and implementing web-based surveys can help to preserve valuable resources as well as speed the collection and analysis of data. When compared to paper based surveys, serious measurement issues have overshadowed the benefits that web-based surveys can bring to the researcher (Dillman, 2001). This disparity between paper based and web-based survey methodologies have created the need for further study into the effect that web-based surveys might have on data and its subsequent evaluation. Web-based surveys are a relatively new area of research. Kiesler & Sproull (1986) published one of the first experimental surveys on the differences between email surveys and postal mail surveys. With the exception of this article and a few others, the sheer paucity of research into the reliability and validity issues of web-based surveys is troubling. This creates measurement issues because we currently do not know what impact the design of the web-based survey will have on data, nor do we know whether the answers respondents supply on web-based surveys will differ significantly from those provided via a paper-based survey. It is clear that web-based research is a new and untested tool, with further research needed, especially in web-based survey design and implementation as well as a closer comparison of web-based and paper based responses (Dillman, 2001).

The purpose of this study is to determine whether the serious measurement issues of web-based surveys can be overcome through proper implementation and design, and whether the web-based survey will yield equivalent results to those obtained from a paper based survey. In order to examine these questions, researchers will present results from the administration of two like-content survey forms (paper and pencil and web-based) that were administered in a quazi-experimental design to over 300 participants of a teacher training session. This sample provides unique opportunities into determining relative validity and reliability of the web-based survey by non-randomly assigning teacher to control and experimental groups based on previous web experience so that there is equal representation of web abilities in both groups (Roberts & Onwuegbuzie, 2000).

Preliminary results from analyzed data indicate the following responses to the above research questions. First, web-based surveys were more likely to provide complete results by improving examinee fidelity (e.g., accidentally missing an item, skipping blocks of questions or pages, forcing responses to all items). Second, because of completed teacher response, reliability estimates tended to be higher since alpha is negatively affected by persons randomly missing items (Roberts & Onwuegbuzie, 2000). Third, the ease of transfer of data from an already established database to a statistical analysis program in the web-based survey ensures that there is no error when researchers are transferring data from paper to the computer (as in the paper and pencil version). This can prove an important issue in both quantitative and qualitative research. Fourth, as with the previous point, data entry time is dramatically reduced for researchers. And finally, the combination of the above four points in favor of web-based surveys is advanced by the fact that web-based survey lost no reliability or validity in the transfer from paper and pencil form (as will be shown by the data).

Learning English Modal Verbs with the Aid of Didaktos

hong@dte.ua.pt
moreira@dte.ua.pt

Abstract: This paper reports an ongoing Ph.D. program conducted at Department of Didactics and Educational Technology, University of Aveiro, Portugal. The program undertakes to improve English grammar teaching and learning within the field of the English modal verbs at university level employing Didaktos (Didactic Instructional Design for the Acquisition of Knowledge and Transfer to Other Situations) (Moreira et al. 2001), a prototype shell designed on the basis of Cognitive Flexibility Theory (Spiro et al. 1987; 1988; 1989; 1991a; 1991b; Spiro & Jehng 1990).

The paper describes an ongoing study of university students learning English modal verbs in a hypermedia learning environment, Didaktos at Department of Didactics and Educational Technology, University of Aveiro, Portugal. The hypermedia shell is designed following the theoretical orientations of Cognitive Flexibility Theory, a constructivist theory of learning and instruction in complex and ill-structured domains at advanced stages of learning.

Spiro and his collaborators contend that learning and instruction in complex and ill-structured domains require multiple representations, multiple explanations, multiple analogies and multiple dimensions of analysis. The central claim of the theory is the metaphor of a criss-crossed conceptual landscape expounded by Ludwig Wittgenstein in Philosophical Investigations (Wittgenstein 1997). The same materials should be revisited at different times, from different points of view, in different contexts, for different purposes, in rearranged instructional sequences so as to master complexity in understanding and achieve knowledge transfer in new situations. Moreover, the theory provides a solution to the widely reported problem of disorientation in hypertext systems as the user is never more than one link away from the focus of instruction.

The principles of Cognitive Flexibility Theory are best implemented in hypermedia systems because non-linear links can be established to allow for multiple dimensions of knowledge, for multiple interconnections across knowledge components and so on. In accordance with the guidelines of Cognitive Flexibility Theory, Didaktos offers teachers the possibility to present any domain of knowledge through cases divided into chunk-size scenes in different media. The scenes are codified with multiple perspectives together with information on description and context of each scene and thematic commentaries. Furthermore, teachers can build special sequences traversing among the scenes so that users' attention can be called to differences in superficially similar scenes and similarities between apparently different scenes. Students can view the cases one by one, consulting the description and context of each scene, getting access to the thematic commentaries; look for scenes in which particular themes are relevant and follow the pre-defined special sequences.

English modal verbs are selected as the domain under study as they pose difficulty to learners irrespective of their mother languages and noted by their irregularity and complexity embracing various conceptual domains. The problem is aggravated by the traditional out-of-context, oversimplified and fragmentary teaching methods. Modal verbs will be presented in authentic examples of use in diversified genres such as poetry, speech, play, fiction, song, movie, news broadcasts and so on. Cases will be analysed from distinct but complementary perspectives: normative grammar, systemic functional grammar, communicative grammar, semantics and relevance theory. Besides sequences will be drawn among the scenes to show the relationship between modal verbs and time reference, modal verbs and interpersonal relationships, modal verbs and speech acts as well as modal verbs in direct/indirect speech, and modal verbs in formal/informal use.

University students learning English as a foreign language will participate in the experiment assigned to three groups: the control group, the experimental group (consisting of the passive sub-group and the active sub-
We propose implementing two different orientations of the same learning hypertext with contrasting manners of navigation: organising contents in a linear, traditional way and in a flexible, non-linear way. The control group will study the cases in a linear, traditional way while the two experimental groups will be engaged in a flexible, non-linear environment. The control group will look at “view cases sequentially” and “look for specific themes” while the experimental groups will also have access to “get special sequences”. The difference between the two experimental sub-groups is that subjects of the active one will be given more autonomy in interacting with the hypertext. Instead of being offered the thematic commentaries and special sequences as what the passive sub-group will be exposed to, they get the opportunity to provide answers by themselves before checking their answers with the information in the hypertext.

It is expected that the study will yield the following results:
- Subjects of the three groups will make similar performance in post-tests that assess factual knowledge.
- Subjects of the experimental groups will perform better than those of the control group in post-tests that assess procedural knowledge.
- Subjects of the experimental groups will obtain better results on the post-tests than on the pre-tests assessing procedural knowledge in comparison to those of the control group.
- Subjects of the active sub-group will obtain better scores than those of the passive sub-group in post-test assessing procedural knowledge.
- Subjects assigned to the active sub-group will hold a more positive attitude towards the hypertext and the experience than those assigned to the passive sub-group.
- Subjects' epistemological learning beliefs and preferences will change after the treatment.
- The epistemological learning beliefs and preferences differ in gender.

An Experimental Comparison of Effects of Lively and Lifeless Animated Characters on Comprehension and Attention Performances in Multimedia Presentation

mlewis@mail.sis.pitt.edu

Abstract: The paper reports the effects of animated characters in multimedia presentations on comprehension and attention. The results showed that the lively character did not influence learner's comprehension of presented material; nevertheless, they showed the significant differences of the effect of lively character in recall performance. In addition, because pedagogical benefits of different learning environments tend to be significant among individuals, this paper revealed that introverts had significantly greater recall performance than did extroverts.

Introduction

Drawing attention and active engagement are pedagogical techniques for designing effective multimedia presentation. The value of directing attention is based on cognitive information processing theories which hold that attended information consumes more cognitive resources and is more thoroughly processed than unattended information. Research reports that anthropomorphics computer interfaces have more capabilities for drawing users' attention and engaging them in active tasks than nonanthromopormphic interfaces (Dehn, & van Mulken, 2000). Therefore, human-like characters could be more effective presenters or guiders in multimedia presentations where comprehension and recall of materials need to be enhanced.

The focus of this study is to examine the effects of anthropomorphics on comprehension and attention in multimedia presentations of technical content. With respect to (King, & Ohyea, 1996; Laurel, 1997), in this study a lively character was defined as a human-like representation, which is capable of displaying emotional expressions, while a lifeless character was an object or a part of human form, which was not able to express emotions. The study measures the degree of attentiveness attributed to animated characters by their effects on incidental learning, measured as the accuracy of recall performance for attended visual messages and the number of errors in recall performance for unattended visual messages. This study also examined the effect of animated characters as a function of the participant's degree of extroversion.

Manipulation

In this study the PowerPoint slides used in an actual computer graphics course were used. The script for each slide comprised of both the instructor's explanation and a sequence of locations to which attention should be directed. The manipulation of the characters accounted for three conditions as screen examples in Figure 1.

<table>
<thead>
<tr>
<th>Condition 1: Control</th>
<th>Condition 2: Lifeless</th>
<th>Condition 3: Lively</th>
</tr>
</thead>
<tbody>
<tr>
<td>Occluding Objects</td>
<td>Occluding Objects</td>
<td>Occluding Objects</td>
</tr>
</tbody>
</table>

Figure 1: Screenshot examples of Pointing Behaviors
Findings and Conclusion

An analysis of variance showed that there were no significant differences of comprehension among three conditions. For attention, there were significant differences of recall involving the pointed objects ($F(2,27)=4.40$, $p<0.022$), while there were no differences of recall involving objects that were not explicitly pointed. The post-hoc analysis resulted that the subjects in the lively character condition had better recall involving the pointed objects than the subjects in the lifeless character condition.

With respect to the degree of extroversion, the results of t-test showed that there were no significant differences on the comprehension between the low and high extroversion groups. However, the results showed that the subjects in the low group had better recall involving objects explicitly pointed out than the subjects in the high group ($t_6=2.298$, $p<0.025$).

The results correspond to the previous studies (Andre, Rist, & Muller, 1998) in which the personified characters did not contribute to the students' comprehension of technical materials. Nevertheless, the lively character was better able to draw student's attention to the messages that were being presented than the lifeless character. Therefore, although lively animated characters may not help learners digest presented materials, they can be an effective peripheral learning tool for directing attention. This study also found that introverted learners had better recall involving objects in the presentation than extroverted learners. This may result from difficulty that extroverted learners find in maintaining concentration in non-interactive environments since they prefer non-structured materials with lots of collaborative activities and interactivity. Introverts, on the other hand, benefited from the structured material and quiet learning environment suggests that personality should be taken into account when designing multimedia presentation.

Situation, Problems and Pedagogical Prospective of the Mexican Basic Education System at Distance: Some Research Questions on Numeracy for Adults

Verónica Hoyos, Universidad Pedagógica Nacional, México, vhoysa@upn.mx
Esther Amador, Dirección General de Materiales y Métodos Educativos (SEP), México, amadormaye@hotmail.com

Abstract. SEA, the Mexican at distance system of Secondary Education for Adults is characterised by being an educational program on basic education whose aim is to fulfill needs and characteristics of the working young and adult population who has not finished nor studied secondary school. This educational proposal is based on the use of certain printed materials, TV programs and Saturday tutorship bearing in mind the adult's learning achievement processes. Furthermore, its aim is to acknowledge that the learner is an active being, capable of developing study skills to achieve autonomous learning. In this paper we emphasise on Saturday tutorship on numeracy as an observant instrument which has produced information on the system's efficiency. Especially regarding the tutors requirements in order to promote learning autonomy.

Introduction

An Open System on Basic Mathematical Education in Mexico

On the 21st of May 2001 it was published in the Official Federation Diary the 295 Agreement about the Secondary School at Distance for Adults. This document states that: "The general aim of the Secondary Education at Distance for Adults (SEA) is to offer a model on Education based on needs and special characteristics of the adult population who remained behind regarding further education. In this, it is expected to help adults develop knowledge, skills, attitudes and useful values to face distinct problems, as well as getting access to higher educational levels." This system provides learners with two learning guides of mathematics (Square Accounts, SEP, 1998, for beginners and Figures, Problems and Solutions, SEP, 2000, for advanced level), based on calculus and problem solving, to lead and help them along eight months of instruction. In addition, and with the purpose of backing up learning activities, 36 support and 18 tutorial TV programs are transmitted. Finally, there are Saturday tutorships which provide further support to those learners whose doubts arose when studying.

From the pedagogical point of view, the main objective is to acknowledge adults' experience and needs, developing knowledge from adult life contexts, to study contents meaningful to life and continual study. Also, to improve studying methods to become an independent learner and last, to set up a way of assessing according to the approach.

Problems Coming up within the System and Research Methodology

Adult's autonomy for studying

Adult education is essentially basic education addressed to people older than 15. Adult education arises as a result of the educational system's inefficiency, and has specific connotations, socially as much as political and economical (Schmelkes y Kalman, 1994).

One of the fundamental principles is to acknowledge the adult person as an active being in his or her learning process. Adult education should fulfill different requirements from those pertaining to common education, due to the fact that it is focused, in great extent, to working people who have certain responsibilities distinctive to adults. Thus, education should not absorb learner's full time and effort. On the other hand, adult's interests are different from those of children, as most adults expect to apply or get immediate benefit from their studies commitment.
Numeracy through problem solving

Both texts of calculus and problem solving are organized in units whose content is shown from problematic situations and immersed in contexts assumed to be close to adult life. Taken as a syllabus axis, for instance, trading, health, etc. But without neglecting formal mathematical knowledge and consequential generalizations. Under these pedagogical principles, the aim is in fact, that students develop mathematical skills and learn mathematics by building them up, identifying, selecting and using strategies adopted by mathematicians.

Due to the fact that some teachers do not know how to make up mathematics and doubt their own mathematical skills (Santos, 1997), some questions arise: How does the SEA-tutor face the concrete curriculum proposal in his hands? How to achieve that (or what learning actions carry out for this purpose) the tutor in this educational system could build up a wide criterion to be able to decide, and formulate the kind of answers he will be giving to his or her students?

Saturday tutorships: Realm of interaction and meaning negotiation

In fact, acknowledgement, meaning build up or productions are being developed during the interaction process itself (Hoyos, 1998). Meaning assignation is rather given from a joint process in which the teacher thinks of the student’s work in order to state a suitable question or proposal to allow him elicit different meanings. Then, with the purpose of identifying the main components intervening in this system’s tutorship, we carried out an exploratory study (Amador, 2000) with one of the SEA tutors trainer and three workers. The following results were obtained: A) In spite of tutor’s efforts to regain the learner’s previous experiences and knowledge, he is not always successful. Usually, because the tutor forgets to retrieve the idea adults brought up on this subject and focus on the procedure; B) Each participant made up a different interpretation of the guide-text. Some times, such interpretations may be taken as wrong or not conclusive; C) Tutorship sessions were a negotiation realm for interpretations arose from the text and for helping the adult learner in his or her ongoing learning.

As a means of conclusion: A Prospective on research and re-education at distance for SEA tutors

It has been detected that tutors try to cover in one session the learning students should develop in five sessions of independent study. May be an important number of SEA students are not developing their skills for independent study. Therefore, their study activities are sometimes restricted to tutorship session. How often is this practice repeated? Which constitute the possible causes of this phenomenon? In what way do this affect mathematics learning? What obstacles hinder SEA students from developing skills for achieving independent study? One of our research hypothesis is that technology, communication and telematics will provide new perspectives regarding the open and at distance education system discussed in this paper. These new resources may be advantageous allies to endure initial practices of mathematical communication, at least between re-educators and tutors. It may be feasible to reproduce in the SEA, during the Saturday tutorship, communicative practices that could produce achievements in learners’ autonomy.

References

The three workers have daily jobs, are older than forty and finished elementary education. They were a locksmith, a secretary and a customers flow supervisor in a dining room. In a whole, three tutorial sessions were carried out under the SEA system, on the subject of decimal numbers; all of them were videotaped, transcribed and analysed.
The Use of Multiple Representations in a Web-Based and Situated Learning Environment

Ying-Shao Hsu, yshsu@cc.ntnu.edu.tw
National Taiwan Normal University, Taiwan
Fu-Kwun Hwang, hwang@phy.ntnu.edu.tw
National Taiwan Normal University, Taiwan

Abstract
This article presents the development and evaluation of a web-based lesson with multiple representations that is developed to cultivate situated learning. The quasi-experimental method along with semi-structured interviews was used to investigate the effects of a web-based lesson on science learning at the senior high school level. Three classes of second-year students from two senior high schools in Taipei were selected as the participants for this study. The total number of participants was 110 including 49 males and 61 females. The statistical results indicated that (a) student conceptual progress almost reached the significant level (t=1.98, p<0.051) before and after the experiment, (b) there were significant differences between the conceptual progress of male and female students on their conceptual progress before and after the experiment (F=11.48, p<0.001), (c) computer logs also showed that less male students participated in the online discussion than female students did, and that (d) most students had positive opinions about this web-based lesson. The qualitative data analysis indicated that some students thought that the web-based lesson, named Lesson Rainbow, provided a daily-life situation could promote their motivation on learning and help them integrate knowledge.

Keywords: Web-Based Learning, Situated Learning, Hypermedia, Science Learning

Introduction
Many researchers have suggested that computer hypermedia and networking technology are effective tools to simulate realistic situations when a realistic situation can not be provided in a traditional classroom (Winn, 1993; Hay, 1996; McLellan, 1994; The Cognition and Technology Group at Vanderbilt, 1997; Harley, 1993). If learning activities can make a connection between the real situation and its underlying theory, it is realistic to learners (Moor et al., 1994). If computer multimedia can simulate realistic situation in a meaningful way, it can make learners to immerse in and to feel it realistic. This study attempts to develop a web-based lesson according to the theory of situated learning and examing the Internet supports student situated learning.

Internet technology can not only integrate the advantages of traditional CAI into instruction but also provide a variety of learning environments from self-directed learning to individual learning, one-to-one interactive learning, group learning, and situational learning (Mason, 1995). With the Internet, students are able to work with current data that are much more up-to-date, and authentic than the material in textbooks. Online resources can help students make connections between their schoolwork and the concerns of people in the real world. In these ways new technologies can make learning and curriculum more generative (Wiske, 2000). Many researches have shown that web-based instructions produced positive effects on student learning motivation, scientific attitude and learning efficiency (Hsu & Thomas, in press; Krausk, 2000; Edelson, 2001; Hoadley & Linn, 2000). Most of these researches concluded that the positive effects came from careful designs on web pages, learning materials and web managements. The benefits of web-based instructions are not reaped automatically but only come as a result of careful planning.

In this study, we chose the theory of situated learning as the theoretical base for the development of a web-based lesson, named “Lesson Rainbow”. It is because most teaching contents and processes in school activities do not start from real-life situations. This produces students who can not apply their learning to solve problems in real life or work related situations. Educational reform in many countries focused primarily on lifelong learning and transfer of what students learn to real-life situations (Ministry of Education in Taiwan, 1999; National Science Education Standards, 1996). Situated learning emphasizes that learning occurs in real situations and the construction of knowledge is in the continuous interaction between humans and situations (Brown et al., 1989; Lave & Wenger, 1991; McLellan, 1996). This leads students to gain synthetic knowledge instead of inert knowledge. Three realistic situations can be used in class: (1) taking students to the real workplace; (2) immersing students in an authentic or similar situation; (3) providing students an anchoring context (McLellan, 1996). This study used flash animations to immerse students in an authentic situation, a trip to the northeast in Taiwan.

Goldenberg (1995) claimed that we can not expect to understand how students learn if we look only at the student’s facility with one representation or student’s handling of each representation in isolation. It is limited to understanding students’ understanding when research is preformed only in a single-representation environment because it is hard to tell whether a particular observation is or is not merely an artifact of that representation. In a multiple representation environment, the researcher can easily discriminate between surface confusions about any one representation and true misconstructions of the concept. Multi-representational simulations embedded in a situated learning environment provide scaffolds and context for students to explore the simulations. Some multi-representational simulations are designed in Lesson Rainbow. Through the Internet, we record student actions in detail so that we can describe a web-based environment that instantiates this approach, and we analyze formative...
evaluation data to test the hypothesized mechanisms of learning. This study attempts to investigate how multiple representations support students with different learning preference on the construction of their scientific concepts, whether students with different learning characteristics prefer different functions design in the situated learning environment, and how students benefit from multi-representation simulations in a situated learning environment.

Method
This research project employed the quasi-experimental method along with semi-structured interviews to investigate the effects of a web-based lesson on science learning at the senior high school level.

Participants
The participants for this study were selected from two senior high schools (called as School A and School B) in Taipei. They were second-year students and their majors were social sciences. There were four classes who enrolled in Earth Science class at School A and two of them were randomly chosen as our participants including forty-four males and forty-two females. One of two classes who enrolled in Earth Science class at school B was selected randomly as the sample including 16 males and 30 females. Totally, the participants were 132. After excluding invalid data, the number of the valid participants was 110 (49 males and 61 females).

Instrumentation
In addition to the web-based lesson (called as Lesson Rainbow), there were three other instruments, a test, a questionnaire and a follow-up interview, that were developed to collect data on student conceptual progress and their opinions about the web-based lesson. Experts validated all instructions used in this study. The characteristics of each instrument are shown as follows:

Lesson Rainbow: McLellan (1996) suggested there are eight key components included in situated learning: stories, reflection, cognitive apprenticeship, collaboration, coaching, multiple practices, articulation of learning skills and technology. Five of these were designed in Lesson Rainbow except for cognitive apprenticeship, coaching, and articulation of learning skills. How did we apply situated learning theory to Lesson Rainbow? The learning activities are designed with story-based animations to display situations, discipline-integrated themes to integrate the concepts of mathematics, physics, biology and earth sciences, problem-based assessments, social interaction to empower knowledge construction, and implicit hints to scaffold student learning. Associated with the design of animated tutorials (Berger et al., 1994), we provide some analytic or problem-based questions which can guide students apply, analyze and synthesize data or information shown in the Lesson Rainbow. Animated tutorials aim to increase new concepts into students' schema so the computer program provide only guiding feedback but not correct answers. The learning tools provided in Lesson Rainbow include an electronic notebook, an equation editor, a discussion board, and an electronic map. The mapping between these components and Lesson Rainbow is shown as below (see Table 1):

<table>

</table>

Test: A test was conducted to detect student understanding of the concepts related to rainbows, humidity, and condensation. There were 23 items on the test, which were validated and was examined for reliability (The Cronbach's $\alpha = 0.76$) before the formal experiment.

Questionnaire: A questionnaire with 34 Likert-type items was used to conduct student opinions about the design of this web-based lesson. Four dimensions in the questionnaire solicited opinions on interface design, situation design, the design of learning tools and the overall design of Lesson Rainbow. The Cronbach's $\alpha$ of the questionnaire was reported as 0.87.
The follow-up interviews: Semi-structured interviews were conducted to investigate student understanding of the relative concepts and to collect their opinions about the lesson. Twenty students (8 males and 12 females) were selected for interviews based on specific purposes. Each student was interviewed for 20-30 minutes.

Procedure
This study included three stages: (1) The preparation stage (01/2000-11/2000): In this stage, the major work was to develop Lesson Rainbow and the instruments. After a pilot study, the instruments were validated and revised for the experimental stage. (2) The experimental stage (12/2000-1/2001): A pretest on the concepts was conducted in the week before the experiment. In the experiment, students received a training session for one hour and completed Lesson Rainbow in two hours. The week after the experiment, a posttest on the concepts and the questionnaire were administrated. The selected students received follow-up interviews a few weeks later because we needed time to analyze the data and determine typical cases for the interviews. (3) The data analysis stage (1/2001-5/2001): Data analysis and concluding remarks were the major jobs in this stage.

Data Analysis
The data were analyzed in several ways. In order to examine if there was a significant difference between before and after treatments, the paired t-test was used to compare the pretest and posttest scores on concepts. A mixed design of repeated ANOVA was used to test the hypotheses that stated male and female students had a significant difference before and after the experiment. We used descriptive statistics for the analysis of each item in the questionnaire and used Chi square to test if there was a significant difference among the four dimensions (the opinions on the interface design, the design of situations, the design of learning tools and the overall design of Lesson Rainbow) in the questionnaire. The collected data was analyzed using SPSS (Statistical Package for Social Science, version 7.0). The assumptions of normal distribution and homogeneity of variance for dependent variables were tested before applying statistic methods, t test and ANOVA. If the dependent variable did not display a normal distribution, the significant level was cut to 0.04 in order to reduce the Type I error (Stevens, 1996). Qualitative data were coded and summarized to show a deep understanding of student learning processes and perspectives using the web-based lesson, Lesson Rainbow.

Results and Discussion
It was hypothesized that there was a significant difference between student pre and post concept tests. For Lesson Rainbow, the mean for the pretest was 16.7 with a standard deviation of 2.32. In contrast, the posttest mean was 17.4 with a standard deviation of 2.45. The result of repeated t-test showed that there was nearly a significant difference (at a 0.04 significant level because of the abnormally-distributed scores of tests) between student pretest and posttests on concepts (t= 1.98, p<0.051; The data is shown in Table 2).

The pretest mean was 16.6 for male students and that for female students was 17.0. In contrast, the posttest mean for male students was 16.5 and that for female was 18.1 (The data is shown in Table 4). The result of mixed design of 2X2 ANOVA showed that there was a significant difference between male and female student performances on the pretest and posttest (F=11.48, p<0.001; The data is shown in Table 5). Few male students said that the animations in Lesson Rainbow were not as attractive as online games in interviews. Their low attention to the learning materials leaded to their low performances on the posttest. Computer logs also showed that less male students participated in the online discussion than female students did. This may reduce male students to construct their knowledge when they used Lesson Rainbow. These two reasons made male students could not learn better than female students.

The data from interviewing the 20 students showed that most students thought the web-based lesson was more interesting than textbooks because of the animations and interactions. The online discussions made students feel more involved in the learning activities. Five of the twenty students suggested that the teacher should participate in the online discussion with them because sometimes they did not know how to solve problems without the teacher's scaffolding. A student said in his interview: "If the teacher could participate in the online discussion, it would increase the interactions and cleared confusions. I would learn better if the teacher involved in the online discussion." Different students have different needs in a web-based learning environment. Few of them need teachers' assistances because they are lack of skills on communication and reflective thinking. It is advised that the well-trained teachers involve in online communications with students in order to help weak students overcome their obstacles.

Conclusions
This study investigated the effect of a web-based lesson (Lesson Rainbow) developed to cultivate situated learning. A realistic situation served as a bridge to connect student daily-life experiences and constructing knowledge. Most students had positive opinions about Lesson Rainbow. From the interviews, some students said that the animations for the simulated authentic situations could promote their learning motivation and immerse them in an interesting context for meaningful learning.

Networked technologies supported collaborative work in which the students combined components or worked together to make successive drafts (Wiske, 2000). Social learning theory emphasized the value of dialogue and collaboration in helping students to develop and articulate their understanding. In order to reach effective cooperation, students needed to share ideas, adventure and argue with others so that they could come to reasonable interpretations of the subjects they were studying (Blumfnfeld, et al., 1997). Students can compare the varied views of a topic and enhance cohesive understanding of science from a well-designed online asynchronous discussion. In this study, Lesson Rainbow succeeded in helping students to integrate knowledge by evoking discussions to search for answers to the questions following realistic situations. When students communicate with others, they retrieve their pre-knowledge and reconstruct concepts. Meaningful learning occurs when students interact with others or environments (Savery & Duffy, 1995). Therefore, online asynchronous discussion designed for a situated learning environment can promote knowledge integration.

The effects of metaphor on computer users' mental models and information search behaviors

Authors: * Yu-chen Hsu, ** Jiunde Lee
Affiliation: * National Tsing-Hua University, ** National Chung-Cheng University, Taiwan
Email: * ychsu@mx.nthu.edu.tw, ** telljl@ccu.edu.tw

Abstract

The purpose of this study is to compare the effects of single versus multiple metaphors in computer expert and novice users' change of mental models as well as information search performance. Related issues, such as mental models, differences between novice and expert users, and effects of single versus multiple metaphors will be reviewed first in this paper, followed by the discussions of methodology and expected results. The research findings will suggest useful guidelines in designing metaphorical interfaces in the area of human-computer interaction.

Introduction

People often use metaphors to build bridges from the known to the unknown. In the area of human-computer interaction, metaphors have been used by practitioners to design computer interfaces to facilitate user learning since 1981. As to their effects in facilitating user learning, studies show that metaphors may better help novices in learning computer programs, because they have less complete mental models compared to the mental models of experts. However, the effects of metaphors on experts may be questionable.

Metaphor (conceptual model) vs. mental models

The use of conceptual models (or metaphors) to help users construct their mental models has been advocated by several researchers. A mental model is an internal model that an individual uses to facilitate interaction with the environment, with other individuals, or with technology (Norman, 1983). When people interact with a new system, they formulate mental models of that system and continue to modify their mental models to get a workable result.

Eberts (1994) notes that designers apply their conceptual model to the design of interface, and this model is conveyed to users through display representation. In order to understand the operations of the system, users need to develop mental models of the computer tasks. The mental models of a computer user will continuously change with the increase of one's computer experience. Metaphor is a type of conceptual model. By explaining the workings of the system, good conceptual models help users to form more comprehensive mental models of the system. There is a close relationship existing between the provision of metaphors and the formation of more comprehensive mental models, which results in better performance as users carry out computer tasks. However, this relation has not been well examined by researchers.

Expert / novice users

Expert and novice users differ in the degree of the integration of their knowledge, but even experts may still possess fragmentary mental models; that is, their "mental models continue to
be specified by both assimilated and fragmented components" (Sebrechts, Marsh, and Furstenburg 1990, p376). Because novice users possess less computer knowledge and their mental models are more fragmented than expert users, the use of metaphors will be most useful for novices who are learning new computer systems. In the present study, the researchers will also compare the effects of metaphorical interfaces on novice and expert’s information search performances as well as the chance of their mental models.

**Single metaphor vs. multiple metaphor**

According to Gentner’s (1997a, 1997b) structure mapping theory, the major advantage of a metaphor lies in the relationship of objects with the metaphor. The unified structure of an integral metaphor allows users to see the interrelationships between elements in order to identify each element’s function. On the other hand, mismatches happen in situations in which the attributes and relations of a single metaphor cannot be perfectly correlated with the attributes and relations of the target domain. This is especially true when the target domain is so complex that no individual model can fully explain anticipated behavior. In this case, the use of multiple metaphors to design interfaces may be a solution (William, Hollan, and Stevens, 1983). A study (Hsu, 2000) compared the effects of single metaphor and multiple metaphors in designing interfaces, the findings show that interface cues from multiple metaphors helped subjects to find a greater number of accurate answers in a shorter time. However, little was known about what change happened in subjects’ brain. It may be a better way to use the think aloud method to explore subjects’ changes of mental models of the system.

**Methodology and expected findings**

The independent variables in the study are the three interfaces with different degrees of structural cues derived from single or multiple metaphors. The dependent variables are the subjects’ search performances in terms of the accuracy of their search results, time spent on each task, navigational paths chosen for completing each task, and their satisfaction. Another variable to evaluate is their mental model. Interview and questionnaire will be used to collect data regarding the change of subjects’ mental models. A total of 90 college students will be used as the subjects to perform some information search tasks. Some of the subjects will be asked to perform think aloud tasks to further identify their change of mental models.

The researchers are collecting experimental data and the analysis will be completed in June 2002. It is expected that the research findings will suggest useful guidelines in designing metaphorical interfaces for users with different degrees of computer expertise.

Barriers Encountered Using WBI to Deliver Courses

Pei-Wen Nicole Huang
Applied Foreign Language Department
National Huwei Institute of Technology
Taiwan
huang_nicole@hotmail.com

Abstract: The purpose of this study is to determine and compare faculty perceptions regarding the use of WebCT in selected public universities in the Midwest on United States. Specifically, the study examined the demographic characteristics of faculty who deliver courses using WebCT and barriers encountered in their use WebCT. The Web-based survey was sent to 300 faculty members who use WebCT to deliver courses in the selected Midwestern universities. The data were analyzed using descriptive and inferential statistics. Primary conclusions to emerge from the study include the following. (1) The majority of university faculty who use WebCT to deliver courses in the Midwestern United States are female. (2) Most WebCT courses are offered both on and off campus. (3) The majority of faculty believe WebCT is moderately ease to learn and use. (4) Lack of time and heavy instructional load are the greatest barriers for faculty using WebCT to deliver courses.

Introduction

As technological innovations continue to change and expand, it becomes increasingly necessary to support faculty in adopting innovations to keep up with the educational demands of the 21st century. These demands include the changing learning environment, computer-aided instruction, Web-based course management, and distance education. Web-based Instruction (WBI) is defined as an innovative approach for delivering instruction to a remote audience using the World Wide Web as the instructional delivery system (Khan, 1997). Currently, WBI is growing faster than any other instructional technology (Hill & Raven, 2000). It has been used not only in exclusive distance programs but also in supporting face-to-face traditional classroom instruction. According to research conducted by McIsaac & Gunawardena (1996) distance learning is the fastest growing form of education and there will be a continued expansion of Web-based technologies in higher education. Although new technology is creating new educational challenges and opportunities, it also creates new problems. Moreover, WBI is primarily a mechanism for delivering instructions, it cannot resolve problems created by inadequate or poor teaching. As the Web will be increasingly used as a teaching and learning medium, it is important to consider the emerging roles of instructors and learning environments (Shotsberger, 1997). Consequently, as expanding and improving instructor usage is the key to enhancing the success of WBI, increasing attention has been focused on faculty assistance and student's needs. This present study investigated faculty perspectives of delivering courses using WebCT in Web-based Instruction. The purpose of this study is to determine and compare faculty perceptions regarding the use of WebCT in selected public universities in the Midwest United States. Specifically, the study examined the demographic characteristics of faculty who delivered courses using WebCT and any barriers encountered in their use of WebCT. The following questions were considered in guiding this study:

1. What are the demographic characteristics, in terms of age, gender, tenure status, rank, academic teaching areas, level of training, and location of course delivery, of faculty who utilize courses using WebCT?

2. What is the extent of barriers encountered when faculty deliver courses using WebCT?

The Study

The population for this study consisted of all faculty members who use WebCT for delivering courses in four selected public universities located in the Midwest on United States. The Web-based survey was sent to 300 faculty members who use WebCT to deliver courses at selected universities. Out of the 106 surveys returned, 52.8% were in the 36-50 age bracket. Regarding faculty status, most faculty were in the tenured group. In addition, more assistant professors (32.1%) participated in the study than professors (21.7%), associate professors (20.8%), and instructors (20.8%). The majority of faculty in the study were in the School of Education (38.1%) and College of Arts and Sciences (30.5%). Regarding the level of skill as a WebCT user, a large group of faculty (49.1%) rated themselves at the
intermediate level. Nevertheless, more faculty participating in the study were delivering WebCT both on and off campus (54.3%) than off campus exclusively (6.7%).

Lack of time (time consuming) (M = 4.25) and heavy instructional load (M = 3.50) are the greatest barriers for faculty using WebCT to deliver courses. Other barriers reported by faculty are lack of technical skills, lack of incentives, lack of technical support, lack of technical training resources. The least important barriers faculty indicated for delivering courses using WebCT were class size too large (M = 2.59) and lack of personal interests (M = 2.67).

Conclusion

The majority of faculty responded that WebCT is moderately easy to learn and use; however, lack of time and heavy teaching loads are the greatest barriers and weakness associated with delivering courses using WebCT. For many years, a systems approach has been adopted as essential to the successful practice of instructional design among industries and education for many years. When a system approach is applied to Web-based instruction, departments, administrators, teaching assistants, instructional designers, technical supports, students, and training programs are integrated. As a matter of fact, education is one of the few areas where division of labor or specialization is still not practiced to any extent (Kearsley & Moore, 1996). Individual teachers who develop and deliver their own courses try to be effective curriculum designers, evaluators, motivators, group discussions facilitators, and content experts as well. Kearsley & Moore (1996) claimed this is a huge waste of human resources. Williams & Peters (1997) also reported that the current atmosphere in major research universities is still competitive, not collaborative.

Time and resources are inevitable obstacles to developing good WBI. Neither the teacher nor the technology alone can make WBI work. One solution would be for faculty members with similar courses to collaborate and share their expertise and resources. To establish an instructional team involving faculty peers, TAs, student technology fellows, and technical support personnel could help by sharing the workload and designing the program to accommodate both courses.

WBI will benefit from supportive faculty input resulting in technological advancements. In spite of providing fundamental technical skills, there is also a need to regularly provide and update faculty knowledge about the technological developments and strategies that impact teaching and learning that will foster collaboration by faculty with common curricular interests.

A Tool for Creating, Editing and Tracking Virtual SMIL Presentations

Suzanne Little¹, Jane Hunter²

¹ ITEE Department, ² DSTC,
GP South, University of Queensland,
St Lucia, Queensland, Australia 4072
{little@itee.uq.edu.au, jane@dstc.edu.au}

Abstract: The ability to easily find, edit and re-use content adds significant value to that content. When the content consists of complex, multimedia objects, both the difficulty of implementing such capabilities and the added-value are multiplied. A distributed archive of SMIL presentations was built and indexed using tools, developed by the authors, which enable digitized videos of lectures to be automatically synchronized with their corresponding PowerPoint slides. In addition a full-text and keyword search interface was developed. As the archive grew, it became clear that the ability to edit, update or customize existing presentations by deleting, adding or replacing specific slides without re-filming the entire lecture was extremely desirable. This paper describes the application that was built to satisfy this need and the changes necessary to the original metadata schema to ensure that editions could be easily tracked and new versions of presentations easily managed.

1 Introduction

The use of digital, synchronised, multimedia presentations in education is increasing and as the volume of presentations available grows, so does the need for tools to facilitate the re-use and management of these presentations. Presentation editing tools, which permit updates, additions and concatenations of existing presentations, whilst maintaining synchronization and updating metadata, can improve the quality of the content and reduce the time involved in production and indexing. Simple functionality such as cut, copy, paste and delete would enable educators to re-use existing presentation segments, update presentations with more recent or topical material and customize presentations for particular audiences, without having to re-film the entire lecture each time.

This work is part of an ongoing project [1] in which a set of tools were developed to automate the synchronisation of digitized lecture videos with their corresponding PowerPoint slides. These tools, described briefly in the next section, enable the cost-effective, streamlined production of SMIL presentations and associated metadata for archival and searching. Such online presentations provide an extremely useful educational resource, particularly in a distance learning environment. However, as the size of the presentation archive grew, so did the need to edit, update or customize existing presentations by deleting, adding or replacing specific slides without re-filming. The economic benefits associated with such re-use are obvious. This paper describes the PresentationEditor application which was developed to satisfy this need.

In developing an editor for the synchronised multimedia presentations a number of requirements were identified. Firstly the editor should maintain the synchronization of the video and PowerPoint slides, automatically, without need for user input. Secondly the metadata created for the presentation must be updated to reflect the changes made, who made them and when they were made. The system also needs to record details of the composition of new ‘virtual’ presentations (i.e., presentations that are composed of edited segments of previous presentations, but which have never been presented in reality) to enable accurate, fine-grained (full-text or keyword) searching across the presentations. Finally it is important that the editor is easy to use and lightweight. No knowledge of SMIL or the underlying structure of the presentation should be required in order to use the application.

In the next section we describe previous related work and how the work described here differs from and builds on top of that.

2 Previous Work/Background

DSTC’s SMIL Presentation Project [1] developed a suite of tools to cost-effectively create and index synchronized PowerPoint/Video presentations for deployment either on the Internet, CD-ROM or a LAN. The PresentationLogger records the time that each PowerPoint slide is displayed. The PresentationIndexer collects the metadata about the presentation in a semi-automated fashion and creates an XML file containing a complete description of the presentation, its contents and structure. The PresentationBuilder/Archiver creates the finished SMIL presentation and stores the metadata as a separate stand-alone XML file or inserts the metadata into a database. An Internet search and browse interface [2] has also been built and can search either flat XML
files or utilise the database for more efficient searching. Figure 1 shows the system components and architecture. In this paper we describe the Presentation Editor component, at the bottom of Figure 1.

Synchronized Multimedia Integration Language (SMIL 1.0) [3] is a W3C Recommendation designed for choreographing web-based multimedia presentations which combine audio, video, text and graphics in real-time. It uses a simple XML-based mark-up language, similar to HTML, which enables an author to describe the temporal behaviour of a multimedia presentation, associate hyperlinks with media objects and describe the layout of the presentation on a screen. Since this work was started, the W3C SYMM (Synchronised Multimedia) Working Group has released the SMIL 2.0 Recommendation [4] which extends the functionality contained in SMIL 1.0 by enabling interactivity in multimedia presentations, advancing the timing model and improving the accessibility features. In the work described here we have used SMIL 1.0 to layout the presentations spatially and to temporally synchronize the video and PowerPoint slides. Possibilities for improvement exist as SMIL 2.0 is more widely deployed and more SMIL 2.0 tools/players become available.

SMIL has the following advantages to offer:

- Dynamic generation – similar to HTML this makes for easy, cheap alterations to presentations as opposed to complex and intensive digital editing
- Platform independence – as a W3C recommendation, SMIL is not a proprietary technology and hence does not tie the implementation to particular platforms or programming languages;
- Network and client adaptability – SMIL provides a switch tag which can be used to dynamically choose the most appropriate media object to stream, depending on client display capabilities or connection speed e.g., use audio instead of video for low bandwidths;
- Ready availability of SMIL players – there are nine SMIL 1.0 players available covering a wide range of platforms [5]. The most popular of these are Apple's QuickTime 4.1, Microsoft's Internet Explorer 5.5 Browser and RealNetworks' RealPlayer 8.

Figure 2 illustrates the Replay interface for browsing and viewing SMIL presentations.
A number of commercial and research tools are available for multimedia and SMIL editing. These include RealPresenter [6], RealSlideshow [7], Fluition [8] and GRINS [9]. RealPresenter and RealSlideshow are specifically for generating multimedia presentations while Fluition and GRINS are general SMIL editing tools. While the Real tools provide good support for generating basic multimedia presentations, they lack the metadata required for fine-grained searching and archiving of multimedia presentations or for recording changes or tracking versions. In addition, the presentation interfaces are somewhat restricted and the Slideshow tool, which has perhaps the most user-friendly interface, is limited to only providing audio with the slides. GRINS and Fluition are both very capable SMIL editors but assume a level of technical knowledge far above that which could reasonably be expected in this case. They also do not provide any support for complex and fine-grained or editing event metadata.

Hence the major goal of the work described in this paper was to develop a tool that provides a simple, intuitive, graphical user interface which supports presentation editing and a metadata model to enable both fine-grained searching and re-use tracking. The next section describes the system design and functionality.

3 System Description

The PresentationEditor is a Visual Basic application that exploits the temporal information and media links contained within a presentation’s metadata (XML) file to divide the presentation into manageable self-contained segments which can be manipulated to implement easy editing. Each segment consists of a video component (video source, start and end times) and its associated metadata (pointer to corresponding PowerPoint slide, keywords, text etc.), expressed as an XML file. Using a graphical user interface, these segments can be cut, paste, reordered or moved within and between presentations to create new virtual presentations. Once the rearrangement of the presentation is complete, the editor generates the new RealMedia video and the new SMIL file which represents a synchronized presentation. The PresentationEditor also includes search facilities to help the user find relevant segments for insertion into the new presentation and previewing facilities for viewing draft presentations during editing.
Figure 3 illustrates a typical editing process in which the user creates a new virtual presentation by combining parts of existing presentations with new segments that have been filmed to replace outdated sections of the original presentation.

The PresentationEditor incorporates and integrates the following functionality:

- Search tools to find and retrieve relevant presentation segments;
- Ability to cut, copy and paste of segments both between and within presentations;
- Re-ordering of slide/segments through drag-and-drop;
- Direct updating of metadata for the presentation;
- Automatic adjustments to indexing and temporal synchronization information resulting from post-production editing of the video;
- Updating and correction to segment contents;
- Previewing of draft presentations during editing;
- Saving of updated metadata XML files;
- Re-construction of edited video files (RealMedia) and creation of new presentations (SMIL).

Figure 4 illustrates the graphical user interface to the PresentationEditor. The interface includes a video replay window, a PowerPoint slide window and an editing panel. In the example in Figure 4: extra slides have been added to the original presentation ("6: Metadata Standards" and "5: Metadata Requirements"); the original slide 6 has been deleted and the order of the slides in the original presentation have been rearranged using drag-and-drop tools in the bottom editing panel.

4 Changes to the Metadata Model

A metadata model was developed for the original system, which enabled both coarse and fine-grained discovery of complete presentations and individual slide-segments respectively. The resource discovery of complete presentations was supported through metadata such as: presentation location, lecturer, department, institution, description. The search and retrieval of segments was possible through either full-text or keyword searches over the textual content of each PowerPoint slide. The segment-level metadata consisted of: source, keywords, text, start and end time, duration, related materials. The XML Schema corresponding to the complete metadata model for the original system is available at [10].

The development of the PresentationEditor demanded certain changes to the original metadata model. The recording of additional metadata associated with "editing events" was required to ensure effective tracking of re-use and version control. This additional metadata included:

- details of the person who performed the editing (the editor's Name and Email);
- when and why they did this (Date.Modified, Purpose);
- the version number of the new presentation;
5 Problems and Limitations

Whilst the segmentation approach has a number of advantages in this context, it may not be suitable for all lecturing styles. The indexing and synchronisation of our SMIL presentations is based on the assumption that the video can be precisely segmented according to slide changes and that within each segment, the lecturer only refers to the currently displayed slide. However some presenters may refer to slides other than the currently-displayed one or begin an introduction to the next slide whilst the previous slide is still displayed. Such situations can lead to incongruities between slides and video content. Irrelevant and distracting information may be present or valuable and important information could be misplaced.

A lack of continuity between contiguous video segments recorded at different times or at different places, is an obvious problem that may occur within "virtual" presentations and distract viewers from the content. A presenter may be wearing different clothes, or have a different hairstyle between contiguous slides. Background and lighting may vary widely within a single virtual presentation. The extent to which this variation disturbs viewers and detracts from the learning experience needs to be assessed.

Originally the presentation incorporates a single continuous video but after editing and the rearrangement of presentation segments, the video consists of a collection of separate video segments in a particular order. The segmentation and reorganisation of the video components can be time- and resource-intensive and result in decreased video quality and reduced playback performance. Consequently the PresentationEditor provides two alternative options for generating the virtual presentation. The first option involves dividing and then recombining the video to create a single digital video object which plays in parallel with the synchronised slide images in exactly the same manner as the original presentations. The second approach involves the creation of a SMIL file which defines the start and end times of a sequence of video sections - giving the illusion of a continuous video file playing in parallel with the slide images. Both solutions offer advantages and disadvantages. Choosing to divide and recombine the video is extremely time consuming, CPU-intensive and restricted by a number of factors including video frame sizes. It also requires a large amount of storage space and the quality of the final video is reduced. Never-the-less, the playback quality is reasonable with no loading or seek problems and there is a single video file associated with the presentation. Using SMIL timing to artificially rearrange the video file results in greatly reduced playback quality. The player must load the video file to the requested start time at the beginning of each presentation segment which can cause disruptions in the synchronisation. However this second approach is cheaper, faster, more flexible and less reliant on external factors such as video size or quality and, since the video file itself is not changed, the video quality remains the same.

The PresentationEditor operates primarily through the manipulation of flat XML files, either SMIL files or metadata XML files. The application does not support the direct editing of digital media objects such as the video files or PowerPoint slides. While this functionality may be useful, it can also be complex and resource intensive and maintaining synchronisation would be problematic. One of the advantages of the SMIL Presentation Tools is that they rely solely on manipulation of textual descriptions and thus avoid expensive and complex digital video editing.

6 Conclusions and Future Work
6.1 Conclusions

The PresentationEditor tool described here has the potential to increase the value of multimedia presentation content and enable more efficient and cost-effective production of distance learning resources by maximizing re-use, providing more effective metadata and facilitating ease of management. It provides educators with greater flexibility in the development, maintenance and management of a digital multimedia presentation archive - allowing them to improve, update and customize digital multimedia presentations for specific audiences and to provide a richer, more flexible means of learning, with a minimum of time, effort or cost.

6.2 Future Work

Our immediate objective is to deploy this application within a university department and to carry out user trials to obtain feedback from lecturers/content creators and students on the user interface and the application's usefulness as a tool for building and re-using effective online learning resources.

Future improvements in multimedia players and streaming technologies are expected to result in improvements to the SMIL presentation development tools, the replay interface and the PresentationEditor. For example, RealNetworks have recently released the RealONE player [12], which includes the ability to display related hyperlinks and references. Upgrading the system to SMIL 2.0, which provides greater interactivity and embedded metadata [13], should also result in further changes and improvements.

Finally, an area of research requiring more work is that of customized dynamic SMIL generation. In a manner similar to that of third generation HTML web pages [14], it may be possible to combine semantically-related mixed media objects to dynamically generate knowledge-enhanced SMIL presentations, which have been customized for particular users or a given set of constraints.

Cognitive Tools and User-Centered Learning Environments: Rethinking Tools, Functions, and Applications

Abstract: This paper introduces and analyzes problems and issues in the design and use of cognitive tools in open, user-centered learning environments, introduces a classification scheme for tool functions, and showcases several tools in a current educational hypermedia research and development effort. Implications for future research and development in the design and use of cognitive tools in hypermedia learning environments are addressed.

Background

Many hypermedia applications support open-ended, user-centered, interactive constructivist learning environments (Hannafin & Land, 2000). In hypermedia, multimedia resources are linked dynamically in web-like form. Hyper-links emphasize expanding versus constraining the user's access to multimedia resources, thereby supporting a myriad of potential uses and learners. Hypermedia systems "open up" knowledge domains and support learners in exploring issues of unique interest and need (Hannafin & Land, 1997). Hypermedia systems can also facilitate construction via student-centered exploration, manipulation, and inquiry (Allen & Hoffman, 1991; Oliver & Hannafin, 2000). Despite considerable interest and potential, however, "open" hypermedia systems present unique challenges to both designers and users. Due to the absence of explicit pedagogical support typical in direct instruction, users can become disoriented and overtaxed cognitively in open hypermedia learning systems (Roselli, 1991). A principal cause of disorientation and cognitive overload is the quantity of simultaneous, and largely undifferentiated, multimedia resources available. The learner is responsible for accessing, selecting, organizing, and analyzing information according to his or her unique needs (Jonassen & Grabinger, 1990; Land & Hannafin, 2000), but the systems provide little guidance. Learners are often ill-equipped cognitively to navigate vast multimedia networks and interpret their meanings.

The shift in pedagogical control to the individual involves providing more than resources of increasingly powerful multimedia images; it involves the deployment of well-reasoned strategic uses of available multimedia resources. The shift requires more than procedural assistance; it requires tools that scaffold the open-learning processes of diverse learners for varied purposes. The purpose of this paper is to describe and illustrate the functions of cognitive tools in hypermedia learning environments.

Cognitive Tools: Functions and Examples

Cognitive tools include both mental and computational devices that support, guide, and extend the cognitive processes of learners. They can amplify cognitive functioning and facilitate the creation of personal knowledge (Pea, 1985; Salomon, Perkins, & Globerson, 1991). Within hypermedia environments, cognitive tools enable learners to regulate the amount, sequence, and flow of available resources, make metacognitive judgments while navigating, and evaluate relevance (Park & Hannafin, 1993). Cognitive tools may also assist users in locating key information, recording or modifying available resources, connecting available resources, generating and linking personally relevant ideas with existing multimedia resources, and creating individual pathways that link the various multimedia resources contained in the system.

Tools are not inherently cognitive independent of the manner in which they are used. Their functions vary based upon the manner and context of their use (Jonassen & Carr, 2000). In some instances, a given tool might be used to collect information (e.g., text, illustrations) from a hypermedia learning environment; in others, the same tool might be used to organize relationships among various resources.
Information-Seeking Tools

Information-seeking tools are especially important for open-ended hypermedia learning environments. Information-seeking tools extend the learners’ ability to identify the availability of key information, locate it, and differentiate the nature of the information. Information-seeking includes recognizing and interpreting the problem, establishing a plan for searching, conducting the search, evaluating the results, and if necessary, repeating the process iteratively. Metacognition research suggests that the ability to reflect on actions while searching is critical to success during learning in open-ended environments (Duffy & Knuth, 1990). To enable learners to establish a plan of search, conduct the search, and evaluate the results, cognitive tools should help learners to monitor their information-seeking activities.

In practice, information-seeking activities are influenced by many learner attributes: prior domain knowledge, motivation, cognitive styles, familiarity with learning environments, and gender. Cognitive tools, therefore, support three interrelated seeking functions: locating, viewing, and retrieving relevant information.

Information-Presentation Tools

Information-presentation tools support learners as they attempt to understand the information they encounter. Such tools allow learners to access, then represent, information in varied ways. In open-ended hypermedia learning systems, users frequently encounter too much information. Consequently, they are often unable to identify or establish relationships among information. Thus, information-presentation tools also need to help users manage cognitive load (Oren, 1990).

Effective information-presentation tools extend three basic capabilities: 1) the ability to select relevant attributes and details while ignoring the irrelevant; 2) the ability to select information that enhances interpretation; and 3) the ability to provide alternative representations. The same information can be represented in a variety of forms, such as verbal statements, mathematical expressions, voice narration, tables, and illustrations. Appropriately represented information helps learners to act on their beliefs, construct higher-order relationships, and establish conceptual associations.

Knowledge-Organization Tools

Effective knowledge-organization tools enable learners to manipulate representations and relationships, promoting unique interpretations of, and relationships between, the information encountered. When learners attempt to organize vast amount of new information, they tend to oversimplify; the scope and complexity is often difficult to grasp. Accordingly, while some details may become well-organized, important relationships are often organized inappropriately or incompletely. Knowledge-organization tools, which allow learners to organize knowledge from various perspectives and dimensions, enable learners to establish key relationships among to-be-learned concepts.

Perhaps the most important function of knowledge-organization tools is the ability to tentatively structure (or restructure) information as it is encountered. This enables learners to construct working models of the domain under study. Knowledge-organization tools allow learners to manipulate information from various perspectives, helping them to organize concepts multi-dimensionally. To lessen cognitive load, knowledge-organization tools help learners to simplify organization and reduce unnecessary task complexity.

Knowledge-Integration Tools

Knowledge-integration tools support the connecting new with existing knowledge. One way to facilitate integration is to elaborate and upgrade one’s mental model. Cognitive tools can facilitate conceptual understanding by supporting the testing of presumed relationships between newly organized knowledge and existing knowledge. Salomon (1993) suggested that computer tools may be especially useful in executing lower-level, tedious computational and graphic operations, allowing to the learner to focus on hypothesis generation. Some cognitive activities may seem beyond the reach of users because assistance is unavailable to help establish connections between new information and existing knowledge. Knowledge-integration tools can help to bridge this gap. For example, Sherlock I, a computer-based environment for avionics troubleshooting, supports hypothesis testing by providing multiple paths for technicians to explore and coaching the technicians as they test their hypotheses (Lajoie, 1993). The hierarchical structure of the problem is modeled using a menu interface. Learners can constrain or expand problem parameters systematically as they test the limits of alternative hypotheses.

Knowledge-Generation Tools
The creation of unique learning artifacts is an important component in constructionist views of learning. Knowledge-generation tools help users to manipulate and generate unique interpretations and to represent newly generated knowledge flexibly and meaningfully. Allowing learners to represent newly generated knowledge, using different perspectives and modalities, is essential to deep understanding. Handy, a hypermedia editing tool, enables users to construct scenes and present them via computer (Nix, 1990). The user can generate and re-order scenes according to individual goals, interests, and needs. The scene can integrate source media such as videodisc, audiotape, synthesized voice, digitized voice, animation, and graphics.

Cognitive Tools in Practice: The Human Body

The Human Body is an interactive CD-ROM based on the TV series, The Universe Within Human Body. The Human Body was designed and developed by instructional designers, TV producers, subject matter experts, teachers, and multimedia developers. This open-ended hypermedia environment contains approximately 1,000 individual multimedia-enhanced database screens featuring computer graphics, digital video, sound, and text that support learner-centered, constructivist learning in introductory anatomy and physiology (Iiyoshi & Kikue, 1995, 1996).

A variety of information-seeking tools are provided such as an alphabetical index, keyword search, hypertext and hyperpicture links, and concept maps. These tools enable learners to locate information they need from various perspectives; using their prior knowledge, conceptual relationship among text and pictorial information, and domain structure. For example, using the Structure Map tool illustrated in Figure 1, the learner can determine the availability of a concept using a hierarchically-structured map of each human body system. All components are displayed using both visual images and their corresponding names. The related information for each topic can be accessed by clicking the image or term of each concept. This tool provides a topical overview of related terms and concepts.

Tools are also provided to support information selection and embedding into presentations. The Bookmark tool shown in Figure 2 allows the learner to “flag” key information they encounter, then subsequently access that information quickly and accurately. The learner can place a bookmark on any information screen, and generate a list of all selected screens. In effect, the cognitive load associated with ongoing review is managed by selecting screens for subsequent review.

As previously noted, tools are not inherently cognitive; the context and nature of their use determine whether or not the tool augments, extends, or enhances the cognitive processes of users, and the manner in which such processes have been influenced. Stated differently, the same computer tool can support multiple cognitive processes. For instance, the previously described Structure Map presents a detailed concept map of each system also helps the learner to construct and elaborate the relationship between and among the systems and their components. Likewise, the Bookmark also enables learners to traverse selected information screens in user-customized ways.

The Text Memo tool, shown in Figure 3, also supports information organization. It allows the user to elaborate or annotate information contained in any information screen. When a learner writes a memo, the corresponding screen is automatically bookmarked. This electronic memo can then be linked to other information within the system. The tool aids not only in information organization, but also supports the development of user-specified, customized links.

To integrate newly organized information into pre-existing knowledge, metacognitive tools are provided. Path Tracker plays back all the information screens the learner went through since beginning study. This helps
learners to monitor what they have learned for better integration of their knowledge. Another example is Reviewer (Figure 4), which allows learners to monitor the information screens they examine. The ratio of the number of screens examined to the total screens in a particular component or a system is displayed. The tool is useful to identify the distribution of information they have looked through the system.

Figure 3: Text Memo

In addition, some tools aid learners in both integrating their knowledge as well as in generating new knowledge. The Presentation Maker enables learners to create individual collections, combining information screens and their personal comments. As shown in Figure 5, users can organize bookmarked and/or annotated resources via the Text Memo tool to indicate how the body reacted to create a personal affliction (e.g., heart attack of a family member). System contents are both modified according to unique experiences and integrated with the experiences of each individual user. In the presentation mode illustrated in Figure 6, each screen can be displayed according to the user's specifications.

Figure 5: Presentation Maker (Authoring Mode)

Implications

Hypermedia systems provide open-ended environments for learner-centered, constructivist learning. However, learners' cognitive resources are often overtaxed when exploring these vast information networks, limiting their ability to use the systems effectively. Although tools have supported cognitive processes in directed learning contexts, research is needed to better understand how they support processing in open-ended learning environments. Several significant research issues remain related to the design and use of cognitive tools.
Facilitation of Tool Use

Simply providing cognitive tools with open-ended hypermedia systems ensures neither usage nor success. We need to better understand how to facilitate the use of multiple tools; we also need to learn more about how creative users actually employ the tools we provide. Providing a variety of tools may be important to accommodate learners with different prior knowledge and tool-use skills. While it is evident that well-designed and implemented tools can facilitate, it is also apparent that tool use can hinder learning and performance. The cognitive load associated with tool use can actually increase rather than lessen the demands of the learning task. Individuals must often invest considerable cognitive resources learning how to use a tool; this problem becomes magnified as the number and variety of tool features increase. It is important to determine how tool use can be facilitated—both prior to as well as during use—to support user-centered learning.

Domain-Free Tools Versus Domain-Specialized Tools

The rapid growth in open hypermedia systems, such as the World Wide Web, suggests a paramount need for generalizable cognitive tools. However, such tools have rarely been developed much less validated. Increased attention to the design of general cognitive tools, rooted in theory and research on human cognition and open-ended learning rather than particularized domain nuances, is needed. It may be possible to provide "meta tools" that help learners to construct and customize tools needed for a content domain, that is, to select and adapt from a suite of tools that are well-known and broadly applicable. While the widespread interest in tools that are uniquely crafted to support learning in particular domains has proven the viability and utility of cognitive tools, research on scalable tools is needed.

Evaluation of Tool Use

In order to examine how cognitive tools are used to support learners with open-ended hypermedia learning environments, close evaluation of actual tool use is critical. Several significant questions need to be addressed.

(1) Are tools used as initially intended?
(2) Do patterns of cognitive tools utilization exist?
(3) How do individuals use multiple cognitive tools in their learning?

The proposed research is of significant potential consequence. Few researchers have immersed themselves in issues of design, and few designers are attuned to available research and theory. Tremendous interest has been generated in open learning environments, but little research and theory is available to guide or support the interest. We have taken large steps, but we may not be making needed progress. Neither the research nor the applied community has been, or will likely be able, to singularly advance the state of the art. Greater convergence of interest and expertise between theoreticians and practitioners is needed.

Abstract: This paper analyzes problems and issues in making knowledge of teaching and learning visible and sharable online. It also describes some of the ongoing research and development efforts at the Carnegie Foundation's Knowledge Media Laboratory that advance this work through the use of emerging technologies. Implications for future research and development are also addressed.

Background and Rationale

The Carnegie Knowledge Media Laboratory (KML) uses some of the newest technologies to challenge one of the oldest problems in education—making the knowledge of teaching and learning visible and sharable through the use of multimedia and the Internet. Beyond increasing the quantity or availability of materials for teachers to use, the KML hopes to support the development of a qualitatively different approach to professional development: one which views faculty as critical producers of knowledge and the Internet as a new medium through which they can represent and exchange aspects of their practice and knowledge that often cannot be captured in conventional written texts.

In order to accomplish this mission, the work of KML addresses three critical issues. First, merely documenting what goes on in a classroom or course does not communicate what teachers have learned or the ideas and expertise they have developed. For example, if one were to film every hour of class time and put every document related to a class online, it would be extremely difficult to make sense of all that material or to figure out why the teacher had designed the course as they did or what they had learned in the process. It would be like looking at all the field notes that an anthropologist collected or all the data from an experiment without any of the rationale, context, or analysis that the anthropologist or scientist provides in a book or document. Second, even if many teachers do succeed in developing and producing books, videos, websites or other products that reflect the knowledge implicit in their teaching, there are few means for helping other educators or the wider public to find and take advantage of those that may be most useful for them. Third, even if faculty members can find a wide range of examples of the scholarship of teaching relatively easily, there is no guarantee that they will choose to do so. It may take considerable time before people discover how to take advantage of and build on the knowledge of teaching and learning that can be represented in multimedia and online materials.

Over the past three years, the KML has pursued a set of activities which address these problems. In particular, since few models or examples exist that can give faculty a chance to imagine how they can use the online environment to create new and more powerful representations of their practice, we have worked with accomplished faculty in both K-12 and higher education to create a small number of multimedia websites (Figure 1 & Figure 2).
These sites model how teachers can organize carefully selected materials, images, videos, and reflections that make the ideas and expertise that go into their teaching public and available for others to examine and build upon (Cambridge, et al., 2001). In order to make it easier for faculty to create these kinds of sites and CD-ROMs, DVDs, or videos in which they articulate their ideas and examine their practice, we have also developed a small set of resources and formed an online gallery and exhibition space for the display of their multimedia work. In addition, we have established a virtual workspace that now supports the review and exchange of work by over two hundred scholars who are participating in the Carnegie Academy for the Scholarship of Teaching and Learning (CASTL).

At the KML, we are currently working with the groups and individuals affiliated with the Foundation’s programs to expand this work by:

- Inventing new means for faculty to develop and represent the knowledge needed to design powerful learning experiences.
- Constructing the tools and resources that faculty can use to develop and represent their knowledge,
- Fostering the exchange and use of that knowledge in more effective educational programs.

Ultimately, we believe that these activities will help to ensure that the tremendous energy and resources that are being invested in putting courses and resources for both teachers and students online actually lead to significant improvements in teaching, learning, and professional development.

In education, with the development of the Internet and digital media in particular, the latest wave of changes in technology are making their way into the lives of teachers and students. While equity of access remains a constant concern, one can imagine a time in the not too distant future when students and teachers in many different communities can have computers and Internet hookups and communicate and exchange information and ideas with their peers; when they can use digital cameras and video to conduct research and record their work to present to others; and when they can design and take advantage of a wide range of online classes for their personal, academic and professional development. But how will they take advantage of the opportunities to use these new technologies to share ideas that can improve teaching and learning?

The impact of new technologies on the educational system depends on a host of factors outside the control of a single organization or initiative. At the same time, the Carnegie Knowledge Media Laboratory is poised to carry out the kind of research and development that can demonstrate how new technologies can transform key aspects of teachers’ work and professional development. Through strategic initiatives and the national reach of the Carnegie Foundation, the KML can help educators to build the understanding, resources, and support needed to use emerging technologies in new ways to transform the development and dissemination of knowledge among teachers at all levels.

Making Teaching Visible

Already teachers can get access to lesson plans, standards, syllabi and other teaching resources through the Internet. In some cases, they can see the work of students in other schools and classrooms by
visiting recently created school websites. Nevertheless, while the possibility to place many of the artifacts and resources of teaching online seemed particularly promising initially, in our work at the KML, we have seen that simply making a large number of teaching-related materials available through the Internet does not provide easy access to the ideas and expertise that went into the development of those documents.

For example, the Internet is often used primarily to present the same kinds of lesson plans or syllabi that one can receive in a paper format. Furthermore, although some sites link these lesson plans with related resources, student work, or, increasingly for K-12 work, lists of standards, relatively few integrate sites these materials with the reflections and examinations by faculty that can make visible the thought that went into the design of courses or lessons or what the faculty member learned in the process. As a result, many critical aspects of teaching and learning—classroom discussions and interactions, relationships among students and between teachers and students—remain invisible and unexamined and the culture and character of classroom activity remain undocumented. Under these circumstances, viewers cannot easily assess the value of many of the materials that exist online or learn much about how to build them into their own teaching practice.

In contrast, the websites that the KML has helped to develop over the past three years explore new ways of integrating teachers' reflections and conclusions about their teaching with extensive collections of their materials—including syllabi, assignments, student work, rubrics, images from the classroom, and videos of classroom discussions and presentations (Iiyoshi, Hatch, and Pointer, 2000). Over the next five years, we seek to expand this initiative on “making teaching visible” to develop new and even more succinct and accessible formats for organizing and displaying teachers' knowledge and to explore the possibilities for creating school websites that capture and convey the ideas and practices of particularly effective programs and institutions in K-12 and higher education.

Building Teachers' Knowledge

In addition to the growth of online teaching materials, numerous campuses and organizations are at work creating online courses and web-based learning platforms. Already, many universities have “virtual offerings”—for students, alumni and others—and organizations like the “virtual high school” are creating online classes that give younger students across the country access to faculty and subjects that might not ordinarily be available to them. Web CT, Blackboard, and other companies are establishing online platforms that foster communication and the sharing of resources among students and faculty. But so far these courses and platforms are used primarily for the conventional delivery of information not the production of knowledge or the generation of new ideas. In order to create “knowledge-building systems” in which many faculty can share their ideas and build on the work of others, they need tools and resources that even those without extensive technical expertise can use to make their teaching visible.

The KML is currently developing a variety of tools and online portfolio templates that can be built into online learning platforms (Figure 3 & Figure 4). In conjunction with articles, presentations and online guides already in development, these tools and templates will provide faculty with the means to collect and organize their teaching materials and make what they have learned available to others. Furthermore, we will work with those who are developing these platforms to take advantage of the possibilities that these kinds of tools and others can offer to faculty. By prototyping tools and templates in this way, the KML will increase the chances that faculty across the country have relatively easy access both to the materials and expertise of their colleagues.
Creating a Professional Knowledge-Base

Along with the growth in the forums and platforms for sharing their examinations of classroom practice online, faculty at many levels are also encountering more online opportunities to discuss one another's work. Many schools, departments, disciplines, and professional organizations are already sponsoring listservs, discussion forums, "virtual chats," and online conferences. However, our experiences at the KML and our work with others in the field suggest that these resources remain underused; they remain the province of those who are most interested in technology, and they do not necessarily lead to the level of critique and discussion that can promote significant and widespread improvements in teaching practice.

In our own work at the KML, we have created a "gallery for the scholarship of teaching and learning" (http://www.carnegiefoundation.org/KML/) in which faculty can view some of the multimedia examples that we have developed in conjunction with CASTL faculty (Figure 5). Furthermore, we have pioneered the development of a virtual workspace that can support the review and exchange of many aspects of teaching including videos, images, student work, assignments, reflections, and articles and presentations (Figure 6). This workspace has grown into a rich resource with contributions from over 200 faculties from the K-12 and higher education programs of the Carnegie Academy of the Scholarship of Teaching and Learning (Iiyoshi, 2000). Yet, despite the possibilities of the virtual environment, the faculty who view these materials often respond in the same way that they do to materials they find in journals or hear about in workshops or presentations. While they refer to and draw on these materials, they seem to be more likely to use this material "offline" either in the development of their own work or in face-to-face discussions or private email exchanges.

Figure 3: Tool Example

Figure 4: Portfolio Template Example

Figure 5: KML Gallery

Figure 6: Carnegie Workspace
In order to better understand how to stimulate and support online opportunities for communication, exchange and peer review, in the next year we plan to examine the most effective sites and contexts for the exchange and development of knowledge of teaching. To follow-up on that research, in conjunction with our partners in other Carnegie programs, we plan to establish a small number of web forums, galleries and exhibition spaces that create a context to display representations of classroom practice, and more significantly, foster the critical examination and use of those representations. For example, as part of a major initiative on learning in the liberal arts carried out by Carnegie and the Hewlett Foundation, we expect to work with selected liberal arts colleges to create websites that capture their approach to learning and provide the materials and information that can be used to assess that approach. Ultimately, we expect that these sites could be accessed through a web-based gallery that facilitates comparisons and fosters exchanges across colleges. In this manner, we hope to contribute to the development of a professional knowledge-base that extends beyond the individuals and across institutions.

**Imagining a Future that Demands High Quality Teaching**

Together, these major initiatives of the KML are designed to contribute to a future in which many faculty members can be involved in very different kinds of activities than they engage in today:

We imagine that faculty will begin planning learning activities by looking not only at related syllabi and lesson plans but also by examining the analyses, ideas and knowledge that have gone into the teaching of their colleagues. In the process, they will also be able to access student work and faculty comments and evaluations so that they can develop their own capacity to judge their students' learning and compare their students' performances to others.

During their courses, faculty will put many of their assignments and resources online, and students will be able to submit some or all of their work in an electronic form. As a result, as the course proceeds or afterwards, with relatively little effort, faculty will be able to create web pages or "electronic portfolios" that illustrate significant findings and analyze key artifacts and resources.

After the completion of a course, should they wish to, faculty could contribute their web pages or "portfolios" to archives and forums organized by their school, discipline, or professional organizations. These archives and forums could provide a platform for deep and rich discussions of the teaching taking place in many levels across the country. In turn, these models of teachers' work and the related discussions could inspire others to make changes in their own practice and document the results.

While these activities focus directly on using new media and emerging technologies to develop a high quality teaching force and create an accessible professional knowledgebase, they also create opportunities for many people to see what really goes on in classrooms. By making teaching public online, for the first time, administrators and policymakers will be able to see what really goes on inside schools and classrooms. Should faculty or schools and colleges wish to, they will have the materials and the means to help parents and other members of their school communities to see beyond grades and test scores, instead, they will get a glimpse of the kinds of classes and work in which students are involved. As some schools and colleges make the teaching that goes on inside them public, students and their parents may well begin to expect to be able to view the teaching that goes on in others and to demand the kind of high quality instruction they can see in some of the most advanced schools and institutions.

It is these kinds of demands to see, analyze, and understand teachers' work that require changes in priorities. Those changes in priorities, in turn, can create changes in the ways time is spent. With new demands to see what is really going on in classrooms, K-12 teachers may be able to shift some of their time so they can engage in the kind of reflection and professional development they need to teach effectively and efficiently. Similarly, this kind of demand can begin to influence the formal and informal reward systems and provide some new incentives for faculty in higher education to focus on their teaching and give teaching the attention it deserves.

Abstract: The purpose of this research is to establish a community model in a large number of classrooms. “Rice Club” is a Web community to promote collaborative learning with a TV program. Teachers and students exchange their opinion on the TV program and relevant practices on the Web. The result of log analysis and interviews to the teachers show that the choice of communication tools is conducted by intentions of the teachers and their curriculum.

Introduction

NHK educational channel has been broadcasting “Okome,” rice in Japanese, as a series of TV program for elementary school’s students since April 2001. They learn about rice from various aspects, such as cultivation, gastronomic culture, and circulation of rice. Inagaki et al. (2001) developed “Rice Club” which works on the Web for inter-classroom collaborative learning. It has four types of asynchronous chatting board (BBS). Each BBS plays a different role for collaboration (Table.1). Kurokami et al. (1999) pointed out that it is necessary for inter-classroom collaboration to have both personal communication and classroom communication. As the solution, the four types of BBS in Rice Club is designed to cover both levels of communication.

Method

For encouraging to build the Web community, this project started with 13 invited classrooms on April 2001. The coordinators explained how to use BBS as occasion demands. By the end of March, 65 classrooms participated and 10,258 messages are currently on the BBS. We focused on the longitudinal change of the numbers of opinion on each BBS. It will reflect the qualitative shift of communication in classrooms. In addition, to grasp the purpose of teachers’ usage of BBS, interviews to 13 teachers including 9 invited classroom teachers and 4 volunteer classroom teachers are conducted.

Result

From the trends of messages and the BBS (Fig. 1), the quality of the Web community shifted from training with non-friendly communication in all participants to intensive collaboration in the specific classrooms. In the beginning, they used Open-ended Type boards for a training to send topics triggered by the TV program and to find out suitable classrooms for collaboration. By September, about a half-year

</tr>
</tbody>
</table>

Table 1. Types of BBS
passed of the grade, Specific Type boards and Diary Type boards became to be used much more. The students had well consciousness for the partner and grew up messages about the focused theme in the Specific Type boards. On the other, Diary Type boards tend to use for wide open communication among various classrooms.

From the result of interviews, three types of collaboration are extracted: Open Collaboration, In-depth Collaboration, and Mixed Collaboration (Fig. 2). These differences are caused by an influence of teacher's attitude toward their practice. In open collaboration, studentes made short term collaborations with any other students from any classrooms. The teachers let their students to use Open-ended type and Diary type boards. On the contrary, the teachers who expected In-depth collaboration, had a tendency to fix the classroom to exchange opinions and narrow the argument down on a specific theme. The theme was decided through the negotiation on Specific Type board. Mixed Collaboration was used in order to the both purpose of the above collaborations.

Conclusion

From the log analysis, it is showed that the quality of community gradually changed from non-friendly communication in all participants to well-consciousness collaboration with a specific partner. In addition, it is clear from the interviews that there were three types of collaboration by the purpose: Open Collaboration, In-depth Collaboration, and Mixed Collaboration. In a conclusion, intentions of teachers were clearly concerned for collaborative learning. That is, curriculum of teachers affects process of students' collaboration. Therefore, differences in types of BBS are well understood by teachers and students and used as we designed. To promote collaboration on the BBS more, we should strengthen the feature of each BBS.

ABSTRACT: Alberta recently mandated an ICT Program of Studies that requires the infusion of digital technologies into core curricula and across all grades. Effective implementation of ICT demands that all teachers create inquiry-based, technology enabled learning environments for children. The design of digital and media rich learning experiences calls for a dramatic shift in teacher preparation. Student teachers must routinely encounter the effective infusion of technology in all aspects of on-campus learning as well as in classroom placements in schools. This paper describes the design, implementation and evaluation of an undergraduate seminar offered to student teachers in the fourth semester of a two-year degree program at the University of Calgary. Outlined are ways in which fundamental issues in technology integration were addressed, how successes were achieved, and how discoveries from the first two seminars direct on-going modifications.

In September 2000, teachers in Alberta, Canada began a three-year implementation process for an ICT Program of Studies (Alberta Learning, 2000). This innovative curriculum, demanding the effective infusion of technology for communicating, inquiring, problem-solving and decision-making in core curricula, raises important questions about what it means for students to think and learn with the full range of digital technologies that are so much a part of today’s changed—and changing—world.

Educational technology research (Clifford & Friesen, 2001a; diSessa, 2000; Goldman-Segall, 1998; Jacobsen & Goldman, 2001; Papert, 2000, 1980) and the experience of the Galileo Educational Network (http://www.galileo.org) paint a similar picture of what thinking and learning need to look like in a knowledge era. We no longer live in a world in which information is scarce. The old certainties of a world defined by four classroom walls and impermeable boundaries have disappeared forever, replaced by global interdependencies and complex systems that require flexibility, responsiveness, and imagination. Overwhelmed by information from a wealth of sources, students desperately need the skills to create new knowledge, not just consume the old. Problems do not come neatly packaged, defined-in-advance, and amenable to the rote application of familiar strategies.

Our society can no longer afford to think of engaged learning, nimbleness, creativity and commitment to action as educational embellishments to “the basics”. Multiple and conflicting perspectives are not problems to be fixed, ignored or eliminated; they are the way the world works. Our human survival depends on an ability to learn new things, imagine creative possibilities and design useful solutions in deeply ambiguous and confusing situations. It depends on our ability to teach our children how to do this, too. And thus, questions of how to prepare a new generation of teachers, many of whom have been schooled in old ways despite their relative youth, are increasingly pressing in their urgency.

NEW WAYS OF LEARNING DEMAND NEW WAYS OF TEACHING

Today’s classrooms do not look much different than they did 20 years ago when schools began to invest heavily in technology. While recognizing that there are pockets of genuine innovation in classrooms, schools, and universities across North America, we feel confident in making a few generalizations about the current state of affairs. First, while many school and university students are using technology in their personal lives in a wide variety of ways, they are not using computers very extensively in classrooms in order to learn effectively in a variety of subject areas. The gap between presence and use of technology is particularly wide in high school (Cuban, Kirkpatrick & Peck, 2001). In fact, there is a growing “digital divide” between what students actually do with technology at home and what they are allowed to do in school. A growing number of students routinely expect their school computers to be out of date, connectivity to be slow, networks to be unstable, and their teachers' knowledge and confidence about technology to be significantly less than their own.
A second general trend is that many classroom teachers and faculty members in teacher preparation programs lack confidence in their own ability to think broadly with technology. Conventional models of professional development, like workshops and courses, have not been particularly successful in helping educators find ways to integrate technology for learning. Related to this second trend is our third observation that even education faculty and teachers who feel confident about their own ability to use computers for professional tasks often feel uncertain about how to use technology in their teaching. Almost by default, visions for the use of technology for teaching and learning are often created by IT specialists who are not educators. Network designs and levels of student access are often determined according to what is standard, easy to monitor and maintain, rather than according to what is educationally sound. Dominant curriculum models and assessment agendas tend to emphasize course delivery and information-transfer rather than knowledge creation and designing something new. While there are thousands of examples of digital media objects and teacher-created units and lessons that claim a meaningful technology component, there are far fewer authentic images of the effective and imaginative use of technology to create new learning experiences.

Teachers and leaders in the schools and school districts are looking to new teachers to shore up the gap between technology presence and use. However, our fourth observation is that the current generation of student teachers simply do not routinely infuse technology in their own learning and teaching, and thus, too few of them graduate with the skills and experiences that are needed to transform today's classrooms. People entering the profession today are as unlikely to have experienced technology-rich, constructivist learning environments as their more experienced colleagues in schools. There is a great deal of talk about constructivism on North American campuses, but very few actual examples either on campuses or in schools of how to live, learn and lead in these ways.

TEACHER PREPARATION AND TECHNOLOGY INTEGRATION

A shift in thinking is required for teacher preparation that is similar to that needed in professional development for classroom teachers (Clifford & Friesen, 2001b; Jacobsen, 2002, 2001). It is simply not good enough to teach the next generation of teachers in ways we were taught. Student teachers must routinely encounter the effective infusion of technology in the normal course of their learning at the university and in their practicum placements in schools. The three of us have co-taught students teachers about integrating technology into their learning and teaching for two years. Our planning for this special topics seminar on integrating technology across the curriculum was guided by our vision of engaged learning and educational reform (Clifford & Friesen, 2001b, 1998, 1993; Jacobsen, 2002, 2001), and our commitment to address the kinds of concerns that we outlined at the beginning of this paper. Our seminar was not about technology; it was about teaching and thinking with technology. Moving well beyond skills acquisition or a focus on software applications, we instead created a context of use within which student teachers learned by designing learning opportunities for real children in real classrooms.

Opportunities were created for student teachers to learn in just the ways they will be called upon to teach children (Clifford, Friesen & Jacobsen 1998). We drew on what we know about good professional development practice: (1) technology is best learned just-in-time, instead of just-in-case, (2) planning, designing, implementing and evaluating are best done in collaboration with others, (3) learning must be situated in authentic, challenging and multidisciplinary tasks, (4) a culture of inquiry around technology for learning supports risk-taking and knowledge creation, and (5) teachers need intentional and meaningful opportunities to reflect on professional development and growth.

**Technology Is Best Learned Just-In-Time, Not Just-In-Case**

In our seminar, student teachers took advantage of new technology-enabled learning spaces in the Faculty of Education. Our learning environment leveraged the ubiquitous and unfettered access to technology in the seminar space (i.e., 16 networked workstations) and also in the larger public learning spaces (i.e., additional workstations, multimedia development suites, scanners, digital cameras, CD burners, and so on). The fluid access to technology tools, Internet access and to each other enabled students to gather around a workstation or deskspace to collaborate, and to move out into public spaces as needed. The permeable environment permitted flexible arrangements and grouping, and also provided ready access to other experts (i.e., Faculty support staff). Technology skill was developed in the context of developing a web-based portfolio, completing a group-selected focused technology task, constructing an integrated, multidisciplinary unit of studies, and carrying out an independent inquiry project in the field.
“Oh, easy for Leonardo”

Our first task seemed simple enough; students were required to engage with the program of studies, and publish a reflective response on a web site they themselves had to design and maintain. Predictably, it sent many into a tailspin (not unlike that experienced by seasoned classroom teachers and faculty members when they attempt a new technology project). Some students cried, a few complained, and many were worried about a perceived mismatch between their present ability and our expectations. Some students had created web pages before, and set to designing their web site at once. Others worked with us to learn how to use the template and how to upload their finished sites to the university server. Each time a new site went up, there were whoops and squeals and broad grins of pure delight. Students felt the special rush of seeing their own work on the web. They were like parents with a newborn – even though some of the initial sites were a little plain and a bit wrinkled, they were beautiful to their creators.

Several of our students talked about “being inspired into a culture of use” which is different in kind than the application focus of many preservice teacher courses on computers. The pervasive assumption of most courses available to student teachers is that everyone needs to learn the same technology skills at the same time before they can do anything meaningful with them. Different assumptions permit new possibilities to emerge. We concentrated on just-in-time, not just-in-case, instruction with technology applications. We introduced meaningful, challenging and multidisciplinary tasks that posed complex and meaningful learning problems, and that enabled a host of possible solutions. In the context of these tasks, the three of us coached and guided individuals and groups of students to design creative solutions, and to acquire the skills and competencies they needed to solve their problem in the way they wanted to approach the task, and respected their individual starting points and needs.

Collaborative Planning, Design, Implementation And Evaluation

All of our approaches to using and learning technology in the seminar were in service of actual design tasks, not in service of learning technology for its own sake. We put student teachers in the position of the children they are going to teach. In collaborative groups, students completed one of eleven tasks initially designed for kindergarten to grade eleven students. The tasks required little prior experience with technology in order to get started. However, because of the nature of the tasks, there was no upper limit on the sophistication of technology use that was possible. Thus, there were steep learning curves for all students no matter what their starting point. Everybody got to sweat the same, all students experienced the value and necessity of working in teams to build on the strengths and diversity in the group, and everyone began with the experience of actually designing and constructing a solution to an interesting problem.

Situating Learning In Authentic, Challenging And Multidisciplinary Tasks

Planning for engaged student learning (NCREL, 2000) and technology integration requires an applied understanding of project, instructional and task design. To move beyond the “add on” approach of using PowerPoint™ or word processing as ends in themselves, teachers need to think and plan carefully about how to infuse technology in teaching and learning. Working in small groups, students collaborated on the design and development of an Integrated Unit of Study for authentic and meaningful integration of technology into one or more core curricular area.

A major requirement of the fourth semester in the University of Calgary program is that students engage in an independent inquiry project that is curriculum and practice oriented. Ideally, these are field-oriented projects at a school or Community Work Place site that enable student teachers to work side-by-side with classroom teachers and students to study essential questions to do with teaching practice. Students engage in critical inquiry in a systematic and intentional manner, contribute to ongoing efforts to improve teaching and learning at the field site, and demonstrate the understandings and skills acquired throughout the first three semesters of the Master of Teaching program. There is an expectation that the students’ work will leave a legacy in the field. Inquiry projects were designed to immerse student teachers in challenging and multidisciplinary work that made a difference in the present. One of our students, Heather, learned how to construct and program Lego® robots alongside grade one and two students and their teachers in an elementary school. As the opportunity to work with robotics progressed through each grade, Heather became part of the coaching team, working with teachers and students right up to grade five. As her own expertise grew, the school came to depend on Heather’s contribution, her insights and her creative solutions. She focused her inquiry project on documenting and interpreting her experiences with young children and robotics. The result of the inquiry project is not simply a research report; instead, the inquiry process fosters closer connections between campus and field experiences, observations and learning.
Creating A Culture Of Inquiry Around Technology For Learning

One of the most powerful aspects of our special topics seminar was the intentional placement of students in enriched field settings for their inquiry projects. About one third of the class worked in schools in which the Galileo Educational Network provided on-site support to teachers to design new learning experiences via effective technology infusion. In most teacher preparation programs, field placements are more generic: students are matched to schools and partner teachers according to grade and subject specialty. This approach to field placements builds on the notion that the main goal is to make sure the numbers work given certain broad category matches. It assumes that, in essence, schools and classrooms are convenient places for student teachers to “practice”. Teacher associations, that vehemently argue that all teachers are equally excellent in exactly the same way, present an obstacle; to them, targeted placements smack of elitism. Our experience counters this view; we did not target “good” or “better” schools and teachers.

Instead, we asked ourselves: what energies can we leverage by placing student teachers committed to developing their ability to infuse technology into classrooms with experienced teachers who are also intentionally pursuing their own professional growth in this area? Given a four-month semester, we knew that we could maximize the impact of students’ on-campus work by placing them in field placements where the infusion of technology was also a priority.

Reflection On Professional Development And Growth

All certified Alberta teachers are required to complete an annual professional growth plan that includes goals, strategies and evaluation. Teachers are expected to consider the Teacher Quality Standard (Alberta Learning, 1996), the school division's goals and plans, and their own school's improvement plan when developing professional growth plans. While plans of such detail were not appropriate in a special topics seminar, we did reinforce the experience of our students throughout the whole MT program: the importance of cultivating reflective and thoughtful habits of mind about professional practice. To that end, our students prepared a professional growth plan throughout the seminar that included three self-assessments that were published as part of a web-based, electronic portfolio.

WHY DID THIS SEMINAR WORK?

The most significant indicator that our seminar was successful is the high caliber of the students' scholarship. The quality of their work, their thinking and their reflection was exemplary. Each student was able to meet seminar requirements for curriculum design, for planning and carrying out substantive inquiry, for reflection on professional growth, and for the acquisition of technology skills. We prepared a CD ROM of all the units of study that students created, and the focused tasks on which they had worked. From our perspectives both in staff development and in graduate level teaching, we have no hesitation in saying that each of our students left the class better prepared to infuse technology in their own classrooms than many experienced teachers. Many tackled inquiry projects at a level of complexity that approached performance expectations for graduate work. It was hard work. For most, there was a huge learning curve, coupled with a determination to dig in and learn what was needed in service of important ideas. That is, the culture of inquiry we talked about creating in classrooms became a living part of the seminar, itself.

Building on Diversity - We believe the exceptional degree of student success and engagement was an outcome of deliberate design and instructional decisions that were informed by our knowledge of the current state of affairs in schools and on campus. First, the space in the seminar was open enough for all students to define a place for themselves. We designed the seminar so that it required a wide range and diversity of experience, ideas and projects. From the first day, our students learned that it did not matter what grade or subject they were preparing to teach. We were not concerned whether they had extensive experience with technology or none at all. It was all right to prefer different platforms, different software, and alternative approaches to tasks than the ones we suggested. That is, we structured exactly the situation we wanted tomorrow’s teachers to create for their own students. Students came to see that diversity was not a problem to be overcome, but an essential resource on which we all can draw when asked to complete complex and demanding tasks together.

Insisting on a Pedagogical Focus - Second, all aspects of the seminar were centered on pedagogical issues rather than technology issues. There are two apparently contradictory consequences of a strong initial focus on technology skills acquisition in the common kinds of workshops and courses designed for those who are new to technology. The first consequence is that participants often seize on one or two of the applications they first learn to use, assuming that now
the job of covering technology is taken care of. This enthusiasm is apparent in how often teachers introduced to planning a technology enriched experience for students start with statements like this, "I was thinking of letting kids do Power Point™ reports on an animal they choose..." Jamie McKenzie (2000) uses the felicitous phrase "power pointlessness" to describe the careless adoption of an otherwise effective presentation tool as if it were the be-all and end-all of technology use in the classroom. The second consequence of an initial focus on skills acquisition is that such a focus feeds the growing sense of panic that sets in when many of us squarely face a harsh, but often unspoken reality about technology: no mere mortal can keep up with the innovations. No one in a classroom is going to win the race against new hardware, new applications, and new capabilities. There is always a new version, a new digital device or a new idea coming down the pipe. Considering the range of applications now available to students and teachers, and the rate at which new versions are introduced, it is easy to feel overwhelmed even by finding a starting place.

When student teachers can be convinced to give up the idea that they need to know this application, and this application, and this application, and accept that they will never know everything about every piece of software, they undergo a transformation. Many suddenly feel liberated. They feel a burden lifted when we say to them, "Look, there is no way you will ever be faster, more fluent, or more knowledgeable about the technology that is out there than all of your students. And you know what—that's okay. It actually gives you a whole lot more room to get important things happening. There are some things that the kids will always do better than you. Let them. And there are important things that they need to be taught. Your job as a teacher is to design rich and meaningful learning experiences. They don't know how to do that. You have to figure out what these applications are good for. The kids will figure out how to drive them."

It is often the ideas that accompany technology integration that intimidate teachers and university faculty alike. Teachers sometimes ask us, "If I start letting the kids use all this technology, what's happened to my role as a teacher?" Of course, what they are really asking is what will happen to me? Do I still have anything of value to offer? Confident technology users ourselves, we know that deep understandings of the character of inquiry-based learning and knowledge construction have never been more important than they are in digitally rich environments (Clifford & Friesen, 2001a; Jacobsen & Goldman, 2001). It is entirely possible to do foolish things with powerful tools just because they are there. Our challenge was to help our student teachers develop fluency with teaching and learning with technology, not just with technology, itself. A critical awareness of issues to do with technology integration was revealed when one of our students wrote to us about her reaction to the ICT program of studies and our talk about teaching and learning as the primary focus of the seminar. "I thought", she told us, "that only people who were against technology ever raised questions about ethics and values and what is worth doing. I was amazed to find it in the ICT program of studies, and to hear the three of you say critical things, too".

Team Teaching – The three of us worked collaboratively with one another and with the support staff who were available to assist our students. The seminar was enacted through the genuine collaboration and diverse range of skills that are required to get complex things done. We depended on our own collaborative efforts, and we valued and encouraged opportunities for students to access one another's expertise. This collaboration extended to the field placements, and the students contributed to and benefited from the diversity among teaching staff as well. In a world in which we know we must prepare students to work effectively in teams both to define and to solve problems in ambiguous situations, teacher isolation is a terrible problem. The culture of schooling makes it very difficult for teachers to form strong work teams. As part of helping student teachers both experience and understand the power of collegial support, we required students to become interdependent. There was no way that any student could meet the demands of this seminar alone. They needed each other, they sought out one another, and they had to negotiate all the ordinary troubles of working together as part of their learning.

CONCLUSIONS

A deep commitment to the principles that pervade the entire teacher preparation program at the University of Calgary guided the creation of our special topics learning environment. We opened spaces in which student teachers used ICT fluently for personal productivity in the creation and maintenance of scholarly work. Student teachers developed an understanding of Alberta Learning's (2000) ICT Program of Studies, and discussed implications for learning and teaching in their discipline/grade level and for their own professional growth plans. Students were articulate in describing the ways that technology had influenced their own learning and in describing the ways they had seen
technology play a role in others' teaching and learning. In groups, and as individuals, students wrote, communicated, made decisions, and conducted inquiry smoothly and effectively using technological aids if and when these digital tools contributed to those processes. Students intelligently questioned uses of ICT and were appropriately skeptical about naive enthusiasms and overly simple solutions. In the context of focused tasks and integrated units of study that they designed and created, students discussed the strengths and weaknesses of ICT in a wide range of applications.

In the course of this special topics seminar, students moved beyond being mere proponents of ICT usage, or already-hardened skeptics, and developed further as thoughtful professionals who choose and design tools appropriate for the tasks they needed to accomplish. Students developed an informed personal position on technology integration in education and articulated and defended that position with each other. In the context of their own creative work, student teachers encouraged children both to actively question the place of ICT in their learning and to make responsible use of ICT in their own work. In the course of this special topics seminar, students moved beyond being mere proponents of ICT usage, or already-hardened skeptics, and developed further as thoughtful professionals who choose and design tools appropriate for the tasks they needed to accomplish. Students developed an informed personal position on technology integration in education and articulated and defended that position with each other. In the context of their own creative work, student teachers understood and developed ethical dispositions and practices in relation to the uses of technology in the classroom. Finally, our student teachers developed a capacity for critical inquiry in the applications of technology in learning and teaching, an essential disposition given the rapid pace at which information technologies are transforming our world.

ABSTRACT: The Galileo Educational Network is an innovative educational reform initiative that brings learning to learners. Expert teachers work alongside teachers and students in schools to create new images of engaged learning, technology integration and professional development. This case study is based on the nine schools involved with Galileo in 2000/2001. Field visits and interviews (n=113) with Galileo staff, school administrators, teachers and students yielded rich information about the initiative. Indicators of success include: 1) demand for Galileo Network’s services, 2) corporate investment in Intelligence Online (IO), 3) satisfaction among stakeholders at each level of the initiative, 4) evidence of engaged student learning, and 5) evidence of transformed teaching practice. Essential conditions for the sustainability and growth of the Galileo Network initiative are described. Factors that both contributed to and hindered the success of the initiative are discussed.

The Galileo Educational Network Association (GENA) is a continuous professional development and research organization in Alberta, Canada, that focuses on the fundamental changes to teaching and learning required by digital media and technology. GENA’s expert teachers work in schools alongside teachers and students to create new images of engaged learning, technology integration and professional development. GENA works on-line to develop and share examples of innovative and high quality student work and sustains face-to-face initiatives via its website [http://www.galileo.org] and Intelligence Online (IO) professional development service. The professional development and leadership approaches of the Galileo Network are firmly grounded in current educational research, and Galileo Network members contribute to new knowledge by actively publishing and disseminating results of their efforts (Clifford & Friesen, 2001a, 2001b, 1998, 1993; Clifford, Friesen & Jacobsen, 1998; Jacobsen 2001).

GENA has developed a number of strategic alliances with private, corporate, community and government organizations to generate innovative approaches and strategies for professional development. GENA is a charitable organization that began operations in 1999 in office space provided by the Faculty of Education at the University of Calgary. The Galileo Network operates autonomously from any one school district or division as it pursues a province-wide educational reform agenda. The majority of GENA’s funding, both cash and in-kind, comes from a variety of government, private, corporate and institutional organizations. Each school division and/or individual school funds their participation with the Galileo Educational Network differently.

Classroom teachers need ongoing support and professional development for the effective implementation of technology for meaningful student learning. Conventional approaches to professional development for technology integration, usually short-term skill-based workshops and seminars about working the computer, do not transform pedagogy. What makes the Galileo Educational Network approach innovative is that teachers are provided with time during the school day to collaborate, to participate in professional conversations about practice, and to work with a trusted mentor who supports and extends their technology integration efforts. The professional development relationship is guided by essential principles of engaged student learning and high technology performance, and is responsive to the individual teacher’s current practice and needs. Therefore, the professional development is more closely aligned with mentorship than with coaching from the side. Far from being a set model, the GENA approach is generative, flexible and responsive to the individual teacher’s needs and ideas for his or her own learning. Galileo teachers start from where classroom teachers are in their development and beliefs. The individual starting point for each teacher is respected in much the same way that teachers respond to the diverse needs and capabilities of their students. Different questions and needs are honored, and projects that arise from the relationship come from the teacher’s current practice, beliefs and ideas about teaching, technology and student learning.
Transformational Professional Development

It is important to pause here, and provide operational definitions of key terms. A decade ago, Leithwood (1992) described a move towards transformational leadership, which he defined as school leaders and classroom teachers seeking meaning together as a community, and supporting individuals as they seek meaning in their professional lives. The Galileo Network's approach to transformational professional development extends this tradition by building mutually beneficial relationships at all levels of a school system at once with the goal of empowering teachers to be innovative curriculum designers, and to free teachers to author rich learning experiences with their students. Terms like empowerment and freedom are chosen deliberately to convey the vision of enfranchisement and democracy that is at the foundation of GENA's work in schools. The Galileo approach is not just about enabling, or making possible, although this is an important and powerful part of their work with educators and educational leaders. Galileo's approach to transformational professional development aims to empower teachers and school leaders to be learners themselves again, and to form supportive communities that are committed to staff and individual growth. Galileo teachers work alongside teachers to help them develop as learners themselves so that they can translate this new freedom of inquiry into the design, implementation and evaluation of meaningful, authentic and challenging learning experiences for children.

Research Context

The present evaluation of the second year of the Galileo Network's professional development initiative builds and extends upon a study conducted at three elementary schools involved with the Galileo Educational Network in 1999/2000, its first year of operations (Jacobsen, 2001). A goal of the present investigation was to expand upon findings from three schools by investigating further the relationship between teacher and student perceptions about classroom events, the role of the Galileo Network in schools, and the duty of leadership in supporting and extending professional development initiatives during the second year of operations. The study was essentially guided by two overall research objectives: (1) Evaluate the impact of effective technology integration on engaged student learning, and (2) Evaluate the impact of the Galileo Educational Network on teaching practice and transformed learning environments by evaluating the sustainability of these professional development initiatives.

Case study research methods (Merriam, 1998; Stake, 1995) were employed to identify appropriate sources of data, and gather information. Field visits were made to eight schools to observe daily classroom events and instruction, and to conduct in-depth interviews. Over one hundred interviews (n=113) were conducted with Galileo Network staff, school administrators and technical personnel, classroom teachers and students. Observations of whole class dynamics, small group collaborative work and individual student engagement in learning were made, and observation notes recorded. The 26 indicators of engaged learning and 22 indicators of high technology performance developed by the North Central Regional Educational Laboratory (2000, 1995) provided a conceptual framework through which interview and observational data was understood, analyzed and discussed.

This case study research was rarely a linear, step-by-step process that proceeded logically from data collection to analysis. Instead, "data collection and analysis is a simultaneous activity" (Merriam, 1998, p. 151). Analysis began by framing the present study in the context of first-year findings, and continued as both an iterative and recursive process with each site visit and interview. The triangulation of data and information from site visits, interviews and observations enabled researchers to analyze and report on themes, trends and understandings of the group as well as honor individual experiences and observations in a rich, thick description of the case. Interview data was evaluated using: (1) content analysis (Merriam, 1998) of themes and recurring patterns of meaning, (2) constant comparative method (developed by Glaser & Strauss, 1967, described in Merriam, 1998) to identify emergent themes and categories, and (3) narrative analysis (Merriam, 1998) to study experience via the stories that people tell and remember. Field notes, observation and reflection on site visits, photographs of learning environments provided rich data for content analysis, and also categorical aggregation and direct interpretation (Stake, 1995). Aggregation of instances that suggested trends and shared understandings of the group, along with direct interpretation of an individual's stance, contributed to the development of themes.

DISCUSSION

Initial findings that have emerged from this case study of Galileo Network's second year of operations are summarized as follows: (1) sustainability of the initiative requires a long-term relationship be established and
maintained between school teachers and Galileo teachers, (2) sustainability requires that teacher leaders who can champion the initiative be identified and cultivated; (3) the role of district and school-based leaders is vital to the effective establishment and cultivation of a inquiry-based learning environment in which teachers were prepared to take risks, and (4) indicators of success were focused on what the children could do differently, and how technology provided opportunities for learning that were previously unavailable. The context for these findings will be discussed in subsequent sections of the paper.

Transforming Pedagogy

Both philosophical and pedagogical barriers to innovation exist when teachers shift from information-transmission to designing technology-enabled, constructivist learning environments. When teaching roles change from content expert to designer of technology-rich, inquiry-based projects, some parents and educational leaders get nervous. A supportive and continuous relationship with Galileo Network teachers over an extended period of time is perceived by classroom teachers and school administrators to be an essential condition for achieving transformed teaching practices with technology. The Galileo Network recognized early on that in order to transform classroom teaching, they had to work at all levels of the educational system at once. To that end, the Galileo Network has formed strategic alliances with the provincial ministry of education, superintendents of schools, district technology and curriculum leaders, school-based administration, school teachers, parents and students to support the growth of innovative practices in schools. Educators can often be under intense pressure from the public, the ministry, the school board, their administrators, and even from themselves, to change practices and processes overnight. However, the pressure to change quickly is an unrealistic expectation, and Galileo teachers help classroom teachers to set realistic and achievable goals for inquiry-based learning and technology integration.

Creating Supportive Environments for Risk-Taking and Knowledge Creation

When asked to describe the nature of their on-site relationships with each teacher or group of teachers, co-founders Dr. Pat Clifford and Dr. Sharon Friesen explained that the work with teachers

...really showed us very clearly that there is no model for doing this...it's not models that make a difference, it's ideas that make a difference and it's relationships that make a difference. So it's in hearing what people want to do. It's just like teaching in a classroom where you work literally from where people are... because people can't be in any other place than where they are. You can't wish them to be somewhere else. They are where they are from the start. And so you listen to that. Where's your opening? And then around the opening they provide you, the job of the expert then, we think, is to say what could we put in place for this person, given who they are, what they want to accomplish, and what they're working with? So it looks different, as it ought to, for each person. We called it being responsive and... it's actually to say if you're going to have people work with kids in this way, you have to provide them, as teachers, a learning experience that's like that.

The intent of the Galileo Network initiative is to model transformed approaches to leadership, teaching and learning that inspire and foster inquiry in learners of all ages. Pat and Sharon believe that...

...the work we do here, it's not without huge impact and it's not about individuals. It's far bigger than any individual. You are equal to get involved in it. You have to let it go. It's the gift you give to people. But they pick it up in ways that you don't anticipate. It's far bigger than any person. So we may work with the people, but what we put them in touch with is a part of themselves that, I think, they're often apt to give up when they enter the classroom. And once they get a hold of it, they don't want to let go because they see the impact. It's right in front of their face. You see what's happening to those kids.

An ongoing and sustained relationship with a Galileo Network teacher provided some teachers with a safe and caring environment for exploring new approaches to teaching, and the motivation to continue when faced with questions and challenges from parents and other colleagues. For many teachers, the fact that Galileo teachers had been where they wanted to go was an important motivator for getting involved, and taking the necessary risks to change their teaching practice. Whether or not changes to practice are sustainable has a great deal to do with the ongoing nature of the relationship between teachers and the Galileo Network. Teaching practices are developed over years of experience with children, and years of observations in classrooms — hence, they are rarely transformed quickly. For a teacher to transform practices that have become comfortable, to abandon methods that have enabled
her/him to achieve some form of results with children, the teacher needs ongoing support and professional dialogue with other teachers who understand her/his concerns, and can provide images of how it can work with children. The teacher has to trust that the changes being made offer some relative advantage over what is being done right now.

Inquiry Based Learning With Technology

What is the nature of change that occurs when meaningful partnerships are formed between learners and digital media? Teachers who designed and implemented inquiry projects emphasized the importance of student questions versus teacher questions. One of the desired learning goals for teachers was to promote student’s meaningful and personal connections to the topic of study. Instead of designing integrated units or students’ projects with pre-determined outcomes, inquiry projects were designed in such a way that students’ ideas, questions and prior knowledge became an important contribution, and an assessment strategy was developed that accommodated multiple outcomes. Students made choices about questions that they would pursue in the context of the inquiry project, and formed collaborative groups based on shared interests rather than teacher-formed groups. Learning tasks were big and complex enough that students needed to rely on each other to gather the information needed to solve problems and generate solutions. Students shared their ideas and knowledge with their peers, not just with the teacher. Students were encouraged to use a variety of means to demonstrate their understanding of concepts and problems, from textual explanations, concept maps, and drawings to dramatizations, multimedia presentations, functional robots and web sites.

Teachers rarely used whole class instruction as a method of delivering the curriculum. In response to the student’s emerging learning needs, the teacher’s role became one of scholarly mentor and guide as she met with groups of students for discussion about specific problems, and with individual students who needed assistance. Within the context of a well-structured and challenging inquiry project, and with readily available guidance and instruction as they needed it from the teacher, students worked collaboratively with their peers to design creative, innovative and diverse projects. Instead of there being one best solution to a complex problem posed by the teacher, students were given the license to design alternate and unique interpretations and projects, and inquire into topics and questions that reflected their own interests, knowledge and understanding.

Different groups of students required different technology tools to create their designs and construct their projects. Technology skills were taught just-in-time in service of learning tasks and goals, rather than taught to the whole class at once. One group might need a spreadsheet program to model their data, while another group may choose to represent their understanding of relationships between concepts using a semantic mapping tool. To the extent possible, given the design and resources of the school, computers were at hand wherever and whenever the students needed them, rather than walking students down the hall to a computer lab for a booked amount of time each day. Novel solutions were created in schools where there were only 2–4 workstations available in the classroom. For example, at one elementary school, teachers negotiated arrangements whereby students could use computers distributed throughout the school and in other classrooms as needed for their projects. A culture of inquiry was created in this particular school such that students were trusted to work where they needed to be for their inquiry tasks and projects, and appropriate behavior was continuously demonstrated.

Among educators in Galileo schools, there was a monumental shift in the perception of the role of technology in teaching and learning. Through professional dialogue, mentoring and working alongside teachers with their students, the Galileo Network has facilitated a changed understanding of the intent and fundamental goals of Alberta Learning’s ICT Program of Studies, from an initial perception of an emphasis on technology, to an understanding of the emphasis on higher order thinking, inquiry, communicating, problem solving, and decision making. Teachers clearly regarded Galileo’s vision and methods as a focus on teaching and learning, which was a shift from their initial perception that GENA was all about technology.

Developing A Culture of Inquiry for Teachers

The Galileo Network worked with people at all levels of the educational organization in order to help build a culture that supports and expects reformed ways of teaching and learning with ICT. A social and political culture of reform and innovation, and the expectation that people would be charting new territory, helped to support teachers in making changes to their practice. An integral component of the culture of expectation in each of these schools was the support for change provided by regular access to onsite support and expertise, and the time to make optimal use
of the onsite professional development. Teachers felt energized and excited about the changes to their practice, and were convinced by evidence of student ownership, joy and success in their learning. There were many reasons why schools and teachers first became involved, and then were highly motivated to continue, with the Galileo Network: (1) The Galileo Network teachers have worked with children on innovative and successful technology-enhanced projects, and share many examples of high-quality scholarship achieved by students; (2) The reputations of Galileo Network staff as experts and innovators, and the personal relationship networks that these experienced educators and managers have established in the Alberta education system, attract educators, and provide a basis on which to build trusting and productive relationships; (3) The push in Alberta to implement the ICT Program of Studies provides an important source of motivation; the Galileo Network bridges a professional development gap in the province with regard to achieving the expected ICT learning outcomes with students; (4) Teachers’ desire for continuous professional development, and support while implementing a new program of studies, makes them highly value the opportunity to rediscover the learner and scholar within, and cherish the opportunity to work with dynamic, approachable and trusted Galileo colleagues; (5) The satisfaction of being involved with an innovative organization, and working side-by-side with energetic, enthusiastic and experienced Galileo Network teachers; (6) After participating in single or multiple projects with Galileo Network staff, the satisfaction of achieving higher results with students is a motivating factor for continued participation.

**Indicators of Success**

The first indicator of success is the continued demand for Galileo Educational Network’s services. There is a great demand from schools all over the province to get involved in the Galileo Educational Network. In its third year of operation, the Galileo Network initiative is growing from the current 9 schools in five school divisions to working in 18 schools in 7 different school districts in 2001/2002. A second indicator used to evaluate the success of the initiative is corporate investment in co-developing an online professional development service, Intelligence Online (IO), to extend and grow the Galileo Network’s capacity to provide support to teachers. A third indicator used to assess whether the Galileo Network has been successful in achieving their objectives is stakeholder satisfaction. Overall, it can be reported with confidence that there were very high levels of satisfaction among stakeholders at every level of the Galileo Network initiative. Conversations with Galileo Network staff and school administrators yielded positive indications that key school board personnel are not only satisfied, but are actively developing strategies to spread the Galileo Network initiative to other schools in their division. A fourth indicator used to assess whether the Galileo Network has been successful in achieving their objectives is evidence of engaged student learning. Instead of designing integrated units or students tasks that had pre-determined outcomes, teachers designed projects in such a way that students ideas, questions and prior knowledge become an important contribution, and developed assessment strategies that responded to multiple ways of being right. Experienced teachers became convinced of the value of an inquiry-based approach to technology integration when they observed the enthusiasm, interest and independence of their students. Teachers and school administrators commented on how learning was enhanced for students of diverse abilities, and that the quality of work achieved by many students went well beyond their expectations. A fifth indicator used to assess whether the Galileo Network has been successful in achieving their objectives is evidence of transformed teaching practice. The professional development support provided by the Galileo Network is much less about technology integration, per se, and is instead focused more on inquiry into fundamental teaching and learning issues. Teachers appreciated having ongoing contact with a Galileo teaching colleague who has lived experience with integrating technology with children and can assist in pedagogical, project and technology skill development. Teachers critically examined their practice and determine next steps for pushing their practice forward with the onsite support of the Galileo Network.

**CONCLUSIONS**

Sustaining learning environments that enable technology-infused, inquiry-based approaches to teaching require that a number of essential conditions in the school be maintained, of which this is a non-exhaustive list: (1) Supportive Leadership; (2) A Learning, Risk-Taking Culture Among Staff; (3) A Colleague, From Within Or Without, To Walk This Road With You; (4) Ubiquitous Access To Reliable Technology; (5) Time For Professional Dialogue And Connections; And (6) School Board And Parent Support. A number of essential conditions for the sustainability of the Galileo Network initiative within a school emerged from conversations with school leaders, classroom teachers and Galileo staff. Among these were: (1) Securing Sustainable Sources of Funding, (2) Building On-Site Capacity And Leadership, (3) Diffusion Of The Mentorship Relationships, and (4) Designing Learning Communities to Resist the Urge To Turn Back.
Key Factors that contributed to the success of the Galileo Educational Network initiative during the 2000/2001 can be summarized as follows: (i) the vision, commitment and credibility (i.e., reputation) of the founding members of the Galileo Educational Network; (ii) the effective enculturization and professional development of new staff who join the Galileo Educational Network (i.e., cultivation of a learning organization); (iii) an organization-wide vision and mandate for transformational leadership and educational reform in the area of technology integration for teaching and learning; (iv) authentic examples and images of best practice and engaged learning to share with school teachers; (v) active involvement of Galileo staff in teaching, coaching and mentoring within the classroom context; (vi) open and clear communication with, and support from, district and school administration; (vii) willingness and preparedness of school staff members to examine practice and to try new approaches to teaching and learning; (viii) maintenance and growth of a research agenda, and a mutually beneficial relationship with Alberta universities and research partners; (ix) the simultaneous development and cultivation of mutually beneficial relationships with key personnel at the school board/district level, the school level, and with corporate, public and private partners; (x) strategic leverage of existing district structures and personnel; (xi) widespread satisfaction of participant stakeholders at all levels of the initiative; (xii) a professional development model that is responsive to the needs and differences within and between school districts and schools; (xiii) ability to be innovative, flexible and responsive to stakeholders because the Galileo Network operates as an autonomous organization that is not subject to the political or bureaucratic constraints of any one educational, corporate, public or private partner; (xiv) building and extending upon innovative ideas, creative solutions and information on latest trends through strategic alliances with critical and political friends, corporations, public and private organizations within and beyond education; (xv) a focus on school-wide initiatives that permit buy-in as teachers feel able and willing to participate.

ACKNOWLEDGEMENTS

The present case study is part of a larger investigation funded by the Federal Office of Learning Technologies (OLT) entitled, "An Evaluation Of Learning Technologies Initiatives In Continuing Professional Development (CPD)", led by principal Investigators, Dr. Bert Einsiedel & Dr. Stanley Varnhagen, from the University of Alberta. The Galileo Educational Network sponsored this part of the investigation. The authors are grateful to the many school leaders, teachers and students who agreed to participate in this case study. The authors sincerely thank the two graduate students, Linda Flanagan and Diane Nowlan, who helped to conduct interviews and did an initial analysis of data and information collected for the study.

Student Perspectives of Workload Pacing in International Online Graduate Education:  
A Case Study

Diane P. Janes  
University of British Columbia

The Context: In 1997 the Distance Education and Technology unit of Continuing Studies at the  
University of British Columbia (UBC), Canada, in partnership with the Virtual University of the Monterrey  
Institute of Technology (ITESM), Mexico launched a five course post-graduate Certificate in Technology-  
based Distributed Learning (TBDL). (For details on the partnership see Bates and Escamilla de los Santos,  
1997). The first course in the certificate was offered in September of that year and by 2001 students  
participating came from over 27 countries with over 400 students taking the courses with UBC and more  
than 1500 students with our ITESM partners. The keystone to the design of each of the courses is  
collaborative online learning and constructivist interactivity.

This paper/presentation is a case study of one of these courses (Research and Evaluation Issues in TBDL).  
Using a quasi-Stake Responsive Model and participant-observation for data-gathering this paper will  
review the issues raised by the students, while the presentation will review the lessons learned and  
recommendations for future online collaboration and research.

Issues Raised by Students...Workload: In this course, one of the first issues raised by the students  
involved the concept of heavy workload. All of the learners were adult (ranging in age from early 20s to  
early 60s) with family, community and work responsibilities, in addition to their learning. Given the  
graduate-level nature of the course, a blend of reading, reflection, online posting/discussion and  
collaborative group work formed the basis for interaction and eventual assessment, if the learners were  
taking the course for credit (There were opportunities to take the course as an audit student).

As one student noted early on in the course: “...I've been wondering all weekend - as I write assignment 2 -  
how am I going to have the time to read all the postings that are going to arrive by Monday?...” [Student J,  
online posting, January 2001]

Another issue of concern surrounded the group assignments. Collaborative assignments required students  
to work together online through time zones, language barriers and different experiences. The group work  
culminated in a joint paper or project submission and students expressed concerns about: 1. the need to  
bright trust within the group as each member was unknown to the other and 2. how to focus the group. As a  
student asked for help, she questioned “...Should I look for people with shared interests or who have  
different backgrounds to complement my lack of expertise in certain areas?” [Student C, online posting,  
January 2001]

The third issue of workload does appear, as well, to be more an issue of groups in general rather than  
specific to online group work. As one student noted, “[The] Last time I worked with a group, was on a  
project proposal. I ended up writing the whole thing because the other people let me down....” [Student M,  
online posting, January 2001]

Working with Different First Languages: While this course was taught in English and all course  
requirements were in English, the two partners, UBC and ITESM, found a great deal of interest on the part  
of the international community. As part of the strength of the course, many learners with English as their  
second or third language joined the international collaborative online group work. Students who were  
experienced in working online with ESL (English as a Second Language) colleagues, offered this advice:  
“When you have ESL issues you also need to allow time to sort out what the non-native speaker of English  
is trying to say, unless their English is very good (as was the case with one of the Mexican students). As the  
only native English speaker, I...volunteered to be the editor. However, I found that I often wasn't certain  
what they were trying to say due to the second language issues. When I edited, I needed time to check  
back...to make sure I hadn't changed...intended meaning, which turned out to be the case a few times...”  
[Student Q, online posting, January 2001]
“Getting your feet wet” vs. “lurking”: One of the areas that instructional developers, online course designers, and instructors struggle with is how one might offer the learner the ‘safest’ way to enter the course and the learning. What we found over the five courses that make up the certificate, is that each student has his or her own way of coping and that often we cannot predict which, of the choices available to them, they might choose. The key is to offer options rather than one option. In this course, one student suggested, after finding the beginning introduction to the new concepts a bit overwhelming, that “…It might be worth creating a dynamic FAQ page in this course, which captures and presents these…[general and process] questions and responses…” [Student D, online posting, January 2001]

Another student acknowledged his suggestion but offered this rationale for letting these general and process questions and responses be encouraged early on in a course: “…I am just thinking out loud here so I could be way off base…Perhaps the confusion provided opportunities for people to "get their feet wet" by asking relatively safe information and clarification questions rather than jumping in with their own opinions. A way of hanging out in the “student union” developing the social context needed for dialogical teaching…” [Student N, online posting, January 2001]

This opinion, was followed up by another participant who noted that “…There's another point as well, though, which is that the learning styles of some (e.g. moi) contain less of the hanging out at the Student Union, discussing and arriving at a collective conclusion and more of the researching, cogitating and reflecting before we feel informed enough to venture an opinion. I think a rough parallel could be made between those who learn and retain knowledge through mainly oral means and those who need to see something written to absorb it.” [Student Z, online posting, January 2001]

Conclusion: In many circumstances, pacing the workload is both physical and psychological for the instructor and the learner. It is important to address the reality of the online learning as well as its perception by the new online learner. It has been the experience of this online instructor that once comfortable many initial workload issues become more familiar and less stressful. The instructors and the learners shared a number of lessons. The accompanying presentation will review these lessons and identify areas that need to be addressed by those new and experienced in the field of online teaching and learning.

E-Games: Improvisation through Open Platform Design

Marie Jasinski
Principal Lecturer
MindMedia
Douglas Mawson Institute of Technology
Australia
mariejas@bigpond.com

Abstract: A diverse range of instructional design and facilitation strategies are emerging as alternatives to content-focused courseware designed for self-paced independent learning. Improvisation through open platform design is one such emergence. My colleague, Dr Sivasailam Thiagarajan and I have been using improvisation as a fast, cheap and effective strategy to adapt, re-use and continually improve over 20 instructional templates we call email learning games. Improvisation allows us to play with the rules, not by the rules.

Introduction

Since 1998, my colleague Dr Sivasailam Thiagarajan and I have designed and facilitated email learning games with over 2,500 people worldwide (Jasinski, M & Thiagarajan, S, 2000a, Jasinski, M. & Thiagarajan, S, 2000b). An email learning game is a reusable text-based template. It provides a pre-structured process for guiding a group of participants through a series of tasks. These tasks are designed to progressively generate and process content around a salient issue. A game is played in several rounds and through a facilitated process, participants engage in activities like brainstorming, analyzing, evaluating, synthesizing, predicting and persuading each other. While individual games have a specific purpose and outcome, they all encourage the construction and sharing of new knowledge, understanding, perspectives, and insights.

Open platform design and the emergence of improvisation

Our work with email learning games has been accelerated by our practice of open platform design, where we provide a growing community of colleagues with access to our templates to use, improve, customize and return. We have found open platform design to be powerful in rapidly improving design and facilitation processes for these games and for confirming their usability in a range of contexts. Through this iterative and dynamic process, what has also emerged is the concept and practice of improvisation as an instructional design framework. Improvisation is a mix of ad-hockery and know-how.

Improvisation involves reworking precomposed material and designs in relation to unanticipated ideas conceived, shaped and transformed under the special conditions of performance, thereby adding unique features to every creation (Berliner, 1994 p.241).

Like improvisation in jazz, instructional design using improvisation is a disciplined craft that works creatively within a planning framework, yet can take advantage of the unexpected. In short: Improvisation does not involve the complete discarding of planning, but a change in how planning is done and in how the plan is viewed (Isenberg, 1987, p. 92).

Improvisation as an instructional design concept exploits and works with contradictions and paradox: stable and unstable, structured and flexible, predictable and spontaneous, planned and random, content and process.
Improvisation: dimensions of complexity

Weick (1998) offers a particularly useful insight that is both conceptually and practically relevant to the context of improvisation as an instruction design framework. As well as an all-or-nothing process, Weick suggests improvisation can also be incremental with varying dimensions or levels of complexity. This staged approach requires...increased demand on imagination and concentration (p. 544).

These stages range from interpretation (taking minor liberties with the original), embellishment (reworking parts of the original without changing it drastically) variation (new aspects are inserted but align with the original) to improvisation (transforming the original to create a drastically different version).

This supports the experience we have had with coaching practitioners to adopt and adapt our email learning games. The emphasis on experiencing, experimenting and incremental development, lends itself to work-based methodologies that support ‘designing-by-doing’.

Design jamming: playing with the rules not by the rules

The construction of email learning game templates and their subsequent facilitation, involves what we call ‘design jamming’, a concept adopted from jazz improvisation and applied to the instructional design context. Based on improvisation, design jamming is a dynamic and iterative co-design process of constructing, performing and adjusting instructional designs as a result of close contact with the learning audience and a community of colleagues. The essence of design jamming is to play with the rules, not by the rules.

Conclusion

Improvisation provides an alternative instructional design strategy for the fast changing environment of the online world for the following reasons:

- Small and incremental changes can be effected quickly, allowing fast responses to user requirements.
- Improvisation provides high levels of feedback and closer contact between teacher and learner.
- Design jamming involves co-designing with a learning audience and a community of colleagues allowing for rapid improvement of both design and facilitation processes.

Improvisation through open platform design is a complex game simply played. The key to improvisation is to play with the rules, not by the rules – or to create new ones.

Navigating the Information Space of a PC Computer-Based Aviation Flight Training Device: an Expert Evaluation of Information Search and Retrieval

Jeffrey S. Forrest, James L. Simmons, and Steven D. Zink

The Department of Transportation’s Federal Aviation Administration (FAA) administers aviation flight training and pilot certification within the United States. Beginning in 1997, the FAA began permitting the use of PC-based Aviation Training Devices (called PCATD’s) for flight training. Research has provided information evaluating PCATD interface design and usability, the transfer of learning associated with various PCATD related training procedures, and pilots’ attitudes concerning the PCATD concept. Most of the current research that has been applied to the PCATD system has focused on assessing simulation fidelities and their influence upon training effectiveness.

However, recent concern has focused on problems associated with a “multidimensional information space,” since a PCATD system is analogous to the computer based interface or “glass cockpit.” PC-based flight displays have introduced a new concern regarding human factors identified as “navigating through an information space.” These systems must balance the considerations of determining what information should be provided with properly designed features that enable successful operational control by the user.

The particular PCATD used in this study, a commercially available Jeppesen Model FS-200AC, operates in essentially two modes: (1) a full-screen “glass simulator” mode, showing a view from the pilot’s seat of the full aircraft instrument panel, including a modest amount of ground features such as runways, and a “map-screen” mode, essentially showing representations of aviation charts. Thus, three-dimensional information is simulated within a two dimensional electronic environment.
The goal of this study was to identify factors affecting the user's ability to navigate and find information identified as necessary for the enhancement of situational awareness while using the PCATD's map-screen. Five expert flight and ground instructors evaluated PCATD system. These experts were given a basic orientation to the PCATD hardware and software; specifically, they were shown how to "toggle" back-and-forth between the two main modes of presentation. They were then asked to fly a series of "precision instrument approaches" to various runways contained in the database. Expert evaluators were not given specific information about either the precision instrument approaches (e.g., altitudes, headings, radio frequencies, etc.) or related data contained within various presentations in the map-screens. Thus, they needed to successfully formulate and execute searches using the map-screen for precise information needed to successfully complete each task.

Although the relatively small number of expert evaluators to this study precluded the usage of inferential or parametric statistical analysis, the experts were able to describe relevant issues of situational awareness, information searching, and knowledge are generally qualitative in nature by the use of open-ended questioning.

Overall, the experts reported that it was moderately difficult to locate and identify tools inherent to the map-screen that would help in formulating, searching, and retrieving information. Considerable exploration of icons, menus, and menu commands was needed to find pertinent information. The experts suggested the need for "finding aids," such as intermediary help menus or screens. The "zoom control" was particularly problematic, since it frequently contributed to the loss of situational awareness of the instrument approach being flown. The experts generally thought a "pop-up" quick-search function, ideally one that would allow for the use of a specific search term, would be the most helpful.
The Realization of Interaction in Cognitive Science Network Studies

Abstract. This article deals with the research of the realization interaction in the Finnish Virtual University's network-based studies of cognitive science in the autumn 2001. In this research, we examine the independent study of cognitive science which occurs through a network and the face-to-face study that takes place in cooperation in a group and the study that occurs in WebCT groups. The research seeks answers to the kind of interaction that promotes network-based studies and what causes a lack of interaction. The data has been collected by questionnaires and observation. The results indicated that students considered interaction with the teacher and other students more binding than self-directed study. The expectations and biases of students did not always correspond to the objectives of studies and thus have prevented functional interaction in a network.

1. Introduction

The objective of the study is to examine the realization of interaction in cognitive science network studies in the Finnish Virtual University. Good interaction with both the teacher and other students motivates and binds students to a greater degree of study (Richardson 2001). Interaction occurring through a network with the teacher and with other students is important from the perspective of learning, even if it is seen as far more laborious than studying face-to-face (Heikkinen 2000).

Interaction in a network is created by the relationship of interaction between a student, a teacher, technology, and the others who are part of the process (Ruokamo & Pohjolainen 1999). In network studies, interaction between the teacher and the student is limited, neither does it always occur in real time, and thus it presents its own challenge to successful study (Paakkola 1992).

Cognitive science can be studied in a self-directed manner, under the direction of the teacher, or with other students using a WebCT as well as on the Internet through contact teaching by studying in groups [http://www.virtuaaliyliopisto.fi/osahankkeet/connet/webct.htm].

In studying cognitive science, we utilize problem-based learning and exercises are performed face-to-face as group work (Hakkarainen, Lonka & Lipponen 1999). In the study, we examine the realization of interaction in network studies, self-directed study, as well as the adaptability of group work face-to-face exercises as part of network-based studies, and the types of problems that arise in interactive study through a network, and what the lack of interaction causes.

2. Background

The Finnish Virtual University Project [http://www.virtuaaliyliopisto.fi/English/index.php] has been established based on the information strategy of the Ministry of Education (for the years 2000–2004). Its concept is a joint virtual university in Finland consisting of several institutions for advanced learning, businesses, and research institutions that provides internationally high quality competitive training services. (Ministry of Education 1999).

The study of cognitive science in a network, in other words the Connet Project, has been planned since 1999 [http://www.virtuaaliyliopisto.fi/osahankkeet/connet/]. The project includes students from eight different universities: Helsinki, Tampere, Turku, Joensuu, Oulu, Lapland, Jyväskylä, and the Helsinki University of
Technology. The Connet Project was coordinated by the University of Helsinki during the autumn semester 2001; with respect to the University of Lapland, it was coordinated by the Centre for Media Pedagogy (Ruokamo, Syrjäkari & Karpinnen 2002). Basic studies in cognitive science began at all the universities participating in the project in the autumn 2001. Seventy-eight students had registered for the common e-mail list. Following their basic studies, the students will have the opportunity to conduct their cognitive science studies as network studies. Each university is responsible for a defined credit unit and studies will consist of modules chosen by the student.

Teaching consists of study periods in cognitive science, data processing, psychology, labour science, pedagogy, media education, cognitive technology, and the philosophy of technology. Teaching methods use the possibilities brought about by new technology that utilizes problem-based project-oriented method.

In network studies, learning is a process and a social event that needs for its support feedback and support from teachers as well as interactive study with the other students (Richardson 2001). Network students are generally highly motivated, even if the lack of social communication, interaction, and unclear expectations affect studying (Bonk 2001).

Interaction skills are important cooperative skills, but group-centred skills are broader in nature. The cooperative skills of an individual come into play only when in a community where the social activity that rewards them is organized. It is perceived that in learning, there are still too many individually centred learning models that prevent interaction and forms of communal activity. The individual needs an encouraging and socially respected operating environment. (Kuusinen 2001.)

3. The Objective and Research Questions of the Study

The study examines the realization of interaction in cognitive science network studies. Network interaction is created from different interactive contexts. The forms of interaction are the interaction between students, teacher and student, student and technology, and between the actors (Ruokamo & Pohjolainen 1999). The study examines the type of interaction that promotes network learning in the study of cognitive science and what causes the lack of interaction. A focus for examination is also self-directed study, inter-student interaction in WebCT, and the face-to-face study that takes place in groups with other course members. This study seeks answers to how self-directed study is located within the context of interaction. In multiform teaching, there is a reduction in teacher leadership; different forms of interaction, the purpose of which would be to support study, replace interaction between student and teacher (Paakkola 1992). Moreover, the study examines whether face-to-face group study best supports a student's motivation and learning in network studies, and whether it binds the student more firmly to his or her studies.

The culture of interaction in a network environment is a broad area and thus it places its own challenges on the work of research and its analysis. Research into network studies has increased in recent times, but most of the research has focused on analysing information produced for the network and the nature of student participation. The nature of a network-based social information structure and the characteristics of its interaction process have still to be studied whereas, in addition to the network environment, the entire interaction context with its discussions must receive attention. Learning is perceived as a communal process and interaction and, from the perspective of learning, it is created outside of the network environment. (Salo, Hurme & Järvelä 2001.)

4. Research Method

The study is limited to the study periods realized during basic studies in cognitive science in the autumn semester of 2001. The interaction in a network linked to study is a multiactor phenomenon. The phenomenon consists of students, teachers, the network tools of the learning environment, and other essential actors (Ruokamo & Pohjolainen 1999). In order to gain relevant information and new perspectives, interaction should be examined both quantitatively and qualitatively.

The data was collected by questionnaires and observation. The first questionnaire was performed using an Internet form and through e-mail before the actual course began. The questionnaire was sent to the 78 students that had registered for the common cognitive science students' e-mail list. The questionnaire measured the students' biases, expectations, and thoughts on the realization of interaction in the study of cognitive science.

A second questionnaire was performed at the end of the autumn semester courses. It was sent to the 78 students and to 43 students that had performed their practice work. The second questionnaire focussed on the realization of interaction in the network-based study of cognitive science and the use of WebCT tools. In
addition, the same questionnaire included questions directed at the students on the Project Working and Creative Planning and Communication and Cognition courses. The students on the Project Working and Creative Planning course studied in groups using the WebCT and the students on the Communication and Cognition course studied in face-to-face groups.

The perspective of teachers on interaction has been studied in a questionnaire directed at those teachers who gave their permission for the form to be sent. The aim has been to resolve how they think they have succeeded in creating interaction with the students, how group work has been articulated for network-based studies, and how they have experienced teaching through a network.

The project researcher has participated in cognitive science planning meetings as a participatory observer since the spring of 2001 and she has collected data using the teachers' and assistants' common e-mail list. Moreover, the researcher has participated as a student-observer for the video lectures on the Communication and Cognition course.

The Likert scale theorems of the questionnaires have been processed by quantitative methods using the SPSS statistics application. The participatory observations of the researcher as well as the data collected using open questionnaires has been analysed using qualitative methods.

5. Results and Conclusions of the Study

Eleven students (15.4 %) returned the first questionnaire and 16 students (13.2 %) returned the second questionnaire. The students encountered technical problems in returning both the Internet-based questionnaire and the one sent by e-mail in Word format. Twenty-seven forms were used in the study. There were more returned, but these were either empty or insufficiently completed or the student had not completed his or her network-based studies into cognitive science even though his or her name appeared on the e-mail list.

When examining self-directed study in a network in relation to other network interaction, students saw interaction with teachers and other students as more binding that self-directed study. Network interaction was seen as more binding in relation to time and place than self-directed study was. Part of the courses had to be completed as video lectures and study diaries. The defined times of video lectures and their related study diaries to a degree prevented graduate students and those students at work from completing the courses in question. Network-based study is generally seen as study independent of time and place and it is also marketed as such. In this relation, the pre-expectations of the students for study independent of time and place were not realized.

In the pre-expectations of the students before courses began, it was apparent that teachers did not have a clear picture of the possibilities provided by network-based teaching. The students in different localities considered important the help and guidance of a local guide and responsible person, the possibility to discuss courses, as well as the opportunity for technical support. Interaction with the teacher, especially in the initial phase of the courses, acts as a motivating factor for a course.

The interaction between the students in the study has been examined in the face-to-face group work on the Communication and Cognition course and in the WebCT group work on the Project Working and Creative Planning course. Face-to-face group work was conceived as being part of network-based studies. It was seen to make handling matters easier and students thus gained extra motivation for other network-based study. Typical problems related to the performance of group work, such as the heterogeneity of the group and the uneven distribution of responsibility, were seen in the face-to-face group work. The groups included students from different localities, so distances and timetables prevented and slowed study. The students did not consider slowing or preventing studies as the intention of network-based studies.

Based on the open questions in the qualitative examination of face-to-face practice, contact teaching arose as the best form of guidance, next was video-conferencing and in addition to these, e-mail. The students thought all forms of teaching supported one another, when they were well organized.

In the students' (N=11) pre-expectations, it was apparent that almost half the students (45.5 %) to a degree believed that WebCT supported interaction between a student and other students. Almost one-third of the students (27.3 %) did not have the same or a different opinion; less than one-fifth (18.2 %) was somewhat of a different opinion and only one student was of a different opinion. Over one-third of the students had pre-expectations that WebCT would to a degree support the interaction between the student and teacher. Only one student has the same opinion. Less than one-fifth (18.2 %) of the students did not have the same or a different opinion, similarly were to a degree of a different opinion and the same number were of a different opinion (18.2 %).

The group on the Project Working and Creative Planning course was formed though WebCT discussions field. More real-time discussion would have been needed at the beginning of studies and there would have been a
need for functional group working. There was limited experimenting with WebCT in group work, and it was not found to support the group’s joint writing process.

The students (N=16) evaluated the best interactive situations on a scale of 4–10. The best interactive situations among the students were created: 1. in practice work (mean = 9), 2. with e-mail (mean = 8.3), 3. in contact teaching (mean = 8.2) and 4. in WebCT discussions (mean = 7.6). Other interactive situations were realized using WebCT communication and group tools, the mean of which varied between 5.8–6.5.

The students (N=16) chose the best interactive tools on a scale of 4–10. The best interactive tools were: 1. some e-mail other than WebCT (mean = 8.5), 2. video-conferencing (mean = 7.8), 3. contact teaching (mean = 7.6), 4. in WebCT discussions (mean = 7), 5. WebCT e-mail (mean = 6.6), 6. the WebCT notice board (mean = 6.3), 7. telephone discussions (mean = 6), and 8. WebCT real-time discussion (mean = 5.7).

The fluent and versatile use of a learning environment appears to increase the entire interaction with the student, teacher, and other students. Those coming on a network-based course for the first time need guidance and instructions on the use of the learning environment and its tools. The use of WebCT in the study of cognitive science could include credits during the orientation phase to studies. In other respects, the biases of the students to computers, the use of e-mail and information searches were good in relation to their own skills.

The interaction between actors was observed using the common email list. E-mail functions as a common information channel between teachers, designers, and assistants. A common email list provides support for the actors to agree on plans, timetable, and meetings.

The objectives of teaching and the expectations of students do not always correspond to each other. A factor affecting interaction is the cultural background to the organization arranging teaching. The results of the research support the importance of guiding teachers and other students in network-based studies. Face-to-face study should be a part of network-based studies. However, self-directed study in a network should be respected and various opportunities should be provided on courses for interactive contexts.

The research has examined interaction from various interaction contexts as well as noted self-directed study and how it is located within the context of interaction. The research has become extensive and it has provided a lot of information and additional material for those organizations arranging teaching and for all those interested in interaction in network-based study and teaching. The information and additional material from the research can benefit educational purposes, the development of learning environments, and follow-up research both in Finland and internationally.

This study examined different face-to-face group work and the group work that takes place in a learning environment. The researcher’s personal interest has grown in studying face-to-face group work and the integration of group work into a network-based learning environment and thus into the appearance of the observed problems as well as into the development of the fluent and versatile opportunities for network-based group work.

Phone: 781-271-2018, Email: jfjohns@mitre.org

Abstract: This paper describes our experiences with sequence learning activities for intelligent 3-D practice environments. An intelligent practice environment offers learning by doing and learning by discovery in a realistic practice situation. A Knowledge-Based-System (KBS) improves learning opportunities with dynamic advice and feedback. An expert system monitors user interactions to provide dynamic advice for the expected sequence of user activities and updates objects in the 3-D world for the current state in the sequence. A prototype implementation is described for intelligent 3-dimensional (3-D) practice environments developed using a web browser, the Virtual Reality Modeling Language (VRML), JAVA, and an expert system. The VRML enabled web browser provides an interactive 3-D world where the user can learn and practice sequential tasks.

Overview

This paper focuses on our experiences integrating 3-D practice environments with a sequence learning strategy managed by an expert system. Sequences are a foundation for learning complex skills and high-level problem solving. An example sequence learning approach was developed to illustrate the capabilities of intelligent 3-D practice environments for mechanical skills training. This is an on-going research activity whose long-term success is largely determined by the maturity of the technology needed to implement the intelligent 3-D practice environments. The ability to implement a few working prototypes has been proven by integrating the technologies described in this paper. Our goals are:

- Understand the capabilities required to ensure users can learn by doing and discovery
- Identify and investigate useful learning strategies, such as sequence learning, that take advantage of the exploratory learning process offered by practice environments
- Develop a basic framework or architecture that supports re-using basic components
- Devise ways to separate practice session content from the basic re-usable framework

Cost is always an issue and affordability is a major objective. Finding ways to make practice environments an affordable solution is a critical success factor for adoption of the technology. There are two major cost considerations for this web technology, first we must be able to afford to develop the practice environments and second we must be able to afford to deploy the content to the users. One way of reducing development cost is to develop modular components that can be reused. There is a high reuse potential for the components we have developed. The expert system with its JAVA applet and VRML interface applet are reusable. The rule base for processing sequence learning procedural steps and goals is reusable. The sequence learning fact structure is reusable. The specific facts for the procedures and the VRML worlds are content specific and have to be developed as lesson content. Techniques for deploying content to the user will evolve as the technologies mature.

Sequence Learning Strategies

The objective of intelligent 3-D practice environments is to provide a highly interactive, realistic learning experience where the user learns by doing and by discovery. Sequence learning is an important component of learning complex skills and advanced problem-solving skills. Sequence learning strategies can provide practice and discovery activities for the user. To develop advanced skills, the user needs to practice solving a wide range of problems and handling different situations. A highly interactive practice environment encourages the
user to explore complex relationships and increases the development of advanced skills through self-motivated
discovery and problem solving activities. Sequence learning features of a practice environment are:
1. Monitoring and controlling the situation in the 3-D world
2. Recognizing goals accomplished by the user
3. Using facts and rules to recognize correct sequences of actions by the user
4. Offering advice and feedback for correct and incorrect sequences of user actions
5. Generating actions for the objects in the 3-D world based on the current sequence location
6. Dynamically controlling the behavior of objects in the 3-D world based on user actions.

Practice Environment Development Process

There are two main phases in our current prototype development process. First, the technology must be
developed and integrated to create the desired capabilities of the practice environment. Our research activities
have shown that it is critical for the technology to be sufficiently mature and robust to support the
implementation of the desired practice environment capabilities and learning strategies. Second, after a practice
environment has been developed and tested, learning content must be developed for the practice sessions.

Developing an intelligent 3-D practice environment requires software developers, instructional designers, 3-D
graphics experts, subject matter experts, and rule base programmers. The initial development of an intelligent
practice environment requires a technical team that can implement the practice environment with the desired
learning strategies. A robust practice environment can be developed with re-usable software components,
expert system rule bases, and expert system fact bases. Once a re-usable practice environment has been
developed, the focus shifts to learning content development.

Learning content development for an intelligent 3-D practice environment involves three critical activities in
addition to the traditional subject matter expertise required for creating a good learning session. For a sequence
learning practice session, the subject matter expert first decomposes the tasks into interactive actions and
sequences of actions that can be performed by the user. The behavior of objects in the practice environment is
identified for each user action and accumulated sequence of user actions. Second, 3-D worlds must be created
and populated with 3-D objects that support the required user interactions, controls, and object behaviors.
Based on the desired practice and exploratory activities, sensors must be added to the 3-D objects to control
their behavior and trigger actions, to manage user-controlled movement and placement of objects, to monitor
user interactions with the objects, to monitor the user’s position, and to control the state of objects. Third,
knowledge engineering is required to define the facts and develop the rules necessary to support the learning
and practice activities performed by the user in the 3-D world.

Example Prototype Architecture

Technology and especially the maturity of current technologies are critical to the development of intelligent 3-D
practice environments. For the intelligent 3-D practice environment illustrated in this paper, we used the
VRML External Authoring Interface (EAI) to integrate the Jess expert system with VRML practice
an expert system shell written in JAVA. The source code for Jess is available for integration with a practice
environment. Jess is also distributed with sample applets and console applications. We modified the Jess
expert system interface to include buttons for feedback and advice. Figure 1 shows the configuration of existing
products and developed software integrated to create an intelligent 3-D practice environment.

A simple knowledge base manages the sequence of practice activities, feedback, and advice for the practice
environment. A set of facts defines the practice activities, the sequence of activities, advice for each activity
the user can accomplish at the current time, and feedback when an activity is successfully accomplished. The
knowledge base contains a set of rules that manage the user’s practice activities and the behavior of objects in
the practice environment by determining which activities are valid at the current point in time and updating the
3-D world based on the current situation. Table 1 provides information about each of the interfaces in the
implementation.

Table 1: Interfaces in the Intelligent Practice Environment

Mechanical Skills Example

An example is the best way to illustrate the intelligent 3-D practice environment concepts. This example was developed to teach maintenance technicians how to perform shaft alignment tasks. Figure 2 shows a horizontal parallel misalignment correction practice environment. The expert system advice and feedback is displayed at the top of the screen. The user receives feedback from his actions in the expert system display. The expert system determines which activities the user can perform at the current time in the 3-D scene. State information from the expert system is used to activate sensors, animations, and user selections in the 3-D scene. The expert system display has two buttons that give the user access to advice and feedback at any time. The user requests advice with the advice button. The user automatically receives feedback when he accomplishes one of the active tasks. The effectiveness of the advice and feedback is dependent on the quality of the knowledge captured in the knowledge base.
The practice session in Figure 2 illustrates problem solving for a set of sequential activities that the user will accomplish in the 3-D practice environment. An example of the fact data for this sequence learning problem is shown in Table 2. The initial fact data is loaded into the knowledge base when the practice environment is started and the facts are updated as the user works in the practice environment. The data in Table 2 reflects the current fact set for the situation shown in Figure 2 where the user has completed steps 1 through 5 and is ready to perform step 6 in the sequence.

The rules in the rule base interact with the 3-D practice environment to activate objects that the user must work with to accomplish goals in the procedure. These objects include the dial indicator, the reset or zero knob on the dial indicator, the motor, and the motor mounting bolts. For step 6, the only active component in the 3-D practice environment is the dial indicator that needs to be mounted on the 9:00 side of the motor near the back mounting bolt. There were 3 active components in step 5 where the user was required to tighten 3 bolts in an undefined order.

The current rules implemented in the sequence learning rule base have the following behavior:
1. All goals for the current step are activated and can be accomplished by the user.
2. All goals in a step must be accomplished before activating the goals in the next step.
3. The user can accomplish the active goals in the current step in any order.
4. When requesting advice, advice for any of the active goals can be given to the user.
5. Feedback is automatically given to the user whenever the user accomplishes a goal or a step.
6. The user can request feedback identifying their current situation at any time.

Related Research

There are several research areas that should continue to have a positive impact on our ability to add intelligence to 3D practice environments to make them more effective training tools. 3D worlds offer a rich environment for visualization and expression of ideas. Researchers have already begun to populate and inhabit 3D worlds so they can gain knowledge about the unique challenges and potential of 3D learning environments. The interaction between man and machine is often viewed as a dialog. An effective practice environment needs to be able to participate in a meaningful dialog with the user(s) in a problem solving session. Two important areas of research aimed at improving the ability for man and machine to communicate are mixed-initiative interactions [Hearst 1999] and intelligent dialog systems [McRoy, Ali, Restificar, and Songsak 1999]. Researchers in these areas are developing new techniques to improve communications between man and machine through more meaningful and flexible interaction strategies. Collaboration among real and simulated users in multi-user worlds is another hot research area. Pedagogical agents [Lester, Towns, and FitzGerald 1999] are being created to act as teachers and tutors in future 3-D learning environments. Other researchers are simulating the actions of peers for team problem solving activities. Dynamic, real-time explanations [Callaway, Daniel, and Lester 1999] should increase learning effectiveness for future generations of practice environments.

Summary

This project is an on-going research activity. We have not conducted any large-scale user evaluations or trials. However, we are able to provide the following assessment of the current state of the technologies used for our experiments. The mechanical skills training example demonstrates the integration of existing technologies with
a minimum amount of software development. With the objective of making 3-D practice environments an affordable training solution, reuse was a prime consideration in the design of the implementation.

1. The Java applet encapsulating the Jess expert system is reusable and is not training content dependent.
2. The Java EAI event handler applet is reusable. A table linking the Jess fact base with the VRML nodes and sensors in the practice environment is content specific and must be created for each practice session.
3. The rules developed for the sequential activity knowledge base are totally reusable. These rules provide the logic for managing the user activities and VRML objects for a sequential procedure practice environment. The rules also provide the logic needed to determine the advice and feedback requested by the user with the Jess applet interface buttons.
4. The fact structure for the knowledge base is reusable for other sequential procedure practice environments. The facts are content specific and must be created for each practice session.
5. Reusing 3-D Computer Aided Design (CAD) objects adds realism to the practice environments. Reuse is never easy. The original CAD model designer's objectives are very different than those of a training practice environment designer. Inevitably, the objects must be edited. A good approach is to create a hierarchical scene with each object of interest in a separate VRML file. The 3-D scene is created as a composite of all of the individual VRML objects. The user's interactions are easier to monitor and analyze with a hierarchical scene composition.

A Historical Virtual Environment
for Archeology and Creative Writing Students

Eunice Johnston, Brian M. Slator, Jeffrey T. Clark, Gary K. Clambey, Shawn Fisher, James E. Landrum III, David Martinson, J. Liessmann Vantine, Justin Hawley, Joshua Dorothy, and Tim Rousch
Departments of English, Computer Science, Anthropology, and Biological Sciences
North Dakota State University, Fargo, ND 58105

Abstract. This project is an extension of ongoing efforts to develop Immersive Virtual Environments (IVEs) for education at North Dakota State University. This IVE recreates a Native American village and the adjacent fur trading post as they existed when they were inhabited in 1854 and also as the area appeared while being excavated by archeologists in 1954. One version will be used by archeology students who will learn the methods and reasoning used by archeologists; another version will be used by creative writing students at NDSU and at Fort Berthold Community College as they write historical fiction about the area. This presentation will focus mostly on the version being developed for use by creative writing students.

For the past several years, the NDSU World Wide Web Committee has been engaged in the development of Immersive Virtual Environments (IVEs) for education. These virtual environments, which focus on science education, especially understanding scientific method and reasoning, include The Geology Explorer and The Virtual Cell (Slator et al., 1999). A new development of these efforts is an IVE that will be used by archeology students and creative writing students; information about this project is available at http://vcell.ndsu.nodak.edu/fish-hook/. One version will have a 3-D fly-through, graphically rich interface and a teaching system for archeology. Much like the other IVEs created at NDSU, archeology students will use this version to learn scientific methods and reasoning by doing what an archeologist would do in the simulated environment. The other version, which shares the same basic content, is a largely text-based MOO; this version will be used by creative writing students at both NDSU and at the Fort Berthold Community College in New Town, North Dakota, who will write historical fiction based on their interactions with it. In both cases, the place is an actual Native American village, Like-a-Fishhook, and the adjacent fur trading post, Fort Berthold, an area in western North Dakota that was inhabited during the 1800s. Located on the Fort Berthold Reservation, home of the Three Affiliate Tribes (MHA Nation), this area will be represented as it existed in 1954, during the excavation process, and in 1854, when it was inhabited. It was inhabited by Mandans, Hidatsas, and various European Americans associated with the fur trade. Visitors will be able to "time travel" between the two time periods.

Like-a-Fishhook village was established by Mandans and Hidatsas around 1844. These two tribes had previously lived in separate villages, but decimated by a smallpox epidemic in 1837, the survivors banded together to build a new village of earth lodges on the Missouri River upstream from their old villages. In addition to hunting and gathering, the Mandans and Hidatsas cultivated corn, beans, squash, and tobacco along the river bottoms, and they continued their traditional trading with other tribes and with Europeans in the area. A fur trading company soon established Fort Berthold, and fur trade was important to the economy of the area for the length of its existence. The Arikaras joined the Mandans and Hidatsas in 1862. In the mid-1880s, the United States government pressured the residents of Like-a-Fishhook village to relocate to individual allotments on the reservation, and the village was abandoned. In 1947, despite protests by the Three Affiliated Tribes, construction of Garrison Dam began. Between 1950 and 1954, salvage archeological excavations were conducted by the North Dakota State Historical Society under contracts with the National Park Service and by the River Basin Surveys of the Smithsonian Institution. By late summer of 1954, the rising waters of Lake Sakakawea flooded the site of Life-a-Fishhook village as well as the best farmland on the reservation (Smith, 1972). The Like-a-Fishhook village and Fort Berthold area was chosen for this project for several reasons. In the 1800s, this village, the last earth-lodge settlement on the northern plains, was occupied by three separate and distinct tribes that maintained their cultural identities. In addition, European Americans and people of mixed blood were associated with the
village since shortly after it was first established. In the 1900s, the building of Garrison Dam, the struggle by archaeologists to excavate the area and save the cultural record before the area was flooded, and the inundation of this site and other tribal lands were important events for the Three Affiliated Tribes and for the state as a whole. The history of the area will provide a rich source of material for writers.

Although historical fiction should accurately depict other times and places, it frequently does not. The Like-a-Fishhook/Fort Berthold MOO will serve as a text that provides accurate, detailed information about this place. Visiting the MOO will simulate a field trip to a location and to times that would not otherwise be possible. The MOO interface, which presents authentic details through textual descriptions, interactions, and a limited number of carefully chosen images, is designed to stimulate the imagination of the students. As Ann Bertoff points out, "...looking, seeing, turns on the mind....students of composition and creative writing who do a lot of looking will learn that perspective and context are essential to interpretation. In short, they will learn habits of mind essential to critical and creative thinking" (Bertoff, 1981, p. 37).

The connection between print fiction and recreational MOOs and MUDs is interesting. Some role-playing, recreational MUDs have been inspired by works of fiction, especially by those of J.R.R. Tolkien, Anne McCaffrey, and Frank Herbert; on the other hand, participation in MUDs inspires some mudders to write conventional albeit not particularly meritorious fiction based on the authors' experiences in MUDs. Just as many students are motivated to learn science by environments that incorporate game-like strategies, we believe that students will be creatively inspired by immersion in a MOO environment. Because a MOO is a social environment and because this MOO will be visited by students from varied ethnic backgrounds, including descendants of the inhabitants of the village, this experience will introduce them to the challenges and concerns of depicting a multicultural society. Further, visitors who interact with each other as well as with various bots in the MOO will experience a sort of virtual improvisation that will help them to develop characters and to write dialogue. Creative writing students will have opportunities to write short narratives or poems about objects in the MOO; after a review process, excellent examples of these short writings will be attached to the respective objects in the MOO via an object called a "story point." These story points can be read by other visitors to the MOO. In this way, writing created as a result of interaction with the MOO, some of which will be displayed in the MOO and some of which will exist as conventional print media, will not only be creatively enhanced by the precision of the setting, it will also flow from the students' immersion in virtual time and space and their struggles with the cultural issues they find there.

The creation of this MOO, which represents a real space in two historical time periods, presents several challenges. Extensive historical, ethnographic, and archeological records were used to create the virtual depiction. However, how much prior knowledge of the subject potential users might have as well as cultural perspectives of language, time, and space must be considered. The number and type of visual representations to include in a largely text-based MOO is also a consideration. The engagement of the students who visit the MOO and then write about it will be determined by the use of surveys and interviews. The narratives they write as a result of participation in the MOO will be assessed for accuracy and creativity. Students' understanding of the concerns related to writing historical fiction and their ability to explain the decisions they made when writing historical narratives will be judged by reflective essays they will write after completing the process.

Abstract: This communication presents an educational and collaborative forum : DIACOM (Interactive Case Based Discussions for Medical Training). DIACOM offers a distance, continuous training activity, dedicated to physicians. Its principle is based on the sharing, confrontation and discussion about clinical cases. It can be considered as a more structured and collaborative approach of the discussion forums already in existence on the Internet. Its first function is to allow physicians to describe cases. It permit also to put them in touch with other practitioners, whose cases share common subject and important point of view differences. This operation is performed by a pairing process between described cases. This paper aims to introduce a description of the DIACOM interface module that makes collaboration and interactions between peers, effective and formative.

Introduction

Internet discussion forums constitute a means of communication used to enable the sharing of experiences, in distance education. In medicine, they are particularly interesting. But the themes discussed on these forums are of a general, theoretical or technical nature and rarely focused on the practical content of courses (Peraya 99). Moreover, many users prefer to add their own contribution rather than to try to make contact with someone who has previously related a similar experience.

DIACOM forum (Interactive Case Based Discussions for Medical Training) offers a distance, continuous training activity, dedicated to physicians. Its principle is based on the sharing, confrontation and discussion about clinical cases. In fact, its main function is to allow physicians to describe cases. It permit also to put them in touch with other practitioners, whose cases share common subject and important point of view differences. Thus, the DIACOM forum can be considered as a more structured and collaborative approach to the discussion forums. This operation is performed by a pairing process between described cases.

The DIACOM forum structure is composed of three modules. These modules are described in the second section. Before, in the first part of this paper, we present the medical context of this research work. Then we conclude through the interface module, by describing the collaborative sight of the forum.
A Medical Context

In medicine, learners have frequently to study practical experiences, called clinical cases. These cases studied individually, or by groups, stem from real practices and described by physicians concerning patients. This kind of learning is also called Problem Based Learning (PBL) (Barrows, Tamblyn, 80). In the framework of the Continuing Medical Education (CME), the case based learning approach is also performed. Internet has an abundance of websites that offer interactive clinical cases intended for physicians to train themselves (Interact - http). However, the more experienced a physician is, the less he seems to be content with a simple study of clinical cases. In fact, he would prefer to discuss about these cases with his peers. This is why, aware of this need of collaboration between practitioners on training tasks, continuing education associations still organise regular meetings. During these meetings, real cases are raised and discussed by participants. Firstly, these meetings allow practitioners to improve their own knowledge on a subject. Secondly, these discussions enable also to test physicians skills and to discuss about diagnosis or therapeutic management protocols that occur in their daily practice. Nevertheless, practitioners have less time at their disposal to actively and regularly participate to these meetings. Therefore, it could be interesting to allow physicians share and discuss their views, through the development of a distance learning system based on individual experiences.

Some kind of existing systems have a similar objective. These are Computer Supported Collaborative Learning systems (CSCL) (Dillenbourg and al., 96). In fact, their general functioning principle consist in making the learners learning in small groups, solving common problems and interacting each others. In the medical domain, constructing CSCL environments is very interesting for PBL (Koschman and al., 95) (Mendelez and al., 99). Some CSCL works aims at perpetuate the training, mainly by the way of discussions without considering any problem-solving angle for the system. For example, CONNECT (Baker and al., 99) concerns epistemic interactions between learners in a CSCL environment, dedicated to sciences learning. In CONNECT, the system analyse learners contributions and, thus, evaluate their similarities, in a textual analysis. The DIACOM principle is similar from the CONNECT paradigm. In fact, the learning method of DIACOM is also based on interactions between peers. Nevertheless, DIACOM is dedicated to medical training and doesn't focalise on textual contribution but on structured clinical cases. Moreover, CONNECT is designed for children education organized by a teacher. DIACOM is then designed for CME. Physicians have to learn from each other, by confronting their knowledge and their approaches of a problem. So, they train themselves, and above all autonomously, without any tutor or moderator.

The DIACOM approach is especially relevant when it comes to training practitioners in new medical practices or in domains, for which there is no established guidelines. So, as to raise discussions of clinical cases it is necessary to attribute to the forum, a specific medical topic. It is preferable for the forum to belong to the domains of medical research, and of technical, diagnosis or therapeutic innovations. In fact, in this kind of domain, physicians have their individual methods of practice. Consequently they could express their opinions and demonstrate a willingness to engage in discussions and to participate in training about the subject. So, the pairings and debates resulting from these topics become all the more interesting, efficient and valuable for the learners. The pediatric pain management domain corresponds to these criteria. As patients in this field are very young, consultations or clinical examinations may result in difficulties and complications that are uncommon in other medical fields. Moreover, the consensual guidelines for pain management are still quite rare in the pediatrics domain. Some reference books composed by scientific papers, show how much the pediatrician community is interested in the subject (Ecoffey and Murat, 99). Thus, the cases described in the forum can illustrate different solutions and strategies in solving problems. These are mainly based on a pediatrician's individual experiences of child pain management.

The following section deals with the three modules that make up DIACOM forum architecture.

DIACOM Architecture

DIACOM forum structure is composed of three modules : the data module that aims at making a list of various data's models used by the system ; the pairing module which is charged of the processing realized by the system to manage pairing between cases ; and, the interface module that manages interactions between users and the system.
The data module

DIACOM forum uses a lot of domain dependant knowledge and data, in order to help authors during their case description. These data aims also at performing the pairing comparison of cases. These data are managed by the data module of the DIACOM forum. This module is composed of a generic model, a specific model and a generated model.

Firstly, the generic model allows to generate a modelization of the case structure. In DIACOM forum, a clinical case is considered as a sequence of steps named scenes. Each of these scenes represent a collection of elementary concepts called entities and describing the patient features. In order to get through to the following scene, a scene must contain a conclusive action. This action represents the decision he has taken or he would take, in front of this situation. It contains also a modeling of the solving problem strategies described by physicians in cases. Consequently, the generic model is composed of a modeling of cases, of entities and action, and of entities and action types. It is independent from the pediatric pain management domaine.

Secondly, the specific model contains all the domain dependant data and makes up the generic model instanciation in the pediatric pain management domain. With this specific model, we collect all the entities and action types, defined for the pediatric pain management. This model contains also the complete corpus of cases described by physicians on the domain, and the solving problem strategies associated to each case.

The generated model aims at storing information issued from the pairing. In this way, this model maintains a case categorization, and the whole information about paired cases. It is charged of and also the storage of discussions resulting from the pairing and processed by physicians.

The Pairing Module

The pairing module aims at managing the processing realized on cases in sort to constitute relevant couples of cases for following discussions. These couples of cases are those which present similarities in accordance with sure criteria but mostly important differences in accordance with other ones.

Once a physician enters a new case, the underlying system performs a pairing process based on three domain dependent criteria. The first criterion named the theme represents the pathology illustrated in the case. The second criterion is called the object of the case and identify the case objective next to the pain (evaluating pain or treating pain). At last, the third criterion is the solving problem strategy proposed in the case by the physician. The aim here is to introduce people who deal with the same problems but who have different approaches in solving them. So, as well as being paired through their similarities, the cases are also identified by the differences in opinions expressed by the physicians. The importance in identifying these differences lies in the fact that, if people are in accordance with each other they will not benefit from the forum and as a consequence the discussion becomes useless. The principle of favoring different opinions is presented in (Dillenbourg and Schneider, 95). It is considered as a fundamental element in generating beneficial discussions in a collaborative learning group. Consequently, a socio-cognitive conflict (Doise and Mugny, 84) could arise and provide discussions and debates that are richer and more beneficial in their content.

This pairing module is composed by a general algorithm that manages progress of the processing chain. This algorithm executes mainly two sub-algorithms. The first one is named criteria extracting algorithm. It allows to extract the pairing criteria from cases (the theme, the object and the strategy). These criteria permit to put the cases together by categories in the generated model category level. Next, the second sub-algorithm is the pairing algorithm. This algorithm makes use of the last extracted criteria in order to compare them with those of other cases already stored in the category level. Thus, the collection of cases that deal with the same object is then extracted. The pairing module select cases with a similar theme but a distant strategy, then those with a distant
theme but a similar strategy, and finally those with distant theme and strategy. This retrieval of relevant cases generate three types of paired couples. The pairing can be considered as an uprising of an identified problem by analyzing the two cases. Once relevant case have been extracted, the information concerning the pairing and the reasons of these pairing is stored in the generated model pairing level. This information is then transmitted to cases’ authors through the interface module. Discussions can now take place. In a pedagogic point of view, the discussion is benefic, because physicians learn from the cases of each of them, but also from their own explanation’s tentative (self-explanation effect of Chi (Chi and al. 98)).

The Interface Module

The interface module proposes two user interface. The author interface, DIACOM-IA (DIACOM Interface for Authors) allows a physician to simply describe his experience. This interface can be considered as an author interface because it aims at « allowing authors, non programmers, to describe and to make visible their knowledge » (Murray, 99). By the way, an author, must be able to apprehend the description of a new case in the base, in accordance with a specific process. The current author interface version, is developed in Java. Moreover, because a case contains several composition levels, we have chosen to present it to the user, in form of an « arborescence ». At each level of this arborescence, the user has got the possibility to develop the lower level with a mouse click. At the top of the tree, we can see the name of the case accompanied with a small description. At the lower level, we can see the ordered scene list making up the case. Under each scene appear entities names, and this of the action that allow to go through the next scene. In another way, to manage the user acts we have chosen to offer contextual menus that appear with a right mouse click. On each hierarchy level, the presented menu is then different. For example, at the case level, the contextual menu proposes to modify information about the case, to add a new scene to this case, or to delete the last scene of the case. Nevertheless, at the scene level, it enable to add a new entity or a new action in the clicked scene.

The discussion interface, DIACOM-ID (DIACOM Interface for Discussion), constitutes the part of the interface module that enables the management of discussions between learners. Obviously, discussions proposed on the forum are asynchronous. In fact, the aim of the DIACOM forum is to propose to physicians a tool, easy to use and without any time and place constraint. Moreover, discussions have to be serious and authorized only to regular physicians. Consequently, the access to the DACOM-ID web site content begins with an identification phase in order to authorize discussions and case base consultation only to previous registered physicians. In the first step, an authorized physician access to a customized page in which he can inquire pairing about his own cases. Then he can link to the paired case description or directly to the related discussion page, corresponding to a pairing. When the physician click on one of these discussions, the totality of the discussion is displayed. On another way, the customized page give him an access to the case page that present the whole cases stored in the system, and to the discussion page, that allows to link to the whole current discussions of the DIACOM forum.

These two interfaces are at the center of the collaboration and interaction management of the DIACOM system.

Collaborative Learning Through the Interface Module

The DIACOM forum interface module is a part of the system through which collaborative pedagogical interactions can be effectives. With the DIACOM-IA interface, a physician begins to formulate, formalize and structure his expertise. He take the first plunge in order to integrate a real group discussion, efficient for his continuing education and knowledge improvement. In fact, each collaborative learning could only be efficient if each participant has performed a preliminary individual reflection about the subject that must be discussed and debated. It is the only way to obtain interactions and an exchanges of each individual thought (D’Halluin, 01).

Moreover, DICAOM-ID aims at stimulate these interactions between peers by presenting paired cases to physicians authors of clinical cases. For the moment, it is for example the matter of saying to the practitioner: “Your case has

917
been paired with Dr X's case. His case deals with similar subject as yours, but it doesn’t present the same problem solving approach. You have a real interest to interact with him through a discussion. We encourage you to begin the discussion with him, starting with a presentation of your opinion about his own case. Couples of paired cases generates, on their own, a discussion subject on which two learners doesn’t agree. So make these persons interacting, through asynchronous point of views debates on the subject, is beneficial to the pedagogy in the system. Two persons is the minimal group number required in order to obtain beneficial interaction in terms of knowledge transfer and enriching. This principle of creating couple of cooperative learners is near from the dyads constitution of Quignard and Baker in (Quignard and Baker 99).

Obviously, we have seen in the DIACOM-ID description that the discussion access is not saved for paired case authors. In fact, it’s turned out that the discussions activated by pairing have interest for each physician became aware of the question raised. Thus, the discussion interface allows each participant to participate to the whole discussions currently developed in the forum. By the way, a physician have not to submit a case to interact with other physicians about interesting subjects. It could be noticed that, for a people who has not submitted any case, the access to discussions is not easier than in a traditional discussion forum. Even if group discussions are possible, the choice of these extern participants is not funded on a point of view difference as it is done when people are connected according to the pairing process. Moreover, these participants, didn’t previously have the possibility to describe a clinical case based on the current discussion subject. So, they didn’t make the thought process to structure and formalize their expertise on this specific subject. But, interactions generated by these external people can be a plus for the whole collaborative learning group then constituted. In fact, they can re-incite and re-motivate interactions by introducing new questions about the discussion subject.

The following paragraph conclude on the actual state and on the evolution perspectives of this research work.

## Conclusion

A first experimentation phase has been carried out on the pediatric pain management. These experiences have allowed to collect an experimental corpus in order to constitute the specific model of the forum. Our current works are firstly centered on the strategies modelization and abstractions, from the experimental corpus. Once the author interface would have been validated by experts, a second experimental corpus will be able to be collected. This corpus will support our conclusions on the strategies modelization and by extension the pairing module. A complete prototype of the DIACOM forum will then be finalized. This prototype will allow us to test and validate the complementarity of the two DIACOM interface in the process of collaborative learning, based on interactions between peers.

A Constructivist-based Tool for Operating Systems Education

Abstract: RCOS.java is a simulated, web-based operating system that provides a platform on which to build constructivist-based approaches to teaching operating systems. This paper briefly describes the design, capabilities and availability of RCOS.java.

Introduction

A course covering the algorithms, concepts and theories behind the design, construction and operation of operating systems is a recommended core component for courses in computer science (Denning, 1989). For a number of reasons students find operating systems related topics, like many computer science topics, difficult to learn. In an attempt to address these problems and based on previous experience RCOS.java has been developed. RCOS.java aims to provide a platform on which students can actively experiment with the algorithms, data structures and services of an operating system. RCOS.java combines the capabilities of Java and the World-Wide Web to implement a single system that includes features of previous operating systems courseware including animation, concurrency simulation and toy operating systems.

RCOS.java Components

RCOS.java acts as a simulated operating system within a Web browser. Students can drill down and peer underneath the user interface and interact with graphical animations of the data structures and algorithms used to implement RCOS.java's simulated operating system and hardware. RCOS.java is implemented as a Java application consisting of 250 classes and over 100,000 lines of source code broken up into the following five major categories: hardware, operating system, animators, message passing and compiler.

The lowest levels of RCOS.java are a collection simulated computer hardware including a CPU, disk drives, RAM and terminals. The operating system is based on a message passing micro-kernel architecture. The micro-kernel handles interrupts, context switching and generates messages that are passed onto other operating system components that perform higher-level tasks such as memory management, inter-process communication, process and disk scheduling.

The Animators provide the visual representations of RCOS.java's internal operations. The Animators can also provide interface elements that allow students to modify the operation of RCOS.java by choosing between different parameters and algorithms. The animator system also includes a recorder that can store a RCOS.java session for subsequent playback.

The entire RCOS.java system is based on a message based architecture. This architecture allows the replacement of individual components including hardware, operating system and animator with little or no influence on other components. The message passing architecture also enables the implementation of the recorder.
RCOS.java will execute programs written by students. Students write these programs using a programming language similar to C/C++. The RCOS.java compiler will compile these programs into RCOS.java executables. The RCOS.java C/C++ dialect includes simple support for inter-process communication primitives including semaphores and shared memory.

Use of RCOS.java

RCOS.java is designed to enable and encourage active manipulation and experimentation by students. There are four main methods, which can be used including: visual investigation and experimentation, creating presentations, writing user programs, and modifying the internal operations of RCOS.java.

The animators provide visual representation of what is going on under the RCOS.java hood. Students can use these to observe RCOS.java's operation under different scenarios to gain a better understanding of how the algorithms and data structures work. A number of the animators also allow the student to modify the operation of the underlying operating system and hardware further enabling investigation of performance under alternate scenarios.

Using the RCOS.java compiler students can create and execute their own RCOS.java programs. The C/C++ dialect includes support for services, such as semaphores, which students are generally not familiar. By combining their programs with the visual representation provided by the animators students can further investigate and experiment.

The recorder allows students (and teachers) to create stand-alone RCOS.java sessions for future playback. This allows the creation of animations designed to demonstrate important concepts.

Students can also modify the internal operation of RCOS.java by modifying its source code. This allows students to implement alternate algorithms, data structures, animators and simulated hardware. Due to RCOS.java being implemented with a message passing architecture it is possible for students to concentrate solely on the component they are modifying.

Current Status and Future Work

RCOS.java has been under development since 1996. Developing a computer-aided learning package as complex as RCOS.java has been a time consuming process fraught with many difficulties. The long development cycle has itself created a number of problems including project students graduating, changing teaching responsibilities, and changes in the Java platform.

If the potential advantages of RCOS.java are to be realized integration into the curriculum is necessary. RCOS.java is currently a usable tool and yet there is still a significant development effort required to develop the appropriate learning activities and associated support material to enable its use in a course. Current work on RCOS.java is concentrating on this process.

RCOS.java has been released under an open source license and the system itself and the associated resources are available on the web from http://www.rcosjava.org /. Any interest in the use or development of RCOS.java is more than welcome.

Conclusions

RCOS.java is a simulated operating system that aims to enable the use of constructivist based learning activities in operating systems education by providing a concrete platform to enable visualization and experimentation.

Student feedback, anonymity, observable change and course barometers

David Jones
Faculty of Informatics and Communication
Central Queensland University
Australia
d.jones@cqu.edu.au

Abstract: A Course Barometer is a method for addressing the loss of informal feedback in a distance education setting. Originally proposed and used at the University of Trollhattan Uddevella this paper describes how the idea of a course barometer has been adopted by Central Queensland University. The paper suggests connections between anonymity, observable change and the level of student contributions. Usage statistics, staff and student feedback, and stories are used to identify trends, draw conclusions and make suggestions for further improvement.

Introduction

Collis and Oliver (1999) report in their analysis of the papers submitted to EdMedia'99 that the majority of papers report on prototype development and evaluation with few ideas going beyond this stage. One of those papers (Svennsson, Andersson, Gadd, Johansson, 1999) described the initial development and evaluation of the course barometer. A course barometer is a web-based application designed to provide students a simple, anonymous method for providing informal feedback about their feelings toward a course while it is being taught. This paper reflects on the use of the course barometer idea within the Faculty of Informatics and Communication (Infocom) at Central Queensland University (CQU).

The absence of informal, in-term feedback is a major problem within Infocom since most courses are taught with a large number of staff via both print-based distance education and in a face-to-face mode at 13 sites spread through out Australia, Fiji and South-East Asia. The course barometer concept within Infocom was initially intended for a course taught by the author in the second half of 1999. Since then the potential and obvious need for in-term feedback from students has led to the course barometers contributions being received in 67 different course offerings.

The paper starts by offering a brief overview of the course barometer concept followed by a description of the data sources used to examine Infocom's barometer experience. Two stories are then provided which show how a course barometer has made a positive difference for both staff and students. The paper then examines the connection between implementation choices, anonymity, observable change, and the level of student contributions to the course barometers.

Barometer Design and Implementation

There have been three versions of the course barometer concept. Two versions, alpha and beta, have been implemented at the University of Trollhattan (Svensson and Sorenson, 2001) and the Infocom version described here. All three barometers provide a mechanism by which a student can indicate their current mood and provide a small textual comment about a course. All three provide a statistics page where staff and students can view the atmosphere of the course. Minor differences between the barometers include changes in the interface design, moods that can be expressed, administrative mechanisms, and the implementation environment.

A more significant difference between the Trollhattan barometers and the Infocom barometer is the number of times per week students could make contributions. At Trollhattan students could make as many contributions as they wanted, whenever they wanted. In an attempt to increase the value placed on barometer contributions the Infocom barometer restricted students to one contribution per week per course. The intent was to encourage students to be more thoughtful in their contributions. This limitation also prevents the possibility of the barometer taking on an unbalanced view due to large numbers of repeat
contributions from a small number of students. Lowder and Hagan (1999), writing about another web-based anonymous feedback system, report on a student using the ability to make multiple postings as a nuisance technique.

To implement this restriction it was necessary to be able to identify which student was making a contribution. This violates the aim of providing an anonymous environment where students need not fear repercussions for making negative comments. Recognizing the negative impact this may have upon student participation the implementation of the password protection system aimed to make it as difficult as possible to identify which student made a specific contribution. Additionally, teaching staff are never provided with any access to information connecting students to contributions and an effort was made to communicate this information to students. A positive side effect of the password requirement was to address another problem. Infocom course websites generally are not password protected. In the past this has led to non-CQU students misusing facilities that allow for visitor contributions.

The alpha and beta barometers at Trollhattan were used over a four-week period in a single course during two different terms. There were a total of 213 submissions for the alpha and 308 for the beta barometer (Svennson and Sorenson, 2002). The Infocom barometers have been used for the entire 12 weeks of 5 different terms and contributions received for 67 different course offerings. For all but the last term the Infocom course barometers were only included at the request of the course coordinator. In the last term of 2001 the course barometer was made a standard part of the default web site for all Infocom courses. In this term there was a total of around 100 courses with default web sites. Barometer contributions were only received in 46 of these courses.

Data Sources

Information about student contributions to the Infocom course barometer is stored in two database tables. One table stores the course, week, feeling (good, bad or indifferent) and any comments. The other table stores the student number, course, and week. It is this second table that is used to prevent students making more than one comment per course, per week. The data in these tables has been used to generate statistics about students and their contributions. The student comments on the Trollhattan alpha-barometer underwent content analysis. Due to time and resource limitations such analysis has not yet been performed on the Infocom data.

Logs from the Infocom website have been archived since early 1997. These logs record the date, time and web page of every visit to the Infocom website. The web server logs have been used to compare the number of visitors to course barometers with the number of people making contributions.

To gather more information about student feeling toward the course barometers a 15-question survey was placed on the Web toward the end of 2001. The survey contained 8 likert style questions and 7 short answer questions. An email message announcing the survey was sent to all students enrolled in Infocom courses during the second half of the year. CQU's student record system contained email addresses for 948 of these students. 350 of those email addresses suffered from a number of problems that prevented delivery. A week after the first email initial results were released on the web and another email sent informing students and reminding them about the survey.

61 responses to the survey were received giving a response rate of 10.2%. 70% of the students who responded to the survey knew about the course barometer. 58% of respondents agreed or strongly agreed with the statement "The course barometer is a useful feature". While responses to the survey are a useful guide to student feeling there is some bias in the sample. The type of students who had correctly entered an email address into CQU's student records system and completed an online survey during the final stages of a term are more likely to make use of an online resource like the course barometers.

An email message about the course barometers was distributed on the Infocom staff mailing list early in the second half of 2001. Of the 60+ course coordinators within Infocom, many of whom had previously never used or known of the course barometer facility, there were 6 replies. In some cases there was on-going discussion between the author and individual staff.
Statistics, Trends and Potential Reasons

Over three years of use 1188 student contributions were made via the Infocom course barometers. The average length of a comment on the Infocom barometers was 120 characters. Over the 5 terms of year the average number of contributions per course offering was less than 18. However, three of these terms had significantly higher levels of contributions. The three busy terms had an average of 40 contributions per course offering. While the two slow terms had an average of 7 contributions per course offering. The defining difference between these two groups of terms appears to have been the motivation and involvement of the course coordinators in encouraging and responding to barometer contributions.

In the last main term for 2001 the course barometers were, for the first time, a compulsory part of every Infocom course website. However, staff were not required to encourage students to contribute to the course barometers. In this term 448 contributions in 46 different course offerings were made for an average of 9.7 per course. Only 16 of the 100+ courses in this term had greater 10 contributions.

29.5% of the Trollhattan alpha-barometer submissions included comments (Svennson, et al, 1999) while 71.7% of the Infocom submissions included comments. Trollhattan contributions showed overall student feelings of 57% bad, 10% indifferent, and 33% good. The Infocom breakdown was 29% bad, 20% indifferent and 51% good with the 1188 student contributions being made by 538 different students. The most prolific student made 50 contributions over 6 courses during two terms in 2001.

If you accept that the one comment, per week, per course increased the effort placed into the Infocom barometer contributions this may help explain why the number of contributions with comments at Infocom is almost the inverse of that at Trollhattan, 29.5% to 71.7%. It may also explain the switch in reported feelings from 33% good at Trollhattan to 51% good within Infocom. Especially given the observation that both the Trollhattan and Infocom barometers have been used primarily in courses with staff interested in improving the students' experience.

The number of contributions per week for almost all courses follow a common trend. There is an initial spike early in the term when the course barometer is first discovered. Followed by a gradual drop off until some minimum level is found and maintained until the last week or so of term. At this stage there is usually a small increase in contributions due to the end of term. Any exceptions to this trend were caused by events specific to the individual course that encouraged students to contribute.

Two Stories

While the overall level of contributions to the Infocom course barometers has been limited there have been a number of specific incidents where they have played an important role in improving the experience of both students and staff. The first story takes place during the first term in which the Infocom course barometers were used. In the second week of the term a serious student complaint was made about a relatively new staff member. The complaint was very critical of the staff member's lecture style. The week after the complaint was raised the number of comments on the course's barometer was over four times the average. Almost all contributions directly addressed the topic of the initial complaint and all were very positive. For example,

After hearing XXXX talk about the student who pretty much is jeopardizing his job, I feel really bad for him. He is a GREAT lecturer and the way he has summed up Programming A in just a matter of weeks I understand the concepts a lot better.

The second story comes from the last main term in 2001 and demonstrates how the course barometer was able to contribute toward an improvement in the student's experience. Many of Infocom's courses are delivered via video-conferencing between four regional campuses. Such presentations are usually made as traditional lectures originating from CQU's Rockhampton campus where most course coordinators are located. In 2001 a new lecturer located on the Bundaberg campus was given responsibility for a course that had to be delivered by video-conferencing. During the first three weeks the course barometer shows an increasingly negative feeling from students about the course. Most of the comments related to the quality of the lecture delivery. It should be noted that contributions in these early weeks involved less than 10% of the students attending these lectures.

Lecturers voice fades, notably at the end of sentences. There were technology problems as well, but lecturing techniques need to be improved....
72% of the comments in those first three weeks came from students at the Rockhampton campus (11% Bundaberg, 16% Mackay). Many of the Rockhampton students would have been on the receiving end of a videoconference delivered lecture for the first time. The difference in viewpoints between campuses became more obvious during the following weeks.

You people in Rockhampton are pathetic. You complain that the lecturer was late. I know for a fact that he was not......

You think the students in Bundy should think before they speak or in this case write.....

Often problems such as this would have continued throughout the term with little or no change. However, in this case the problems raised were addressed in a variety of ways and from week 4 onwards the overall student feeling on the barometer was positive.

The lecture was far different than last week, the voice of the lecturer was much better.....

Why don't students contribute?

In the period July 1999 to November 2001 there were an average of just less than 18 barometer contributions per course offering. This raises concern about why more students are not making contributions to course barometers. This section draws on data from web logs, student barometer comments and responses to the student survey to examine this issue further.

Of the students surveyed who knew about the course barometer 7% never read the contributions, 21% read them once, 36% every now and then, 17% once every couple of weeks, and 19% once a week. Of the students surveyed who read contributions 57% never made a contribution, 34% made a comment every now and then. Only 9% of students surveyed made a contribution every week. Using web logs it is possible to determine that during the three busy terms 6% of the people looking at a course barometer made a comment. During the last term of 2001, where all Infocom courses had barometers, only 1.5% of visitors made a contribution.

When asked why they didn't make a contribution the most popular student responses included: having no complaints or strong opinions to contribute, having a preference for using another medium, and the belief that there would be no change if a contribution was made. Other reasons given included a lack of other comments, didn't want to repeat an existing comment and having no time.

When asked why they made contributions the most common reasons included: the importance of giving feedback in order for change to happen, having strong feelings about an issue and supporting a lecturer against negative comments. Other reasons included agreeing with a comment, disagreeing with a comment and because the lecturer asked.

69% of survey respondents agreed or strongly agreed with the statement, "If visible changes were made because of comments to the course barometer I would be more likely to add comments to the course barometer". Student comments to various survey questions include:

- Because the lecturer "really" wanted feedback – asked every week. I thought it was worth the trouble to help improve the course for the future......
- Does it get back to the Dean or Head of school? It's no use going to the lecturer. If the barometer will serve to fix slackness then yes it will be useful. It is just another mouthpiece for the University not to take into consideration. It is the same as the evaluations. None of them are ever taken into consideration.
- Any changes that were made came to late for the majority of the class. In fact, when the changes were made they advantaged the few and disadvantaged the majority of the class.
- I don't think I saw any changes. I did however notice in one nameless subject that I did this semester, that at the start there were some very negative comments about it (that I totally agreed with) but when nothing changed the use of the barometer just died.....
- The lack of anonymity was not given by any student as a reason for not contributing. However, a barometer contribution did show that at least one student had a problem with the apparent lack of anonymity.

I suppose you think that if no-one submits a comment, then everyone must be going ok. Not! Just maybe, its the fact that the submission doesn't appear to be anonymous when your asked for your student details to submit your comments. I have lots of concerns and would like to pass comments to the course barometer, but am concerned that its the messenger that will be shot and not the message addressed.

Other students expressed concern about anonymity when answering the survey question "What didn't you like about the course barometer?".
While realising the need to prevent malicious access, it was disconcerting to need to use username and password to access an anonymous site. When you submit you need to logon. This gives the feeling that who is responding is being recorded instead of it being anonymous.

Some students appear to have believed that the course barometer was anonymous. Responses to the survey question “What did you like about the course barometer?” included students can feel safe in that it is anonymous, so they won’t be attacked for their opinion. Allows student who do not wish to be named to provide any kind of feedback without fear of it being held against them come marking time.

Some students, usually when supporting a lecturer against negative contributions, defeated the supposed anonymity of the barometer contribution by including their name, for example. I do not feel the need to make my comments anonymously, so here goes. ....Linda.

Though this practice was given other interpretations by other students ....It is amazing how some students say they don’t need to be anonymous about their comments and then piss in the lecturers pocket and attach their name

Some students perceived that the anonymity provided by the course barometer was actually a negative attribute. ....I would approach the lecturer/Co-ordinator directly. I believe that the barometer restricts/reduces open communication with the source of the problem. Often I noticed other students use anonymity to feel OK about not bothering to construct appropriate arguments and blurt out unconstructive criticism.

Other students suggested that knowledge of the contributors identity should be used Force student ID, student number would suffice, so that course organisers can follow up true complaints. Very good thing, maybe every time somebody votes, they get an entry into a prizepool to win something, maybe a textbook refund or something simple like that.

While the apparent lack of anonymity was a problem for some students it appears it is not as important a factor as the lack of observable change. Students do not wish to give feedback if there is no visible response.

**Staff Impact and Views**

Only a small number of motivated staff have made significant use of the course barometers. As a result all of these staff see the potential benefits that the barometer can provide. ..the Course Barometer is an excellent tool, and staying “in the green” all term is a good challenge for teaching staff. At a glance, you can see how some students are going. And because there is no way for teaching staff to see who made which comment, students can say how they are going without fear of recriminations.

However, they have also experienced a number of problems including: unconstructive feedback, inability to help students with problems directly, and frustration caused by negative feedback when trying their best.

Because the tool keeps students anonymous, the feedback tends to attract occasional students who want to have a little rant or hissy fit without any chance of people finding out who they were. So, instead of these students seeking help or doing something really useful, they vent their frustrations. We need to reach these students and help them, but instead they hide behind anonymous feedback ....So, maybe this student is looking at the slides for the wrong subject, or simply cannot put two and two together, or else has some severe fundamental misunderstandings, or is on another planet, or something. In any case, I cannot find out who they are or contact them or help them, and this is a real shame.

Comments made on the feedback barometer can be incredibly frustrating because the students who make them can sometimes need urgent help or assistance, but they have chosen the barometer to make their comments, and this keeps them anonymous, so we have no chance to find out who they are or help them. This is incredibly frustrating. I want to help these students, but my hands are completely tied - unless they also decide to email me or contact me in some other way - which sadly, does not seem to happen. These students seem to replace email with the feedback barometer, so they seem to use one instead of the other.
Conclusions

A course barometer is a method for addressing the loss of informal feedback in a distance education setting. While the use of course barometers within Infocom has been done in an ad hoc manner with limited contributions by students there have been a number of situations where its presence has helped students, staff and the organization.

The small number of contributions on the Infocom barometers can be explained by a number of factors. It appears that a combination of staff promotion of the barometers and observable change in response to student feedback are amongst the most important factors for promoting student contributions. It appears that the lack of anonymity provided by the Infocom implementation of course barometers, while an issue for some, is not of prime concern and some students and staff actually see it as a negative influence over the quality of contributions.

In the future tools such as the course barometer will be of increasing importance to Infocom. Recent moves to increase the importance of quality assurance within the Australian University environment is one factor. Infocom's increasingly complex mix of distributed campuses and distance education also increase the importance of having a simple, heavily used student feedback mechanism.

As a result the Infocom barometer concept is likely to have an expanded role with a number of planned changes to improve the level of student contributions. In particular, it is likely that responsibility for promoting student contributions and ensuring changes are seen to happen will be given to a position seen as being independent and separate from teaching staff. Another likely change is the combination of the course barometer idea with the anonymous threaded discussion functionality described in Lowder and Hagan (1999). This would allow discussions and responses to develop around a particular student contribution. This would provide a place where change can be seen and also encourage further learning (Lowder and Hagan, 1999) and facilitate informal student interaction.

The work described here is still in the stage of early investigation. More research is required to further test and clarify some the observations and conclusions that have been made. As the use of the course barometer concept expands it will become increasingly important to investigate how the course barometer fits in with and relates to other mediums used to support teaching and learning. However, course barometers can be a positive and useful tool.

Abstract
Many tertiary institutions in Australia provide support to develop online teaching and learning resources, an environment characterised by demands from students for quality face-to-face and distance education, staff concern over workloads, institutional budgeting constraints and an imperative to use management systems. There also remains a legitimate focus on using online learning to facilitate new learning strategies within a complex social setting. This paper presents an extended instructional design model in which the development cycle for online teaching and learning materials uses a scaffolding strategy in order to cater for learner-centred activities and to maximise scarce developer and academic resources. The model also integrates accepted phases of the instructional development process to provide guidelines for the disposition of staff and to more accurately reflect the creation of resources as learning design rather than instructional design.

Introduction
Teaching and learning in tertiary education has shifted over the past two decades to an environment where technology is a significant component of the overall infrastructure and the skills and credentials of both teachers and learners are crucial to enable them to work effectively with collaborative, online activities. While many teachers have embraced these new environments and take responsibility for the development and delivery of resources, many other academic staff rely on central support units to provide expertise in both curriculum design and strategies for online teaching and learning. It is this latter group of people to whom this paper is specifically directed, although the concepts will also have ramifications for all online development.

As leaders of support units in two Australian universities, one Faculty-based the other University-wide, we find that academic staff often have too little time or too few skills to maximise the benefits of online learning. At the same time our institutions, like many others, are emphasising the role of enterprise-based Learning Management Systems. Within this environment, our roles involve the design and development of online teaching and learning resources within tight timeframes and institutional constraints, which often force the units to be in a ‘responsive or reactionary mode’ without proper and significant long term planning. This can result in just-in-time delivery packages rather than more preferable long-term rollouts.

This short paper speculates on extending the way in which instructional design strategies are applied to educational resource development such that that production efficiency can be increased and the ongoing maintenance of online environments enabled. While instructional design and development processes integrate current good practice, the proposed variations from existing models are based on an extended approach to the development process conceptualised in three discrete phases and the integration of professional development scaffolding to effectively align online teaching resources with learner needs and expectations. In essence, the model articulated provides a means to enhance the production environment for online materials while maintaining or even increasing quality by conceptualising the design and delivery environment within the iterative and rapid prototyping methods available through contemporary development systems.
Three Phase Design and Scaffolding

The general instructional design model (for example, Morrison, Ross & Kemp, 2001) typically prescribes the creation of resources, their implementation and delivery that is then followed by evaluation and improvement. Our enhancement proposes the initial creation of a fully functional prototype, which is then used for delivery, with the evaluation and improvement activities being integrated with scaffolding (support) for the teacher and learners to provide a dynamic teaching and learning environment in which resources or strategies can be developed or modified during the actual delivery stage. The need for scaffolding has largely arisen because of the rapid implementation of learning management systems, the increased use of online teaching and learning and the evolution of learner-centred educational paradigms (Herrington & Oliver, 2001).

Integral to this process is the notion of iterative development or successive approximations, with initial prototypes being built to test the water before completion of the entire course. In the first iteration learning environments are generally created to provide functional delivery with the necessary componentry for effective online teaching and learning. This can include the outputs of a preliminary needs analysis of the learning environment and resources that are scaled to fit the proposed teaching and learning context. However with the second and subsequent iterations, development can be enhanced with each generational change. In addition, the model is based on a team approach, bringing together the three main elements of course development in a more lateral manner. No longer is process driving the development, but the project itself (i.e. the course) is dictating the make up of the teams (a cross section of skills from educational design and production) in a much more targeted and effective manner. These teams ideally stay formed for the duration of the project, potentially over a number of semesters, with communication and collaboration between academic staff and developers a key focus.

Evaluation and feedback

Modify (add or remove) resources, activities or strategies based on evaluative feedback

Figure 1: Three-Phase Design & Scaffolding
The model therefore reinforces both the team-based approach to the design and provision of resources as well as an iterative development process. One of the essential aspects of the model is the specification of baselines in levels that correspond to these iterations - the first relating to course functional and essential elements, the second to multimedia enhancement or interactivity and the third to ongoing maintenance. These iterations are identified within the strategy as three scheduled phases of development that integrate both a methodological approach to unit development, scaffolding and quality controls and assurance, as illustrated in Figure 1.

The triangles indicate the relative efforts of the critical members of the project team at each phase of the process, based on the influence model (Sims, 1997), which articulated the period at which factors had specific influence over the project. The allocation of resources to enable this process involves establishing "unit teams" whose commitment will vary according to the position of the unit in the development cycle, with expertise based on the varying requirements of the course. More importantly, within the context of our work environment, it is the allocation of resources for the duration of the project life that differentiates the model, as detailed in the following description of the phases.

Phase 1: Prototype Development

The aim of this phase is to design and create a functional teaching and learning online environment that will meet all learning outcomes as well as faculty teaching and learning strategies. The first phase therefore becomes easier or simpler than more traditional models of instructional design, as it is functional, and production does not try to complete a final package at the first attempt - the process can therefore be likened to enabling a "dress rehearsal" for both teacher and learner. The process also involves specifying the core items for this phase, such as specific teaching resources (e.g. unit guides, study guides, readings), their mode of access (e.g. print, online) and the essential educational strategies (e.g. experiential, situated, learner-centred). In this way the academic who has minimal experience with online teaching and learning environments has a relatively easy introduction to the environment while knowing that ongoing support will enable the generational development of that environment.

An equally important aspect of this phase is the allocation of team members and their specific role within the project, which can be articulated in terms of:

- **The Support Team**: Providing the Educational Designer (responsible for educational advice and curriculum design), the Interactive Architect (responsible for ensuring the online interactions and communications are consistent with the design) and Information Analyst (responsible for ensuring all required learning resources and objects are available). In addition, Project Management support will be required.

- **The Faculty Team**: Allocating the Content Specialist(s), who are responsible for ensuring all necessary content is defined and that all learning outcomes, learning activities and assessment tasks are defined. In addition, a commitment to the schedule and baselines/guidelines is critical.

In addition, an Online Developer, Network Specialist and Technical Specialist will both advise and be advised on required and/or appropriate learning environments. As an extension to the triangular concept indicated in Figure 1, the detailed representation of influence (see Sims, 1997) is elaborated in Figure 2 for each of the perceived roles, where the apex of the triangle or polygon represents the phase in the development cycle at which that team member will have most influence. In this illustration, the different skills are also aligned with a particular unit - Support representing the central unit within the institution that provides educational advice and development services, Faculty representing the knowledge based to be provided from the teaching unit and IT representing the potential need for highly specialised network and programming expertise. In addition, these teams will also link across the various phases as the courseware assembly process progresses.

Another aspect of the concept of influence is that members of the development team are understood to have potential levels of influence at any stage of the development and delivery process, although that influence will be affected by the current status of the project. For example the Interactive Architect, who has the main responsibility (influence) for creating the design specifications, may also be active in the quality review of the project as it nears completion. An important concept underpinning this model is that, like actors in a play, the
team members all have roles to play and particular *scenes or acts* within that process will require their leadership. But they can also have smaller, but by no means unimportant, roles throughout the whole development, delivery and maintenance cycle.

**Figure 2: Influence of Team Members During Project Life-Cycle**

**Phase 2: Evaluating and Enhancing Delivery**

The second phase is conceptualised to take place during the delivery of the unit, with feedback from both teachers and learners used to modify and enhance the delivery environment. This may include the introduction of content items and enhancement of teacher:learner, learner:content or learner:learner interaction conditions (cf Sims, Dobbs & Hand, 2001). It is also an opportunity for teachers to work in a scaffolded environment to maximise the effectiveness of online environments, where the efforts of both teacher and learner can be evaluated and the delivery environment enhanced on the basis of that evaluation. This process also allows for clearer scheduling of resources and consequently planning, production and workflow processes.

This phase will require a *team-based* approach to delivery combining, where appropriate, both academic and technical staff in two discrete components. The first requires more technically-oriented teams to “shadow” the delivery of the unit materials defined and created in Phase 1 to both assess their efficacy as well as integrate additional content, interactive learning objects and collaborative activities. The second includes the provision of targeted professional development or scaffolding on an “as required” basis for all participants in the learning process. Overall, this phase emphasises generational changes with an increased emphasis on the production (completion) of resources, with the students or learners having the role of research or evaluation assistants. There is less emphasis on handover, and more emphasis on *duty of care* through the availability of sustainable course materials and teaching resources.

**Phase 3: Maintenance**

Following completion of the course of study, additional modifications and enhancements are prescribed and implemented for subsequent delivery. The unit would then continue in “maintenance mode”, involving ongoing support and training, until it undergoes a more formal review. Again, the important concept underpinning this model is that the original functional system developed will always be subject to change and that any development environment must cater for resources to be available for the duration of the life-time of a course (or
Within tertiary institutions this can be as long as five years, the time between a unit’s conception and its formal review for reaccreditation. However, the sustainability of the course is catered for by the continual process of gathering and incorporating evaluation data.

The success factors will depend not only on the concept being accepted but also for academic staff, students and the development team to reconceptualise their roles in the design and delivery of online educational resources. For teachers there is the option to collaborate with an online development expert while delivering the course to implement modifications based on student feedback; for learners there is the opportunity to contribute to both the content base and the educational strategies.

In Figure 3 following, a sample model is provided to demonstrate how the model may be implemented over a three-year cycle, with the assumption that units of study are delivered on a semester basis.

**Figure 3: Implementing the Plan**

**Conclusion**

Higher education in Australia is changing and to meet these changes and challenges innovative models for academic support are required. The model proposed in this paper articulates an enhancement to traditional instructional design processes where specific aspects of development and delivery are viewed in parallel rather than in sequence. Instead of a development team watching delivery of resources remotely, it is proposed that, where feasible, members of the development team actively participate with both teachers and learners in the delivery process. In this way support or scaffolding in the form of professional development can be provided on an as required basis while technical specialists can implement modifications to both content and pedagogy.

The value of this model can therefore be realised through the innovative ways in which it conceives the development process as develop baseline - implement/evaluate/develop - maintain/evaluate rather than the more traditional process of design - develop - implement - evaluate. The model provides an holistic framework consisting of long-term development teams, course templates, design and delivery standards and specified delivery platforms. The development of course materials is therefore not a short-term production process but a long-term collaborative process by all.

Based on this analysis we believe the benefits to teaching and learning in higher education will include the following:

- it can be a try it and see approach, where the first phase enables strategies to 'test the water' so initial budgets aren't blown out in expensive experiments, as has been evidenced in many multimedia projects;
funds can be allocated across more projects for a longer period of time, such as towards second
iteration enhancements that really target the learners and are appropriate to the learning
environment; and

course design in this development model includes both teacher and learner feedback and is
enhanced incrementally to match learner needs.

HyWeb: A Holistic Approach to Technology-based Tertiary Education

Vicki Jones, Jun H. Jo and Greg Cranitch
School of Information Technology
Faculty of Engineering and Information Technology
Griffith University Gold Coast, Qld 9726, Australia
Email: {v.jones, j.jo, g.cranitch}@gu.edu.au

Abstract: For the last few years, we have been developing an online/in-house teaching environment in Web-design and multimedia animation. At this stage, the outcome is a hybrid system, known as HyWeb (Hybrid-Web). It is the result of combining online delivery with traditional teaching. The experience has led to the belief that a holistic approach to course design and delivery is not only practical but also essential. As certain features are added to enhance the quality and efficiency of the system, making it a dynamic and evolving entity. This paper discusses the approach used for course development within the Multimedia degree, School of Information Technology at Griffith University, Gold Coast campus.

1. Introduction

At Griffith University Gold Coast, several faculty members of the School of IT are working together to create a holistic and evolving teaching environment aimed at meeting the needs of their students. Two important components of good online instruction are: methods to cope with the limited bandwidth of today, and the inclusion of the human element. The problem of limited bandwidth is diminishing with time, but the “human element” still needs to be considered. Communication, involvement and connectivity can be addressed by a more flexible approach to online education.

2. Online Delivery System

HyWeb was developed at Griffith University, Gold Coast and implementation has been ongoing since 1999. The system focuses on delivery and can be applied to any field of study. There are two major limitations:
- Bandwidth and Data Transfer Rates – with the increasing amount of Internet traffic, it is difficult to guarantee adequate data transfer speeds, site availability and consistency. One of the major problems reported by students using the system has been the slow data transfer rate (Jones, et al., 2000). High bandwidth options, such as broadband, are still expensive and not practical for many students.
- Communication and the “human element” - another limitation reported by students is the reduced face-to-face contact (Jones, et al., 2000). Student feedback has shown that they prefer some face-to-face contact during an online-delivered course. At Griffith University Gold Coast, we have endeavoured to maintain a face-to-face component within the online system, using a combination of traditional-style lectures, tutorials, lecturer/tutor consultation and online delivery. The one-hour consultations, available weekdays, provide the opportunity for students to seek assistance and have contact with the lecturer/tutors. The students have used this resource extensively, especially before assignments and examinations are due.

3. HyWeb – The Evolving System

HyWeb is still evolving. As needs arise, these needs are met by system growth. Communication is an essential component and has been maintained in the HyWeb model via several media: email, online forum, online notice board and face-to-face (Jones, et al., 2001). By introducing a wireless component, additional communication via WAP-based email, Internet-based forwarded email and SMS (short message service) can be achieved.
3.1 Wireless System Component

To provide more options for students, wireless technology is being incorporated within the system. It will be available through either a Web-enabled mobile phone and/or a handheld device such as a PDA. Students can also have limited access to the wireless system using a non-WAP mobile phone, by receiving SMS notifications and email through various Internet-based free, email forwarding services.

Along with its versatility and adaptability, wireless technology has certain limitations, which include: mainly text-based information; small screen size; high running costs; no keyboard or mouse (although a plug-in keyboard is now available for some models); and lack of storage space. Wireless communication bandwidth is low (transfer rates are currently around 9600 bps), but WAP was designed to cope with low bandwidth and intermittent coverage. There are many positive aspects and promising features of wireless technology, such as: portability and mobility; flexibility; convenience; remote access; and user-friendly devices (Jo, et al., 2001).

The idea of mobile innovations and a wireless university campus is not new. Minnesota State University, Mankato (MSU) introduced a wireless system in mid-2000. Mobile handsets were provided and the students were expected to perform many of their daily tasks using wireless services (Virtanen, et al., 2000). Mobile innovations were also introduced at Twente University in Holland, where the mobile phone is now considered to become an important tool for learning (Dorsey, 2001). Wireless technology in education is also referred to as wireless e-learning, and can offer many benefits. Grimes (2000) states that, “If wireless communication is still in its infancy, wireless e-learning is in an embryonic stage”. Convenience is a key element of this technology, allowing anytime/anyplace access. Using wireless technology within the established delivery system, students will be able to: check assignment due dates and exam timetables; send email to the lecturer; access a web-lecture using a PDA; check the online notice-board; and join an online forum or chat session.

4. Conclusion

The HyWeb system has undergone many changes over the last few years, the most recent being the introduction of wireless technology. This is expected to have a positive effect on the students and their perception of the course. Handheld and wireless devices are used extensively in today’s society and the concept of using such technology is both exciting and inspiring. HyWeb is constantly evolving with new technology being integrated into the system as it emerges. HyWeb enables easy modification of the system and allows for growth and flexibility. By constant reviews and modifications, ideas, inspiration and motivation are maintained and those involved strive to develop the system into the more fully expanded and improved structure. This is an ongoing project aiming at an effective and efficient dynamic learning environment, which can demonstrate increased flexibility, portability and convenience.

Introducing ICT into Irish Schools. A Case Study report – Interim Findings

Miriam Judge
Government of Ireland Senior Scholar
Dublin City University, Ireland.
miriam.judge@dcu.ie

Abstract: In terms of education technology the Irish education system is a late developer. In 1997 a government led initiative, “Schools IT 2000” was launched to computerize the nation’s schools. This qualitative research study documents the experience of five schools involved in piloring a communications and collaborative project called “Wired for Learning” that was sponsored by IBM and the Department of Education and Science. The data and the findings discussed pertain to the first year of the project's introduction in the participating schools. A follow-up study will be completed on the project’s overall progress and development when the three-year project period comes to an end in 2002.

Introduction

In 1997 the Irish Government launched a major drive to computerize Ireland’s schools when it established the National Center for Technology in Education (NCTE) to implement its “Schools IT 2000” policy initiative. The Schools Integration Project (SIP), administered by the NCTE, was a key strand of this initiative. Its remit was to explore creative ways in which ICT could be successfully integrated into the existing education system at primary and post primary levels. To achieve this, SIP invited schools to establish best practice models across a wide variety of school settings including, special needs, curricular and technical support. One of the SIP projects, known as “Wired for Learning” is the focus of this research.

Wired for Learning (WFL) is a secure communications and collaboration tool designed to develop the use of ICT for communications and collaboration purposes for the entire school community i.e. teachers, pupils, parents and mentors. It was developed by IBM as part of its global ‘Reinventing Education’ programme that began in 1994 in the U.S. In 1998 IBM Ireland and the Department of Education and Science announced a special education partnership and a $1 million investment in Ireland’s school system to bring the WFL platform to a number of Irish schools under the SIP umbrella. Its core stated objectives were (a) To empower teachers with the capability to share resources and knowledge within and across primary and post-primary schools and (b) To facilitate communication and collaboration between schools, parents and the wider community.

There were five schools in total in the WFL project, 3 primary schools and 2 post-primary schools at two sites. Site one comprised three schools located in a disadvantaged suburban community in Dublin. Site two, was located in a more affluent semi-urban area in the far south of the country. As part of the project all schools were equipped with a state of the art networked computer lab.

Access to the WFL environment is facilitated via a standard web browser, a registered user ID and password. The environment is made up of a suite of tools or applications that support communication, collaboration and learning. Communication tools include secure email for all pupils, teachers, parents and mentors and a bulletin board interface which supports conferencing between parents, teachers and students. Collaboration tools facilitate student team projects, a private area where teachers can work together and the involvement of both local and global mentors. A suite of related databases known as the Instructional Planner support the learning process. A demo version of WFL is available for downloading at www.wiredforlearning.net/.
The Research Context and Research Questions

The research was carried out by a full time PhD Research Fellow located at Dublin City University using a case study methodology. Research tools included: (a) Classroom observations of how ICT was being used to support teaching and learning; (b) Attendance at project strategy meetings and staff training courses and (c) In-depth interviews with key personnel i.e. I.T. coordinators, school principals and teachers (n=37). The key three research questions focused on (1) teachers’ perceptions of the innovation; (2) its usefulness as a communications and collaboration tool and (3) the sustainability and scalability of the innovation.

Teachers’ views on the innovation were mixed. Many however questioned its usefulness and relevance to their classroom teaching and practice. The Instructional Planner section of WFL was particularly criticised in this regard. The main reason being that (a) it forced them to plan out lessons in a very structured way which was not how they traditionally planned their lessons; (b) the system was too cumbersome; (c) the process was too time consuming and (d) there was a deep suspicion that it was an attempt to bring in greater teacher accountability through the back door. In fact opposition to the Instructional Planner was so strong that most schools had effectively abandoned its use as a lesson-planning tool by the time the interviews were conducted. Instead the IT coordinators and principals were concentrating their efforts on encouraging staff to use other aspects of the innovation.

In general most teachers reported that WFL had given them the opportunity to collaborate more with each other. Teachers reported how training opportunities to learn the software as a group, in addition to the use of teacher release time which gave them the opportunity to plan how to use the system and to input lessons and resources into WFL, all helped this process. As one teacher phrased it — “the project has given us a chance to work together as adults”. The facility afforded by the system to create a repository of resources for each year group was cited as a particularly welcome feature of the system and evidence of greater transparency, co-operation and collaboration among staff members. One school reported how its use of the system for encouraging staff members to electronically communicate agenda items for staff meetings had increased teacher involvement and contributions.

Opinions on its usefulness as a communications tool were less positive. Many could not see the point of sending another member of staff an email when they could talk to them in the staff room during break time or in the corridor. Email communications with parents was viewed in an even more problematic light. Teachers expressed a fear that emailing parents could potentially lead to a situation where too much teacher time would be required to service parent emails, particularly those of a demanding parent. The schools in the disadvantaged area also felt that emailing was impractical because very few of their students had PC’s at home anyhow. Consequently none of the schools in this cluster group had yet put procedures in place to involve the parents in the project.

A number of reservations were expressed at both sites in relation to the sustainability and scalability of the innovation. Some of the main reasons given were (a) the expense involved in purchasing the WFL system which the pilot project sites did not have to incur; (b) a feeling that there were other systems available on the open market which could do the same thing in a more efficient and less cumbersome manner and (c) a belief that the WFL was culturally more suited to the American education system than to the Irish system. There was also a strong feeling among participating teachers that teaching colleagues in other schools would not be prepared to invest the same level of time and effort as they had. In addition many were of the view that any attempt to roll out the project nationwide would be opposed by the teachers unions. It was also difficult to see how other schools would be prepared to run with such a system if they were not going to receive outside technical assistance and support, on a par with that provided to the two start-up sites.

Conclusion

All in all the early evidence seemed to indicate that schools were struggling to integrate WFL successfully into the school environment and that it was unlikely to be a success if rolled out to other schools. However, as the project still had another year to run, the researcher is of the view that it is probably too early to make any substantive claims about the innovation’s long-term sustainability and scalability.
Development and Application of CyberPedia: a New Platform for Internet-based Collaborative Encyclopedias for K-12 Education

1. Introduction
Integrating encyclopedias with the Internet is changing the way K-12 students study with encyclopedias from looking at an encyclopedia to making one with all students and teachers participating and contributing. From this point of view, we have developed an Internet-based collaborative encyclopedia platform called CyberPedia for K-12 education.

It has three main features. (1) Easy uploading: Anyone can contribute to the encyclopedia by uploading his/her knowledge or learning results with multimedia contents via the Internet. (2) Easy Searching: Anyone can easily search for them. (3) Easy Authoring: Anyone can make a custom encyclopedia on a browser without having a database of technical knowledge.

2. Basic Design
CyberPedia supposes three types of users: a student, a teacher, and a site manager who is an expert or educator supervising designs and contents of CyberPedia as well as being a database manager.

(1) Student
First, a student explores and studies existing data in CyberPedia, which mean initial contents that site managers prepared beforehand. Then, he/she chooses an attractive topic and goes out in the field with a digital camera or a video camera to further investigate it independently. After returning to the school, the student completes observations in a template and submits them to CyberPedia. Finally, the student broadens his/her knowledge by comparing it to other's reports. CyberPedia offers students the opportunity to explain what they gathered so that it has some meaning for others.

(2) Teacher
The teacher's main tasks are to register user information beforehand and to manage data uploaded by students. CyberPedia enables the teacher to return comments or advice on each student's work and to make it public or private on the Internet. The default is private.

(3) Site manager
The site manager designs CyberPedia itself according to a learning theme. The design of an encyclopedia necessarily differs according to its contents or the author's expertise. Therefore, CyberPedia offers the site manager authoring functions to decide what search conditions are, what object data categories are, and so on. Moreover, the site manager can change the web site visually and insert the initial data into it. In short, CyberPedia is a platform for making custom encyclopedias. It can also provide students with multiple different encyclopedias at the same time.

3. Implementation
We used Linux as the operating system, Apache as the Web server, and PostgreSQL as the database because this software is all free and stable. The programming language is Java servlet and JSP.

Figure 1 shows a screen-shot of the search window of the microorganism guide housed in Sendai Science Museum and used by junior high school students in Sendai. The left frame is for specifying characteristics of the search conditions. Each entry in the encyclopedia (which we call an object) is linked with relevant characteristics. The middle one lists object names of the search results. Objects have the same data categories to classify data according to the contents. When one selects an object and a data category, its contents are shown in the right frame.

Needless to say, fixing the format reduces the flexibility of the encyclopedia's design to some degree. However, we considered simplicity and productivity to be more important than flexibility. This enables site managers to make a custom encyclopedia by editing characteristics, objects, and data categories and to design it by inserting icons and changing colors.
on a browser. They can do almost all of the operations to make an encyclopedia just by selecting from menus.

Figure 2 shows a screen-shot of the upload window. This one page is a template for students to submit observations. They have only to input or select some items such as a title, object, data category, and comments. When the submit button is pressed, all information is automatically accumulated in CyberPedia. Contents can be uploaded in various formats, such as JPEG, MPEG1, and Quicktime movies.

4. Discussion about the applications using CyberPedia

The strengths of CyberPedia are to teach science as a process, to provide a good opportunity for students to express their thoughts, and to facilitate collaboration among distant students and experts. In some applications using CyberPedia (Kura 2001), the students tackled the learning theme independently. From the results of questionnaires, we found that all students were interested in uploading their findings and in debating with peers using CyberPedia. Not only exploring the initial contents but also observing the neighboring natural environment and uploading observations to CyberPedia were good opportunities for students to think deeply about science as a real natural phenomenon. Simply working in the CyberPedia environment challenged both teachers and students to change their teaching and learning methods.

However, the experiments revealed a lack of functions. For example, teachers said that the page uploading format did not challenge students to develop their own means of organizing information. Of course, it depends on students' skills, but we should offer alternative functions supporting drawing tools on the Web to develop the students' creativity (Sugiyama 2001). Besides that, we will also think about team-building activities and reflective writing tools in future.

CyberPedia is really a simple structure and has a great potential to various applications such as digital museums and community platforms. We think the most promising area is student portfolios. CyberPedia offers the potential for individual students to develop portfolios that they might develop over a lifetime of learning.

5. Conclusions

We described the concept and development of a new encyclopedia platform called CyberPedia. It is a web-based application; therefore it can provide an opportunity for distant students and teachers to make an encyclopedia in collaboration. This is very effective pedagogically, because uploaded contents include the position, date, and time of the observation, and students all over the country can study and investigate a specific theme, for example, the movement of the cherry-blossom front in spring or the distribution of growing trees, collaboratively.

Abstract: This paper deals with a specific aspect of the joint project "Wissenswerkstatt Rechensysteme" (WWR, Knowledge Factory for Computing Systems) of twelve German universities. It describes how to integrate external simulators and experiments into courseware based on an XML teaching and learning environment. The approach is based on wrapping experiments as Web Services. It provides an indirect access to the experiments through the central university learning system. We are convinced that learning by experiencing the phenomena of computer systems in simulation or/and in real working systems is very helpful for helps a computer science student to comprehend and to get acquainted with the more complicated topics in this field.

Introduction

In the ongoing joint project "Wissenswerkstatt Rechensysteme" [1] (WWR, Knowledge Factory for Computer Systems) (Lucke, 2002), a broad set of multimedia teaching and learning modules are being developed in the field of computer engineering. Each module can be offered at three levels, such as basic, advanced, and expert as per the target group (teachers, learners) in following output formats (HTML for Internet-based learning material, PDF for printed manuscripts, PPT for slide presentations). In order to achieve such a flexibility, modules are prepared in the Extensible Markup Language (XML) (Bradley, 2000), maintained in a repository and organized using metadata based on the IEEE Learning Objects Metadata (LOM) standard (IEEE, 2000), (Monthienvichienchai, 2001). Based on learning objectives, teachers select the modules as per the needs of their students and offer these as a course. As a result, the materials required for a course are generated as per the request in the desired formats from/by the content repository using XSL (Extensible Style sheet Language) (W3C, 2001) processing techniques.

The WWW-based online course material so generated is described below in greater detail. For students, such courses mainly consist of pieces of HTML text, diagrams, pictures and other embedded multimedia documents. But computing systems and especially operating systems are not directly perceivable by human beings! A student cannot see, listen, touch and smell the running processes, the events happening etc. The most complicated are the practical exercises. In order to really comprehend and understand, how the system works, probably the best way is to experience a running system with all its effects and side effects, its dynamics, the occurring events and exceptional situations, the relations "if...then..." etc. (Gershon, 2001). As a consequence, a much higher degree of interactivity is required compared to traditional course materials. This means incorporating simulators and interacting in real-time with external real-life systems and experiments. This type of environment was set up and used with great success for practical exercises about operating systems based on a more traditional technical platform and hand-coded experiment interfaces (Kalfa, 1997).

This paper deals with the higher degree of interactivity required and proposes a method for solving the technical problems arising from the external applications put on the Internet as if they were locally available to the student. The university has to keep the control on the interaction of a large number of students during such prearranged experiments. Chapter 2 discusses the problem of interactivity in more detail. Chapter 3 provides

[1] This work is supported by the German Ministry of Education and Research (BMBF).
insight into the architecture developed, while chapter 4 discusses the initial examples of the application of this architecture.

The Problem of Interactivity

Web-based interactive course materials are written in HTML. Such courses run locally on the student's computer and use a standard browser as the user's interface. HTML links are used for referring to the local and external Web documents. Interactivity is typically based on buttons, animated GIFs, image maps and animations. Here, animation is defined as a time-based manipulation of some target elements visualizing some (e.g. technical) process.Animations are considered to be running locally as a part of the interactive course. They are well-suited for illustrating specific aspects of the behavior of the complex processes. In this sense, an animation is typically based on an abstract model of the real-world, and it is completely specified at design time concerning its time behavior. Thus, an animation can not be considered as a substitute for a real-life experiment. Today, for example, Macromedia Flash (Macromedia, 2001) is a well accepted commercial solution for defining animations in the Web environment. It allows link-based navigation to other elements of the course and requires a browser plug-in for playing the so-called Flash movies. In future, open W3C standards for animation like SMIL (W3C, 2001a, 2002b) may become important as well, when they are directly supported by browsers.

Compared to animations running locally, interfacing of external simulators and real-life experiments is more complicated. The principal architectural requirements are illustrated in figure 1. The protocol "user-experiment" demonstrates the dynamic interaction. The user can change the parameter of the simulation as well as the kind of measurements and the monitoring time interval, on the fly. The minimum requirements are a control window, a visualization window, and a measurements window.

Figure 1: Requirements of the architecture (full lines designate the data flow, and the dashed lines the control flow)

A simulation program or a running experiment typically requires some control input and will produce measurement data and other output information. Measurements are feasible in a simulation model or can be implemented by monitoring a real-life experiment. In the second case, an instrumentation of the system under measurement is necessary. Operating systems, such as UNIX/LINUX as well as Microsoft Windows offer services for information about the parameters specific to the running system. Other may be added to operating systems, if the source code of the operating system is given, i.e. LINUX and now Windows, as well. The integration problem is even harder, when a "tight" integration is required, i.e. when the experiment or the simulator output affects the course materials presented. In this case, a different paragraph of the text may be presented, some alternative link in the presentation may be followed etc. Such cases require a dynamic
The rearrangement of the course material presented. Besides, the teacher may be interested in providing all his students access to the supplied experiments and in monitoring the students' progress.

Architectural Approach

This chapter describes the current approach to solve the problem of interactivity as outlined in the last chapter. The architecture developed is illustrated in figure 2. It distinguishes between the interactive course and the external simulators or experiments. The interactive course may be running on the learner's computer, perhaps at home, and on the learning system server running at the university site. The external simulators or experiments may be running somewhere, usually also at the university site. In some cases, it may be desirable to access these on the learner's computer. In other cases, a complex and expensive experiment setup may need to be provided centrally for several universities over the Internet. Principally, interaction between the learner and the experiment takes place indirectly through the learning system at the university. This ensures full supervision, control and feedback. It also keeps account of the learner's actions and controls his access to the experiments offered as well as synchronizes these.

![System Architecture Diagram](image)

**Figure 2: System Architecture**

A general approach for interacting with a remote program component is called the Remote Procedure Call (RPC) paradigm, considering the request/response type of interaction between a client and a server. Classical RPC systems, like SunRPC or DCE/Microsoft RPC are based on a binary encoding scheme for parameters and results. This binary communication scheme is quite inadequate for the WWR learning modules, programmed as XML documents. Thus, a new approach is needed, which allows for a seamless integration of the simulator/experiment results into the final HTML pages visible to the learner. Especially, this approach should be as generic as possible to cover all types of external components for all the different WWR modules under development as Boolean logic, circuit synthesis, processors, caches and something like this.

Our approach is based on XML documents. We currently envisage to use the so-called Web Service paradigm based on the Simple Object Access Protocol (SOAP) with attachments (W3C 2001c) for interaction between the learning system and an external experiment. SOAP uses XML documents for encoding input and output parameters and forwards requests using the HTTP protocol. The Web Services Description Language (WSDL) (W3Cd) is another XML-based notation. This describes services as a set of endpoints operating on messages.
These may contain either document- or procedure-oriented information. As a result, existing simulators or real experiments can be wrapped in order to transform them into a Web service. A big advantage is that SOAP wrappers can be often generated automatically, if an appropriate interface description is available.

Thus, the following interaction pattern results therefrom: The student is able to work most of the time locally on the course. Only when dynamic information is required for the external experiment or simulator, the browser will contact the learning system at the university site (1). Beside other components, which are not important for the discussion here, the learning system consists of a Web server with an associated servlet engine, an XML parser and a style sheet processor. Based on the student's input, a servlet will generate a SOAP request for the simulator/experiment Web service (2). When the response comes back as an XML document (3), it will be parsed and merged with the stored XML fragments. These are generated at course creation time by the included modules and processed by a stored style sheet. Its output is the final HTML page (4). This goes back to the student's browser (5). If a real-time measurement data stream from the experiment to the learner has to be supported as well, the approach described here can open a private communication channel between the experiment and a signed applet running on the student's browser, after this applet has been loaded from the university learning server (dashed lines).

This approach fulfils all requirements related to the dynamic generation of HTML pages and also has some other advantages: it keeps the student's environment simple. It just consists of his browser displaying standard HTML pages. The burden is put on the central learning system server at the university site which generates the more complicated dynamic HTML pages. This central server is able to uniformly interact with all simulators or real-life experiments used in all active courses. Furthermore, the learning system server is able to collect information about the students' access to the external simulators/experiments. This information may be useful for other components of the learning environment.

Examples

Currently two modules are being prepared for evaluating the approach described in the previous chapter. The "source code" of the modules are stored in an XML-based repository. From this repository, different kinds of modules of the same subject can be generated:
- pictures and interactive animation of phenomena supporting real lectures
- textbooks with pictures and interactive animation for self-study and for complementing real lectures (s. Figure 3)
- local and/or in a client/server architecture usable experiments (simulation or on a real system).

![Prozessorscheduling](image)

**Figure 3:** Snapshot of a “textbook-like” module
By means of the first module "Processor Scheduling" the student can measure the arrival rate, the service rate as well as the waiting time, the actual queue length and utilization in a simulation experiment for processor scheduling. Thereafter, he is able to compare the simulation results with the theoretical ones according to the model.

Figure 4: Snapshot of the visualization in an "experiment" module

The second module presents "Inter-Process Communication (IPC)", another topic of a classical lecture on operating systems. Here, the learning module interacts with real inter process communication examples being carried out on a remote Linux machine or a remote Windows NT system. In this way, the student experiences the classical UNIX IPC primitives like pipes and message queues and recognizes differences to similar NT abstractions.

Conclusions

We are convinced that learning by experiencing the phenomena of computer systems in simulation or/and in real working systems is very helpful for a computer science student to comprehend and to get acquainted with the more complicated topics in this field. Based on this assumption, we presented an architecture for integrating the external simulators and real-life experiments seamlessly into the course materials. These are being currently developed for the XML teaching and learning environment in the joint project "Wissenswerkstatt Rechensysteme" (WWR, Knowledge Factory for Computing Systems).

Abstract: The purpose of this research is to evaluate the new interface designs of the digital video clips for K-6 from the data, questionnaires, and interviews. The interface was changed on the following two points by the result of the previous research (Kamei et al., 2001): 1) Add up a function to stop a key scene of a clip for teaching, 2) Add up a function to connect the related clips. These two changes clearly meet teachers' needs and help their utilization in the classroom.

Introduction

The Japanese government promises that every classroom will have access to the Internet and have two PCs and a projector by 2005. From the promise, digital video clips, one of the digital materials, will have been much more developed near future. On our previous research, we grasped the tendency of the teachers' utilization and problems when teachers use the clips. In this time, we fixed the interface for viewing the clips by the above findings.

Research and Development

Clips Background
The clips and the interface were customized for elementary schools (K-6) in Japan. It was assumed that teachers would show the clips for their students. The subject is Japanese History. The image on the clips, 30-90 seconds, were selected from NHK (Japanese public broadcaster) archives, and re-edited.

1st Change: Add up a function to stop a key scene of a clip for teaching
It was clear that teachers often try to make a stop in the middle of clips, but they struggled. Therefore, we put small pictures which shows the position where the key scene is (Fig. 2).

2nd Change: Add up a function to connect the related clips
It was clear that teachers combined the clips in the different units. Although they wanted to use such way, it was very hard because each clip was isolated by the era categories. From that, our solution to this problem is to put and link a small picture which is related (Fig. 3).

Methodology

25 teachers were chosen and 72 clips were prepared for this research, April-July, 2001. Questionnaires and interviews were made in order to evaluate the changes. 22 of the 25 teachers were replied our questionnaire after using the clips. The interviews were made to 12 of the 22 teachers.
Results and Implements

1st change
In the first investigation, we compared with two groups, a group of key scenes with small pictures and without small pictures by the number of the teachers who stop and use the clips. As a result, the clips with small pictures are more stopped by teachers, comparing with the clips without small pictures (t=4.75, p<0.01)(Tab. 1).

From the interviews, there are two types of reactions: one is positive and the other is average. The reason of the positive reaction is that it is easy to show clips quickly. In addition, the teachers who are novice for teaching could easily recognize the key scene where many teachers think it is important for teaching.

The reason of the average reaction is mostly from the teachers who have much experienced for teaching because they did not care the key scene.

From these results, we concluded that the first change was efficient for the teachers because there is no negative opinion.

<table>
<thead>
<tr>
<th></th>
<th>Mean</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>With small pictures(43 scenes)</td>
<td>6.95</td>
<td>3.92</td>
</tr>
<tr>
<td>Without small pictures(293 scenes)</td>
<td>4.03</td>
<td>2.50</td>
</tr>
</tbody>
</table>

Welch's t-test (N=22, t=4.75, p<0.01)

Table 1. Scene stopped

2nd change
Table 2 shows the ratio of the pair of clips (A and B) with the new interface. The utilization of the clip A in 2002, which is put and linked the small pictures, is higher than Clip A in 2001.

From the interviews, all teachers evaluated that the second change were efficient. The main reason is that it is easy to show clips quickly because they did not need to go back to the top page of the unit one after another.

From these results, the second change, put and link the small pictures on the same page, was efficient for the teachers.

<table>
<thead>
<tr>
<th></th>
<th>Clip A</th>
<th>Clip B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2002 (N=22)</td>
<td>95.5%</td>
<td>100.0%</td>
</tr>
<tr>
<td>2001 (N=27)</td>
<td>77.8%</td>
<td>-</td>
</tr>
</tbody>
</table>

Table 2. Utilization of a pair of clips

Conclusion

It is concluded that the new interfaces, which put small pictures under control bar, would be helpful for a teacher to select a key scene. Teachers immediately could show the scene that they want the students to watch. The second change, put and link the small pictures on the same page, are also efficient for the teachers.

Further research would be needed especially on the following three points:1) Needs to conduct experimental study. 2) Needs to collect more data about the teacher’s utilization of the clips.3) Needs to develop the system to reflect the data from the teachers’ past usage.

Bringing Computer-Supported Reading One Step Further
Individual Assistance through Screen Typography and Speech Synthesis

Gjertrud W. Kamstrup, Eva Mjøvik
Norwegian Computing Center, kamstrup@nr.no

Anne-Lise Rygvold
Department of Special Needs Education, University of Oslo, Norway

and Bjørn Gunnar Saltnes
Aschehoug Education, Oslo, Norway

Abstract: The research focus of this study is how to use computers to support and improve dyslexic students' reading and writing performance. More than 10% of the population is estimated to experience substantial difficulties. We propose to offer personalised text formatting according to individual profiles when reading screen texts, and preliminary studies indicate improved reading performance among poor readers. We also propose to use speech synthesis in order to give auditive support to the reading process. Improved reading is of importance both to the students' motivation and the overall learning outcome. It is important that the increasing use of computers in primary schools does not result in just another arena for shortcoming for dyslectic students.

Introduction

Reading consists of two components; decoding and comprehension. Decoding refers to the technical skill that enables the reader to transform printed letters into recognised words as the basis for activation of meaning. Comprehension is a cognitive process that allows the reader to interpret the text, which includes thinking processes on higher levels. This basic concept of reading must be completed with an additional component; motivation. Motivation is crucial in all learning tasks.

Some research shows that as many as 15--20% of the students in primary and secondary schools have problems in meeting the required level of literacy in today’s society (Catts and Kahmi 1999, Solheim and Tonnesen 1999). Other studies, however, show a substantially lower prevalence of reading problems. At the onset of the 21st century the computer is increasingly being adopted as a relevant tool (and medium) for reading and writing. Both in Norway and internationally, the number of computers per student has increased over the last few years as well as the time spent working with them. It is of great importance, however, to realise that the introduction of computer technology in schools implies both a risk and a possibility. If the special needs of students with literacy problems are not recognised and taken into account, the use of computers in classroom based project groups may well represent an additional hurdle instead of a compensatory asset.

In our work we have developed a prototype to support reading on screen for persons with reading disabilities. The basic functionalities offered in the first version are:
- personalised text formatting;
- auditive support using speech synthesis (single words, sentences and paragraphs).

The target group is students (primary and secondary school), but the software may be useful to adults with reading difficulties as well. In a future version functionality supporting writing and project work will be added. Our study has a twofold focus: a) utilisation of the computer to help students with reading and writing difficulties to decode and comprehend, and b) application of technology in such a way that these children are integrated in the computer-based activities in the classroom.

948
Reading: support for decoding, comprehension and motivation

Decoding support: From research conducted over the past 20 years, we know that many factors influence legibility of texts on computer screens, see (Kamstrup et al., 2002 and Harrell 1999). Computer texts may be formatted according to individual reading levels and personal preferences, a possibility the printed book does not offer. Our prototype supports adaptation of font type, font size, line length, line spacing, word spacing, type colour and background colour (see Kamstrup et al., 2002). Each student can create her own individual profile, and subsequently all texts that the student chooses to read will be formatted according to her established profile.

Comprehension support: Several researchers have recommended the use of speech synthesis to support decoding and comprehension in children with reading difficulties (Wise 1997, Lewin 2000). Wise et al. (1997) found that speech synthesis substantially improved the disabled reader's reading performance, and this has recently been confirmed by Lewin (2000). The prototype offers a "read-it-loud-to-me" functionality through speech synthesis. The student can choose to listen to words, sentences or paragraphs according to the individual needs. The words are highlighted while being read.

Motivation: Speech synthesis supports comprehension, and provides for the poor reader a necessary distance to the laborious task of technical decoding and as such strengthens the communicative aspect of literacy. This may make the reading task more enjoyable, stimulate further reading, enhance a sense of mastery, and trigger more motivation.

Results and future research

We have conducted preliminary studies that indicate both improved reading performance (Haugen 2001) for poor readers and increased motivation for reading when using our prototype. Further and more in depth studies are necessary to show the real effect of reading individually adapted texts on the computer screen as compared to traditional paper-based reading, and experimental designs that can show this effect must be developed. Such studies will be carried out in the context of this research project over the next two years.

Conclusion

Knowing that children with reading and writing difficulties are motivated by certain uses of computer technology, this must be exploited for the best of struggling readers. Computers are an integral part of the daily life of many children, and we must ensure that the process of introducing computers in the classrooms will be an asset for all students. Several researchers have shown improved reading either by the means of screen design and typography or by speech synthesis. In our prototype we have integrated these two options to make an even better support for dyslexic children.

Abstract: The purpose of this research is to develop a collaborative architectural design system. Design collaboration requires an extensive use of communication methods as well as the participation of various experts from different domains. Such facts address several issues when the Internet and digital media are able to create a completely new work environment. The building design process was studied, and possible modes of design collaboration were defined. A prototype system is being developed in accordance with the defined collaboration model. The system integrates a set of communication tools and web-based design media. Such media include a synchronous multi-user Web CAD tool, a schematic 3D design tool, and a graphic whiteboard. A project database was designed in order to coordinate the project-wide communication which elaborates technologies such as web-based data access. In order to find out the effectiveness of the system, a usability test was performed both in quantitative and qualitative manner. The research will contribute to the development of world-wide design and construction collaboration through the Internet, which is becoming a mainstream building process model.

Introduction

In architectural design team works are often required, and thus collaboration from a number of participants of various specializations is needed to complete a project. For collaboration the design process should be formalized, and communication methods should be established. Since Internet and multimedia play an important role in current computer applications, it is desirable to develop a collaboration system which manages and integrates design data and project data by various communication tools and digital media [11]. Collaboration based on multimedia communication though World Wide Web enables designers to share both synchronous and asynchronous information on database, and thus to manage design project effectively. This is due to enhancement of operating system tool libraries and programming API's which make Web-based programs efficiently share 3 dimensional design data and work space among multi-users. These kinds of technological opportunities and communication needs in design process naturally lead to the development of real time design information sharing system, virtual design studio for collaboration.

Recently efforts on the development of collaborative systems have been made, but they focused on asynchronous text-based document management instead of synchronous information sharing. For a collaborative system to share
design work space, it is required not only to overcome technical barriers but also to understand the design process. The purpose of this study is to develop a collaborative design system which let designers generate design objects and discuss them synchronously through the Internet. For the system a number of different types of graphic tools are introduced according to design development stages; graphical whiteboard, Space Builder, Space Planner and WebCAD. The system also supports asynchronous communication means like web-mail, project bulletin board, chatting board and video conferencing.

For effective collaboration in architectural design following aspects should be considered. First, visual communication by graphics is more prevalent than by text or dialogue. Second, design data should be stored in a database along with media objects as their container and project management schedules [7]. Third, collaborative working environment should be differentiated and be supported accordingly. Fourth, such design related information as building regulations should be linked to generated design data for design evaluation.

**Conceptual model and system components**

In order to develop the system the communication model of the design process was investigated, and then tools are defined for model components. The system environment is designed to integrate these tools (Figure 1), while multicasting technology is adopted for synchronous communication (Figure 2). The system has project database for design data at the center, and design data are reported by project work schedule.

![Figure 1 System structure](image1)

**Design and communication tools**

To support design and communication activities through the design process Web-based functional tools are implemented. The design process consists of primitive sketch, conceptual modeling, schematic modeling and detail construction modeling. For this study three early stages are taken into consideration to cover design studio curriculum at colleges. Light-weighted graphic programs which have limited graphic functions but enable designers to share work space in real time is very important for synchronous communication during early design stages. Following tools are developed to share work space by Internet for multi-users,

*Early sketch tool : Graphic whiteboard*

At an early design stage designers need to communicate with a simple sketch tool. Graphic whiteboard is similar to existing electronic whiteboard augmented with graphics functions. However, sketch data are stored for reuse at later stages.
Mass design and study tool: Mass Builder
For a conceptual model 3 dimensional solid design objects (building mass) are represented and displayed in real time to project participants.

Space configuring tool: Space Planner
After a building mass is studied, division of the mass vertically and horizontally for interior space configuration is required. Space planner is developed as a separate module.

Schematic design and drawing tool: WebCAD
At the schematic design stage spaces are defined elaborately with precise dimensions and antidotes for building elements. For this purpose a Web-based CAD program is developed.

Design Information Center and Project scheduler
To evaluate a proposed design, related information is retrieved from the database through Web page interface. Building codes, construction and engineering specifications and similar project design data are primary data sets which will be growing richer as users contribute relevant information. When users participate in a project session, the project scheduler will provide work management space of a calendar type interface.
Notable features of virtual design system

Virtual design system provides an integrated collaboration design environment. Collaboration design environment requires a number of networked computer application softwares which enable multiple users at different locations to share ideas, design information and data both synchronously and asynchronously. The system supports this kind of work environment.

The system has a number of rich multimedia databases. Architectural design information is documented in tow primary formats; text and geometric objects. Project database, case database and scheduling database are constructed with various multimedia formats such as graphics, images, animated data, video and voice data. In an era of multimedia generation, it would be quite natural to store, search and use multimedia data for design projects.

The system has convenient visual communication tools. General purpose communication tools such as web mail, text and voice chatting are included in the system. Furthermore, synchronous whiteboard for sharing ideas and data is embedded in the system. Therefore, synchronous / asynchronous and text/multimedia communications are supported in the system.

The system has outstanding web-based architectural design tools. In architectural design, visual objects are used for effectiveness and efficiency in communicating with other members who are involved in the same project. At the early stage of design, visual objects are sketched images. As the design proceeds, they become geometric objects that have mathematical properties. To be more precise, physical object specification annotations are added to the objects. For the system, web-based visual tools for sketching, 2D drawing and 3D modeling are implanted.

The system has near-perfect work schedule management tools. Design project management involves precise scheduling of design process and workers in various areas such as construction, electrical field, etc. Therefore, the system provides work calendars for keeping track of work progress. That could be used as checking points.

Usability test

Usability testing has been performed to evaluate the efficiency and effectiveness of the system. In order to increase the test authenticity, three real architectural design projects - museum, office and house design- were assigned to three different groups. Each group consists of three designers. The entire design process of three teams has been recorded using videotapes. A survey and interviews were also conducted to investigate the perception of the...
participants toward the function of the system.

On the basis of videotape data analysis, the design process of each team has been identified and integrated as the following steps:
First, after the log-in process, the designers opened the whiteboard and chatting board to communicate their initial ideas synchronously. They used the picture files of the ground and surrounding environment to review the possibilities. Secondly, the designers used the Info-center to search for the similar drawings and related regulations. Thirdly, they started to Mass Builder to generate 3D mass and communicate through the chatting board. Finally, they used the WebCAD to draw the 2D drawing and share their comments using bulletin board. Designers were hardly used the Space Planner to avoid the risk of spending too much time to build the 3D simulation.

The results of the survey and interviews identified the most used and comfortable functions and identified the most needed modification of the system. Whiteboard and Mass Builder were the two most used functions. Info-center, Mass Builder and whiteboard are the most comfortable functions perceived by the designers.

Designers asked to modify the following four functions the most:
First, designers asked to integrate the drawing and writing functions of the whiteboard. Second, designers asked to integrate the whiteboard and Mass Builder in order to share their ideas effectively as well as efficiently. Third, designers wanted to have their own team bulletin board and team Info-center for better communication and ownership. Finally, and mostly designers required to have data transfer. For example, data generated by whiteboard should transmit to the Mass Builder for the foundation to avoid the repeated work.

Other than functional requirement, the role of team leader or facilitator is a major variable to the success factor in collaboration. Therefore, the training or assisting function a team leader or project manager should be included in the system.

Conclusions and future works

Using the Internet as a communication method arises security problem of the system. This problem is not solely subject to technical solution, but multitudinously subject to communication models during the design process.

Virtual design system also needs extended works in following areas. First, graphic data file format should be standardized for the data exchange with existing systems. Second, mark-up methods should be developed to search and manage semantic values of design objects. Third, formalization of the design process should be elaborated to establish project schedule by stages.

Abstract: This paper describes development of the Media Literacy Tool (MLT), a web-based media literacy and media effects research and learning tool. Media messages have permeated our world. Humans today, in many cultures, are bombarded with communications from advertising television, video games, etc. Many of these messages are created with specific intentions to evoke particular responses. Most of us are not equipped to critically receive these signals, and many of us fall victim to effects of media exposure. MLT is designed to address the poverty in media research and education. As a tool for supporting collaborative content research, critical observation and emotional awareness, MLT will facilitate media effects, literacy and resiliency research.

Rationale

Television, video games and music have been cited as a causal factor in increased levels of violent behavior in many studies including National Institute of Mental Health, 1982; Murray, 1980; Rehman & Reilly, 1985. Heavy viewing of television has been tied to increased fear about real world personal safety (Signorielli, 1991). Videogames have been found to play a role in the development of unhealthy self-image among girls (Children Now, 2000). Positive effects of viewing television have also been documented through the demonstration of increased prosocial behavior (Fairchild 1984) and the development of academic skills (Rice, Huston, Truglio & Wright, 1990).

Media educates both intentionally and unintentionally. Yet not enough research is conducted to document the contents of media messages and examine the effects of media exposure and possibilities of media education. Only a few countries, such as Canada and England, have recognized the need for formal media education at the pre-college level.

Many public interest groups and concerned individuals have recognized the need to have a media savvy society. Groups like Action for Children’s Television, The Center for Media Education, Alliance for a Media Literate America, National Institute on Media and the Family, and Citizens for Media Literacy were formed to have greater political and programmatic influence over the production, consumption and monitoring of media.

The Media Literacy movement is desperate for consistent broad research and data collection. In only a handful of published studies have researchers taken a sustained look at a breadth of elements and their relationships. Research has focused on analyzing a specific aspect of a particular medium during a brief time period. Quantification and deconstruction of various media has never been done on a large scale for a sustained time period.

Media educator Rene Hobbs emphasizes the skills of reading and writing in relation to media literacy. In addition to data compilation, MLT focuses on the reading of media. Through the act of critical observation, participants will become more cognizant of what they are viewing. Becoming more observant and critical of media messages perhaps makes one more resilient to media exposure. As Anderson and Ploghoft (1993) suggest, awareness individuals build allow for better comparison and contrast with every day life. Pilot research will explore the potential of critical observation in viewing and its influence in developing media resiliency.

Program Design

MLT will collect, compile and organize information about the content and structure of various media, including television, music, movies, magazines, Internet, videogames and advertisements. The databases will be accessible through the web, enabling a wide range of individuals to access and contribute to the data and fields, and perform analyses of variables across different media. Example variable sets include character (such as species, gender, race, age, sexual orientation, occupation, behavior [acts of kindness]), setting (indoor/outdoor, view of sky), time (day/night, sequence of events, period, season), formal features (#cuts per
second, dissolves). The goal is to compile the most comprehensive database, tracking all messages transmitted through various media, while fostering more critical observation of television content and greater consciousness of emotional reactions in media viewing experiences.

The original concept for MLT arose in development of “Television and Development of Youth” online (Kaplan, Espinet, Mouza, & Van Nest, 1999) and was discussed in a paper on tools for online collaboration (Mouza, Kaplan, & Espinet, 2000). Rough drafts of MLT were piloted by the Fall 1999 and Fall 2001 classes. Pooled data collected during individual television viewing was informative, documenting ethnic, gender and behavioral trends in television programming, and serving as a communal resource in discussion and research. Students reported that observation activity led to greater awareness of media messages.

MLT will include several interfaces for various age levels including: children age 2-5; age 6-11; adolescents from age 12-17; and adults age 18 and up. Each interface will be designed for age appropriateness, informed consent will differ, and certain variables will not be accessible to all audiences. Most fields will be common to all users.

MLT encourages community data collection. One pool of “data” will be submitted by trained coders. Example media will be viewed, analyzed and discussed in order to achieve the highest degree of inter-coder reliability. A second pool of data will be contributed by participants who access the MLT via the web. A personal profile will include personal characteristics fields, and track submitted data (with permission).

Participants will respond to sets of fields about media under observation. Fields will be divided into sections based on characters, action, setting, and formal features. Databases will allow for comparison and compilation of fields. Participants will be able to customize the interface and variables sets for personal observation or for facilitation of use by a target group, curriculum or research study. A media diary will be available for participants to indicate what shows, songs, etc., they have experienced on a particular day, and thoughts and feelings they inspire. A lesson archive will provide frameworks around which to design, submit and conduct lessons involving viewing, observing and analyzing data. Printable forms will be available for offline work.

The project team plans to connect with several other database projects currently under development at Columbia University. One tool under development by Kaplan and Hasher, the Ecology Observer, will facilitate observation, data collection and analysis of ecological elements in real spaces, as in the corner of 120th and Broadway, over space and time. The combined use of both tools will allow for comparisons of the real world to the media world.

Abstract. GAIA is a microworld-based learning environment aiming to provide means for exploratory learning to secondary school students in the fields of physics, mathematics and geosciences. This paper presents Gilbert, one of GAIA's microworlds aiming to familiarize students with contemporary geosciences.

Introduction

Unlike in other fields of studies, such as physics and mathematics (Thornton and Sokolo, 1990), most of the available commercial educational software related to Earth School Studies, is either drill-and-practice oriented, where students are presented with problems to solve and they receive feedback about the accuracy of their responses, or tutorial-based oriented, following the archetypal form of text, graphics or multimedia information associated with relevant self-evaluation tests. However, such environments (Kali et al. 1997) do not strongly facilitate students towards constructing their own knowledge through open-ended experimentation (Jonassen, 2000). On the other hand, microworld-based educational software can provide the means for exploratory learning, by providing the environment for students to learn-by-doing, rather than just watch or listen to a description of how something operates. Briefly, a microworld is a computer-assisted problem exploration and experimentation space in which one can explore and construct. Typically, they are constrained versions of reality that enable learners to manipulate variables and experiments within parameters of some system. Furthermore, the most advanced microworld-based educational software provides the means to educators and learners to construct their own exploration spaces. This is this the case of GAIA which allows learners to represent their own thinking in the ways that they explore, manipulate and experiment with the environment.

Figure 1. Overview of the GAIA Project Design and Development Process (Papageorgiou et al, 2001)
GAIA is a microworld-based exploratory learning environment in the field of geosciences education, physics and mathematics. This is accomplished through constrained simulations of real-world phenomena in which students can navigate, manipulate or even create objects, and experiment with their effect on each other. In the current version of GAIA, seven microworlds - named after great scientists - are designed and developed to provide the environment for replicating the essential functionalities needed to explore phenomena about the Earth and the planets, regarding their interior, atmosphere, morphology, magnetic field, their orbits in space as well as their astronomical environment. Figure 1 gives an overview of the GAIA project design and development process (Papageorgiou et al, 2001). The development of GAIA is based on the component-based educational authoring environment “E-Slate” (Birbilis G. et al, 2000), which provides a workbench for creating highly dynamic software with rich functionality (Roschelle et al, 1999).

The Gilbert microworld, presented in this paper, deals with Earth's magnetic field, within the frame of the school curriculum. This microworld aims to the comprehension of Earth's magnetic field concept and how contemporary science studies and explores this field. The Earth's magnetic field is one of the most attractive concepts to students' imagination, but its teaching becomes difficult as it is hard for them to resolve its vector within the 3D space in relation to geographical coordinates, and to precisely comprehend its existence as they do for instance with the concept of temperature. The Gilbert microworld contributes to all the aforementioned and familiarizes students with the existence and nature of Earth's magnetic field.

Earth's magnetic field study through GAIA software

The Earth’s magnetic field can be directly noticed by the students with the use of a magnetic needle and that is the reason why they must be familiarized with the compass use in school laboratory. This is usually done through the measurement of the field's direction. Although laboratory measurement is useful, it limits students to identify and measure earth’s magnetic field, only at the place they are.

The GAIA interactive software presented in this paper allows students to virtually travel everywhere on Earth, and measure earth’s magnetic field elements (Figure 2). Students have also the possibility, besides the compass, to use a total magnetic field magnetometer. The selection of the virtual site for the experiment is accomplished either on a 3D rotating globe (see Figure 2: top left window) or on a plane geophysical map. The altitude where the measurement is taken place is set in another window (see Figure 2: top right window), by pointing the mouse on a magnetometer sketch on the screen, or alternatively by regulating a properly designed "slider" (see Figure 2: bottom right window). The perspective of earth’s projection is done in such a way, as to show the magnetometer's sketch on the screen. In another window (see Figure 2: bottom left window) students can observe and use three instruments: a horizontally positioned compass that measures declination, a compass placed in the magnetic meridian plane that measures magnetic inclination and a total field magnetometer.

In parallel to the virtual measuring of the field, students can also observe the resolved components of the magnetic field vector at any point around the Earth (see Figure 2: top middle window). In this resolution the quantities of field's intensity, declination and inclination are clearly noticeable. The students have also the possibility to visualize and resolve the vector within the Cartesian system coordinates. In addition, they can rotate the projection of the vector representation for more convenient observation of the relative angles and vectors.

At a higher knowledge level, students can also change the value of the measurement date parameter, provided that they have been introduced in the field's variation with time. Of course, it is assumed that the students have also learned some basic notions about the origin of the Earth's magnetic field. Measurement values are simulated to real ones as they based on the IGRF (International Geomagnetic Reference Model) geomagnetic field model of International Association of Geomagnetism and Aeronomy (IAGA 1995). This model is designed to approximately calculate Earth’s magnetic field from Earth’s interior upwards into space without taking into account external magnetic field sources. It is based on the usual expansion of the spherical harmonics of the potential in geocentric coordinates (Campbell, 1997; Lowrie, 1997) and describes the field’s variation within time. At regular times, new spherical harmonics coefficients supplement it in order to renew and fix its anticipation in the future. In view of the educational purposes for which the model was used, the magnetic field values had no higher accuracy than that of the order of 1 μT.
Figure 2. In a special configured environment, students can select whichever place of the world they like on a 3D rotating globe or on a plane map, and to measure the magnetic field's elements at a certain height, meanwhile they can see the field’s vector analysis.

Figure 3. A window of Gilbert microworld that presents Earth’s magnetic field main dipole component. Students experiment with placing and moving a number of compasses and finally become accustomed to the lines of force notion.

The dipole component of the Earth’s magnetic field, which consists the 95% of the total field, is presented in another window of the Gilbert microworld (Figure 3). In that window, students can test the field’s existence around the whole planet Earth by a number of compasses that can freely move into space. In this environment, students can easily learn the lines of force as well as to magnetic poles natural position. Field’s lines of force may be displayed at student’s choice.

Displaying the three elements of the magnetic field (intensity, declination, inclination) on maps (Figure 4), it helps students to realize that these three elements coexist in every point and are modified at the same time. For instance, students can observe the magnetic poles in the three maps, to compare their observations and to realize that in all of these three plots the poles have characteristic features. Students also realize that in many places on earth, compass points out to a direction deviating considerably from the North. The coincident display of these three maps reveals the value of the “multiple representations” as well as the “direct manipulation” of the objects (Teodoro, 1990; Shama and Layman 1997).

The introduction of examples from an Applied Geophysics geomagnetic survey was one of the essential innovations of GAIA in the teaching of the magnetic field in secondary education level. Beyond the comprehension of notions as the induced magnetization, the addition of the induced field vector to the Earth’s field and the magnetic permeability of the materials, the microworld further aimed to present a simplified example of a practical application of Earth’s magnetic field measurements, such as the detection of mineral deposits and the antiquities.

In the environment shown in Figure 5, students experiment with a buried plate of square or rectangular section. The plate is considered infinitely elongated in order to simplify the problem from the existence of edge anomalies. The plate is oriented E-W while the magnetometer is moving and measuring vertically to the plate, to N-S (Figure 6). The plate’s magnetization is considered only induced and its material can be selected out of a large variety of geological rocks with different values of magnetic permeability. For each rock, typical values of permeability and susceptibility are given, in companion with the range of these values in the real state.
Although the virtual experiment can take place everywhere on Earth, we suggest the choice of three places with characteristic inclination (θ) values. These are: the North magnetic Pole (θ = 90°), the magnetic equator (θ = 0) and an intermediate place like North Africa with inclination equal to 45°. Anomalies observed in measurements of the total field above the buried plate in these three areas are advisable for the induced magnetization presentation to the high school students.
At the North magnetic Pole the Earth’s magnetic field vector is perpendicular to the plane of measurements. Since the particle magnets of a paramagnetic material are polarized according to the field (a diamagnetic material causes the opposite effect) the induced magnetization will be also perpendicular to the plane of measurements. In the case of paramagnetic materials, which are the most common in nature, the plate’s induced magnetization is shown in Figure 7. The lines of force of the induced magnetization field of the body are symmetrical relative to the vertical axis that passes through the centre of the body’s section. The values of the measurements are increased at the points where the body’s field has the same direction with Earth’s field, while are reduced where the two vectors are opposed. At the points where body’s field is horizontal (like on body’s sides), no essential variation is resulted.

In magnetic equator \(\varphi = 0^\circ\) Earth’s magnetic field vector is horizontal. Following the aforementioned technique, it is easy to find out that the diagram of the measurements is also symmetric to the body but inverted in sign in relation to the one of the North magnetic Pole (Figure 8). In body’s centre, the lines of force of the body’s induced magnetization are opposed to the Earth’s magnetic field and thus the field’s anomaly is negative. In the case that inclination is \(45^\circ\), the lines of force are symmetrical to body’s diagonal (Figure 9). The magnetic field’s anomaly has an asymmetrical pattern and therefore its interpretation regarding body’s position becomes more complicated. The point where Earth’s field vector is vertical to that of dynamic lines is just above the body, and there we observe that field’s anomaly is practically zero. With exception to the magnetic poles and equator the diagram is asymmetric at all the other positions (More details in Dobrin and Savit, 1988).

By the final stage of the microworld Gilbert students can comprehend the notion of induced magnetization and how it is depending on the magnetic properties of materials. From the example of the magnetic survey the students are introduced to the field of Applied Geophysics and its contribution to the detection of oil deposits, minerals, antiquities, etc. Contemporary science can provide students with many such examples, possibly exciting their interest for acquiring new knowledge.

Figure 8. Earth’s magnetic field anomaly caused by the induced magnetization of the square section buried plate in the magnetic Equator.

Figure 9. Earth’s magnetic field anomaly caused by the induced magnetization of the square section buried plate in position with magnetic inclination equal to \(45^\circ\) (e.g. North Africa)
Conclusions

The GAIA software was designed and developed to allow to operate a virtual educational laboratory addressed in secondary school students. Students may comprehend basic notions of Earth’s magnetic field and become accustomed to them as well as with other more fundamental notions of magnetic field theory, such as induced magnetization. A number of activities based on Gilbert microworld have been already created. Students, working in teams under teacher’s guidance, can enhance their knowledge on Earth’s magnetic field by experimenting with Gilbert. Initial evaluation of students performance indicate a significant advantage in their understanding on basic Geoscience concepts when using GAIA as compared to their traditional school teaching methods.

Online Privacy, Security and Ethical dilemma: a Recent Study

Nitya L. Karmakar Ph.D
School of Management
College of Law and Business
University of Western Sydney, Australia
e-mail: karmakar@it.uts.edu.au

Abstract: The Internet remains as a wonder for the 21st century and its growth is phenomenon. According to a recent survey the online population is now about 500 million globally and this trend continues, it should reach 700 million by the end of 2002. This exponential growth of the Internet has given rise to several security, privacy and ethical concerns. There are laws governing those issues at several countries, but hard to apply it due to the rapid change of the technology and also security breach. Internet commerce or electronic commerce (e-commerce) poses constant threats to privacy and security. The web has become a playground for lawbreakers. The aim of this article is to give a snapshot of the current status of the Internet and also how it is creating a nightmare for governments to find a way to safeguard both consumers and providers of information from possible misuse. The author argues that the use of the Internet must be controlled with proper legislation to minimize its negative impact on our society. There should be an international law and or a 3rd party monitoring authority so that proper protection could be offered to the users of this ever-expanding technology.

Introduction

The rapid development of information technology and the Internet have dramatically increased the quantity of information available in digital form. This has resulted in a proliferation of uses of personal information. Some of these have major implications for the privacy of individuals. The World Wide Web (WWW or the Web) has created a totally new global business culture and environment. The new way of doing business across the globe is called electronic commerce (e-commerce) or online or Internet commerce or business by computers and networks. So the Internet will create a huge market in cyberspace and carry valuable information to a large number of people worldwide. This will give rise to a global knowledge based economy or information economy (Karmakar, 2001a & 2001b). The emerging electronically networked-based information economy will affect how we are governed and how we live (Kobrin 1998). The growth of the information economy also means that there are new threats of security, privacy, ethics and other types of online harassment such as fraud and deception.

The Internet Statistics in a Nutshell

The convergence of information and communication technology (ICT) is transforming most aspects of business and consumer activities. The growth of the Internet is dramatic. According to a recent survey by Nua¹, Internet population worldwide as of August 2001 was 513.41 million. The same survey gives the estimated number of online population around the world [Table 1].

Electronic Commerce: A Challenge

Electronic commerce will significantly increase online business across countries. It will help the delivery of wide range of goods and services in a cost-effective way. With e-commerce set to top US$1000 billion at the end of 2002, the potential for making a fortune by exploiting security breaches is huge. A recent survey of Fortune 500 companies indicated that 62 per cent of firms have suffered computer break-ins during the past year. Identity theft – the use of another person's credit card number and personal details – is on the rise, and threatens the viability of electronic trading (Besserglik, 2000). As more and more business goes online, confidential files are increasingly exposed to the risk of infiltration.

Cyber crime in the new millennium

Companies worldwide have lost $3 trillion from cyber crime. Requests for assistance from the Australian Securities and Investment Commission have increased from eight to 200 in the past two years (Cant, 2002). Research shows companies fail to report cyber crime for fear of negative publicity. A survey by the US department of Defence Cyber Crime centre showed 36 percent of companies reported such crimes. In one of the biggest attempted cyber-scams to date, a thief stole 300,000 credit card number from Internet music company CD Universe in December 1999 and posted them on a website after it refused to pay a US$100,000 ransom. From January 1 to December 31, 2001, federal ID Theft Data Clearinghouse received 86,168 reports of identity theft from across the US, with the District of Columbia and California being the main hot spots. Other uses for stolen information involved employment related fraud (9 per cent) and government benefits fraud (6 per cent)(Deanne, 2000). Network security is not generally very strong, and web and web server vulnerabilities are the main source of credit card information breaches.

Ethical Issues in Cyberspace

Ethics is at the heart of social and political debates about the Internet. Ethics is the study of principles that individuals and organizations can use to determine right and wrong courses of action (Laudon & Traver, 2002). Companies using Web sites to conduct electronic commerce should adhere to the same ethical standards that other businesses follow. Ethical considerations are important in determining advertising policy on the Web. Shea (Shea, 1994) identified 10 Core Rules of Netiquette:

i. Remember the Human
ii. Adhere to the same standards of behaviour online that you follow in real life
iii. Know where you are in cyberspace
iv. Respect other people's time and bandwidth
v. Make yourself look good online
vi. Share expert knowledge
vii. Help keep flame wars under control
viii. Respect other people's privacy
ix. Don't abuse your power
x. Be forgiving of other people's mistake

Issues on Security and Privacy

Security and privacy are interrelated. Information should be used only for the purpose it is collected. Many companies are using the Internet with caution because of concern about network and transaction security. Similarly many customers do not feel secured to making payments over the Internet. As the information concerning credit card numbers or other confidential records traverses on the Internet, there is not yet a reliable method of preventing third parties from accessing this confidential information. A third party unlawful intervention arises when a hacker or some other source has the potential to interrupt data or network resources. This may bring to a company heavy economic loss, which may be in the form of destruction, disclosure, modification of data and other form of abuses. In order to allay consumer fear and protect the confidential data on public networks, companies are starting to pay greater attention to transaction privacy, authentication, and anonymity.

The Internet with no legal boundaries raises concerns about personal privacy. The security and privacy issues are very serious as long as hackers continue to hack on the Net. Personal information and privacy of communications must be protected without any question. Business and consumer concerns about security are legitimate irrespective of countries we live. To minimise risks, the protocols and infrastructure for secure transmission of information are in place or developing.

Security, Privacy in Cyberspace: Legal Framework
Real space means our physical environment consisting of temporal and geographic boundaries, whereas cyberspace is defined as the realm of digital transmission not limited by geography. Privacy online is a legal issue, and there is difficulty of applying traditional law to the Internet. The creation and use of knowledge or information are key economic activities all over the world. Sometimes information does harm. It ruins reputations, exposes personal secrets, inflicts emotional injury, and misleads people into mistaken purchases and investments. The law must determine who bears the risk of loss from such harm—not only originators and victims, but also among originators, victims, and all the intermediaries who handle injurious information (Perritt, Jr. 1996).

Commercialization of the Internet has created a difficult task to establish an international legal framework to maintain security and privacy in cyberspace. There should be technological means to secure data on the net and also a legal safeguard to protect individuals from the possible misuse of the medium. Electronic commerce presents a fundamental challenge to the law. The suitable law should tackle the threat of security and privacy when we do business online in the digital economy (Karmakar et al., 2001).

Network security will help to protect privacy. Legal systems must be adaptive to the rapid changes of technology. Existing legal frameworks are outdated for protecting privacy (Loudon 1996). Until the legal environment of privacy regulation becomes clearer, electronic commerce sites should be conservative in their collection and use of customer data. Mark Van Name and Bill Catchings, writing in PC Week in 1998, outlines four principles for handling customer data that provide a good online for Web site administrators. These principles include (Schneider and Perry, 2000):

- Use the data collected to provide improved customer service,
- Do not share customer data with others outside your company without the customer’s permission,
- Tell customers what data you are collecting and what you are doing with it,
- Give customers the right to have you delete any of the data you have collected about them.

International Dilemmas

Surveys have found that privacy, piracy, and pornography are the most serious concerns of Internet users. The European Union has established strict privacy laws: “all members countries of the European Union must restrict the export of personal data to countries that do not provide privacy protection that is up to European standards, at least from October 1998 for those that have not already done so, and the restrictions are much tougher than in previous European laws.” The European Union’s privacy Directive of 1995 is the most significant international statement of information privacy principles since the early 1980s [Greenleaf 1998]. The Organisation for Economic Cooperation and Development’s Guidelines on the Protection of Privacy and Transborder Flows of Personal Data attempt to balance the protection of privacy and individual liberties and the advancement of free flows of personal data through eight privacy principles: Collection Limitation, Data Quality, Purpose Specification, Use Limitation, Security Safeguards, Openness, Individual Participation and Accountability which, if observed, are supposed to guarantee a free flow of personal information from other OECD countries [Greenleaf 1998]. All 25-member countries of the OECD have adopted the Guidelines [Tucker 1988]. Most European countries have passed laws for the public and private sectors based on the OECD principles. New Zealand, Hong Kong and Taiwan also have privacy laws that apply to both public and private sectors. Other countries like Australia have implemented them in part only.

The Council of the OECD has adopted Guidelines for a Cryptography Policy in March 1997, setting out criteria for encryption of computerised information for governments to adopt and for businesses, individuals and law enforcement officials to apply in safeguarding electronic transactions, communications and data storage.

The U.S. Government's Framework for Global Electronic Commerce calls for governing commercial transactions on the Internet ‘consistent principles across state, national, and international borders that lead to predictable results regardless of the jurisdiction in which a particular buyer or seller resides’ (Clinton & Gore 1997). European-American disagreement on encryption and piracy may lead to a constant problem to introduce a uniform safeguard (Kobrin 1998). An increase in the use of tools such as E-mail, data bases and computer networks has Canadian companies generally feeling more exposed when it comes to the security of internal communications and proprietary information (Church 1998). Northern Telecom, based in Toronto, Canada has programs to ensure that its employees realize how important it is to safeguard sensitive information. It also conducts physical and electronic audits to ensure that important papers aren’t left on desks.

2 http://europa.eu.int/comm/dg15/en/media/dataprot/priv.htm
3 The 11 Information Privacy Principles in the Privacy Act 1988 (Cth) are intended to implement the OECD’s 8 principles insofar as personal information held by Commonwealth public sector agencies are concerned. Australia has still failed to comply with the guidelines for thirteen years after announcing its adherence in 1984.
4 http://www.oecd.org/dsti/sti/it/secur/index.htm
The global Internet governance is a big issue. Under the present system, an Australian company in dispute with a multinational company over a domain might have to fight that battle in a US court. There is now a genuine concern that Australian companies are going to be faced with having to go US courts to have their Internet disputes resolved (Riley 1998). The law should respond to business concern in the information economy. The existing law cannot cope with the transborder data flow. Technology and business are changing very rapidly, but law is somewhat static. Many business firms are very adaptive to rapidly changing global environment due to the information revolution (Johnston et al. 1997).

Privacy & Australia

The Commonwealth Privacy Act 1988\(^5\) lays down strict privacy safeguards which Commonwealth (federal) and ACT government agencies must observe when collecting, storing, using and disclosing personal information. The Act also gives individuals access and correction rights in relation to their own personal information. The Act applies to the wider community (including the private sector and state and local governments) only in relation to specific categories of information: tax file number information and consumer credit information.

Privacy issues arise in a wide range of areas and circumstances. Privacy legislation deals mainly with information privacy - the handling of personal information. Other privacy issues such as video surveillance, telephone interception or 'bugging', and other laws may cover physical intrusion into private spaces.

In December 2000, the Privacy Amendment (Private Sector) Act 2000 (the Amendment Act) was passed by federal Parliament. The private enterprises became subject to privacy laws on December 21, 2001. The application of the Privacy Act is triggered by the financial size of the organization and the nature and use of the data it collects or processes. It is also subject to some ad hoc exceptions and differing start dates. The National Privacy Principles (NPPs) in the Privacy Act set out how private sector organisations should collect, use, keep secure and disclose personal information. The principles give individuals a right to know what information an organisation holds about them and a right to correct that information if it is wrong.

The surveys showed that Australians regard privacy as a closely held and highly personal value. People look for signals that an organisation will manage their personal information well, for example, 59% said they would trust an organisation more if that organisation gave them control over how their information was to be used, 55% said that organisations with privacy policies would be more likely to gain their trust. Various government bodies have been involved in projects and activities designed to encourage the uptake of E-commerce and Electronic Service Delivery.

Among critics of the private sector privacy regime has been the European Commission (EC), which commented unfavorably. In essence, the EC said it did not regard Australia’s privacy regime as sufficiently protective on about nine grounds. All in all, as noted at the time of its passage into law, the application criteria is open to criticism for being arbitrary and the wording of the provisions makes it less than crystal clear how, or even if, it is to apply in given cases, especially, to small businesses (Minahan, 2002).

Australia should be prepared to keep pace with technological innovation and join the new global business environment if it is to remain competitive internationally. Australian Business law in the current form cannot cope with the contemporary business operations. The technological change is revolutionary, but the change in the legal system is evolutionary. There should be a number of changes in Australian legal systems to accommodate electronic commerce.

Under Australian law, if someone steals a credit card it is not an offence until the card is used. But in the US it is against the law to misuse an identity with the intention of committing a crime.

Concluding Remarks

We have introduced debate concerning Internet regulation. The U.S.A is the key player to bring about any effective change. There is a need to keep clean our online information environment through generally accepted international laws or other regulatory mechanisms. The Internet is global, multi-jurisdictional structure; national legal systems will not control the uses and abuses of Internet use. The continuing growth of the Internet has seen a corresponding growth in concern about online ethical privacy and security. Surveys continue to show that users are concerned about the collection, security, use and disclosure of information about them on the Net.

The author expresses his gratitude to the School of Management, University of Western Sydney for allowing him to present this paper at the prestigious World Conference on Educational Multimedia, Hypermedia & Telecommunications (ED-MEDIA 2002), Denver, Colorado, USA, during June 24 -29, 2002. Special thanks to Professor Len Fertuck, Professor of Information Systems, Joseph L. Rotman School of Management, University of Toronto, Canada for contributing ideas and suggestions. Finally, last but not least, he would like to thank his wife, Mrs Mitra Karmakar, daughter, Indira and son, Bikram, without whose support this paper would not have been possible.
ABSTRACT

Curricular goals that traditionally focused on the delivery of the teaching rather than the outcomes of the learning are in a state of major transition. Implementation of academic standards requires the application of content and not merely its delivery. As a result, colleges of education must prepare a new genre of teacher leaders equipped to align students’ classroom experiences with the changing realities of performance learning in an information era. This presentation focuses on preparing teachers who can link electronic information resources with engaging learning experiences. The work is grounded in the beliefs of cognitive theory and applied practice. It presents educational media as a support structure in the curricular architecture of teaching and learning rather than as an ancillary element. It specifically focuses on preparing educators to motivate their students through comparative, investigative, and collaborative problem solving.

1. INTRODUCTION

Words such as excellence, quality, equity, and opportunity dominate the rhetoric of school reform. But behind the words is a serious confrontation to rethink how we organize learning opportunities. Possibly nothing has more dramatically challenged curriculum construction than the accessibility and availability of electronic resources.

Much of my work over the last decade has addressed educational change in
de-Sovietizing environments in East Central Europe. In that transitional time I observed teachers, administrators, and policy makers struggling with what they called the ‘tunnel at the end of the light.’ In this frequently used metaphor, the light symbolized political changes that externally were cause for celebration. The tunnel symbolized the internal challenges and the new mismatch of learning and life. For although simultaneous political, economic, and educational transitions created new opportunities, they also created new challenges regarding the organization of schooling and the acquisition of information. Presently my work environment is an American college of education. But although the geography of my attention has shifted, the circumstances that influence new alignments between school and society is marked by similar uncertainty regarding the realignment of learning experiences in a digital era.

2. GOALS OF TECHNOLOGICAL IMPROVEMENT: AN ISSUE OF USE

Policy makers in many nations portray social transitions to an information era and school improvement as associated concerns. As a result, schools on a global basis are in the midst of technology related reforms and their associated challenges. Linda Darling-Hammond (1997, p.2) aptly captures the cultural climate of this transitional time:

“Never before has the success, perhaps even the survival, of nations and people been so tightly tied to their ability to learn. Consequently, our future depends now, as never before on our ability to teach.”

The teachers at the core of these changes are realizing, however, that successful past practices may be incongruent or even obsolete in electronically rich environments. If teachers are indeed “navigators” (Bruer, 1994) into the future, then the altered fit of technology, teaching, and learning presents a contemporary navigational challenge.

The scope of technologies that have historically impacted education is vast. This work concentrates only on one technology that has dramatically altered available resource information in the past decade, the Internet. Although the Internet provides a powerful platform for accessing information, the educational impact of that body of information is dependent on its use.

3. DILEMMAS REGARDING TECHNOLOGY INVESTMENT

At both national and community levels, increasing expenditures are being appropriated to enhance student learning through technology. But unless such efforts give adequate attention to the changing alignment between resources and applied knowledge, such expenditures are questionable (Dede, 1997).

American studies indicate that over seventy-five percent of the general
public believe that technology improves both teaching and learning (Trotter, 1997). But teachers who have Internet access do not necessarily change their pedagogical strategies (Johnston, 1997). And student learning does not increase in relationship to time spent with electronic resources, but rather in the manner in which new information is linked to problem solving (ETS, 1998). If we contemplate similar relationships for networked learning without attention to how teachers can most effectively use this resource as a means to better thinking, access to vast information banks may have limited impact on student achievement. So what should we do differently? Papert (1998) contends that we must stop trying to merely improve current practices, that we must fundamentally change how we organize learning opportunities to incorporate technological tools rather than teaching about them.

4. CHALLENGES TO EFFECTIVE TEACHING AND LEARNING

Studies indicate that while most teachers have incorporated technology’s storage capabilities, they have not fully capitalized on its capacity to motivate knowledge construction and to facilitate problem-solving (Nicaisc and Barnes, 1996; Perkins, 1992a). These two elements, constructing new knowledge and engaging students in the application of information to problem solving, are the focus of the following examples that share the use of Internet resources in a manner that is interesting, sustaining, and rewarding for both student and teacher.

5. SAMPLE EXPERIENCES BASED ON ELECTRONIC RESOURCES

Because of the dire statistics about American teachers’ knowledge of geography, these examples grew from a core assignment requiring teachers to construct new knowledge about a global region about which they previously knew little or nothing. The follow-up assignment involved translating their new learning as adults into problem related experiences for students. Several examples follow.

In an electronic trip to France, one educator used her own new knowledge about art as a means to motivate the construction of historic and cultural knowledge that incorporated a multitude of Internet museum sites. Through focusing on a selection of chosen works of Impressionist art, she asked her students to hypothesize about the cultural climate of that era. Students themselves were then required to explore additional sites to gather more information through which they could support or negate ideas they had formulated. An extension opportunity encouraged students to further examine the life and work of an artist of their choice and compare it with the same art forms on other continents during that time frame.

An electronic field trip to Poland enabled another teacher to inspire his students to create comparative journals for an American teen living in the
Appalachian Mountains and a Polish teen in the Carpathian Mountains. Resources reprinted from the Internet ensured that students would have accurate data for this literacy-based activity that integrated written communication skills with geographical and cultural information sources.

Another prospective educator used her electronic trip to Switzerland as the foundation for an innovative health unit that examined the effects of altitude on the human body. An electronic field trip to Kenya led to a lesson that asked students to first use Internet resources to explore actual habitats and then use data to assess whether community proposals for a new wildlife sanctuary were scientifically grounded. A less traditional journey involved applying Internet learning from the NASA site to design a playground in space addressing the particular problem solving challenges in building a playground in zero gravity.

A final case exemplifies how teachers can use Internet resources to motivate the synergy that results when students assume not only greater responsibility for their individual learning, but also contribute in a manner in which the whole class benefits from the combined efforts of its members. Their teacher used Internet resources to explore the themes of economic production, distribution, and consumption and to apply them in environmental relations within ecosystems. Students discovered how bacterium in geysers contributes to medical research on Lyme disease and AIDS, and they evaluated conflicting interests introduced by mining and the economic needs of communities surrounding protected environmental areas. As a follow up on the economic effects of oil spills, students used the Internet to share findings about how negative circumstances such as environmental disasters for some populations can create opportunity for other groups, such as new financial markets in environmental clean-up.

Traditionally, when teachers sent students to the library for independent research, most came back with similar information from the same basic sources. The richness of electronic resources provides opportunity for more expansive and encompassing learning opportunities for students if their teachers rethink the traditional construction of teaching and learning experiences.

6. FINDINGS AND CONCLUSIONS

Although no generalizations regarding variances in academic achievement can be drawn from these examples implemented in different school settings, one recurrent comment from other educators who observed and supervised the redesigned use of resources was how they enabled students to target particular standards for the social studies with greater clarity. Of ten particular national
standards for the social studies, four performance areas were noted as being apparent to students. These were: 1) global connections, 2) time, continuity, and change, 3) people, places, and environments, and 4) production, distribution, and consumption.

The manner in which teachers align technology with curricular goals is largely dependent on the beliefs and experiences established in teacher preparation programs. If graduates of universities and colleges are to be effective navigators for their students, then they must become comfortable and competent in transforming large networks of mere information into significant problem solving experiences.

The process of redesigning the learning process in any nation must begin with the adult learners, the teachers. In order for educational change to be institutionalized it must be part of the teachers' foundational competencies (Hargreaves, 1992, Greenfield, 1995, Fullan, 1993). Just as successful businesses need workers who are better thinkers, so too do educational enterprises need both learners and leaders who use technology to become better thinkers (Crouter and Manke, 1994). These projects reflect the juxtaposition of electronic information and the thinking process. They use computers for what they do best, storage and organization, and the human mind for what it does best, judging, interpreting, analyzing, synthesizing, and constructing meaning (Jonassen, 1995). They present ideas that foster connections between information and thinking rather than fragmented and isolated approaches that mark failed educational changes (Fullan, 1996).

Although the long-term impact of cyberspace learning on student achievement is yet to be determined, the integration of Internet resources gives teachers the opportunity to significantly alter curricular construction. While the Internet has the potential to bring the world into the classroom, quality teaching results from quality thinking. Teachers who successfully navigate journeys into more electronic environments are those whose old way of thinking become transformed and who see themselves as both learners and leaders, as change agents, and as individuals who can consistently add value to their profession.

Abstract: This paper presents a review of the Virtual Factory Teaching (VFTS) project, a web-based, multi-media collaborative learning network. The system allows students, working alone or in teams, to build factories, forecast demand for products, plan production, establish release rules for new work into the factory, and set scheduling rules for workstations. Included in the paper are a system description and list of project tasks. The evaluation component involving three different campuses is described and the results of three-years of analyses are presented, including demographic descriptions, self-assessment results, performance results, attitudinal responses, and usability. In addition, instructor observations and course project output is also examined as components of the VFTS evaluation effort. It is believed through the analysis that the VFTS is an excellent instructional method to teach students the integration of the different modules in operations planning.

Background

To address the manufacturing educational needs of new engineers, a web-based, multi-media collaborative learning network, referred to as a Virtual Factory Teaching System (VFTS), was developed under an National Science Foundation (NSF) grant (Dessouky, et. al. 1998; Dessouky, et. al. 2001; Kazlauskas, et. al. 2000; Kazlauskas, 2001). This tool is currently being used by engineering students from the University of Southern California, San Jose State University, the University of Virginia, and most recently North Carolina Agricultural and Technical State University. The overall aims of the project are:

- To provide, disseminate, and evaluate a manufacturing education pedagogical tool that promotes student understanding of complex factory dynamics.
- To improve student skills in communication, persuasion, negotiation, and management, as well as in the technical arenas of production planning, forecasting, simulation, scheduling, and integration.
- To provide a forum in which engineering and business school students can participate in virtual teams that cut across universities.

The research plan of the project is aimed at exploring the interface between virtual factories, engineering education, intelligent agents, and the Internet for new ways of teaching modern manufacturing problems, practices, theory, and techniques to engineering and business undergraduate students. In
addition, it is aimed at examining its potential for use as an information vehicle on the topic of manufacturing for K-12 students. Various research questions are addressed, such as: how students perform when using new technology-enhanced modes of learning; what are the effects on attitudes; how intelligent agents might assume tutoring and participative roles; and how team performance, hampered by geographical separation, might be enhanced via advanced communication technologies.

The project timetable consisted of the following: a Baseline period to provide an understanding of the Industrial Engineering courses (with scheduling content) using traditional instructional methodologies, i.e. without the VFTS; the use of the VFTS to provide an understanding of the Industrial Engineering courses (with scheduling content) offered at the various institutions; then the use of an expanded version of the VFTS at the same institutions with pedagogical agents and use of virtual teaming included. The following presents an overview of the features of the VFTS; a description of the evaluation approaches; and three-year project results.

System Description

The architecture of the VFTS was kept simple and modular. There are three layers in the design: AweSim Server, VFTS Java Server and Clients. Clients, which are students in our case, use standard WWW browsers like Microsoft Internet Explorer, to connect to the VFTS Java Server using its Web Page. Most of the communication between the clients and the server takes place using Java applets. The Java-Server functions as a mediator between the AweSim factory servers and the clients. The Awesim Server is responsible for factory knowledge and simulation. The layers interface using a message protocol set up to minimize bandwidth requirements. Other components of the VFTS include the use of Ptolemy, a graphing package, and Drasys, an Operations Research (OR) package.

The system allows students, working alone or in teams, to build factories, forecast demand for products, plan production, establish release rules for new work into the factory, and set scheduling rules for workstations. They can run simulations where an animated panel displays jobs progressing through their factory, with queue counts, finished goods counts, graphs, and reporting functions all available. Students access via the VFTS, using computers in university computer labs, or in their dorms or homes, a virtual representation of the factory. The professor posts assignments related to this factory over the Internet, "unfreezing" parameters as necessary so students may experiment without redefining the entire factory. Students observe the effects of their decisions, and student teams assume factory roles to solve problems; if they reach an impasse, intelligent agents provide guidance. Selective information may be given based on student roles; for example, the production supervisor may have equipment information, the engineer new technology information, etc. Students sort out strategies and can discuss options via e-mail and electronic chat rooms. Since this course is a common one found in many universities, collaboration among universities is feasible. Faculty members virtually "team teach" the course. Intelligent agents are incorporated into the VFTS to monitor student progress and provide immediate feedback.

The latest version of the VFTS software includes support for user account management, adding security to allow students within a group to share data while preventing access to it from students outside the group, a more easy to use interface, instrumentation so that the software will gather data on student usage patterns, on-line help, on-line documentation and an on-line tutorial to help for students and faculty learn how to use the VFTS, and an introductory homework exercise to help students learn how to integrate the VFTS into the course. A project that uses the VFTS was developed to complement the students' classroom learning and was integrated into the courses at the participating universities. The latest version also includes a pedagogical agent that monitors students' use of the VFTS and provide guidance. This required integrating the pedagogical agent software (ALI) into the VFTS, adding the ability for ALI to maintain a persistent model of each student's knowledge across sessions, extending ALI to include more sophisticated explanation capabilities, adding VFTS-specific knowledge to allow ALI to understand the instructional objectives of the VFTS and provide appropriate support to students, and instrumenting ALI to maintain a log of interactions with students to aid our evaluation.

The current version VFTS is available at http://vfts.isi.edu.
Project Tasks

The VFTS project included a large set of tasks involving design, development, usage, evaluation, and dissemination. The various tasks associated with the VFTS project are as follows:

- Define instructional objectives and complete evaluation design.
- Develop and/or acquire evaluation instruments.
- Solicit feedback on the instructional objectives, evaluation design, and VFTS use from each university.
- Gather evaluation data for control group (engineering classes without the VFTS).
- Analyze evaluation results for control groups.
- Complete instrumentation of the software to support evaluation.
- Teach engineering classes with the VFTS and gather evaluation data.
- Analyze evaluation results for experimental group and compare to control group.
- Use the evaluation results to revise and refine the VFTS and its use in the engineering curricula, its instrumentation, and the pedagogical agents.
- Teach engineering classes with the VFTS, including the use of virtual teams that span multiple universities, and gather evaluation data for this final experimental group.
- Analyze summative evaluation results.
- Make final revisions to the VFTS software based on evaluation results.

Evaluation

In the preceding list of project tasks, it should be noted that considerable emphasis is placed on the design and implementation of an extensive, multi-university evaluation, which is a central component of the VFTS project. The initial evaluation efforts were used a) to check to make sure each project step was implemented according to plan and that milestones are being met; and b) to consider project modification. This evaluation, formative in nature, assisted in modifying the design and development of the evaluation, as well as of the overall design of the web-based VFTS. For example, a Computer Competencies Multiple Domains instrument that was used initially to determine the level of entering competency in such areas as spreadsheets and statistical packages was dropped. It was determined through initial surveys that the learners were homogeneous in terms of a high level of computer competencies. Through the evaluation process, it was decided to gather more data on such issues as the ease of use and operation of the web-based VFTS, and to modify the actual design by changing the opening screen, and by including more tutorial help.

An emphasis of this project is to evaluate learner outcomes, attitudes, and learning. This effort includes the use of various instruments and examination of student work.

The following are the instruments that are presently being used in evaluation:

- Student Pre-course and Post-course Survey instruments which are used to gather data on student demographics and student self-rated assessment of entering/post-course knowledge of operations scheduling, such as the skills, knowledge, and abilities in the use of gantt charts and regression and time series models.
- Operations Scheduling Pre-test/Post-test instruments which are used measure course content before and after instruction and use of the VFTS.
- Affective-Level/Attitudes Instrument (VFTS Participant Opinion Survey) Pre-test/Post-test instrument which are used to measure reactions to the use of the VFTS, such as reactions to use of simulations, working collaboratively, and relevance to future career.
- Usability Evaluation instrument which is used to gather data on such issues on the ease of use and operation of the web-based VFTS.

The VFTS Studies

Various studies were conducted in the VFTS Project. The first of these was the Baseline evaluation conducted at the various universities, to provide an understanding of the Industrial Engineering
courses (with scheduling content) using traditional instructional methodologies. The second of these was an investigation of the use of the VFTS at the same universities, to provide an understanding of the Industrial Engineering courses (with scheduling content). A second usage of the VFTS occurred, an enhanced version with teaming and pedagogical agency. The following represents the findings from these investigations (at three universities to-date).

Demographics

For the most part the demographic analyses showed similarities between both the Baseline and VFTS groups at the various universities, and the demographics appear to parallel those that are found in most engineering programs. Most students were in the 21-22 age category, with the age distributions at most universities typical of a 'traditional' undergraduate student. However, students at one institution had an older mean and the age range was quite large. At all institutions, students were mostly seniors. The majority of students at all three campuses were male, as reflects the common engineering enrollment pattern. There was no significant difference on the gender variable between the groups. The primary language was English but many other languages were represented, with 50% or more students at two institutions having a language other than English as their first language.

Self-Assessment

Instruments gathered pre and post data on a student's interest in the course and on their self-assessment of knowledge of course content, such as whether they could apply forecasting methods to new problems.

Students have a moderate interest in the course. One can support the general statement that students know little, if anything, about the content of the course but think that it will help them in a more general way. At two institutions, students indicated that they did see the course assisting in developing industrial engineering fundamentals. Pre and post-test measures of self-assessment indicate significant gains in most areas. In particular, the overall gains in self-assessment in the second year offerings of the VFTS at two universities were significant. The self-report assessment provides evidence that the students feel as if they have learned the subject in the course.

Performance

As a general statement, it seemed desirable to determine if there are significant differences between and among the participant groups. Representative analyses reflect: performance at each institution in both the Baseline and VFTS options; and Baseline to VFTS Comparisons. In examining Baseline and VFTS groups at the various institutions, analysis indicated overall gains in learning in each offering of the course between pre-test and post-test, and in specific content areas of scheduling. There appears to be a significant difference among the schools on the pretest measure, with one institution scoring significantly higher than the others. Comparison between the Baseline and VFTS performance at each institution indicated a difference on selected pre-test items. Correlations were calculated for the pretest instruments, Baseline to VFTS groups. Although there were some correlations between age and certain items and among certain items, it appears that these results were of no significance in this particular study. There were no significant difference between the Baseline and the VFTS groups on the final exam except for a few selected items. As noted, the VFTS groups did not perform as well on the pretest as the Baseline groups, yet scored approximately the same on the final examination. This could imply that the less strong content-knowledge groups, using the VFTS, performed equivalent to the stronger content-knowledge groups. The post-test scores at one institution are significantly higher than at the other universities. We remark that at only this university was the post-test a component of the student's final grade. In fact, it was treated as the final examination so in this case the students took it much more seriously where they most likely studied.
for the examination. A comparison of the post-test scores between the baseline and VFTS groups at this university show a significant gain for the VFTS group, although for a smaller class size.

Attitudes

Instruments gathered pre and post data on a student's opinions, on such scales as usefulness, interest, importance, difficulty, and confidence, for example whether students thought learning to use computer simulations to work on class assignments would be useful to their future career. Results of the analysis indicated that there was no significant change in the attitudes of the students, even with the use of the VFTS.

Usability

In regard to the use of the VFTS, most students seem to be using Internet Explorer on a Windows 98 platform. Student comments on the usability of the software isolated several problems that were resolved in the updated version of the VFTS. The various modules well-received; for the most part the online documentation and tutorials not used or students commented that they were of limited value; students were not positive towards the use of the VFTS teaming aspect of the course. However, effort is being made to modify the teaming aspect of the course with the assertion that this may impact usability findings on this topic.

Other Results

Input was solicited from the instructors of the courses at the various universities. Their comments regarding the use of the VFTS were positive. They noted, in particular, that students using the VFTS had a more realistic course project than their counterparts in the Baseline classes.

The NSF funding for this project has supported five graduate students at the University of Southern California. These students have gained valuable experience in Web-based software development, user interface principles, pedagogical agent technology, educational materials development, and educational evaluation. Perhaps the most valuable training for all the students is the close multidisciplinary collaboration between computer scientists, engineering educators, and educational researchers and educators. These students will have a much broader perspective on research than typical graduate students that work closely with others only in their own field.

Conclusion

The VFTS was instrumental in facilitating students' understanding of the integration between the models for forecasting, production planning, material planning, inventory planning, and scheduling.

It was demonstrated through an analysis of project reports that students had a better understanding of the integration between the different modules. This was illustrated by the fact that students clearly spent a good part of their time, with the VFTS, in testing many different scenarios, and students were able to see the impact of changing a parameter on the output. It is suggested that another major benefit of the VFTS is that a more complex system can be modeled than otherwise. Thus, it was seen that students had a more realistic project than their counterparts in the Baseline groups. To summarize, it is believed through the analysis that the VFTS is an excellent instructional method to teach students the integration of the different modules in operations planning.

Faculty Development in Technology: Outcomes of a Project Based Team Approach

Mario Kelly, Hunter College of the City University of New York, USA

This paper is a report on the implementation of a grant funded project designed to provide faculty development in the effective integration of technology into the teacher education programs at a large, public, urban university in the Eastern United States. The principal immediate goal of the project was for the faculty to acquire specific basic knowledge and skills regarding computer hardware and software. The principal medium-range goal was that faculty would develop technology related products or projects that would result in more effective and/or efficient teaching and learning of a unit of a teacher education course. A long range-goal was the modification of the teacher education curriculum to reflect greater integration of technology and to meet technology standards of various professional organizations and government agencies. This paper will describe the faculty, the intervention strategy utilized with the faculty, and finally, the types of data that have been obtained, and on the basis of this data, the degree to which each of the principal goals has been achieved to date.

The Faculty

The subjects were 17 faculty members who teach pre-service teachers in an urban, public university program, and 4 public school teachers who serve as master or mentor teachers to pre-service teacher candidates during the required semester of student teaching in a public school. At the start of the project a modified version of the School Hardware Technology Survey (U.S. Department of Education, 1998) was administered to the population of faculty from which the sample was drawn. The results of the survey, which faculty completed anonymously, were supplemented with data from faculty focus groups, and information from the college's administration regarding funds allocated for the purchase of equipment. The data revealed that faculty all had basic computers with Internet access and printers in their offices. However, at the time the most common uses of technology reported were word processing and accessing e-mail. Only 1 of the 17 in the sample was teaching a course that specifically included computers and was taught in a computer laboratory. Most faculty members could not identify the specific configuration of their office computer or report the specific software it contained.

The Intervention

The main focus of the intervention was the provision of staff development activities to enable faculty to integrate technology into coursework. Development activities followed a constructivist model in which each faculty member was responsible for developing a technology product to improve the effectiveness and efficiency of teaching and learning one unit of a course they were currently teaching. Intervention activities unfolded in 4 phases over the course of one academic year.

Phase 1: Faculty attended an intensive 2-day, hands-on staff development workshop on PowerPoint Basics, Advanced PowerPoint, Internet Searching Strategies, and Inspiration (semantic mapping/outlining software) conducted by national experts in the integration of technology into teaching. The workshop included application components that allowed faculty and staff to create an actual “mini” product by the end of the second day.

Phase 2: Faculty worked on their individual projects to develop technology products for use in a course. While the projects were individual, following a constructivist approach, the faculty was grouped into supportive teams, to share ideas, assist each other, and perhaps most importantly, have a forum for discussion.

Faculty development teams: Five (5) teams, each consisting of 2-5 members were established, in each case with the mutual consent of all team members. The focus of 4 teams, and hence the projects of
team members, was a specific content area. Each of these teams was named according to the respective content area: Educational Research, Science Instruction, Language & Literacy, and Social Studies. The 5th team was Interdisciplinary, and included special education, health education, and art education. On each of the teams, with the exception of the Science Team, one of the 4 technology-skilled public school master teachers served as a consultant to the faculty. As consultants the master teachers did not have to produce a technology product. Instead, the consultant's role was to assist with design and implementation issues, and in particular, provide feedback regarding the real-life classroom viability of the technology products being developed. Also consistent with the constructivist tradition, faculty members were given a set of guidelines for completing the technology projects. The guidelines required that faculty demonstrate application, analysis, synthesis and evaluation on Bloom's Taxonomy for the cognitive domain.

**Phase 3:** Faculty incorporated their technology products into the course.

**Phase 4:** Faculty evaluated the effectiveness of the technology products.

As an incentive for successful completion of all phases of the project faculty are released from teaching 1 course a subsequent semester.

**The Outcomes**

**Phase 1:** The benefits of staff development activities were almost immediately noticeable.

- Most of the faculty had not used PowerPoint and were not even aware of the existence of Inspiration. By the end of the workshop each person had produced a PowerPoint presentation for one lesson of a current course, some also incorporating a search strategy or an Inspiration concept map.
- Most faculty members used the PowerPoint and Inspiration software in classes and presentations in the weeks immediately following the workshop.
- 16 of the 17 faculty had never utilized the computer laboratory, where the workshop was conducted. They learned about the networked computers and how the network functions.
- 14 of the 17 faculty have since independently taken an additional workshop offered at the college, to learn Blackboard, a Web-based course management system.

**Phase 2:** The teams varied considerably in the degree to which they completed Phase 2. See Table 1 below.

</table>

**TABLE 1**

982
On the basis of the number of members who completed Phase 2 and Phase 3, the Science and the Social Studies teams, those with the fewest number of members, were clearly the most successful. However, the numbers do not reflect another aspect of the teams' success, namely the degree to which team members were engaged in the process of not only developing their projects, but also in the process of acquiring technology knowledge and skills. By this measure the Language & Literacy group was clearly the most successful, as indicated by responses to formal interview questions, email communications among group team members (teams were asked to send a confirmation copy of team emails to the project director), and number of queries for assistance with hardware, software, or expertise. The Language & Literacy Team communicated with the greatest frequency and engaged in the greatest number of technology skill building activities. They met and/or exchanged emails almost weekly, and placed the greatest and most consistent demand on the project staff for assistance. The difference among the teams is an issue worthy of further analysis which due to space limitations is not possible here.

**Phase 3:** As Table 1 reveals, faculty who completed the design of their projects were almost certain to implement the projects in a course the following semester. The single exception to this rule was found in the Social Studies Team and was due to the fact that the faculty member did not teach the course for which the project was designed.

**Phase 4:** As Table 1 reveals, only 1 of the faculty members has completed the evaluation of the implementation of the project. However, the numbers do not adequately represent state of completion of the projects. In actuality all faculty who completed Phase 3 did gather obtain data to evaluate the effectiveness of the implementation. However, until a formal written analysis of the data is provided, Phase 4 is not considered completed.

**DISCUSSION**

In summary, technology faculty development activities for faculty who teach pre-service teachers were described. These activities, aimed at increasing the faculty’s level of technology proficiency and its ability to integrate technology into teacher education courses were based on constructivist principles. Among the constructivist elements were hands-on workshops, project-based learning, and learning teams of mutually supportive members. The development activities were divided into 4 phases and the success of the members of each team at each phase was compared and analyzed. The role of the incentive provided to faculty for successful completion of the project and a detailed analysis of the various dimensions of the teams that may have fostered or inhibited project completion are areas worthy of further study.

Brownfield Action: An Integrated Environmental Science Simulation Experience for Undergraduates
By Ryan Kelsey, Columbia University Center for New Media Teaching and Learning

Abstract: This paper presents the results of three years of development, implementation, and evaluation of a cd-rom/web hybrid simulation known as Brownfield Action for an introductory environmental science course at an independent college for women located in a large city in the northeastern USA. Brownfield Action is not intended as a cost-cutting measure, a time-saver, or a replacement for other material. It is a method of integrating what was formerly disparate labs and lectures into a seamless learning experience that improves student learning and motivates students to critically consider the importance of all the issues involved in the system of human impact on the environment. Brownfield Action gives students a skill set for conducting scientific work and the perspective that science is connected to one's everyday experience.

Background: Science instructors and students often struggle to link the material in lecture and laboratory. Laboratories are often taught by different personnel, and must fit into constraints of equipment and time, as well as safety and level of difficulty. A large survey course often covers dozens of topics, but a student typically experiences no more than fifteen laboratory periods in a given semester. Life science lectures require rapid note taking and passive concentration as verbal information is streamed at students for one to two hours. Laboratory sessions typically require two to three hours of recipe-following and occasional problem solving. These two elements of the course operate in isolation because there is little time in lecture to discuss experimental technique (if the lecturer even knows that information), and a laboratory is not typically set up for someone to give verbal instruction as occurs in the lecture hall. Typical science students spend most of their time memorizing verbal information for lecture examinations, and memorizing techniques, anatomy, and taxonomies for laboratory practical examinations. Rarely is information from one relevant to the other because the lecture focuses on concepts and the laboratory is intended to teach technique.

In response to this disconnect between laboratory and lecture, many science curricula incorporate problem sets as a third element in an attempt to provide some unification. Unfortunately, the typical drill-and-practice nature of the problems backfires as it encourages students to follow a similar surface study approach that primarily consists of pattern matching. This approach prevents students from tying lectures to laboratories as the problem sets become their own separate entity within the course. Some schools even create separate class sessions monitored by teaching assistants to accommodate this reality, but these sessions only reinforce the separateness of the problem sets. Upon completion of the semester, students of these science courses often feel they have taken two or three courses. They fail to get a sense of the content as a whole, and they never actively engage the content at more than a surface level. One might even propose that in order to succeed in these types of courses as they are designed, it is in the student's best interest to remain at the surface with his or her engagement.

Related Work: Several studies in recent years have led to the development of design principles for the construction of computer-based learning environments such as simulations, many of which can be found in Brent Wilson's compilation Constructivist Learning Environments: Case Studies in Instructional Design (1996). Peter Honebein's “Seven Goals for the Design of Constructivist Learning Environments” outlines a set of instructional design principles. He then evaluates two projects based on those principles (Wilson p11-25). John B. Black and Robert O. McClintock, similarly, provide an “Interpretation Construction Approach to Constructivist Design,” a seven-point system that they apply to three projects created under the Dalton Technology Plan (Wilson p26-31). John R. Savery and Thomas M. Duffy borrow from Barrows' model for case-study teaching and learning in order to create a set of principles for problem-based learning (Wilson p135-148). More specific to simulations, Margaret Gredler examines one approach for the design and evaluation of simulations in Designing and Evaluating Games and Simulations: A Process Approach (1993). Her work involves an interwoven three-part design of role, task, and environment.

The closest work to the experience of the Brownfield Action design and development process is found in Goodrum, Dorsey, and Schwen's work on defining and designing Enriched Learning and Information Environments (ELIEs) (Educational Technology November 1993). In this paper, they describe how their experience with designing educational environments led them away from entirely technology-based and theory-based definitions and more towards what they define as a socio-technical definition that focuses on the people involved and the specific work they are asked to perform. They perceive that the latest learning theory and the latest technology does not necessarily lead to innovation. Instead they claim that all innovations are situated within a context of people trying to accomplish work in a particular environment, and a well-designed teaching and learning tool should support that
work. They go on to describe their design work as a series of relationship building with users, rapid prototyping with mock-ups and a focus on the tasks that users needed to perform.

**Methods:** The Columbia Center for New Media Teaching and Learning (CCNMTL) developed a cd rom/web hybrid simulation from 1999-2001 known as Brownfield Action. It was implemented at Barnard College, a women's college affiliate of Columbia University. The project demonstrates how an undergraduate Environmental Science course can directly integrate its lecture and laboratory components through the use of a simulation. In a semester-long course, students solve a complex problem that requires the application of knowledge and skills learned in lecture and in the laboratory setting. Student performance and engagement is improved while developing real-world problem solving skills, and students experience environmental science as a highly integrated field. Rather than reserving higher level thinking skills such as analysis and synthesis for smaller, more advanced courses, Brownfield Action allows introductory students to see environmental science as an integrated and dynamic part of society, rather than a series of abstract concepts and recipe-driven techniques.

**Context of Brownfield Action:** Brownfield Action is a simulation that provides a learning environment for applying many of the major concepts of environmental science. Students operate in a virtual town serving as consultants to a real estate developer who wants to avoid purchasing potentially contaminated land. Students must become actively involved in the lecture and laboratory in order to succeed. They must learn to explore and to discover a path to a solution to the problems they encounter to reach a valid conclusion. Pairs of students form environmental consulting companies to investigate a hypothetical abandoned factory site in a small town. A mall developer who wishes to purchase the factory site contracts with each two-student company to conduct an investigation. Students collect socio-historical and scientific data, construct maps of the site's basic geology, topography, and any contamination they discover while operating within a given simulated budget. Their investigation culminates in a report to the mall developer that summarizes their results and gives recommendations about how to proceed.

**Socio-Historical Component:**

![Figure 1: the site map interface for Brownfield Action](image)

To complete the maps and report, students must first gather a site history from the town's resources using the Site Map (Figures 1 and 2). Through the simulation, students visit government offices, businesses, and residences to conduct interviews with town's officials and citizens. They also obtain and analyze simulated public documents.
Scientific Testing Component: Using the information obtained from the town’s history, students then conduct a series of environmental tests to determine the presence, extent, and probable cause of any contamination (Figure 3). Some tests, such as soil permeability, are conducted as traditional laboratory exercises placed within the context of the simulation. Other tests, such as well monitoring, are conducted virtually using the computer. Over two million data points are available for collection over the 64,000 square foot virtual site map, including bedrock and water table data as well as contamination concentrations at depths of over 150ft. This vast quantity of data, both through the site history and the environmental testing, allows for an infinite number of strategies for testing and a unique data set for every student company. Successful students work within the given operating budget and clearly identify the cause and extent of the contaminated areas on the site.
Brownfield Action is not intended as a cost-cutting measure, a time-saver, or a replacement for other material. It is a method of integrating what was formerly disparate labs and lectures into a seamless learning experience that improves student learning and motivates students to critically consider the importance of all the issues involved in the system of human impact on the environment. Brownfield Action gives students a skill set for conducting scientific work and the perspective that science is connected to one’s everyday experience.

**Course Objectives:** The primary faculty member and subject matter expert identified the following objectives:

After experiencing Brownfield Action, students will be able to explain how to approach and solve a scientific problem by:

- describing the strategy used to discover contamination sites in Brownfield Action;
- identifying and explaining the outcomes of environmental tests they conduct and related information, making recommendations and being aware of the consequences of their decisions;
- drawing inferences from data about structures that contribute to environmental contamination;

and students will:

- read articles on ecology with different understanding, interest, and personal commitment;
- appreciate that real world decision-making about ecology involves ambiguity rather than certainty.

**Evaluation:** To assess the effectiveness of Brownfield Action (BfA2.0) in meeting its objectives in Fall 2000, students were surveyed at the beginning of the simulation to obtain an indication of their perceptions of the levels of knowledge and skill targeted by the course with which they started. The laboratory directors prepared a daily implementation log providing detailed documentation of the BfA2.0 experience in the labs. The evaluators observed five lectures and six of the three-hour labs to further their understanding of the instructional setting within which the Brownfield Action simulation was conducted. At the end of the course, students rated Brownfield Action on how well it had contributed to the objectives of the course and other matters, and all students participated in hour-long focus groups to provide in-depth responses to questions not amenable to discovery through written survey questionnaire. The evaluators conducted hour-long, post-course interviews with the lead designer of the simulation; the primary faculty member and subject matter expert, and the laboratory directors. Finally, a cross section of the papers prepared by BfA2.0 students in the fall, 2000 was reviewed and compared with student papers from previous years.
Data Sources: The entire course of one hundred and twelve female students were surveyed using two questionnaires (one at the beginning of the semester, one at the end) and a series of focus groups at the end of the term (one for each of the eight lab sections).

In the survey questionnaire and focus groups we investigated students’
- perceptions of pre- and post-test levels of their knowledge;
- perceptions of the success of BfA2.0 in meeting its objectives;
- perceptions of the contributions of various components of BfA2.0 in assisting them to solve the overall problem addressed by BfA2.0, and how well BfA2.0, the lectures and the lab succeeded in directing them to focus on the major problem addressed by BfA2.0.
- overall evaluation of BfA2.0, positive and less positive;
- recommendations for technical improvements in BfA2.0;
- perceptions of the most valuable parts of BfA2.0;
- perceptions of what could be done to improve BfA2.0.

The evaluation team also examined students’ final reports in accordance with the learning objectives outlined by the primary faculty member as well as the daily laboratory implementation log prepared by the laboratory directors.

Summary of Results:
- Students learned more and in greater depth using Brownfield Action than in previous years without it.
- Student work looked more authentic and professional, closer to what would be expected of a professional performing these tasks.
- Students appreciated how the simulation contributed to their understanding of the material.
- Brownfield Action was successful in (1) enhancing the scientific literacy of students, (2) facilitating their construction of new meaning based upon what they saw and experienced and (3) enhancing practices leading to increased student learning.
- Students’ abilities to construct new meaning based upon what they saw and experienced were expanded.
- Students found the content useful and the simulation a good way to learn it.
- More staff development is necessary to foster the teaching strategies needed for a true discovery process and to build comfort with technology.
- Minor technical glitches created levels of frustration that interfered with its ability to meet its educational potential. These glitches notwithstanding, the students gave high ratings to other features of the technology. In particular, eight out of ten students noted the ease with which it was possible to move through information in each of the sections of the simulation.

Simulations: For as long as there has been computing, many have tried to simulate aspects of reality with computing power, but the reality is that all that has been built to date would be better called simulators rather than simulations. Simulators model real-world processes with mathematical equations and variables that can be manipulated so that changes can be observed and analyzed. Simulators have inputs and outputs and variables that can be manipulated. The bulk of the software for Brownfield is no different upon close inspection. It is a model of a town with a mathematically driven contamination event. Students input instructions through the map in order to receive the outputs.

A simulator only becomes a simulation when it is given a narrative, and participants are given roles to fulfill, a problem to solve within a given context, and tools to help them solve the problem. In Brownfield Action, the components of the simulation are in the classroom environment supported by the technology and in technology itself. The course curriculum provides the problem to be solved and the roles to be played in the form of an assignment. The context for the problem is provided in the course lectures. Tools are provided within the software in the form of testing tools, in the laboratory in the form of soil samples and mapping techniques, and in the lectures and reading material in the form of mathematical formulas and models of other investigations.

Brownfield Action could be run in a classroom without any technology at all, and in fact it was done on a smaller scale for many years using an elaborate note card scheme. The computer software supports the expansion of the
simulation created in the classroom, giving it a visual space with the map, a more efficient process for collecting data in the form of better tools, a means for communication with email and links to the course materials, and more definition and depth (literally and figuratively) to the environment that is to be examined in the form of a complex three-dimensional contamination simulator and a cast of characters that creates the socio-historical narrative. The software itself does not teach. Instead it invites the user to engage in the problem. To foster engagement, one needs motivation and a safe space to take risks, and that is where the classroom, the curriculum, and the instructors come in to play.

Simulations can be powerful teaching and learning environments because learning to operate within a simulation is good training for operating within the real world. Everyone has roles to play in the real world (probably more than one), and there are problems, conflicts, and obstacles to be encountered and overcome in each of those roles. The method for overcoming these problems is in communication and experimentation, which includes hypothesizing, collecting data, analyzing, synthesizing, and applying previous discoveries with other role players using the tools that are available. Solving these problems in a simulation is no different. The major difference is that simulations provide a simplified set of conditions within a contained space for students to operate in. A good simulation still has ample noise that must be sorted through in order to find the important, or signal information that will lead them to a solution, but students can operate with confidence that the signal exists. Simulations also provide a safe environment, away from the consequences of the real world: the money involved isn’t real, one’s job isn’t at stake, etc. Students can essentially practice living in the real world by immersing themselves in the problem to be solved in the simulation.

The Context

The problem faced by any university ... is how to structure itself so that its central academic activity is facilitated, not undermined, by technological developments (Laurillard & Margetson, 1997, p. 4).

Monash University is a large institution with campuses or affiliates in Australia, Malaysia, South Africa, Italy and the United Kingdom. The use of ICT is increasing at Monash because of changes in higher education attributed (but not limited) to, funding, diverse student backgrounds (Australian Vice Chancellors' Committee, 1996), changing student expectations and lifestyles, new developments in technology, and opportunities for improved approaches to learning and teaching.

In 1994, Monash University was asked to provide coursework for the Australian Department of Foreign Affairs and Trade (DFAT) in Canberra. At that time, students were either existing or newly appointed officers of DFAT, as well as diplomats from developing countries throughout Africa, Asia and the South Pacific. As a consequence of this endeavour, the Monash University Diplomacy and Trade Program began. The program is run by the Department of Management in the Faculty of Business and Economics of Monash University and is designed specifically for aspiring, trainee or existing diplomats. Successful completion of the course results in the conferring of a Graduate Diploma or Master degree.

For the cohort under review in this paper, students generally range in age from 24 to 40 years of age. Approximately half are Australian, with the other half being international students. In almost all cases, academic backgrounds and vocational experiences are dominated by socio-political training. As a consequence, there is a minimal understanding of the more numerate sciences, of which economics is one. At the time of the review, the numbers in each off-campus class are small (approximately six), though there are approximately 40 students in each concurrent on-campus class. Thus, this unit is economically viable, especially as the fees are high.

Given the importance of economics in a global trade context, the two economics units, Principles of Microeconomics and Macroeconomics, as well as the Economics of Trade and Investment, are core compulsory subjects. This paper discusses the learning design of the unit, Principles of Microeconomics and Macroeconomics. The unit incorporates all of the key issues raised in a full first year course of undergraduate
economics, with the added emphasis of trade protection and microeconomic reform (Reiman, 1999). The challenge is to teach these fundamentals in one semester so that students are conversant with the policy-orientated approach of their next unit, Economics of Trade and Investment. A second challenge involved the physical location of the off-campus students where there are issues of access to the proposed online environment (for example, one student travelled very frequently and logged into the online discussions from a variety of countries during the course of the semester).

The team who developed the unit materials reached consensus on a view of learning based upon constructivist principles, in which knowledge is constructed individually and socially co-constructed by learners based on their interactions and experiences with the world (Biggs, 1999; Jonassen & Rohrer-Murphy, 1999; Kennedy & McNaught, 1997a) Integrating computer-mediated communication (CMC) to support a more student-centred learning environment was a key component of the design of the unit materials. The incorporation of online discussion groups has been shown to foster collaborative learning (Agostino, Lefoe, & Hedberg, 1997), improve flexibility in teaching and learning (Freeman, 1997), and support problem-based learning (Oliver & Omari, 1999).

In the past, the study materials for the off-campus cohort were entirely print-based. These materials were redeveloped to be used in conjunction with concept maps, and a number of online discussion groups. The on-campus students had a traditional set of lectures and tutorials; the concepts maps were given to the students and used by the lecturer during classes.

The Concept Maps and Online Discussion Groups

Concept mapping has a history of extensive use for improving student learning and metacognition. It has been used in domains as diverse as chemistry (Cullen, 1990; Ross & Munby, 1990); biology (Jegede, Alaiyemola, & Okebukola, 1990); physics (Pankratius, 1990); microbiology (Barenholz & Tamir, 1992); hypermedia development (Kennedy, 1995; Kennedy & Taylor, 1994), and the design of computer-based learning tools (Kennedy & McNaught, 1997b).

The concept maps were developed using software called Inspiration (Helfgott, Shankland, Stafford, & Samson, 1997). In Figure 1, the master concept map is shown. Very positive feedback was received from a number of students on its usefulness (discussed later). The master concept map was further broken down into sections that addressed a single week. In Figure 2, the concepts in italics are from past and future weeks, while the concepts related to week 11 are in normal style print.

Online discussion groups were linked to the content of the print-based materials. Five discussion groups were created. These were announcements (read-only by students), general discussion (for ongoing discussions during the semester), and three groups associated with specific assessment tasks. The three online assessable discussion groups were designed to:
- help the students' written communication skills;
- develop their ability to structure an economic argument;
- develop their understanding of economic concepts;
- allow students to share ideas with peers, wherever they may be; and
- develop online collaborative skills.

Students' marks for these discussion groups contributed only 15% to the final grade. The overall assessment strategies were not markedly changed and were similar for both off-campus and on-campus groups.

Development Issues for the Unit

In the frequently perceived headlong rush to put all course content online, academics and students are expected to engage with new ways of thinking and working, while simultaneously developing new skills. In the transition between more traditional approaches to curriculum development and design, older technologies are often disregarded as being irrelevant and outmoded. The second author of this paper was an experienced lecturer in
face-to-face situations, but new to the use of concept maps as a holistic organisational learning tool, and the use and management of asynchronous online discussion groups.

Figure 1: The major concept map for the course

The development of these unit materials represented a departure from his previous experience. The first author is an educational designer, experienced in the use of both learning tools. The development of the unit materials involved building effective electronic communication methods (fax, email and telephone) between the two
authors, as author one was based in Melbourne, while author two was in Canberra, a one-hour air flight away. The development of the concept maps, in particular, required extensive use of the fax, particularly as handwritten comments on the drafts of Figure 1 were crucial to the final outcome.

The development of the concept maps, in particular, required extensive use of the fax, particularly as handwritten comments on the drafts of Figure 1 were crucial to the final outcome.

![Figure 2: The individual concept map for Week 12.](image)

The development of the online communication groups was less problematic, as Monash University had recently developed a web-based virtual doorway (the MyMonash Portal) to support students' administrative and educational needs (Kennedy, Webster, Benson, James, & Bailey, In press). Issues of managing the online discussion groups were addressed in the development of the print-based materials, with particular focus on the assessment linked to the participation in three of the discussion groups, and access to appropriate readings (Berge, 1995; Mason, 1997; Salmon, 2000).

**Evaluation of students’ perceptions of the concept maps**

This small study was with a class taught in 1999, with the evaluation data being collected early in 2000 after the completion of the unit. A questionnaire that focused on the integration of the concept maps in the written materials was given to both the off-campus and on-campus students. The responses to selected questions are shown below in Table 1. None of the students had any prior experience with concept mapping. There were three off-campus students and all replied; there were 48 on-campus students, but only eleven students responded to the questionnaire. As with all groups of students, there are differing levels of interest in the unit matter, and diversity of learning styles, such as whether students were 'visual' in their cognitive approaches. Few of the on-campus students used the concept maps; they cited the complexity of the maps and their lack of time for the reasons. The off-campus students appeared to use the maps more but these questionnaire results suggest that they found the concept maps more useful with revision rather than as a primary learning tool.

| Q1: Did you find that the major concept map was informative? Please explain your answer. |
|-----------------------------------------------|-----------------------------------------------|
| Off-campus | On-campus |
| The Concept Map was useful for seeing how all of the sectors of the course interrelated. It was informative although I didn’t use it or retain the information in it when I was enquiring what was up next. | Yes. It briefly explains the basic concepts and guides us as to the differences (and similarities) between macroeconomic and microeconomics throughout the semester. |
| It was to some extent as it visualised the big picture of economics and where each concept fitted in. However, I only ever used it for reference between topics to see how things interrelated. | By the end of the course I found it useful to assist in reviewing the topics studied and to connect them together in context. |
| Q2: Do you believe that the major concept map assisted you in your overall process of learning in this unit? |
|-----------------------------------------------|-----------------------------------------------|
| Off-campus | On-campus |
| Yes, but not until later, when I had the earlier ideas in my mind | Helped with an overview of the topics when reviewing, and to understand how they connected. |
| It was a good diagrammatical representation of the course’s concepts, and helped me to know where my knowledge was lacking, or where I needed to review my understanding | Didn’t use it. |
| When I first started economics, I was confused because I had to learn so many things in a short time. The concept map guided me in finding the right approach to economics. | There was too much to learn within a short space of time. |
Q3: Did you attempt to construct, as the study guide suggested, your own concept maps of your understanding of economics?

<table>

<td>• It never occurred to me. I would probably do it in the future given time.</td>
</tr>
<tr>
<td></td>
<td>• Yes, specific issues only: not ‘the big picture’.</td>
</tr>
<tr>
<td></td>
<td>• Since we had little time for Economics 1, to understand and learn economics in a systematic way is very crucial. Your map helped me a great deal in understanding the subject.</td>
</tr>
<tr>
<td></td>
<td>• Yes, for microeconomics test.</td>
</tr>
</tbody>
</table>

Table 1: Sample questionnaire responses for both groups of 1999 students

It may be that the lack of familiarity and their inability (mainly a lack of time) to develop their own concept maps were problematic. The development team has learnt that an innovation in learning design, such as the use of concept maps, must be carefully budgeted for in terms of students’ time. Students may appreciate these maps, but the time to become familiar with them, and to explore their potential, must be allocated carefully. The question of whether, to what degree, and how innovations such as concept mapping and online discussion groups should be assessed has not been resolved; assessment is likely to become one of the main curriculum issues in the next few years. The use of the discussion groups was not evaluated by specific questionnaires, or requests for specific feedback. However, all online assessment tasks were completed extremely well, with students able to articulate a deep understanding of specific concepts.

Unit Learning Outcomes

With concept mapping and online discussions providing a focused approach to the learning of economics, it may be anticipated that students might learn more about the unit. This added learning may result in higher marks. These results should be seen as anecdotal rather than definitive, if only due to the small sample size. In this regard, it should be noted that the nature and content of the course work in the two economics units taught in the Diplomacy and Trade program remained relatively unchanged over a two-year period under review in this paper. Specifically, assessment details were available for the year prior to the introduction of concept mapping in Economics 1, as well as in the year during which Economics 1 concept mapping was provided as an additional educational tool. As noted earlier, the major assignments for the two groups, off-campus and on-campus, were similar. Note also that the lecturer was the same for all cohorts. As a consequence, a comparison was made between assessment scores gained by students who had been exposed to concept mapping and online discussion, as well as scores gained by students who had not seen either. As can be seen in Table 2, scores for individual tests, and the total, were higher, on average, for the innovation cohort. An overall advantage of 16.1 per cent is noted between successive years.

Table 2: Sequential first semester results: Before and after concept mapping

Conclusions and Summary

The design and development of the unit materials involved the establishment of trust, understanding and good communication between the content expert and the educational designer. The current structure of the unit is being used by the Faculty of Business Economics as an example for other academics who wish to start the transition from more traditional distance education materials to more engaging, interactive ways of developing
student knowledge. The book (paper-based unit guide) still has its place, but integration of online communication enables students, who are often isolated from their colleagues, to engage with their peers, receive feedback from the lecturer and complete assessment tasks that are more relevant to the desired learning outcomes. Whilst there are potential confounding factors at work when making absolute comparisons between two groups of students across years, the anecdotal inference is that there is a benefit to students who have been exposed to an holistic view of the unit by the use of concept mapping as an advance organiser and revision tool, and had the opportunity to engage in asynchronous online discussions.

Abstract: This paper examines a multimedia learning design which utilises a virtual dental clinic and a fictitious eight year old patient - "Matthew", to situate students within an authentic learning environment. A case is presented which requires the student to examine clinical information about "Matthew" in the form of patient history, clinical slides, radiographs and expert information from teachers, psychologists and an endocrinologist. The dental student creates a legitimate treatment plan for "Matthew" by analysing information typically obtained in a real patient encounter. A situated learning design was adopted as it provided a means of engaging the dental student with a legitimate case of a child with diabetes. A virtual "Matthew" was created because it has become increasingly difficult to access suitable patients, especially child patients, for dental students. Consequently dental students may not be adequately experienced in treating paediatric patients with medical conditions such as diabetes. This scenario aims to improve dental clinical management through case management of medically compromised dental patients - in this case a child with diabetes.

Authentic Learning Environments

Authentic learning experiences are "those which are problem- or case-based, that immerse the learner in the situation requiring him or her to acquire skills or knowledge in order to solve the problem or manipulate the situation" (Jonassen, Mayes, & McAleese, 1992, p. 235). "Authentic tasks enable students to immerse themselves in the culture of the academic domain, much like an apprentice" (Young, 1993, p. 43). Interest in environments that immerse students in authentic learning experiences, where the meaning of knowledge and skills are realistically embedded, has been longstanding (Dewey, 1938; Piaget, 1952). More recently, attempts to enhance cognition in authentic learning-performing tasks have become widespread (e.g., Brown, Collins, & Duguid, 1989; Cognition and Technology Group at Vanderbuilt, 1991, 1992, 1993). The need for realistic experience and real-world problem solving is also advocated. Ramsden (1987) suggests that university graduates are not obtaining deep conceptual knowledge that will allow them to think like experts in their discipline. We contend that a key role of a university education is to produce health professionals who are capable of solving complex and ill-structured problems and have the ability to reflect on their professional practice. This practitioner is capable of reflecting on the practical demands of the real world, continually monitoring their own professional thinking for the ultimate aim of solving related or new professional problems. However, there is a continuum of knowledge acquisition that leads to a fully-fledged expert in professional practice. Jonassen, Mayes, and McAleese (1992) suggest a continuum of introductory, advanced and expert learning phases. The introductory phase is typified by initial knowledge acquisition by the novice learner which involves learning about well-structured content domains. The advanced phase deals with ill-structured domains.
"During this phase, learners acquire more advanced knowledge in order to solve more complex, domain- or context-dependent problems" (Jonassen, Mayes & McAleese, 1992, p. 231). Expertise is the third phase in the continuum. Experts appear to be able to uniquely represent problems, which facilitates the solving of problems in an efficient and effective manner. The role of providing authentic learning experiences in the university setting is an attempt to immerse the learner in the advanced phase in order to move them toward the development of expertise.

Authentic learning contexts like the virtual dental clinic may have a number of advantages over more decontextualised teaching and learning settings. The authentic nature of the technology-enhanced, student-centred learning environment may create a context within which knowledge is anchored in authentic contexts. An effective learning environment enables learners to use its resources and tools to process more deeply and extend thinking (Jonassen, 1996; Jonassen & Reeves, 1996; Kozma, 1987). Harper, Squires and McDougall (2000) suggest that "only in complex, rich environments will learners have the opportunity to construct and reconstruct concepts in idiosyncratic and personally meaningful ways" (p. 118).

Learning Design

Teaching dental students to treat patients safely and efficiently presents many challenges. The declining availability of suitable patients attending the teaching clinics of the Royal Dental Hospital of Melbourne in association with the University of Melbourne prevents students from developing a range of experiences in total patient management. A disadvantage of traditional preclinical laboratory teaching is that students are not able to integrate theoretical and practical skills. Consequently there are concerns that dental students are not competent in combining preventive and restorative management philosophies while integrating diagnosis and treatment planning (Suvinen, Messer, Franco, 1998). Multimedia case simulations were considered to be a viable alternative as they replicate the dental clinic without requiring 'live' patients. The diabetes module provides an opportunity to develop and consolidate the concept of integrated patient care. In particular, the learning outcomes for the modules focus on: (1) competence in history, examination, diagnosis and treatment planning skills, (2) integration of theoretical and practical aspects of total patient management, (3) understanding of the relevance of the medical condition to dental health and dental treatment with attention to precautions when delivering treatment, and (4) recognition of the significance of medical conditions in treatment planning for their dental condition.

In order to create a realistic learning experience for the student dentist it was essential that we immersed the student in an authentic case. We utilised principles of situated learning which suggests that there should be "an active relationship between an agent and the environment, and learning must take place during the time the student is actively engaged in with a complex, realistic instructional context" (Young, 1993, p. 45). We utilised the following principles of authenticity to guide our creation of the diabetes scenario. These include:

- real-life problem-solving
- ill-structured complex goals
- opportunity for the detection of relevant versus irrelevant in formation
- active/generative engagement in finding and defining problems
- involvement of student's beliefs and values
- opportunity to engage in collaborative interpersonal activities (Young, 1993, p. 45). Likewise Herrington and Oliver (1995) suggest nine critical characteristics of situated learning which focus on the interactive multimedia program, implementation and the learner.

The virtual dental clinic provides an authentic learning environment in which the trainee dentist can examine information (patient records, clinical slides, radiographs and expert reports) about a paediatric patient with diabetes. This approach attempts to immerse the learner within a typical clinical scenario and then asks them to create a relevant treatment plan. The virtual case attempts to bridge the gap between novice and expert by asking the trainee dentist to begin thinking and acting like an expert dentist.

The first step in our design process was to select a situation suitable for authentic situated learning. Previously we had created two other modules on Congenital Heart Disease and Down syndrome in which scenarios were used to engage the student with the relevant content. A module on diabetes created unique
challenges for the design team. A virtual paediatric patient with diabetes was created in order to address the difficulty of obtaining relevant patient photographs. In our interactions we wanted to increase the level of student engagement with the content and embarked on contextualising the scenario content within a virtual dental clinic. We were also careful not to overwhelm the dental student with an overly complex case. "While complexity may be necessary to provide authentic learning environments, too much complexity can make learners feel insecure and lose track of learning objectives" (Harper, Squires & McDougall, 2000, p. 127). This setting would allow the embedding of authentic activities such as the examination of radiographs and patient information within a realistic clinical situation. We began by photographing the dental clinic and then creating the virtual dental clinic and waiting room. Figure 1 illustrates the virtual dental clinic with "Matthew", the virtual patient.

![Virtual dental clinic and drop-down menu which allows access to clinical information about "Matthew".](image)

Secondly, we provided multiple entry points into the clinical information. This allowed the user to explore the clinic and obtain the necessary clinical information about Matthew. We wanted the student to "criss-cross the landscape of knowledge" in order to obtain information that would enable them to complete the relevant treatment plan (Young, 1993, p. 46). The user can navigate around the clinic and find information in two ways. By travelling around the clinic they will find 'hotspots' which provide clinical information. A site map also provides clinical information enabling the student to access patient records (patient information, medical history, height and weight, dental history and social history), seven clinical slides, three radiographs, and expert information from a teacher, psychologist and endocrinologist. By providing the necessary scaffolding for the novice learner we attempted to move the learner toward expert case management.

**BEST COPY AVAILABLE**
The Case

Presenting Complaint:
"Matthew" is 8 years old. He presented with sensitive teeth, the left side being worse than the right. His mother mentioned that he will not brush his teeth because they hurt. She is concerned that he has not been eating well during the past few weeks.

Dental History:
"Matthew"s last dental visit was when he was 5 years old. The school dental service performed a checkup and no treatment was required at that stage. Matthew brushes his own teeth once a day and does not floss his teeth. He has fair oral hygiene.

Medical History:
This young boy was diagnosed with insulin dependent diabetes at 14 months of age. He has 2 injections: before breakfast and dinner. The injections consist of a combination of short-acting and intermediate insulin. "Matthew"s parents give the injections. "Matthew" has a high carbohydrate diet with frequent intakes throughout the day. "Matthew" has regular medical checkups with his paediatric endocrinologist every three months. His diabetes is well monitored and stable. There have been no complications.

Height and weight measurements:
Height: 130 cm (75th percentile); Weight: 27 kg (50th-75th percentile)

Social History:
"Matthew" was born in Victoria and lives with his parents and two older brothers. He attends a primary school close to home. He has tennis lessons every Sunday morning, swimming lessons on Thursday afternoons and last year he started rugby on Saturday mornings. "Matthew" has cello lessons on Tuesday after school. "Matthew" belongs to the local cub pack and they meet every Monday evening.

Teacher
Due to his checkups at the hospital, "Matthew" is absent from school for a significant number of days. He is in an age-appropriate level at school and has remedial teaching to keep him at the same level as his class. The other students are aware of "Matthew"s medical condition and they are supportive of him, especially when he misses a day of school to go for his checkups. He has many friends in his class. "Matthew" does not need his insulin injections during school hours. In case of emergencies, "Matthew"s teachers will contact his parents for instructions.

Endocrinologist
"Matthew" has been a diabetic for 7 years. He attends for regular checkups every 3 months to assess his blood glucose control and to decide if there is any need for adjustments in medication. He adapted well to a modified diet and daily administration of medication by his parents. There was a period of time when "Matthew" experienced some frustration regarding his lifestyle. His parents were supportive through this episode. If any treatment under general anaesthesia is required, it should be performed in a major hospital so that the endocrinologist can monitor "Matthew" and adjust his glucose level. "Matthew" should be admitted the day prior to the procedure for blood glucose monitoring. He will be able to return home on the same day as the treatment if his glucose level is stable. It is important that "Matthew" has not had any recent episodes of hypoglycemia.

Psychologist
A year ago "Matthew" went through a difficult stage. He was angry that he needed his insulin injections twice a day. During medication times, he would refuse the injections and his parents would spend significant time convincing "Matthew" to have his medication. At birthday parties "Matthew" was upset that he could not eat the whole bag of sweets like other children. I consulted with "Matthew" and his parents over a number of sessions and these issues were resolved.

Table 1: Case information that can be accessed in the virtual dental clinic

Our third strategy provided an expert-supported learning environment. Lab sessions were scheduled in which students interacted with the module and were supported by specialist paediatric dentists. "From the perspective of situated cognition, the teacher's role should be to 'tune the attention' of students to the important aspects of the situation or problem-solving activity, specifically those attributes that are invariant across a range of similar problems and therefore will transfer to many novel situations" (Young, 1993, p. 47). Educators also assisted the dental academics in the tutorial setting by facilitating their efficient use of the technology-enhanced environment. "Instructional designs for situated learning must not only provide scaffolding for students: they must also provide scaffolding for teachers" (Young, 1993, p. 51). The advantage of expert support is that case information could be clarified, explained and elaborated by the specialist. The use of specialist paediatric dentists was a central focus of our approach as they were able to support learning and monitor student engagement with the module. By providing this support it meant that we did not need to overly simplify the authentic task (Barab & Duffy, 2000).

Young (1993) suggests that traditional forms of assessment in situated learning may prove to be inadequate. Authentic learning tasks must be assessed using methods that best align with the task. Our
fourth strategy was to align activities/assessment with the creation of the authentic learning situation. We matched the task and assessment by asking students to develop a treatment plan using the protocols utilised in a traditional clinic. In order to simulate the use of this chart, an electronic dental chart was created to allow users to create treatment plans within the multimedia module. The electronic dental chart allows the trainee dentist to select a category of dental services and allocate a specific treatment for individual teeth. This chart allows the user to complete cases and submit information to obtain expert feedback. The expert feedback provides precise information about the treatment protocol for each tooth. The student can compare their treatment plan to the expert and then re-enter the virtual clinic to rectify any inaccuracies and misconceptions. This concept of authentic assessment tasks is essential in the instructional design as "assessment should be a seamless, continuous part of the activity (a learning/assessment situation)" (Young, 1993, p. 48).

![Figure 2: Electronic treatment plan utilised for the diabetes clinical case](image)

Our fifth strategy was to provide detailed feedback to the student in relation to the case. At the conclusion of the case and after reinforcement activities the student is provided with comprehensive patient feedback in relation to "Matthew's" case. The following information provides an example of this detailed feedback about the case. "The patient with diabetes should be placed on a frequent recall maintenance program after dental treatment is completed until his susceptibility to recurrent oral disease has been established. Regular topical fluoride applications may be considered at home and professionally. Sealants can be placed as the permanent teeth erupt. A mouthguard for sports activities will need regular replacement with development of the dentition. Patients and parents should be aware of the importance of oral health in relation to the diabetic condition. The dentist should take time to inform them of the potential for increased susceptibility to oral infection and periodontal disease in the inadequately controlled diabetic patient. The well-controlled diabetic patient will have good oral health especially if the child maintains good home oral care and continues recall compliance".

Conclusion

Our next step in the process is to create a number of scenarios that may foster transfer to similar cases and to more ill-defined cases. This is important as "one of the major concerns about situating instruction in specific contexts is that students' understanding and application of these concepts will stay welded to the context" (Cognition and Technology Group at Vanderbuilt, 1993, p. 52). In order to address this issue we intend to construct new dental scenarios that are directly analogous to the diabetes case. This is considered to be 'transfer to analogous problems'. The virtual dental clinic can be reconfigured with different information and different case parameters. Individual treatment plans can be developed in
conjunction with specialist paediatric dentists utilising other cases of importance to the learner. Numerous cases can be completed allowing the trainee dentist to become familiar with expert dentist strategies and treatment plans. The overall aim of designing authentic learning tasks is to improve dental health care. Once we have achieved transfer to real-contexts the individual dentist should continue to adapt to complex real-world cases.

Abstract: The Clinicians Health Channel (CHC) is a resource-based portal web site providing online access to information sources that assist Victorian clinicians in decision making, research and education. Resources include an electronic health library with citation databases and full text journals, links to clinical reference materials and guidelines & protocols. An inter-disciplinary, collaborative team from the University of Melbourne is undertaking an evaluation to determine how successfully the introduction of the CHC has met its original aims specifically in relation to the development, implementation and impact on changing behaviour and increasing usage of evidence-based health care. The addition of online communities of practice may assist the sharing of practitioner knowledge and may complement the resource-based nature of the channel.

Rationale

Clinical decisions about options for a patient’s care should be based on both individual clinical expertise and best available external clinical evidence (Sackett, Rosenberg, Gray, Hayes & Richardson, 1996). However, it has been estimated that for the medical profession to keep up to date with advances in drugs, treatment and technologies alternatives, they would need to read 19 articles per day, 365 days of the year (Evidence-based working group, 1992). Information resources made available to clinicians via telecommunication are increasingly being advocated because it is believed that they can provide better access to and use of the evidence to allow the clinician to keep up to date and enhance the quality of care (Lindberg, Siegel, Rapp, Wallingford & Wilson, 1993; Elson & Connelly, 1995).

However, these resources have had limited use in direct patient care settings, meet only a small part of clinicians' information needs, and have not had significant impact on clinical practice. While some may disagree with the need to prove benefit to advocate the use of information resources, most will agree with the need for further research into the content and delivery methods as well as the social and behavioural impacts of such resources on clinicians, their patients, work practices and organisations (Gorman, Ash & Wykoff, 1994; Covell, Uman & Manning, 1985; NHS Centre for Reviews and Dissemination, 1999; Hersch & Hickam, 1998). Our evaluation is thus concerned with the use of evidence-based information in the context of clinical practice, and with the use of a web-based portal to facilitate evidence based practice.
The introduction of the Clinicians Health Channel (CHC) is a four-year project which aims to provide equity of access to critical clinical knowledge resources for clinicians in the public health care sector throughout Victoria. The CHC (http://www.clinicians.vic.gov.au) is a portal web-site providing online access to current, accurate and reliable sources of information to help inform and assist clinicians in decision-making, research and education.

**Evaluation Approach**

Our approach to the evaluation is notable in three key respects. Firstly, the evaluation is conceptualized as the evaluation of strategic change to work-practices, not simply as the evaluation of a website. Secondly, and as a consequence of this broad conceptualisation, the team is multidisciplinary - made up of people with experience and expertise in medicine, multimedia design, educational evaluation, socio-technical relations, workplace ethnography, and qualitative and quantitative research methods. Thirdly, the approach is one that intends to be formative as well as summative, and takes the CHC to be an emergent system rather than stable or fixed.

The evaluation is an integral part of improving the quality and usefulness of the CHC. The University of Melbourne team has adopted a collaborative approach to research and evaluation of the CHC, and the wide range of disciplines represented on the team is a major strength. The evaluation focuses on issues related to professional clinical practice (specifically, an anticipated increase in the practice of evidence-based health care), and on issues related to technological mediation (specifically, the use of the web to achieve this objective). These two intertwined research areas require an analysis through three dimensions – social, behavioural and technical – and these constitute our conceptual framework for the evaluation of the CHC.

The social dimension focuses on the regional, institutional, professional and education context in which clinical practice occurs. It acknowledges the fact that the CHC is situated in particular social spaces and is attentive to those spaces. It addresses and evaluates the aim of the CHC to provide equity of access to critical clinical knowledge resources for clinicians in the public health care sector throughout Victoria. The evaluation questions will include the "who, when, where" as well as impacts of the CHC on accessibility of resources.

The behavioural and professional dimension focuses on the extent and character of the intersection or overlap of the CHC program and evidence based practice. It addresses and evaluates the aim of the CHC to support integration of evidence based practice into the health care system. The evaluation will address the use of the CHC by clinicians and whether it met their information needs. We will identify knowledge resources, awareness of available resources, ability to access these, current usage patterns and factors influencing utilisation. The evaluation will also address any impact on decision making by measuring clinician change and examining the barriers/opportunities, any relevant forces at work, and strategies to positively influence behaviour.

The technical dimension addresses and evaluates the aim of the CHC to facilitate electronic dissemination of these resources and other clinically relevant information, so that the information can be accessed whenever and wherever required. The evaluation will examine the useability of the system in terms of functionality, frequency of use, purpose of use, user satisfaction, user friendliness, time required to locate information, searching utility, success or failure of searches for relevant information, flexibility, and customisation. Training and support will also be examined here as we consider it an integral component of the CHC program. Evaluation areas will include teaching and learning needs, critical appraisal skills, evaluation of teaching and learning, best practice teaching methods, training models, and the development of a tool kit for trainers.

**Questionnaires**

The first stage of the baseline evaluation comprised a paper based questionnaire survey (online). This survey was provided to both users and non-users of the CHC across Victoria. We focussed on both users and non-users of the CHC as we wanted to begin with how clinicians make decisions before investigating how clinicians use electronic sources of information for making decisions. Over 600 surveys were distributed across Victoria to 114 hospitals. 233 surveys were returned.
153 female and 75 males responded to the survey. The average number of years respondents worked in the health care profession was 18.65 years. Fifty-five allied health, 49 medical doctors, 102 nurses and 26 others (managers, administrators, etc) responded to the survey. A detailed examination of the survey results will not be examined in this paper. However we will examine a question on 'how clinicians use information resources to make a clinical decision'.

How do you use information resources in your clinical decision making?

</table>

Overall refers to percentage of respondents that use the information resources for at least one of the activities listed.

Table 1: Information resources utilised by clinicians (doctors, nurses, allied health) to make a clinical decision

The most frequent resources used to:
- guide current treatments included: paper-based clinical guidelines and protocols, workshops/seminars, journals and consultation with colleagues.
- assist with diagnosis included: consultation with colleagues, textbooks, journals and academic-based websites.
- check patterns of illness included: textbooks, journals, consultation with colleagues and internet search engines.
- confirm my actions included: consultation with colleagues, paper-based clinical guidelines and protocols, workshop/seminars and textbooks.
- refresh my knowledge included: workshop/seminars, conferences, textbooks, journals.
- access local information included: staff meetings, local services directory, consultation with colleagues and workshops/seminars.
- for background research included: journals, academic based websites, internet search engines and computer-based journals.

As seen from Table 1 and the above analysis, clinicians carefully choose information resources appropriate for the function. The most frequent resource utilised to ‘assist with diagnosis’ and ‘confirm my actions’ involved consultation with colleagues. Consultation is a high priority in six out of seven clinical decision making activities. Electronic resources appear to be extensively used for background research as opposed to obtaining point of care information. This emphasis on peer consultation for making decisions is supported by Young and Ward, (2001) who suggested that ‘the most frequently nominated source of information participants actually would turn to in a time of clinical uncertainty were specialists colleagues (74%), textbooks (36%), other GPs (16%) and the Internet (12%)’. (p. 207). This is understandable where colleagues are available for consultation in large metropolitan hospitals. However, a major part of our evaluation is to examine how resources can be accessed more effectively by rural clinicians throughout the state of Victoria. This finding may suggest implications for the redesign of the CHC website in order to provide equity of access to expert colleagues in rural areas. Presently the site acts as a resource-based portal whereas isolated clinicians may require access to colleagues either in person or through an online community.

Focus Groups

In addition to the surveys, eight focus groups have been completed at six sites chosen to represent a range of size, rurality and level of enthusiasm and readiness (infrastructure and organizational processes) for the CHC. The focus groups were conducted as open-ended interviews on targeted or focussed issues surrounding the introduction of computer-based resources to Victorian public hospitals. There were a number of factors, which were indicated to influence clinical decision-making. These included: routines, traditions, commonsense, doctor preferences, patient needs, cost, availability of medical service, number of staff available and time available. As a result, decision-making was seen as situational, depending on the information available at the time.

Focus group participants used computers to access patient records, email, results and local protocols. Less commonly they were also used to access clinical information. Issues of time, training and perceived clinical need for information would decide whether clinicians would become regular users. Participants wanted more efficient computers and more portable computers, so that they could be utilised at the bedside. Speed of computers was a common concern for the participants. The design of online resources utilised by busy clinicians in emergency departments or clinics needs to optimise time and minimise tiers of information. ‘Any web site [requires] minimum key strokes – like to get the information quickly. So even if our computers are slow or fast, if you’ve just got the function keys to get into certain things rather than accessing all the sub menus – short cuts’. Ease of use was an important aspect of the computer environment. Clinicians want computers and resources that are both useful and user-friendly. However, lack of resources, training and time prevented clinicians from making best use of computers.

Interviews

Interviews were structured around the themes of the study – in this case information needs, resources use and computer experience. The project interviews were semi-structured, with questions asked around the themes and opportunity for interviewees to discuss other related issues. Interviews examined participants detailed personal accounts. Twenty-four interviews have been undertaken and are currently being analysed. In the preliminary analysis of interviews there appears to be a number of consistent themes. In particular there were numerous comments on the applicability of databases for research as opposed to point of care information. For instance some databases provide background research whereas others provide specific point of care information. It is also a consistent theme that clinicians desire a ‘readers digest’ of pertinent information and
that access to suitable computers would assist CHC usage. It is also suggested that informal training and support is more appropriate than formal large group sessions. Understandably, isolated rural clinicians also desire access to other professional colleagues or people resources. The use of a 24 hour help desk could provide assistance to the isolated clinician.

Design Principles for the CHC Website

In completing the evaluation for stage 1 of the project it was essential to focus on how clinicians use all types of resources to make a decision - not just web-based resources. In the second stage of the project we are utilising a variety of methodologies including: focus groups, interviews, online questionnaires, direct observation and log analysis in an attempt to improve the CHC portal website. Part of our discussions as an evaluation team focus on redesign of the website. These redesign principles are based on multimedia and online experts' evaluation of the existing website and an analysis of the surveys, focus groups and interviews to date. By accounting for these user viewpoints we recommend a number of principles that may improve clinical use of the CHC.

1. The current website needs to be restructured conceptually in order to improve navigation, usability and access to the resources. Time is a precious commodity in the health care setting as suggested by the following quote. I want to get in, get it, go to the bottom line and get out – I don’t want to be in there for half an hour. The use of a site map, clearer layout and the application of instructional design principles will assist this process.

2. Further instructional design on the CHC website should reduce the time required to access information and make searching for relevant information more intuitive. The application of these principles should provide a seamless entry into using online resources for clinical practice. One participant commented that clinicians need predigested information on specific topics that you encounter frequently in clinical practice, you want a readers digest version, you want to know what to do and you want to know quickly. For unusual cases you want to be able to identify relevant literature and examine it yourself. Frequently asked questions (FAQs) may also assist novice users and their utilisation of resources best suited to clinical practice. The use of FAQs may provide guidelines for “newcomers to move toward full participation in the sociocultural practices of a community” (Lave & Wenger, 1991, p. 29). It is envisioned that these FAQs would be continually updated with user experiences and hints.

3. Training is a major aspect of encouraging utilisation of the CHC for clinical practice. Face-to-face training is currently being undertaken by the Department of Human Services. However there needs to be a variety of training strategies. I think a lot of the time people haven’t got the time to get to the education sessions, it needs to be a little bit more user friendly for people who just want to get on and go in. Another project on the CHC is developing online tutorials to assist clinicians use of the channel. The aim of these tutorials is to teach users evidence-based practice and critical appraisal of research resources. By utilising this approach the user will learn how to use the databases and search mechanisms and also efficiently navigate around the CHC. Training was also seen as a critical issue with participants asking for local, individualised training at their worksites as well as more help on the CHC site itself. Suggestions included context-specific help, on-line tutorials and just-in-time training.

4. The final concept focuses on assisting clinicians in remote areas to interact with colleagues. Currently the CHC is a web-based portal which allows users to access resources similar to a library catalogue. Stuckey, Lockyer & Hedberg, (2001) outline a model for evaluating the characteristics of portals, networks, interest groups and online communities. They suggest that portals are resource-based entities where consumers may be passive, have varied membership with no ties between members and allow users to link to resources and indexed sites that are database driven. In this model there are few interactions with clinical colleagues over the internet. Participants in both focus groups and interviews have suggested that communication with other health professionals could be a major benefit of the CHC. I suppose if there’s one thing that could be added to an online server it would be posting questions. Where a professional dilemma, a diagnostic dilemma – so if you are remote and you are removed from colleagues and you can’t just go to the residents quarters and discuss it with the registrar – you are able to put it online so you can discuss it with a haematology registrar within that system. That’s what they’re doing in physiotherapy – the chat room is fantastic. You can say I’ve got this really difficult patient and get everyone from around the world. The ideal community "requires member participation and contribution, ownership, quality support and
Within this ideal community collaboration between colleagues for the purposes of improving clinical practice requires both experts and novices "to communicate, contribute to and initiate ideas and joint projects" (p. 6). Fostering an online community requires sustained commitment from developers and members, multi-dimensional communication, shared focus of attention on a real problem and members and facilitators who can collaborate, mentor and develop solutions together in a clinical setting (Stuckey, Lockyer & Hedberg, 2001).

Conclusion

Overall this paper has outlined our rationale, approach, evaluation strategies and findings from selected aspects of the questionnaires, focus groups and interviews. Our evaluation website (http://www.medfac.unimelb.edu.au/health_channel/) continues to update our latest findings in relation to the three-year evaluation. The questionnaires, focus groups and interviews provide an insight into clinical decision making and how clinicians use resources in evidence-based practice. In our evaluation of the website portal we have accounted for clinical perspectives and have suggested a number of key principles for the redesign and reorienting of the portal so that it embodies some online community principles that complement the resource-based characteristics of the website. In addition the website should provide recommendations to professional groups regarding information needs and recommendations to novice and experienced clinicians. The use of web-based clinical scenarios will also significantly reinforce navigation and use of the resources on the Clinicians Health Channel. Ultimately that’s what a good single site is about. Where it can offer you two or three different opinions, so that you can be reasonably sure that the decision you’re making is based upon current practice and evidence. Whatever is on there, there should be at least one or two different approaches for a problem. I don’t trust any one person or any one thing; I need to have several approaches before I agree to anything.

Abstract: In the case of executive learning, the imperative is to create new collective knowledge, the fuel of personal and organizational effectiveness. It is also to improve personal and organizational effectiveness, the fuel of new collective knowledge. We discuss this conundrum and how it is addressed: a collaborative approach between participants, who relate the group’s discussion to their own organization’s challenges, and vice versa. However, if ongoing collaboration is desired, virtual collaboration is a necessity given current organizational realities. We consider the impact on instructors and participants, and then show how the use of a relatively simple web-based discussion forum effectively enables this approach.

The Executive Context and the Collaborative Approach

The profile of an executive education participant that we consider here is based on our institute’s experience of conducting programs for over 5000 executives every year. These executives are drawn from a worldwide geographic base, and also come from a wide range of companies, industries and functions. A typical participant is 40+ years old, and has an average of 15 years’ management experience. For these executives, the essence of management is the capability to make decisions and act wisely in a wide range of complex situations, especially those that require judgment, discretion, and risk-taking (Squires, 2001). Decisions are often made under time pressure, in an environment of constant change and pressure for quick results, and with incomplete information and analysis. Such situations typically are found in the fields of leadership, strategy, and others that require adaptive decision-making as more information emerges or conditions change (Mintzberg, 1996).

Given this profile, “an [ideal] executive learning experience exposes one to tensions, interactions and discussions, which in turn result in action, experimentation and implementation, with the ultimate purpose being to improve one's personal effectiveness” (Lorange & Gilbert, 2001). Yet personal effectiveness is only one part of the equation. In organizational life, we cannot discuss and act in isolation. Views on topics such as leadership are beginning to recognize to a much greater extent the collaborative element involved – for example, “all kinds of different people [contribute] critical leadership in initiating and sustaining and diffusing significant organizational innovations” (Senge, 2001).

Through their interactions, executive learning participants construct a shared understanding, or a collective knowledge of how things are represented (Brown & Duguid, 1991). The benefits of creating new collective knowledge are significant: collective knowledge is the most strategically significant advantage that executive managers seek (Spender, 1996).

Not Guides: Instructors are placers, spacers, and provocative challengers

Once settled on a collaborative approach, the traditional role of an instructor is redefined. Tradition says instructors are responsible for delivering content, presentations and lectures to participants who absorb and apply – acting as “sponges”. Being a star instructor who delights and entertains with energetic delivery of well-packaged insights produces instant gratification. These insights fade, however, when the realization sets in that the “lessons learned” are not truly situated in the context of the participant. The instructor has made all of the choices: what is important, for whom, when, and why. It is not the creation of meaning, but the transfer of content, from one to many, in a relationship devoid of significance.

For the delivery of lasting impact, participants need to not only take center stage, but to create the experience themselves. So the instructor structures the time and space in which the dialogue and action occurs.
A complementary role is the highly skilled and sometimes intuitive process of framing the discussions. The highly skilled instructor’s role is to provoke, probe, challenge, surface latent curiosity, encourage divergent thinking, facilitate synthesis, encourage adoption of a systemic view, make sure learning is linked to action, and ensure reflection is built into the process (Kolb, 1984; Lorange et al., 2001).

The Participant’s Realities and Role: Going Virtual – A Fait Accompli

Participants need the opportunity to gather information from different sources to craft arguments, create and explore viewpoints, investigate alternate courses of action, consider complex patterns of interaction within and beyond their own organizations, and observe and reflect on the effects of applied action learning over time. These longer, more complex, more uncertain paths tend to favor longer collaboration timeframes. However, collaborators are rarely co-located all of the time, given today’s global organization structures and division of responsibilities. Virtual collaboration allows participants to carry on the construction and development of shared understanding in multiple contexts and over the longer term of project work. Participants construct new content, as a by-product of collaboratively exploring, making connections, hypotheses, experiments, reflecting, building a new shared understanding and synthesizing and embodying new collective knowledge.

Virtual Collaboration Example: International Political Economy in a Business Context

The assignment is to draw lessons from history regarding the impact of cultural, structural and systemic factors and natural advantages on the competitiveness of a region, and find parallels for business, strategy and competition. Participants have a common basis to begin their discussions due to the assigned reading of a contemporary survey work on this topic. In addition, prior to this assignment, participants have already collaborated face-to-face in an exploration of the political and economic dynamics of a growing city. This increases their personal and group fluency with the topic, and becomes both a basis for further investigation and a shared lens through which participants view the current assignment’s readings and discussions.

The initial task is to read the survey work and post key ideas in a web-based discussion forum, along with explanations of the parallels participants find for business. Then, they read each other’s comments and begin to virtually debate, share, and build further on each other’s ideas. During the process, a particularly striking passage or example from the reading sometimes becomes a shared metaphor, and therefore a shorthand expression of a broader business issue. For example, the metaphor of using instruments to navigate at sea, a key development in the exploration and exploitation of new worlds, could serve as a metaphor for navigating business performance in the modern company. Future reference to an in-depth discussion and its associated dilemmas, talking points, issues of resolution and confusion, can be raised by reference to this metaphor. The most powerful metaphors stay with the participants into their field expeditions assignments and even beyond.

Abstract
Virtual learning environments (VLEs) are often perceived by education establishments as an opportunity to widen access without traditional overheads. An integral part of most VLEs is asynchronous computer conferencing and on-line moderators must help students migrate quickly to the new virtual environment to minimize learning disruption. This paper focuses on 21 new on-line moderators and reports their changing perceptions re their role and concerns, from their first appointment through to the end of the delivery of their first on-line course. The findings suggest that it is only after socialization occurs that information can be exchanged and lead to knowledge construction. These are supported by, and extend, prior research by Z Berge, R Mason, M Paulsen and G Salmon and are reinforced by empirical work with a further 19 new on-line moderators.

1. INTRODUCTION
Virtual Learning Environments (VLE) are increasingly being used in education because they offer a potential solution to current academic problems of increasing student numbers within a climate of reduced funding. Whether they provide the solution is debatable however, it is only by recognising and fully utilising their potential that maximum effectiveness can be achieved [11] [16]. Computer conferencing is an essential part of VLEs [4]. It promises the ability for dispersed students to communicate with each other and experience the pedagogical techniques of collaborative learning and support. When learning moves on-line, students and tutors do not automatically adapt to the new medium [3] and for some people it can even provoke strong negative reactions [1]. Therefore, a cultural shift needs to take place and we “...must learn how to cultivate communication in a largely asynchronous environment.” [5]. This will engender confidence in the new environment, for all participants, and enable effective learning to take place.

This paper follows 40 distance learning tutors during their first experiences as on-line conference moderators within an on-line course. It investigates how they adapt to the role of moderator and focuses on what they perceive as their role and reports on their concerns. Of these, 21 tutors provided the initial focus and further empirical work with 19 tutors, plus previous research in this area, reinforce those findings. Qualitative data is also drawn from students studying on their courses [7]. The results, in conjunction with an analysis of their concerns will enable us to improve the support and training we offer new on-line moderators.

2. PRIOR RESEARCH
Further research in 1995 by Zane Berge and Morten Paulsen built on this work and related it to their native lands—America and Norway. Their results supported and reinforced Mason’s paper with one additional role being added by Berge, i.e., technical. She felt it was important that the moderator should help those new to conferencing to overcome the initial technical issues associated with going online and becoming familiar with new software.

Although it is ten years since Mason’s original classification of an on-line moderator’s role and five years since Berge and Paulsen’s work, the roles and tasks identified are still cited today. The intellectual role is sometimes referred to as pedagogical and the organisation role, managerial. The tasks therein are the same and the original names have been used here for consistency. To provide a frame of reference for the research a matrix depicting the roles and tasks of online moderators identified by these researchers was compiled and is shown in Table 1.

Although some of the tasks listed can be said to be a subset of others, for example a facilitator does support and guide discussions, no attempt has been made to change the level of granularity to enable a more consistent matrix to be compiled.

Gilly Salmon’s action research into on-line moderation introduces a five layer model of teaching and learning on-line through computer mediated communication which she invites us to explore and contextualise into our own discipline. The five layers are: access and motivation; online socialization; information exchange, knowledge construction and development. She summarises her model thus: “Stage One: Individual access and the ability of participants to use CMC are essential prerequisites for conference participation. Stage two involves individual participants establishing their online identities and then finding others with whom to interact. At stage three, participants give information relevant to the course and each other. Up to and including stage three, a form of co-operation occurs, i.e., support for each person’s goals. At stage four, course-related group discussions occur and the interaction becomes more collaborative. At stage five, participants look for more benefits from the system to help them achieve personal goals, explore how to integrate CMC into other forms of learning and reflect on the learning process.”[17]
3. BACKGROUND

1. The Course
The Open University in the UK piloted a pioneering on-line course during 1999 entitled 'You, Your Computer and the Net'. It is a first year degree module and it aims include:
1. introduce students to computers and the internet;
2. give students direct experience of working at a distance by themselves and as a group;
3. develop the new skills needed for studying and communicating using online media;

The course is web based and runs from the middle of February to the beginning of October. The main study material is delivered via the World Wide Web. The asynchronous text based conference facility is central to the delivery model with the primary computer conference being the tutor group i.e the tutor and their students (15-20 members). Moderated by the tutor, it is the main area for course activities, discussions, and general chat. All tutor groups are within one of the 13 Open University regions and this research is based on one of those regions.

2. The Students
All Open University courses use distance learning and students enrol on that premise. They are part-time, usually mature and have other commitments ie work and/or family.

3. The Tutors
Student demand for the 2000 presentation of the course resulted in a large number of tutors being recruited. Two key attributes the interviewers were looking for was either a neutral or positive attitude towards the delivery of a course on-line plus the required underpinning skills and knowledge necessary for the academic content of the course. The 40 tutors who participated were over 30 years of age, predominantly male (76%) and had all tutored a distance learning course before. 61% were in the 41-50 age bracket and almost half are teachers/lecturers. None had used asynchronous conferencing as an integral part of a learning programme.

4. METHODOLOGY

To support new tutors there was a regional briefing day where each tutor met their mentor who they could go to for advice during their first year. Each mentor had tutored on the pilot year of the course. In order to track the new tutors changes in perceptions about their role as an on-line moderators a number of questions were administered at significant points throughout the course. These were at the beginning of the briefing day (November), before the course started (end January), mid course (end June) and at end of the course (October). The questions used to ascertain their perceptions and concerns were:
1. What are your perceptions of the role of an on-line moderator?
2. What concerns do you have about the role of an on-line moderator?

They were open ended because although responses are complex to analyse, if one offered them a list of tasks from the role/task matrix (Table 1) it could stop innovative thoughts and preclude new tasks being identified. The responses for the question 1 were compared to the moderator role/task matrix and any similarities/differences noted. A list detailed their concerns was also produced.

During the regional briefing day in November new tutors were put into groups and participated in a 30 minute session to experience the medium of text based narrow-band communication. No questionnaire was issued at this stage to allow any immediate changes in perception to dissipate. Between their regional briefing day and the start of the course an informal group conference was used to enable them to practice their skills. At the end of January, before the course started, tutors completed a second questionnaire without any reference to the first. It comprised their name and the two key questions given above. The third questionnaire was issued mid course and the final one just after the course was completed. The participants had no reference to their previous responses. Completed questionnaires were analyzed to identify what, if any, changes had occurred. The research was then extended to cover a further 19 new on-line moderators to reinforce, or otherwise, the original findings.

5. RESULTS

Tutor responses to the question “What are your perceptions of the role of an on-line moderator?”, were examined and compared to the on-line moderator role/task matrix (Table 1). It was interesting to note that only two tasks mentioned by tutors did not map directly to one of these tasks, i.e. housekeeping and control. The statistical data gathered from the tutors provided evidence that as the course evolved so did their perception of their role (Figures 1 and 2).
Initially they were concerned primarily with intellectual issues however, after a short submersion in an asynchronous environment there was a significant switch to social issues. It remained their focus two months later just before the start of the course and suggests that they became more concerned with the issue of ensuring that students adapt to the new environment. This concurs with one of the concerns identified for Internet based learning ie loss of social interaction [5] [10]. As the course progressed the perceptions of 21 of the tutors implied that the importance of social issues decreased and by mid-course the balance between intellectual and social tasks equalized (Figure 1). The extended research with a further 19 tutors reinforced this pattern (Figure 2).

The end of course questionnaire was completed by all 40 tutors. It suggests that whereas the number of intellectual tasks almost returns to the original level when they were appointed to the role of an online moderator, the social tasks cited decreased. The following results from the four roles are drawn from the input of all 40 tutors and feedback from their students.

1. Intellectual Role
Four of the tasks under the intellectual role were mentioned (Table 1) ie explainer, facilitator, summarizer and to support/shape/guide discussions with the last task representing over 50% of the replies. All of the remaining tasks except one in the on-line moderator role/task matrix could be considered as a subset of these four. The exception was Paulsen’s “don’t reply to off-line materials”.

2. Social Role
Their initial thoughts were that it was important to encourage contributions for everyone and, when required, they should mediate. After experiencing asynchronous conferencing the number of tutors citing these tasks increased significantly. Providing a good social environment, deter negativity, discourage inappropriate material, and to create context conducive to thought, were also
mentioned. Fewer tasks were identified mid course and by the end of the course only four tasks were cited: encourage contributions, ensure equal participation, deter negativity and mediation. It was interesting to note that tutors did not mention; be sensitive to participants needs, praise and model positive discussant behaviour, provide positive feedback on students' input and to reward positive contributions.

3. Organisational Role
No organisational tasks were mentioned, including; to provide the framework and rules within which the conference will operate [12]. This encompasses the activities, schedule and the requirements of the course. Perhaps this is because all of the module material is provided on the course web site. Housekeeping was mentioned, but does not appear on the role/task matrix in Table 1. It has not therefore been shown in Figure 2 but should be added upon update of the role/task matrix.

4. Technical Role
Only one on-line moderator cited this. The Open University offers a comprehensive computer support service for tutors and students. However, students still raised technical issues [7] as an area for concern and expected that the on-line moderator should solve them.

5. Areas of concern
Time became of increasing concern to 50% of all tutors by the end of the course. It took a lot longer than they had anticipated to assimilate messages and the responses took longer to compose because they were aware that the written word could be misinterpreted. As one student said, “Many people have problems not being able to articulate easily on-line”. They stated that tutors must have superior written skills as body language and voice intonation do not apply [7]. Lack of experience of what the role of an on-line moderator was also a key area for concern. Although it decreased by the end of the course, the post-course student survey showed that some of the students were also unaware of what the role of an on-line moderator is. This is an area for future research.

Table 2: Concerns raised by 40 tutors as they adapted to their role as an on-line moderator.

6. CONCLUSIONS

The results suggest that tutors new to moderating text-based online computer conferences come with the preconception that their primary role is intellectual. However, even a short exposure to the medium raised many new social issues. These were still the overwhelming issues two months later just before the start of the course. As the course progressed and online socialization occurred, social and intellectual issues became of equal importance. At the end of the course social issues had decreased to below their initial level. The issue of gleaming information only from text without any visual and/or oral clues remained an issue, primarily from the students' viewpoint. Some students also expected technical help from online moderators whereas the moderators did not perceive this to be part of their role. There is a need to match the expectations of the online moderator and the students to avoid discontentment.

Stages two, three and four of Gilly Salmon's five layer model of teaching and learning online through CMC [17] is that online socialization must take place before information can be exchanged and lead to knowledge construction, are also supported. No data was available from this research to comment on stages one (access and motivation), or five (development) of her model.
Two key areas for on-line moderator concern were: time and lack of experience. Time became increasingly important as the course progressed. It took far longer than they had anticipated to compose new messages. This may partly answer some students concerns about feedback time. Lack of experience decreased as the course progressed however their knowledge is only based on experiential learning from one group of students on one course and from dialogue with colleagues.

Training and support for new on-line moderators must include on-line conferencing as an integral part of the process in order to cultivate the ability to confidently communicate by text. This will enable them to realize the importance of socialization before pedagogical issues can be fully addressed.

7. ACKNOWLEDGMENTS

Many thanks to “You, Your Computer and the Web” and finally, and most importantly, the tutors and students without whom this paper would not be possible.

Abstract: Developers of computer-based tools face a dual challenge when trying to understand users' mental models, because users are simultaneously building mental models of the tool and of the world represented by the tool. Understanding users' mental models of complex computer-based tools, such as the 4-D modeling tool described in this article, can help inform the design and development of those tools. For this study, usability tests using the teaching method were conducted to determine the method's usefulness for determining the mental models of both advanced and novice users. The results of the tests revealed sufficient information about the differentiation between users' mental models to inform further development of the software.

Introduction

The Virtual Solar System (VSS) is a powerful virtual reality (VR) modeling tool in which students create four-dimensional (4-D) models of the solar system to investigate astronomical phenomena (Hay & Barab, 1998). Students construct and test their models to answer inquiry-oriented questions, using their models as a source of data for their answers. The 4-D environment allows students to navigate through their model in all three physical dimensions as well as backward and forward in time so as to look at astronomical phenomena from multiple viewpoints. For example, students are able to watch solar and lunar eclipses from the viewpoint of the Sun, the Earth, or the Moon, or anywhere else they choose. This tool affords students the ability to explore the solar system from perspectives that were previously unattainable through other media. However, this new environment raises new questions: How do students get their bearings in this new world? Can they understand the tools well enough to explore this world? Are they able to differentiate between their mental models of the solar system and their mental models of the tool and its interface? If so, how do they incorporate this new modeled reality into their existing mental models of the solar system?

Developers of computer-based tools face a dual challenge when trying to understand users' mental models, because users are simultaneously building mental models of the tool and mental models of the concepts represented by the tool. Understanding users' mental models of complex computer-based tools like the VSS 4-D modeling tool can help inform the design and development of such tools. One potential method of exploring users' mental models is through usability testing. Although the term “usability testing” is often used in its most restrictive sense, that is, to find and document usability problems in software and then to make recommendations of how to fix these problems, our definition of, and purposes for, usability testing are much broader. We believe that the data uncovered using certain usability testing methods is suitable for determining novice and advanced users' mental models when they are immersed within complex computer environments.
Theoretical Framework

The VSS project (http://lpsl.coe.uga.edu/vss/index.html) is based on two educational theories: constructionism and inquiry. Constructionist learning environments require students to create artifacts as an essential component of personal knowledge construction (Papert, 1993). Inquiry-oriented instruction recommends that student's individual interests should guide their learning activities (Welch, Klopfer, Aikenhead, & Robinson, 1981). Their natural curiosity into exploring phenomena leads to a cycle of questioning, designing investigations, seeking solutions, and then asking new questions. Student curiosities are satisfied when they have constructed mental frameworks that adequately explain their curiosities (Haury, 1993).

Models are powerful ways of understanding that are integral to scientists' research. The act of model building allows learners to engage in a design process (Jackson, Stratford, Krajcik, & Soloway, 1994; Lehrer, Horvath, & Schauble, 1994), which begins with a set of tentatively accepted theories that evolve into coherent understandings as represented in their models (Roth, 1996). Model building forces learners to make clear their understandings of phenomena, validate their resultant model, and iterate the process to develop increasingly richer conceptions (Confrey & Doerr, 1994). When students use computer tools to work in real and virtual (or modeled) scenarios, they develop richer, more complex mental models of the content being studied, but they must also develop mental models of the software environment itself in order to facilitate their movement between the two realities. The software programs used in modeling are examples of cognitive tools.

Cognitive tools refer to technologies, tangible or intangible, that enhance cognitive powers during thinking, problem solving, and learning (Jonassen, 1996). One goal of cognitive tools is to assist students to follow mental models similar to experts' cognitive processes to find and solve problems, set achievable goals, test hypotheses, and make their own discoveries (Collins, 1991). As visualization, simulation, and modeling become more important for mathematicians and scientists, the use of similar technologies for learning mathematics and science has also increased in importance (Roschelle, Kaput, & Stroup, 2000). For cognitive tools to emulate the professional tools that scientists use, the developers of these tools must be cognizant of the differences in mental models between novice and advanced users.

People try to understand the external world by constructing internal representations of it in their minds; we call these representations mental models (Johnson-Laird, 1989). These models are assumed to have structures that reflect our perception and interpretation of what the world contains, how those pieces are related, how it works, and why it works the way it does (Bibby, 1992; Carroll & Olsen, 1988; Jih & Reeves, 1992; Kearney & Kaplan, 1997). Thus, the process of building mental models becomes an important issue in balancing between what exists in the world and what the knower understands.

Users of computer-based cognitive tools build two kinds of mental models: a mental model of the tool and a mental model of the world represented by the tool (Payne, 1992). Learning about the tool and gaining a clear mental model of it takes place throughout the user's interactions, but it is more pronounced in early stages of learning about the tool. Building mental models of the tool requires users to become aware of what external knowledge they need to acquire and how to approach the provided functionalities (O'Malley & Draper, 1992). The next developmental stage requires users to construct a mental model of the situations and actions of the world that is represented by the system (Bower & Morrow, 1990). Their previous mental models affect the decoding of the meanings and relationships, depending on the level of proximity of the user's language or interface to that of the system (Calvin, 1996).

Novice and expert users' mental models are different in two respects: sharing tasks with the tool and reasoning through the represented world. Novices usually do not have enough knowledge about what the system can do to decide what needs to be internalized by the user and what the tool can do to fill in the gaps (Kelly, 1995). This lack of knowledge might lead novice users to spend too much time on tedious tasks that the system could take care of. Novices build and process their mental models by focusing on visible objects that simulate processes in real time, whereas experts are able to construct mental models of abstract relations and properties (Johnson-Laird, 1989). The greatest challenge of researching mental models comes from our inability to directly observe users' mental models (Kelly, 1995). Additionally, researchers have no choice but to rely on their own mental models to conceptualize users' mental models, which may affect their interpretation of research results (Rouse & Morris, 1986; Rutherford & Wilson, 1992).
Usability Testing

Usability is generally thought of as how easy it is to learn and use a product (Nielsen, 1994). The level of usability for a product can be tested through a variety of methods. Quantitative methods typically include measurements of the length of time users take to complete specific tasks. Qualitative methods are more descriptive in nature and lend themselves to holistic overviews of usability problems. One of the most commonly used methods is the think-aloud method, where a single user interacts with a product and talks aloud about what he is doing and thinking during the test. This method, although highly effective in revealing the thoughts of the user, seems unnatural for many users. A closely related method, the teaching method, pairs an advanced user with a novice user. The advanced user guides the novice through a number of structured tasks, and both users are instructed to talk aloud to each other throughout the test about what they are doing and thinking. The tester can analyze both the advanced and the novice users’ mental models of the system (Nielsen, 1994). The method also reduces the likelihood that the users will try to interact with the testers, which can detract from the validity of the data. We believe the interplay that occurs between the advanced and novice users as they think aloud in the teaching method can give us insight into the mental models of the users.

The Study

Our goal for this study was to determine:
1. What are the differences between novice and advanced users’ mental models of VSS software?
2. Does the teaching method of usability testing provide sufficient information to reveal novice and advanced users’ mental models of the software, and the concepts represented by this software?

The teaching method of usability testing pairs an advanced and novice user together for each usability test. The advanced users for this study were selected from the students currently enrolled in the introductory astronomy lab course that one of the researchers was teaching. The three students who agreed to participate in this study were among the most competent users of the VSS by the end of the course. Additionally, they all received an A in the course, indicating a strong understanding of the astronomy concepts.

Three novice participants were selected from among graduate students working in the Learning and Performance Support Laboratory (LPSL) at the University of Georgia who had no familiarity with the VSS. They all had low to average computer experience, and no background in astronomy.

Data Collection and Analysis

Each pair of users was given a list of four common tasks to perform using the VSS. The tasks ranged from the most basic (e.g., constructing a model of a basic Sun-Earth-only solar system) to moderately complex tasks (e.g., investigating the eccentricity of planetary orbits and the timing of planetary orbits). Each of the advanced users had completed these tasks at least once during the astronomy lab course. Users were discouraged from asking the testers questions about the software or the test itself during the test.

Data consisted of audio and video recordings of the users’ interactions with the software, video recording of the users’ computer screen, researcher entries into usability data-logging software and researcher field notes. The data logs and field notes were analyzed for instances of user talk or action that revealed evidence of the user’s mental model of either the tool or the astronomy content. Each instance was further coded to indicate whether it related to the mental model of a novice user or an advanced user, and whether that instance was a representation of the modeling environment (tool) or of the astronomy content (real world). The findings from each individual were then grouped together by common themes.

Results and Discussion

We found that users have difficulties in building mental models of the tool and the represented world. Four major themes emerged from the data: (a) conflict with existing interface mental models, (b) difficulties in
building and integrating mental models of interface functionality, (c) difficulties in building and integrating mental models of space, and (d) difficulties in building and integrating mental models of space and time.

Conflict with existing interface mental models: Novice users found aspects of the VSS interface to be confusing, particularly the menus and shortcut keys, which are not consistent with Windows software conventions. This did not match the novice users’ existing mental models of how an interface is laid out and how it should work. In tests 1 and 2, even though the advanced users spent considerable time explaining the functions of keys and menus in the program, novice users were still confused. The VSS also relies on keyboards commands for navigating through the space and selecting planets and stars in the space. Novice users expected to use the mouse as their primary navigation tool and often clicked on the screen to navigate through space or to edit parameters of planets and stars.

All of the advanced users were able to articulate clearly the functionality of the interface and were able to accomplish tasks efficiently and effectively. This highlights how users can modify their existing mental model of an interface to adapt to different interfaces. The control needs of a 4-D environment differ so greatly from, and are so much more demanding than, a normal 2-D Windows program that additional documentation and help features need to be incorporated into the software to help new users accelerate their learning and understanding of the controls (see Figure 1).

Figure 1. VSS Basic Screen Controls

Difficulties in building and integrating mental models of interface functionality: The main phenomenon of interest is generally located in the center of the VSS screen, but there is also ancillary information in each corner of the screen at all times. Novice users were unsure of which aspect of the interface to attend to first and which elements of the screen were the most important. A task such as timing the orbital period of a planet required them to use both hands on the keyboard while simultaneously watching three different portions of the screen.

Advanced users built their mental models to accommodate these demands. On many occasions, however, they were using the tools without fully understanding the concept behind it (e.g., negative number for rotation rate, increase or decrease in speed by a factor of ten). Both novice and advanced users suggested that a more simplified method of timing objects, such as a built-in stopwatch, would allow them to conceptually understand the elements involved in determining time in space without distracting their focus from watching the phenomenon occur.

Difficulties in building and integrating mental models of space: All users had difficulty comprehending the vastness of space that is represented in the software, the relatively small size of objects, and the challenges of navigating to other locations. For example, when a student creates an Earth and then observes it from the Sun, the Earth appears as little as a pixel or two of light on the screen. Novice users expected to see larger objects, similar in size to traditional textbook drawings of solar system objects. Their current mental models of the worlds represented by the software did not include the concept that most of space is, in fact, space.

The vastness of space created another problem for novice users when they tried to travel between planets. The A and Z keys controlled the forward and backward movement of the user’s viewpoint. All of the novices consistently overshot their target by accelerating to a high speed, then not decelerating rapidly enough as they
approached another planet. Advanced users were consistently proficient at maneuvering their viewpoint by using the keyboard keys.

**Difficulties in building and integrating mental models of space and time:** Time is the fourth dimension of the VSS. The difficulties in this section arise from the naïve mental models of both novice and advanced users that do not incorporate time as a key element of the modeling environment. VSS has a functionality called waypoints that allows users to create customized views of the solar system by attaching a viewpoint to any object and looking towards any other object. Novice and advanced users’ mental models of a waypoint were based on an incorrect or naïve idea of returning to a specific location at any time, with the expectation that the view would be the same. Even though we do not expect to see stars at the same spot looking into a telescope pointing to a certain part of the sky when we return after a while, the novice users could not integrate the time factor into their mental model at first.

The passage of time is an integral feature of solar system modeling. A view from any one point at any one instant will never be the same as that same view at a different instant. Novice users also expected that VSS would have an "undo" feature of some sort that would enable them to return to a prior position (and time) with the click of the mouse. Time in many ways is the most important dimension in this environment, because without it the solar system model would not run, that is, all of the planetary movement that occurs in the model does so because of the passage of time. More thought should be given to how the user is informed of time on the screen, and how it is controlled by the user.

**Conclusions**

The teaching method of usability testing revealed information about the advanced and novice users’ mental models of the software interface and of the astronomy content. Recommendations from this form of usability testing can help the developers make changes to the interface that would not have been revealed through an expert review, heuristic evaluation, or other forms of usability testing that focus primarily on finding errors with a program. If the interface is too challenging (non-intuitive or counter-intuitive), users may be developing a more complex mental model of the tool but not of the world represented by that tool. An ideal interface would not require significant mental model shifts on the part of novice users, allowing them to focus on the use of the tool for learning the new content.

Further research should be conducted on the users’ understanding of the spatial and temporal world represented by the VSS. The time aspect (the fourth dimension) of the VSS is an important issue, because it enables the users to understand the motion of planetary bodies (by allowing the 3D spatial movement to occur). The spatial dimension is also critical considering that the user in a computer-based 3-D (or 4-D) environment is forced to interact with this environment through a 2-D interface. More research can uncover the tension that must exist between the mental models of a 2-D interface and the mental models of a 3-D (or 4-D) environment.

Educational Application of Dialogue System to Support e-Learning

Youn-Gi Kim, Chul-Hwan Lee, Sun-Gwan Han,
Dept. Computer Education, Inchon National University of Education, Korea

Abstract
This study is on the design and implementation of an educational dialogue system to support e-Learning. The learning domain to apply the dialogue system used the subject of the geometry. The knowledge in dialogue-based system for learning the geometry was created and represented by XML-based AIML. Implemented system in this study can understand the student's context of the dialogue. Moreover the dialogue system can answer the student's question by referring and saving the previous knowledge while having a conversation with a student. To refer and save a student's state of knowledge, we used an overlay student model in this system. Finally, we evaluated an educational dialogue system to test the efficiency of the designed and implemented system with geometry learning.

1. Introduction

The existing web-based learning systems have provided the learner the contents with a simple feedback. The learner interacts to the system through an interface screen simply. These methods do not support an intelligent and efficient learning. The interaction between the learner and the learning system advances on automation by an intelligent dialogue agent.

Established intelligent dialogue systems were used the Natural Language Processing system based on the Expert systems. Because these systems interact with a guided question and restricted answer in system, the system and the learner do not carry on a free dialogue concerning the related learning.[8] Therefore, we design and implement a natural language-based learning system using an intelligent dialogue agent. In order to implement the learning system, we used an engine that is a so-called Tutor-bot using the Pattern Matching(PM) method. We selected the learning domain about the geometry learning and extracted the knowledge base of the Plane Euclidean geometry.

Chapter 2 would introduce the basic concept behind the PM method, and introduce the readers to AIML. Chapter 3 discusses about the design of an intelligent dialogue e-learning system. Chapter 4 talks about the study an implementation with the use of tags. A sample code from geo.aiml is included in this chapter to allow the reader to fully understand the customization process. Then this study ends with Chapter 5, which talks about the future implementation of dialogue-based learning system.

2. Dialogues System for Tutoring

Pattern Matching and AIML

The Pattern Matching(PM) method is usually driven by fairly simple mechanisms. There is several in an existence. The first one was ELIZA created by Joseph Weizenbaum[13], which mimicked a psychotherapist. It made quite a name for itself because it succeeded in fooling some people it was a person. For the most part, they are implemented by rules that map simple pattern matches on the left-hand side to canned responses on right-hand side. Alice is a chatter-bot developed by Dr. Richard S. Wallace[12]. Alice is an acronym for Artificial Linguistic Internet Computer Entity. It's programmed using an XML DTD called AIML(Artificial Intelligence Markup Language). When the user enters statements at a prompt on WebPages, Alice fits that statement to the most 'specific' category it can find, and returns the response associated with that category. It is capable of understanding natural language syntax. However, the natural language is extremely complex. A person is presumed to have implicit or meta-knowledge about the world when having conversation. In human-to-human conversations, implicit and meta-knowledge is always used. This in someway poses as a huge challenge when customizing the Tutor-bot for e-learning system.

The Tutorbot was implemented by AIML(Artificial Intelligence Markup Language), which is a non-standard evolving markup language to create the chat robots. The primary design feature of AIML is
minimalism. Compared with other chat robot languages, AIML is perhaps the simplest. The pattern matching language is very simple, for example permitting only one wild-card ('*') match character per pattern. AIML is an XML language, implying that it obeys certain grammatical meta-rules. The choice of XML syntax permits integration with other tools such as XML editors. Another motivation for XML is its familiar look and feel, especially to people with HTML experience. An AIML tutor agent begins and ends with the <alice> and </alice> tags respectively. Typical Alice category tags have two component tags.

- A pattern, eg: <pattern> I HAVE A * <pattern>
- A template, eg: <template> Where did you get it? <template>

The pattern matching used by Tutor-bot starts with analyzing the words in the phrase entered by the learner[9]. These words are in natural language, separated by spaces and converted to uppercase to enable case independent matching. If a matching category is found, it is possible that the category is a recursive category. If this is the case, the target phrase will be altered and evaluated again by the pattern matcher. This adds the wildcard symbols ... and ' ' to the pattern language. Many AIML patterns start with the same words: {WHAT IS A CIRCLE..., WHAT IS A ..., WHAT IS ..., WHAT OVAL..., WHAT...}

All these patterns overlap in one or more words. This fact suggests the use of a tree to store the patterns in. Alice uses a rooted, directed tree. Each node in the tree contains a hash table, which is used to store its successor nodes. This way, the pattern matching time is almost constant independent of the number of categories. It only depends on the length of the sentence; the longer the sentence, the longer the time to find a matching pattern. Yet, this relation is linear. All patterns are stored in alphabetical order.

Related Works
Numerous experiments have been performed with natural language interfaces. Several domains have been tested with varying success. Here, a few projects are discussed to determine which domains are suitable and which are not. Biermann [3] conducted an experiment to test the feasibility of natural language for programming environments. Subjects had to solve linear equations and calculate averages on a natural language system, which allowed them to manipulate tables and matrices. About 80% of the users' sentences were processed correctly. These results were compared with a similar experiment using a formal programming language called PL/C. Even though the subjects who used the natural language system used up to 50% more characters, they completed the problems using less time than the subjects who used the PL/C. This result can be explained in two ways: either natural language is easier to use and understand, or it is more verbose. As discussed before, verbosity is not a major problem and it must be said PL/C is more suitable for these kinds of problems than natural language because of the tables and matrices. If a domain had been chosen that was not obviously better suited for a mathematical notation, shorter lengths of the natural languages sentences should be expected.

Hauptman and Green [6] compared three interface styles; a command line language, a natural language and a menu-based interface. Each subject was given three hand-sketched diagrams of graphs that they were supposed to reproduce using the interface. It appeared that the natural language mode was not more difficult than any of the other two. It must be said though that this task as well as the previous one are good examples of tasks that are inappropriate for natural language interaction. Domains involving musical notations, algebra and graphical content are other unsuitable domains. Kelley [7] investigated the use of natural language for retrieving information from a calendar. He found that between 86% and 90% of the questions asked by the users were answered correctly. This result may look promising, but it must be noted that the domain is very simple and fairly limited.

3. Intelligent Dialogue Learning System

Overview of Dialogue-based Tutoring System
Figure 1 shows the overview of the intelligent dialogue-based e-learning system architecture. Dialogue-based Tutoring System is composed of 3 parts, learner interface by dialogue system, intelligent dialogue tutoring engine and intelligent tutoring system with learner base. The interface module is the part that learner proceed learning through the web. Dialogue module is embedded in learning content for communication between system and learner. The dialogue module consists of client and server. Moreover, this module is the core of this study. Server of this module contains the pattern matching engine and the knowledge base. Learner's knowledge level has diagnosed through learner profiles and dialogue among learning. The knowledge base saves domain knowledge on geometry information. The intelligent tutoring module is typical
Intelligent Tutoring System. ITS is consisted of student module, tutor module, and expert module. The student model was designed the overlay model, bug model, hybrid model[5].

If learner inputs question, Tutorbot makes an analysis context through preprocessing. At this time, a learner's knowledge and a mistake are stored in learner database. For reasoning a whether last question is related former questions, the pattern matching engine extracts stored former contexts at temporary space. Passing through pattern matching processing, dialogue-based system understands learner's question and shows a suitable reply to learner. Finally, the system stores the result in learner database and repeats.

The reason of former question among the rules of the pattern matching uses recursive method and temporary space tag. This reasoning method is necessary for constructing student model. AIML(Artificial Intelligence Markup Language) contains a simple yet powerful XML markup tag called <srai>. The <srai> tag is the symbolic reduction tag. This allows minimalism. <srai>X</srai> is simple: The <srai> tag always appears in the response template, but the tutorbot treats X just like an input to the tutorbot. The tutorbot scans through its memory and finds the best response for X. The only tricky part is, the response to X may itself contain more <srai> tags. The best way to understand the recursive action of the AIML <srai> tag is by example.

Student: You may say that again Tutorbot
Tutorbot: Once more? "that"

The Tutorbot has no specific response to the pattern "You may say that again Tutorbot." Instead, the Tutorbot builds its response to the learner input in four steps. This simple sentence activated a sequence of four categories linked by <srai> tags. The tutorbot constructed the reply "Once more? "that" recursively as each sub sentence triggered the next matching pattern. <srai> allows the translation of Natural Language to keywords. On the other hand, the tag "that" in Tutorbot refers to whatever the tutorbot said before a user input. Conceptually the choice of "that" comes from the observation of the role of the word "that" in dialogue fragments like:

Tutorbot: Today is yesterday.
Student: That makes no sense.
Tutorbot: The answer is 3.14159
Student: That is cool.

In AIML the syntax <that>...<that> permits an optional "ThatPattern" to match the tutorbot's "that" expression.

Representation of Geometry learning knowledge for AIML Modeling
We should need that analyzes the scheme of geometry knowledge for performing geometry learning. Because the dialogues on the knowledge of the geometry learning are to teach knowledge of geometry domain, the domain knowledge of geometry is represented with a definite rule or context. Geometry object is core that is diagram information. The diagram information is divided the quantity and quality information. The quantity information contains presented independence information in learning spaces as an absolute coordinates, number of pixel, an inclined degrees etc. The quality information represents the ontology of
geometry objects like dot, line, triangle, circle, as well as the proposition alike a connected relation among
each geometry objects, and various knowledge for the form of a proposition. Such information gets to be main
content for constructing learning and presents problem to learner as well as a tutor system. Consequently, this
diagram information determines an efficiency of dialogue-based tutoring system.

The quality information of geometry mainly is divided the structural information and the geometric
information as followed figure 2. The structural information represents knowledge about relation among the
objects and the features of geometry object. The geometric information is an added proposition on the basic
structure. This information is reasoned by the geometric or algebraic knowledge. Efficient dialogue-based
tutoring system needs suitable knowledge representation about the quality information of geometry. Main
knowledge constructed with AIML is represented by structural information; on the other hand, the used
knowledge by answer of dialogue is presented by the geometric information.

![Diagram](image)

**Structural information:**
- The line AB is composed of the dot A and dot B
- The line FD is composed of the dot F and dot D
- The line BC is composed of the dot B and dot C
- The dot B locates on the line AE ...
- Lines A E and FD are parallel
- The distance between the dot and the dot C is 7m
- Alternate interior angles ABC and BCD is same ...

**Geometry information:**
- Lines A E and FD are parallel
- The distance between the dot and the dot C is 7m
- Alternate interior angles ABC and BCD is same ...

Figure 2. Classification of Geometry information

**Student Model and Dialogue Representation**

The geometric knowledge is constructed variously by the learner's knowledge state and learning process
for using intelligent dialogue. Intelligent dialogue method is different complexity by who take the hegemony
of dialogue. The hegemony of dialogue classifies by a case of system-initiative, case of learner-initiative and
hybrid case. A case of system-initiative, system asks to a learner a question and a learner answer mostly. This
method is same the one of an expert system and system reason the learner's knowledge in the course of a
conversation.

On the other hand, a case of learner-initiative doesn't use planned dialogue but system replies the most
suitable answer by learner's question. Because this method doesn't exist a constructed knowledge base
previously, the number of answer is increase exponentially. As a result, system processes dialogue with
restriction the band-with of learner's question.

Hybrid case, if the learner has a mistake or does not understand the learning content, the dialogue method
executes with a system-initiative mode, if learner has understanding or tries review learning, learner-initiative
drives. A learner's knowledge through dialogue is stored by student model and diagnoses a learner' level. The
system-initiated method uses overlay model and fixes up a learner's knowledge and the pre-made dialogue
path. While the learner-initiated method uses bug model to find learner's mistakes. Hybrid method uses a bug
library model namely machine learning for storing new bug.

**AIML Design for Geometry Learning**

Tutorbot is able to understand the flow of conversations by capturing the questions and going into a
particular topic. <topic > allows Tutorbot to prefer responses that deal with the topic currently being
discussed. This creates topical conversation, yet still has the ability to move from one subject to another. For
example, if the questions were asked in relation to Plane Euclidean Geometry, the file Geo.aiml is that will be
put into use.

Example:

```
<Student> Hi!
<Tutorbot> Hi there [general category]
<Student> Can you please tell me more about a quadrangle?
<Tutorbot> Lets move on the geometry section [geometry category]
<Student> How many lines do a quadrangle have?
<Tutorbot> Four.
<Student> How many dots do a quadrangle have?
<Tutorbot> Four, too.
```
<Student> What is an angle?
<Tutorbot> That is the degree of an angle formed where two lines cross each other.
<Student> Thanks you.
<Tutorbot> You're welcome. (general category)

Tutorbot is capable of throwing in random responses along with the proper response. This in a way is like a freebie guide that may assist students. This type of random responses tied with logical responses is feasible in this type of a setting. This gives some form of personality to Tutorbot. It would be like dialogue with an intelligent tutor and from past experience, an intelligent tutor always throws in additional hints to assist students when making decisions about their future.

4. Implementation and Experience

Implementation of intelligent dialogue system

Figure 3 shows the prototype of a dialogue-based e-learning system. This system was designed to learn the plane Euclidean geometry learning with intelligent dialogue method. A learner can learn geometry learning through screen interface and can ask the tutorbot a question by using dialogue interface. For reducing the bandwidth of learner's question, the context of question is limited in related learning contents.

![Figure 3. Screenshot of intelligent dialogue-based e-learning system](image)

The dialogue-based engine used JDK 1.3 program and dialogue server executes by servlet. When server drives by servlet, the dialogue engine loads category items of geo.aiml file in memory. Moreover, server creates log file for grasping the learner's information. Right in figure 3 shows server screenshot of Tutorbot. H/W by using research is Windows 2000server. If a Tutorbot server executes, dialogue port is used the 2001 port with HTTP and all learner can communicate with system. Tutor-bot server in figure 3 can see that geo.aiml was loaded in memory by driving server

Sample of Conversation with Tutor-bot

The category on geometry learning was made with 23000-domain knowledge and knowledge was stored in geo.aiml file. A learner can communicate with a special knowledge in geo.aiml file and a general
knowledge in general. The following Figure 4 was recorded between Tutorbot and a learner. A learner asks a system a question about the quadrangle and we can see that a tutorbot replies a suitable answer. When learner uses an approximated question or an illegal grammar, a tutorbot introduces to change a direction of dialogue.

Figure 4. Conversation with Tutor-bot

5. Conclusion and future work

Dialogue systems are becoming very common in many web sites today. They serve to give personality and intelligent information to web sites. Specially, a dialogue system approves a merit in e-learning system. Typical technique of intelligent tutoring system is intelligent dialogue based student model. We discussed on dialogue technique for such intelligent tutoring system in this paper. Moreover we extracted the domain knowledge of geometry learning and geometry analyzed structural information and geometric information. This information and knowledge could use effectual for intelligent dialogue system. We hope for developing intelligent dialogue-based tutoring system by our study.

Futures works need that study on temporal reasoning method by changing a learner's knowledge as well as research on virtual interface by using 3D and virtual reality. Furthermore, for improving the accuracy of dialogue, we will study on the reasoning method of an ambiguity and uncertain knowledge.

Abstract: The need of authoring tool inspired the creation of VRCapture, which is a module in the Configurable, Incremental and Re-structurable Contributive Learning Environments (CIRCLE) and is capable of providing a tool to capture the authoring teacher's expertise. To ensure the expandability, object-oriented analysis and design methodology is employed, and reusability guides the development process. VRCapture with its environment CIRCLEs assemble a computer-based learning environment that overcomes many traditional CAI systems' deficiencies such as, high development/modification cost, non-modularity/ non-reusability, and commonly low acceptances of end-user teachers.

Introduction

The primary function of the teaching process is to achieve the transfer of knowledge from someone who is richer in terms of these commodities (knowledge) to those who own less. In order to secure the knowledge transfer process, some channels (or mediums) of communication must link the parties involved. Possible channels include:

1. schools/ learning and training institutions
2. home
3. work places
4. social and leisure centres

Channel (1) and (2) are very important in our early life, whereas channels (2) to (4) become of increasing value in our later life. Barker & Yeates (1985) noted that "Home and work environments are two of the most effective ways of disseminating educational information". Computers have been increasingly used to facilitate or even used as the communication channel due to the difficulties for a human teacher to fulfil all requirements, which Barker & Yeates (1985) argued as the necessities of a good teacher:

1. An agent for the dissemination of information and knowledge.
2. A motivator for the development of learning skills.
3. A means of measuring the effectiveness of 1, and 2.
4. Adaptable and patient.
5. Able to modify teaching strategies to the needs of individual students.
6. Always available when needed.

Computer Assisted Learning (CAL) System

High availability is the most obvious contrast between a computer assisted learning system and a real human teacher. And if intelligence is built into the learning systems, they can even provide an adaptable learning environment, which can be tailored to the student's individual needs. For example, CAPIT (Mayo et al., 2000) is an intelligent system that teaches 10-11 years old school children the capitalisation and punctuation rules in English grammar. It can provide selectively appropriate levels (brief to detailed) of feedback to a student, when he/she makes a mistake, based on the individual student's performance.

As explained in the 'Situated Learning' section later, expertise is achieved by continually repetitive practices. Computers are excellent tools for doing repetitive tasks (as they will never complaint!) such as to teach a child how to punctuate English sentences or to provide exercises on an accounting topic. Teachers' time can be spent more on the creativity or strategies of the curriculum design rather than on the repetitive tasks that
many of computerised systems are aimed for. "Computers can make good teachers", said Barker & Yeates (1985), whereas our interpretation is that "computers make it easier for a teacher to be a good one".

**Issues in Computer Assisted Learning Systems**

The CAL systems are generally built by computer programmers who may have only little or no understanding of the theories of education. As a result, those systems created could be excellent in terms of program design, computer resource utilisation and performance optimisation, but useless in real classrooms.

When a traditional CAL system is built, the author has to specify its screen design, instructional content, and instructional flow. Any change has to be preformed explicitly in terms of the design layout, sequences of instructions and the content materials. In other words, the system is non-modular, difficult to reuse and any modification can be very time consuming and costly.

Another issue for traditional CAL systems is that the systems have to be accepted by the teachers who are actually part of the end users. The NDH (Not Developed Here) syndrome psychologically creates the hindrance to the acceptance and leads to a mistrust from teachers to the system. It is already hard to develop a system that could suit two mathematical teachers' flavour let alone a system that could be accepted internationally.

Next in this paper, we shall talk about how VRCapture and the Configurable, Incremental and Re-structurable Contributive Learning Environments (CIRCLE) address those problems mentioned above. We shall then discuss how object-orientation facilitates the achievement of reusability and modularity in the system and how the employment of situated learning theory provides the benefit of more complete and accurate knowledge acquisition. In the last two sections, we shall describe the VRCapture system architecture and future possibilities.

**Contribution from VRCapture**

By using the VRCapture, the authoring task is shifted from the traditional programmers of traditional CAL to the teachers who use the material and know the students. The teachers create what they want the students to learn from the system by themselves. Thus, the teachers would feel more in control of the teaching process and naturally they are motivated to encourage the students to use 'their' systems. In addition, the knowledge repository can be improved directly based on the teachers' teaching experiences and students' feedback.

The knowledge or the rules are stored separately in CIRCLE (see figure 1). Any modification in the knowledge repository immediately brings its effect to the system in front of the students. While the knowledge is not hard-coded into the program, it is an inspectable repository and can be queried. Future expansion could possibly introduce an additional module that could make the knowledge repository runnable. By runnable, we could imagine a portrayal of a system that behaves like an expert system and answering queries by induction or reduction of the rules stored in the repository. Furthermore, the knowledge repository and the program code can be either maintained or even reused for different subject areas independently.

Teachers or instructors do not need to worry about the design of the screen layouts and the construction of instructional sequence. They only need to input appropriate parameters by which the system will determine how to layout and sequence each topic when students come to use them. The simple-to-use and easy-to-learn characteristics provide a friendly environment for the teachers who have less experiences, or who do not wish to spend too much time on the meta-learning of the system.

**VRCapture in a Larger System**

Inside the CIRCLE (see figure 1), VRCapture is responsible for providing an authoring tool to capture the teachers' expertise into the knowledge repository. The knowledge repository contains all the rules and relationships of domain concepts. The data inside the knowledge repository is then fed to the Intelligent Tutor on the demand of students. The main purpose of Intelligent Tutor is for the students to utilise those knowledge
stored in the repository. It provides a user-friendly and adaptive interface from that the students can learn, do exercises, and test themselves.

**Benefit of CIRCLEs Architecture**

Each of the CIRCLEs' components can be developed independently by providing their interface specifications to the developers of the other components. Its modular structure enhances greatly its expandability and maintainability. By this modular architecture, new modules or functions can be just plugged in, or existing modules can be re-structured or disposed without causing any vital effect to the overall system.

![CIRCLEs Architecture Diagram](image)

The users of CIRCLEs can also enjoy the benefits from its light-weightiness. The students only need the part of the system to perform their tasks, so do the teachers. No matter how much the system will expand in the future, the users can still use the version they have processed or just require a small incremental patch.

Openness is a highly valued criteria when the underlying technology is selected. The underlying Java technology ensures the system is portable over platforms. The portable and concise characteristics of CIRCLEs components open to us the possibility and ambition for migrate CIRCLEs on-line and hopefully, in the near future, more distant learner can be benefited from it.

**Object-Orientaion and Reuse**

There are primary two divisions of reuse in terms of the development style; Development-for-Reuse, and Development-with-Reuse. Development-for-Reuse, by Hallsteinsen and Paci's definition, "is the process of developing and preparing components such that they can be reused in future applications and contexts." Therefore, during the design or implementation stage the developer understands that the artefacts under development will be reused. Whereas, Development-with-Reuse is the construction of software by utilising existing reusable components. It is an activity that involves the analysing, organizing, cataloguing, and evaluating of software artefacts which can be placed in reuse library.

VRCapture adopts the Development-For-Reuse guideline and use OO techniques to achieve least coupling of objects and maximum cohesion by clearly and logically separating different concepts into different implementation classes. Now let's look at how the Object-Orientaion helps the reusability by its two distinguishing concepts: encapsulation, and inheritance.

**Encapsulation** provides independence to an object, which can be deployed with other objects to form a functional component. Object independence is an important characteristic in terms of reusability. Object-Orientaion facilitates high cohesion, since every object stands for an explicit concept in the problem domain whereas, low coupling and high modularity are the 'should-be' of Object-Orientaion. Encapsulation also provides a mean to achieve information hiding by which the details that is likely to change over the time are concealed. Very possibly the components that communicate to hardware need a replacement when the system's hardware is upgraded or the system migrates from one platform to another. Database selection can be replaced
just by modifying the 'DBManager' (see figure 2) in VRCapture. Only those that are unlikely to change should be selected as the external interfaces of components.

Class inheritance defines class relationships by reusing the methods and data defined in another class. By doing this, redundancy is removed and tested code can be reused to achieve both quality control and cost saving.

Situated Learning

In the VRCapture system, the main focus is to store the teacher's knowledge electronically, so the knowledge can be accessed without the limitation of time and, may be in the future, even without the limitation of spaces, if a web-based interface is set up for students. The system aims at capturing the domain's knowledge effectively, and this aim is achieved by not applying the theory of situated learning to the students but to the teachers. We will first look at the general theory of situated learning and then we will talk about the application of the theory in the VRCapture.

Situated learning, also called problem-based learning, proposed that the contextual attribute of knowledge makes it not effective to teach conceptual knowledge without defining its application situations. "Real world learning has a backbone of problem solving, production of work-authentic products, and investigation and research, in which all knowledge, processes and techniques connect and are used" (Glasgow, 1997).

What Glasgow (1997) also describes in a traditional school nowadays, is that the teachers hope that the curriculum design and their teaching style will meet the need of the majority of their students, but in fact "Much of today's curriculum is based on teacher's past experience in schools, input from textbook manufactures, discipline frameworks, standards, and information from peers".

However, learning in a real-world situation is usually contextual, continual, and repetitive. For learning to be able to be packed into the long-term memory, continual repetition is a method being employed traditionally and it proves itself successfully (Shou, 1998).

For learning to being contextual, we are able to link pieces of conceptual knowledge with real life situations, which in term helps the validation or incurs more inspirations and associations on the conceptual knowledge. Additionally, real world learning usually happens while there is a need - a problem we encounter in the workplace or a question we want to solve.

It is more difficult initially for the students to grasp the big picture of how to apply the given conceptual knowledge. Brown (1989) gave an analogical links of knowledge to tools, "we should abandon any notion that they (idea and concepts) are abstract, self-contained entities. It may be more useful to consider conceptual knowledge as, in some way, similar to a set of tools". Knowing the description of the tool or the functions of this tool doesn't make a person expert or even capable of using this tool. To master a tool, the apprentice (student) observes, mimics what the master (teacher) does, and then repeats, and explore. The process to master a conceptual knowledge can be similar as well.

Application of situated learning in the VRCapture

Situated learning is applied in this project in the creation of the knowledge that is inputted by the teachers and can be stored in the repository. Experienced teachers, who are in charge of inputting the relationships of the domain concepts, can more completely and more precisely identify the relationships between the concepts. However, for someone who has less experience on both the domain practice and the system, he/she may need some assistance on inputting what he/she knows about the domain concepts. A question is therefore asked, "How can we facilitate the knowledge capturing process and make sure the knowledge is completely and correctly inputted, as far as in the teacher's personal understanding?"

An optional mechanism is created, by which the teacher can refine the stored knowledge by doing exercises. This is optional for more adaptability of power users. This mechanism situates the teacher in the student's point of view in order to provide a different perspective, which is aimed to reverse the tradition of teacher-centred education to a student-centred one. Questions are posed to the teacher randomly and he/she answers the questions like every student would do. By doing the exercise, the teacher has to examine what he/she has inputted into the database, and what he/she will do as a student in response to those questions. The
teacher is actually learning the student's learning process, and hopefully the resulted knowledge capture can be more robust and more suitable for deploying.

Additional knowledge can be found by comparing the teacher's answer to the existing knowledge in database. Mis-concepts or conflicts in existing captured relationship can also be identified and corrected accordingly. Though this is an optional step but it ensures the completeness of the captured knowledge before the students actually start to work on these knowledge. Therefore, even for experienced users, this mechanism is still highly recommended.

![Diagram](image)

**Figure 2: VRCapture system architecture**

The VRCapture system is basically a two-layered system (see figure 2). It uses a database as the knowledge repository to store the captured relationships. A database interface called 'DBManager' is built to interface the transactions with knowledge repository. The implementation details which could change over time or requirements are all placed in ‘DBManager’. Thus, the rest of the program can be database independent. This is the implementation of information hiding mentioned above. Figure 3 shows an interface for formulating and recording relationships/rules.

![Interface](image)

**Figure 3 The screen for teachers formulate relationships**

**Development Process**

The development started by trying to understand the problem or the requirement statements. The initial general requirement statement was expanded into a list of sub statements. Confirmation of those sub statements with the supervisor also confirms my understanding of the problem.
In the next step, the selection of methodology was performed. Object-oriented methodology was selected due to the following reasons:

- The implementation tool, Java, is itself object-oriented.
- Object-oriented system encourages explorative development by which a object can be created, experimented and then kept or discarded.
- Object-oriented system has more flexibility to expand.
- Object-oriented system provides an easier maintenance and debugging environment.
- Object-oriented development facilitates reusability.

In the analysis phase, use cases are used to document and identify required functions. Use cases provide insights of how the system interacts with the outside world and they can be collected into the user manual for a step-by-step guidance. The creation of class diagrams provides a direct mapping from design artefacts to program code. Each class in class diagram represents an implementation class in the VR Capture. The links between classes may be association, relationship or mapping (see Odell and Martin, 1998 for more details about object relationships).

Duplication check is the mechanism to check whether two relationship in conflict; (x + y = 3) and (x + y = 5) are in conflict. When system detects any potential conflict, it will rise a dialog asking the teacher whether this conflict is intentionally allowed or not.

Conclusion and Future Development

The need of authoring tools for computer assisted learning system has inspired the creation of VR Capture. CIRCLEs serve as architecture that different tools can be integrated to perform intelligent tutoring. However, in the near future, we would like to overcome some of the limitations of CIRCLEs to expand the usable coverage to a wider range.

The current system has already the support for use in a local network. The CIRCLEs system can also be expanded to embrace the popularity of Internet. Through the Internet, the system can be within reach of a wider range of audience. The underlying Java technology makes it very easy to have an interface using Internet browsers. Browser interface modules can be created and plugged in to current architecture.

The current system can only takes in rules that have three elements (e.g. element1 + element2 = element3) and only certain operations (+, -, *, /, -). This limitation can be overcome by employing operation stack and operator procedure parsing (Weiss, 1998), which could interpret formulae with no length limitation and can identify operation precedence. And with additional operations, the system can also be used for complex mathematical formulae or other numerical disciplines. Finally, the question of whether computerised system such as CIRCLEs can be used for other non-numerical subjects like philosophy or psychology has to be left open and requires more future corroboration and investigation.

Internet based learning and Knowledge Management

Bhavani Sridharan, Kinshuk, Ashok Patel* and Hong Hong
Massey University, New Zealand
*De Montfort University, United Kingdom
Kinshuk@massey.ac.nz

Abstract: This paper presents the research and development of knowledge management system for Internet based intellectual assets to leverage the learning process for individual learners. The literature review reveals that corporate solutions of knowledge management are not directly applicable due to the lack of adaptivity needed to provide individualized feedback to the learner, and their localized nature that does not directly deal with authentication and verification of distributed information. Architecture has therefore been formulated for the knowledge management system that specifically supports web-based learning.

1. Introduction

Strategic concern for survival in the global information technology and information systems disciplines calls for constant upgrade of knowledge especially in computing related areas. The primary reason for this is the ever-changing technology, which compels employees to be up-to-date in their knowledge. The trend of increasing Internet based learning is evident from the increasing number of universities providing facilities to finish degrees and diplomas through Internet. In many instances it becomes pertinent, as otherwise it would mean loss of job. The implication is working population trying to upgrade their knowledge through Internet based learning.

2. Problems with the existing online education systems

Online education systems provide a great solution for working community. But they do not come with unmixed blessing. One of the primary considerations or constraint for both student and teachers is the time element. This necessitates a means by which the accurate and relevant knowledge can be accessed efficiently by the students without wasting much time. On the other hand, teachers should be able to save their precious time by reusability of knowledge. This warrants the use of a knowledge management system.

In a large distant learning class, it is very often not possible to answer individual queries due to low students to teacher ratio. It also lacks some important benefits of traditional classroom setting such as instructor-student and student-student interaction, collaborative work among peers, and so on. Although these factors can be translated into the Internet based learning by use of newsgroups or mailing lists and use of collaborative technology such as discussion forums, but there are several limitations. The first problem is the hesitation within students to post questions in a public arena such as discussion forum. Instead, they tend to post their queries to individual instructors asking for individual attention. The second problem is the information overload in the collaborative environment over time, and it becomes extremely difficult to mine the knowledge. The information exchange in such environments takes place in a haphazard manner due to different temporal and spatial conditions of individual students. This results in non-synchronization and repetition of information leading to even more tedious process of knowledge mining.

Another inherent problem for students who wants to have an in-depth knowledge on any subject through Internet is the overwhelming amount of information available on the Internet from all over the world. To quote Koniger (Koniger et al., 1995) in the article on "Drowning in information but thirsty for knowledge", "Information is only valuable to the extent that it is structured. Because of a lack of structure in the creation, distribution and reception, information often does not arrive where it is needed and therefore, useless". This disconcert becomes a serious barrier to potential learners. There are no formal mechanisms available to filter the information for the quality and authenticity verification. Added to this is that the information is not adapted to individual learners and therefore learning does not take any consideration of individual student attributes.
Another problem associated with gathering knowledge from the Internet is that the available information is not structured and not available in a uniform format. In other words, the available information is in heterogeneous formats varying even within a single source. This makes it extremely difficult to search and retrieve the information, posing one of the biggest challenges in making flexible and robust knowledge management systems.

3. Solution

In this background, the use of knowledge management in Internet based learning can provide an efficient solution for learners. The benefits of using knowledge management system in internet based learning would include increased efficiency in knowledge solicitation, avoid wasting time on repetitive queries, better use of resources etc.

In the following section we will look at the applicability of knowledge management systems to Internet based learning. The next section will look at the methodology to integrate knowledge management and Internet based systems to alleviate the problems common to Internet based learning. This is aimed to cater for both basic and advanced learners. The following section will look at the prototype showing various processes involved in the system. The next section will look at the benefits of the prototype system, followed by the conclusion.

4. Link between Internet based learning and knowledge management

The central theme of knowledge management perceived by many experts in the field is that it is an integrated and systematic process of acquiring, eliciting, organizing, representing and retrieval of information asset. The objective of the knowledge management in Internet based learning is to generate value in terms of knowledge from intelligent capital to enable faster and efficient learning. According to Liebowitz (1999), knowledge management deals with the conceptualization, review, consolidation, and action phase. Knowledge management in Internet based learning is about connecting learners with learners, and teachers and learners with information and knowledge (Corrall, 1999). It is about getting the right knowledge to the right person at the right time.

The phenomenon of overload of information to learners results in the learners’ inability to cope with the processing of increased amount of available information. Internet based knowledge management systems can prove to be efficient solution to manage the problems associated with Internet based learning. They can improve the productivity through achieving reusability and enhancing educational services to the learners. Also, immediate clarification of doubts of the learners through on-line knowledge management system can enable them to correct the mistakes without waiting for the teachers or tutors to respond to learners. Features specific to learning institutions are knowledge intensive nature and extensive reusability of learning materials. These reasons call for the use of knowledge management system in learning. Synergy of Internet based learning and knowledge management systems would be ideal for saving time, avoiding reinventing wheel, increasing efficiency and so on.

5. Methodology

This paper proposes the use of knowledge management systems for both basic and advance learners. Basic learners are those who would like to just finish the course without any reference to any additional material. The advance learners are those who would like to enhance their knowledge in a given area beyond the requirements of the course curriculum.

Part 1: Catering for basic needs of the learner matching the curriculum

Catering for the basic learners by giving immediate and relevant access to the knowledge is a multi-step process. The first step is the collection of all basic material namely concepts, exercises, definitions, examples etc. and store them in the knowledge base. Additional material can be collected from various sources
like the previous years archives (if available) of all questions including frequently asked questions and answers for them from various sources like newsgroups, discussion forums and mailing list etc. This archive can be used to compile a knowledge base and updated based on the new questions from the current students. Student profile parameters are also collected including extent of learning required, existing level of expertise, key interest, etc. The second step is to organize and transcribe the collected information in the knowledge base. The third step is to create a context-based search technology, which would enable the system for easy retrieval and to provide quick and accurate information to the learner. The search mechanism should allow the students to search by topic or index or by keyword as in common software help systems. The fourth step is the integration of user profile and knowledge base to give the best possible contextual resources related the search query. The fifth and final step is to create a user-friendly and intuitive interface for students to explore the knowledge content and ask queries.

Part 2: Catering for the advanced learner

Catering to advance learners requires quick acquisition, integration and presentation of relevant and correct knowledge from within the knowledge base and from websites distributed on the Internet and related to the context of the learner. The major concern in this process is the explosive growth of information, which lacks any quality checks, and integration of such information to make it useful knowledge in the context of learner’s learning process. This requires meticulous evaluation of material available on the Internet and compiling and organizing the material to suit individual learning. Links to such evaluated material is maintained in the knowledge base for future use. This directory of these links is updated on a frequent basis. The rest of the steps involved in this part of the system are very similar to the first part and include information collection, evaluation for quality and authenticity, organization, creating proper retrieval mechanisms, integration of user profile and knowledge base and finally creation of user interface.

Figure 1 explains the processes involved in knowledge management systems in Internet based learning.

![Figure 1: Knowledge Management Systems' Architecture](image)

The results provided from the knowledge management system to any specific query are precise and concise. In other words students do not have to filter through abundance of information. Instead the knowledge management system does the job of sifting through the available information and gives appropriate and precise query results based on user profile.

6. Prototype

Based on the architecture, a prototype system is being developed which aims to guide the learners a guided discovery learning process. The guidance is individualized, based on the behavioural attributes of the learner. The components of the prototype are knowledge base, user profile database, knowledge engine, inference engine and interface. Knowledge base contains locally available information, references to Internet based distributed information, and cache of frequently accessed information. User profile database refers to the attributes of the learner gathered through user modeling mechanisms. Knowledge engine helps in manipulating
the acquired information and effective indexing and storage. Inference engine enables retrieval of knowledge as per individual learner’s attributes. Interface provide adaptive representation of the knowledge to the learner.

Figure 2 summarizes the sequence of actions as a result of the student’s query and the mechanism used in the processes. Student's question on the interface triggers the following set of activities. Student identification is sent to the learner profile database and the details are integrated with the student query. The modified query is sent to the inference engine. The engine attempts to retrieve the information from the local knowledge database. If the context related information is not available, it fetches it from distributed Internet websites. The newly acquired information is then integrated with the existing information and converted into contextual knowledge before presenting it on the interface to the student.

Figure 2: Student query and knowledge retrieval process
7. Conclusion

Knowledge management systems combined with Internet based learning have a lot to offer to the teaching and learning community. They can save the precious time for both teachers and students through immediate retrieval of knowledge and information. This paper described the rationale behind the development of such a system and provided the details of functionality being developed in a prototype.

Even if the course material is structured very well, there is still a value addition to a system like this for a simple reason, that in distant education, students learning takes place in different points in time and such a system can provide right kind of material at right time, while still taking advantage of the information available on the Internet, and individualized it to a particular learner’s needs. As the Internet grows, the strategic impact of knowledge management in Internet based system will be greatly felt. There is bright, exciting future for this area of research and knowledge management will play an important role in its evolution and integration.

Mobile Agents in Web-based Student Modelling

Hong Hong and Kinshuk
Massey University, New Zealand (kinshuk@massey.ac.nz)

Abstract: This paper presents the application of “Bee-gent” mobile agents technology in designing web-based learning environments that provide adaptivity to the students by having two separate student models: Individual student model for each student; and Group student model for generalizing the attributes of a group of students. This combination enables adaptation in web-based learning environments at different granularity and in different environments, such as on-line mode, off-line mode or unreliable network connection.

Introduction

In recent years, educational information on the web has increased exponentially, and web-based learning is currently an important research and development area. An effective web-based learning environment should interact with the students and adapt to the needs of individual students. Despite previous research in this area, these systems have not yet exploited their full potential in facilitating adaptivity to the individual students. This paper presents the application of “Bee-gent” mobile agents technology in designing web-based learning environments that provide adaptivity to the students by having two separate student models: Individual student model for each student; and Group student model for generalizing the attributes of a group of students.

Design of Two-fold Student Modelling

Kinshuk et al. (1999) pointed out that dynamic adaptation requires consideration of following criteria:
(a) adaptation with respect to current domain competence level of the learner;
(b) suitability with respect to domain content;
(c) adaptation with respect to the context in which the information is being presented.

Based on the above criteria and the nature of web-based environment, we have developed a system, using mobile agents technology. The system uses two separate student models:
1. Individual student model, which serves an individual student and contains the detailed information about particular student’s domain competence level, preferences, interaction information and other relevant details. A partial individual student model resides on the central server and another partial individual student model on the user’s machine (local server).
2. Group student model, which generalises various attributes over a number of students and attempts to classify students in various categories (for various attributes), resides on the host base.

Design with Mobile Agent

In high-level view, a mobile agent interacts with client side inference engine to pick up the data, which in turn relies on individual student model at the client side. Then mobile agent moves to host (or server) side. At host side, mobile agent performs all the processes needed, such as updating the partial individual student model based on summary of client side student model brought by mobile agent, and interacting with group student model to be updated if required. After mobile agent finishes all the tasks at the host side, it gathers all information it needs, and returns to the client side. Then it updates the client side individual student model. In addition, mobile agent approach can work in intermittent connectivity between client and host because mobile agent can be dispatched and it can work autonomously even if the sender is not available any more.

The Bee-gent framework (http://www2.toshiba.co.ip/beegent/index.htm) is used to implement two types of mobile agents in the system (figure 1): agent wrappers and mediation agents.
- Agent Wrappers are used to agentify existing applications.
Mediation Agents support inter-application co-ordination by moving from the site of an application to another where they interact with remote agent wrappers.

Figure 1: Architecture of adaptation mechanism using Bee-gent

Benefits of the Approach

The main benefits of the combination of mobile agents and two-fold student modeling are as follows:

A) Mobile agents can be used to pre-fetch the domain content that will be requested shortly by the student. Thus agents technology avoids unnecessary networking delays, cope the bandwidth limitation and adapt the representations to students, based on the student performance.

B) The distributed nature of mobile agents allows sharing of educational resources on heterogeneous systems and platforms.

C) Mobile agents' migrate-and-disconnect style of operation has lot of appeal for mobile phones, PDAs and other mobile devices that are now commonly used by the on-the-road learners.

Conclusion

In conclusion, the mechanism of the two-fold student modeling and using mobile agents technology provides an attractive alternative to implement and improve web-based learning environments.

Abstract

The purpose of the project is to examine whether digitized speech-text synchronicity combined with other computerized assistive features supports students with learning disabilities who are enrolled in distance-learning programs in institutions of higher education. The technology enables students to follow a text that is presented on a computer screen as they listen to it being read aloud. In addition, for instance, users can navigate within the text, reread and listen again to material in topics that are difficult to understand and add written and voice notes. The preliminary results of a controlled study on the benefits of this technology for a group of distance-learning students with learning disabilities in the Open University of Israel will be presented.

Introduction

Learning disabilities are disturbances in the learning process that are caused by deficits in the functioning of the central nervous system. These disabilities can create discrepancies between learners' academic achievement and their intellectual and cognitive capabilities (Bigler, Lajiness-O'Neil & Howes, 1998). During the second half of the twentieth century, particularly the 1990s, special attention was devoted to research and treatment efforts surrounding learning disabilities. A body of evidence accumulated indicating that assistive technologies, primarily in the areas of computer hardware and software, can help students overcome various kinds and degrees of dyslexia and attention deficiencies and join the mainstream educational system (Raskind & Higgins, 1998; Lewis, 1998; Lewis, 2000). Indeed, according to a report published in 1992, the proportion of students with learning disabilities enrolled in institutions of higher education increased more than the proportion of students with other disabilities (American Council on Education, 1992).

However, research in this area has been limited in scope. For example, most investigations have been conducted on students in kindergarten through twelfth grade, as opposed to adults in either face to face or distance-learning environments. Many questions remain unanswered. Which assistive technology should be used with each kind of learning disability? Does the use of assistive technologies in higher education affect the number of students who complete their studies and earn a degree, particularly in distance-learning programs? Which technology best suits each field of knowledge?

One reason that such issues are still unsolved is that the assistive technologies used by students with learning disabilities are produced primarily by commercial companies for the general population. In countries where English is not the native language, such as Israel, the situation is even more unclear, since most of the commercial programs in use were developed for English-speaking students. In the project described here, we examine whether a learning environment that provides assistive technologies—including the synchronization of digitized speech and text and additional features, might enhance learning in students with learning disabilities who are enrolled in a distance-learning program at the Open University of Israel (OUI).

Students with Learning Disabilities at the Open University of Israel

The number of students with learning disabilities in institutions of higher education is smaller than the number of people with learning disabilities in the general population. For example, the percentage of students with learning disabilities at the OUI is only 2%, whereas in the total population it is 4%. Also, we might assume that students who are enrolled in a distance-learning course face more difficulties than students with learning disabilities in universities where instruction is mainly face to face. At the OUI, the total number of students with learning disabilities who are enrolled each semester reaches about 1,000, and the predominant syndromes are attention deficit and attention deficit hyperactivity disorders (ADD/ADHD), dyslexia, and dyscalculia. The OUI's Center for Students with Learning Disabilities (CSLD) provides the students with special examination conditions, individual instruction by trained tutors, and counseling. However, until now, the OUI has not used any assistive technologies to support these students in their academic studies.

Description of the Project

We developed a CD-ROM that contains speech synchronization for the text of a complete chapter of a textbook as well as other digitized features that are intended to help students with learning disabilities. The CD-ROM enables the user to carry out the following tasks:

- Read text that is displayed on the computer screen and simultaneously listen to it being read aloud
- Read and listen again to a self-selected audio reading of paragraphs that were difficult to understand the first time
- Navigate between topics without having to reread or to listen again to parts of the text that are irrelevant to the understanding of a specific subject
- Jump to a glossary with hyperlinks
- Use different colors to highlight paragraphs that are essential to an understanding of the topic, that need emphasizing, or that require a repeat reading
- Write notes and add them to a text while reading and listening to it
- Use a microphone to add voice notes to a text while reading and listening to it
- Compile the highlighted paragraphs and the notes in a separate file for further studying support
- Alter the way in which text is displayed on the screen; for example, change the size of the font or the amount of space between the lines

The advantage of speech-text synchronicity for school students with learning disabilities has already been described in the literature (Hebert & Murdock, 1994; Wise & Olson, 1995). The other digitized elements and functions were implemented upon the recommendation of specialists
OUI, who have had considerable experience tutoring students at the OUI Center for Students with Learning Disabilities. We used the Acrobat Writer© software to create a learning environment that combines digitized speech and text and to provide the functionality described above. This developer software was convenient for our purposes because, unlike other software that has been developed to present electronic text, it enabled us to combine Hebrew text with digitized speech in the learning environment and to include features that are not present in the standard, widely used Acrobat Reader© and other software. To gain access to all the desired functions in the CDROM, the students installed the same software on their home computers.

The Benefits of the Project

The potential advantages of speech-text synchronicity have been investigated with dyslexic college students and others (Hebert & Murdock, 1994; Elkind, Black & Murray, 1996). The results of the college students' research showed that the assistive technology improved the reading rate and the understanding of most of the students who participated in the study. However, other studies suggest that speech-text synchronicity is beneficial only for students with severe disabilities, whereas for students with mild disorders the technology actually presents a disturbance (Raskind & Higgins, 1998). To the best of our knowledge, the influence of an assistive technology that includes all the computerized features described here has not been explored with adult distance-learning students. This pilot project will enable us to ascertain the kind of disorder that this technology best supports in a large group of students with various learning disabilities.

The Test Group and the Research

Each semester, between 200 and 300 students enroll in an introductory psychology course offered through distance-learning at the OUI, and of them, 10 to 15 usually request support from the CSLD. These students receive all of the course materials in print and have to fulfill the same requirements as their classmates. For our project, we have provided the students who requested aid from the CSLD with a digitized, speech-synchronized version of one chapter of the course's print textbook (a chapter on memory that is 50 pages long).

Through personal interviews, focus groups, and questionnaires, we are looking at the following issues:

- Does the synchronicity of digitized speech and text support the learning process of distance-learning students with learning disabilities and in what way?
- Did the technology help the students complete the assignments related to the chapter in question?
- Is there a difference between the students' grades on the assignments for the chapter in question and their grades on the assignments for the other chapters?
- Did the digitized speech-text synchronicity affect the time that the students invested in learning?
- Which of the digitized features of the CDROM that are described above helped the most in the learning process?
- Did the speech-text synchronicity, along with the additional features, affect the students' need for a tutor?

The control group consists of students with learning disabilities who were assigned the same chapter in the same course during a different semester; these students were provided with the print version of the text without the digitized technology. The two groups of students' attitudes, grades, and achievements related to the chapter will be compared, as well as their success at answering the questions related to the chapter on the final exam.

The research is being conducted over two semesters. At the conference we will demonstrate an English version of the CD-ROM with the assistive technology and present the preliminary results regarding the effects of this approach for distance-learning students with learning disabilities.

Summarizing Links: Issues and Interfaces

Abstract: At the center of hypertext is the link, an active connection from part of one document to another document (or part of that document). In the early days of the World Wide Web, it was easy for readers to identify the links on the page: the unvisited links appeared in blue and underlined, the visited links appeared in red or purple and underlined. With the advent of advanced formatting techniques, such as cascading style sheets, links appear in different ways on different pages. These changes may make pages appear more appealing, but they also make it harder for readers to engage in a key hypertext reading activity, identifying and selecting the most relevant links. At the same time, even easily identifiable links provide readers with very little accompanying information as to why the link is there and where it leads.

In this paper, we describe ongoing research in providing readers with additional access to links and information about those links. We revisit in more detail the need to provide links in a consistent and clear manner, consider ways to make links more useful to readers without affecting the design of a page, suggest techniques for adding information to links, and describe a tool we have built that permits readers to obtain a summary of the links available on each page they visit.

1 Introduction

Where can I go from here? That question forms the center of hypertextual reading. Unlike in traditional linear writing, in which readers simply follow the narrative from beginning to end, in hypertext readers regularly look for links and consider whether or not to follow them. To permit readers to select the links that are most applicable, a hypertext system should provide four key attributes for links, summarized in Table 1.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifiability</td>
<td>The links on a page must be easily identifiable.</td>
</tr>
<tr>
<td>Link Text</td>
<td>The source of the link must be obvious to readers.</td>
</tr>
<tr>
<td>Link Type</td>
<td>The purpose of the link should be clear.</td>
</tr>
<tr>
<td>Link Destination</td>
<td>The destination of each link should be easy to determine.</td>
</tr>
</tbody>
</table>

Table 1: Key Attributes of Hypertext Links

1. **Identifiability**: The links on a page must be easily identifiable. That is, readers should be able to quickly tell what on a page is a link and what on a page is not a link. If readers cannot easily identify the links on the page, they will not follow the links. While some experimental hyperfictions may make the problem of finding the links part of the reading experience, most hypertexts should reveal, rather than obscure the links.

2. **Link Text**: The source of the link should be obvious. Most links do not go from page to page. Rather, they go from part of a page to another page (or part of another page). In a page with many links, readers should be able to clearly identify which part of the page the link is associated with. Typically, the source is a word, phrase, or image (the "anchor text" in HTML).

3. **Link Type**: The purpose of each link should be clear. A reader should know why the link is there. Does it provide a definition of the linked text? Some examples? A related page? A counter-argument to an argument on the page? The next page in a sequence? Without some additional information, readers are unlikely to know what the link is there for. It is this aspect of links that is perhaps least well supported on the Web.

4. **Link Destination**: The destination of each link should be easy to determine. Where does the link go? Is it elsewhere on the page, on the same site, or on another site? What kind of page does it
link to? While many browsers will put a URL in the status bar, a URL only says a little about the destination.

These attributes are particularly desirable for educational hypertexts, since we put links in pages so that students can explore further as their desires or needs for further information guide them. By making links easily identifiable, we let students find information more quickly. By telling them why we put the link there, we help them decide whether it's a kind of link they need to follow. And, by telling them what kind of information they will receive, we help them decide whether or not that information is appropriate before they spend their time following and exploring a link. Note that the last two goals, while similar, are different. For example, we might provide a link for students who do not understand a short reading and need more information (that is, the purpose of the link). But a "need more information" link might lead to another reading, to a problem set, or even to a set of dictionary entries. By providing both kinds of information, we further guide the student.

Unfortunately, as we suggest in Section 2, Web pages are often incomplete in their support of these four key aspects. Designers are making links harder to identify. Page authors too often use "Click here" as their source text. Browsers provide little support for link types. And the primary information most readers get on the destination of a link is little more than the URL for the link. Even if the designer of an educational hypertext is careful to clarify links, choose good link text, type links, and provide information on destinations, students may not be able to access all this information and, in any case, lose these benefits as soon as they leave the site.

So, what can be done? In this paper, we propose a partial solution. We have developed a prototype system that provides a link summary at the end of each page that readers view, no matter where on the Web those pages are located. For each link on the page, the summary includes the source text, the full URL of the destination, the link type (if available), and additional information about the link or destination (if available). In the near future, we expect to add summary information about the destination page (its title, its size, etc.). Because the links appear at the end of the page, they are easy to identify. In pages that provide the appropriate accompanying information, the type of the link and basic information on the destination are available. Hence, the summary helps meet most of the criteria required for the links without affecting the design of the page.

In Section 2 of this paper, we revisit the current status of links on the World Wide Web and describe some deficiencies of current practices. In Section 3, we discuss reasons to provide link summaries on pages. In Section 4, we suggest key aspects that any link summary system should provide. In Section 5, we describe the architecture of our link summary system. In Section 6, we revisit the need to summarize and clarify links. Finally, in Section 7, we describe planned updates to our system.

2 Links and the World Wide Web

The World Wide Web (Berners-Lee et al. 1994) is the leading hypertext system. How good is its support for links? Unfortunately, the answer is "it depends", particularly on the page designer. In the early days of the Web, readers found it easy to identify links: Blue underlined text represented unvisited links, red or purple underlined text represented recently visited links. However, as the Web has evolved to provide authors with more control over the appearance of the page, each page designer has chosen new ways to show links. Readers can no longer easily identify the links on many pages by simply scanning for blue, red, and purple underlined texts.

Jakob Nielsen, one of the leaders in Web design, has emphasized the need for easily identifiable links in a number of his Alertbox columns. He first warned of the problem in 1996.

Links to pages that have not been seen by the user are blue; links to previously seen pages are purple or red. Don't mess with these colors since the ability to understand what links have been followed is one of the few navigational aides that is standard in most web browsers. Consistency is key to teaching users what the link colors mean. (Nielsen 1996, Item 8).

Nielsen returned to this issue in a 1999 column. As new designs were becoming standard for Web sites, he repeated his warning. He also noted the importance of the underline as a way of identifying links.

[Non-standard link colors continue] to be a problem since users rely on the link colors to understand what parts of the site they have visited. I often see users bounce repeatedly among a small set of pages, not knowing that they are going back to the same page again and again. (Also, because non-standard link colors are unpleasantly frequent, users are now getting confused by any underlining of text that is not a link.) (Nielsen 1999)

Designers can, of course, continue to use these standards, but fewer and fewer seem to. Readers must now spend more effort determining whether a word or phrase on a page serves as a link, often by considering the placement of a word or by waving the mouse over the word to see if anything happens.
So, the clarity and text of links were originally quite good on the Web, but have been weakened by the advent of careless design. What about the two other desired characteristics of links: their types and their destinations? Once again, the answer is “it depends”. In part, it depends on the page author. In particular, the current HTML specification (Raggett et al., 1999) provides at least four attributes for every links: title, rel (relationship), rev (reverse relationship, from linked page to current page), and class. The title is a generic form of additional information that may be displayed by the browser. It can provide information about the destination. The relation and reverse relation tags allow authors to specify a link type. Unfortunately, the standard link types (Raggett et al. 1999, Section 6.12) are relatively basic, reflecting simple relationships like “table of contents” or “next element of a sequence” rather than more complex elements like those suggested in (Trigg 1983), such as “abstraction”, “refutation”, “continuation”, “data”. Particularly for educational texts, which will need types like “example”, “exercises”, “simplification”, the basic set does not suffice. Finally, the class attribute exists primarily for formatting, but could also be used to indicate type.

Even more importantly, support for types and destinations depends not only on author, but also on browsers. For example, not all browsers support the important title attribute (e.g., Netscape 4.7 does not) and those that do often require readers to perform specific actions (e.g., pause the cursor for at least a few seconds) to obtain the title text. Few browsers seem to do anything useful with rel and rev attributes. And, while, many browsers support the class attribute, they do so for formatting rather than logical typing.

So, what should page authors do? They can eschew complicated site designs that obscure the links. They can choose careful texts for their links. They can use the title, rel, and rev attributes. But they still need to hope that browsers will support all that they do and that their readers will choose to use those browsers. Is that enough? We think not. By providing link summaries for all pages, we can support careful authors without affecting their careful designs.

3 Why Summarize Links?

In the introduction, we suggested that a link summary system provides one key characteristic that one hopes for in a hypertext system: it makes the links clear (they all appear the same way on every page and in the same place on every page). Since many pages obscure their links, we hope that provides reason enough for link summaries. However, the link summary system provides additional characteristics that readers benefit from: it automatically provides information about the destination of the link and, if the page author has included that information, can include the link type and other comments.

But there are still other reasons to summarize links at the end of a page. One of the benefits we first observed when using the system is that it aids readers in dealing with mistyped links in Web pages. Since the URL appears in the summary, it is possible to look at the URL and identify potentially incorrect parts of the URL. While this is a minor benefit, it is one that many users have found useful.

More importantly, a link summary system can permit readers to organize links. For example, on a page that presents an argument, one might want to follow all the links to counter-arguments. By arranging the link summary by link type, readers can quickly find all the counter-arguments. Similarly, a student reading a long reference piece might want to be able to quickly identify all the examples. Both cases require that authors classify their links, but we hope that as the types of links are made available through tools like ours, authors will be more inclined to classify their links. A reader might also arrange links by destination (e.g., to see whether there is a site or page that is linked to particularly often).

Should these summarized links replace the links on the page? Certainly not. Many links are best understood within a broader context. The link summary system simply provides a way for readers to get additional information on the links available in the page.
4 Design of a Link Summary System

Given the benefits derived from summarizing the links in a page at the end of a page, one would hope to see a number of systems designed to provide such summaries. In considering such systems, we should look for systems that meet a number of key goals that are summarized in Table 2.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universality</td>
<td>Works with any page on the Web.</td>
</tr>
<tr>
<td>Browser Independence</td>
<td>Works with any reasonable browser.</td>
</tr>
<tr>
<td>Design Preservation</td>
<td>Maintains the original design of the page as much as possible.</td>
</tr>
<tr>
<td>Author Support</td>
<td>Takes advantage of information the author provides.</td>
</tr>
<tr>
<td>Customizability</td>
<td>Allows readers to set appropriate preferences.</td>
</tr>
</tbody>
</table>

Table 2: Primary Goals of a Link Summary System

1. Universality. The link summary system should allow readers to obtain summaries of any page on the World Wide Web without requiring modifications to that page. While we could hope that authors would provide their own summaries or use server-side software to provide summaries, not all authors will do so. A client-side system that works with any reasonable Web page provides a more universal system. Since a number of pages do not meet HTML standards, the system should do its best even with incorrect HTML.

2. Browser Independence. The link summary system should work with any browser, past, present, or future. Since different readers clearly prefer to use different browsers, the system should support as many browsers as possible. This requirement suggests that a browser plugin is an inappropriate implementation, since each browser will require a different kind of plugin.

3. Design Preservation. While many of the problems described earlier are caused by designers who ignore standards for link appearance, it is also true that many good designs may require links to appear differently. Hence, the link summary system should not modify the original page, except to add the links at the end (or in a separate window).

4. Author Support. Given that the HTML standard provides a number of attributes for tags that can provide link type and destination information, the system should support those standards. Hence, it should take link types from the rel, rev, and class attributes and additional information from the title attribute.

5. Customizability. As the previous section suggests, different readers will wish to organize their links in different ways. The system should give readers appropriate control over the link summaries. Aspects of summaries that readers may wish to control include: the order of links within the summary (do they appear in the same order as on the page, or ordered by some other characteristics), the information associated with each link (just the source text and URL, or with additional information), and even how they appear (font, etc.).

5 Technical Details

We have developed a prototype system that supports the design goals suggested in the previous section. To provide a relatively universal system that is independent of browser, we rely on the Web Raveler architecture (Kensler and Rebelsky 2000). Web Raveler is a collection of systems that mediate the conversation between browsers and servers. The classic implementation of Web Raveler is as a proxy server. Proxy servers receive each request and response that is sent between client and server. Proxy servers are used for a variety of reasons, including caching of pages, limiting access to certain pages, and logging information about Web use.

Web Raveler provides an infrastructure in which authors can write small “plugins” (to Web Raveler) that receive each page before it goes to the browser and may modify the page as they choose. The Link Summary plugin in our prototype system quickly scans the page for links, extracts information, and adds a table of links at the end of the page.

Web Raveler also provides additional facilities useful for the link summary system. In particular, it provides account information which permits us to store and access user preferences on the appearance of the link summary. In addition, the Web Raveler team is currently developing a Web cache that will make it easy for us to quickly obtain the titles associated with many URLs. While it would possible to obtain the title of a Web page by sending an HTTP request, if there are many links on a page, it would be overly time consuming to send
an HTTP request for each of them. The Web Raveler cache would provide quicker access and user preferences
could determine what the system does if the URL is not in the cache.

Our prototype system does a fairly simple search for links on a page. In particular, it looks for all the
anchor (A) tags in the page. While this strategy works for most pages, it does not work for pages in which the
links are generated on the client by Javascript or other scripting language. We are currently considering
mechanisms for extracting such links and debating the tradeoffs (for example, interpreting a script will take
additional time, making the system slower).

6 Conclusions

While links make hypertext hypertext, they are increasingly difficult to identify in many modern Web designs.
In addition, the HTML standards that permit richer links are insufficiently supported by browsers. In this paper,
we have suggested that a relatively simple mechanism, a link summary automatically generated for each page
viewed, can increase the usability of modern Web pages and better support both readers and authors.

7 Future Work

As we suggest above, we hope to extend the system for provide additional information about the destination of
each link. In its simplest form, this additional information can include the title of the page and the size of the
destination page. However, it might also be useful to provide additional information about the destination, such
as the author (if available) and even a summary.

Our prototype system was built as a basic proof of concept. In the near future we plan to begin some more
careful user testing to see whether readers take advantage of link summaries and whether there are ways to
make them more useful. We also hope to investigate what aspects of link summaries readers want to customize.

Because our link summary system appears to modify pages, we are also working to consider the intellectual
property ramifications of the system. We are hoping to build on the work of the Web Raveler team in this
direction.

Acknowledgements

We are particularly grateful to Grinnell College for the funding for the research described within this paper. The work benefited from the modern computing equipment in the department of Mathematics and Computer Science, equipment funded by Grinnell College and The Arthur Vining Davis foundation. Our work builds upon the prior work of others in the Grinnell Laboratory for Interactive Multimedia Experimentation and Research (Glimmer), particularly Andrew Kensler, who built the first version of Web Raveler, and the Summer 2000 Web Raveler team (Peter Broadwell, Elizabeth Hulse, Chris Kern, and Erin Nichols), who developed a more robust and modular implementation. We are also grateful to the other Summer 2001 research students who provided guidance in the Web Raveler system and who gave us suggestions for our own work: the Annotations team (Khong Lovan, Elias Vafiadis, and Joshua Vickery) and the Clio team (Greg Fuller, Joe Simonson, and Ananta Tiwari).
Internet as an Ideal Technological Tool for Multicultural Education

Mee-Aeng Ko
mak0ea@mizzou.edu

Shenghua Zha
sz5wf@mizzou.edu

University of Missouri-Columbia
303 Townsend Hall
Columbia, MO 65211 USA

Abstract: This brief paper will report the process and results of a website for multicultural education being developed by international graduate students from MU. The resources on this website have important implications for educational technologists who wish to make instruction more responsive and effective for learners with diverse backgrounds. The website includes four components: a discussion forum, opportunities to meet Korean children and read their stories, literacy lesson plans using tri-lingual multimedia stories, and research papers.

Multicultural Education and the Internet

As the United States continues to become more ethnically diverse, the composition of the U.S. classroom is changing. Teachers are encountering students from other cultures whose worldviews, motivational levels, and learning styles are substantially different from those of most teachers and native-born students. Teachers should be prepared to meet the educational needs of ethnically and culturally diverse students (Gay, 1997). Experts in the field of multicultural education recommend specific competencies that will empower teachers to create a learning environment that encourages and supports the academic achievement of students from diverse racial and ethnic groups. In addition to developing positive attitudes and behaviors toward culturally different children, teachers are expected to be able to:

- Understand the learner characteristics that children from different cultural backgrounds bring to the teaching/learning situation which may affect the quality of learning; and
- Create, select, and use appropriate instructional strategies, pedagogical techniques, and materials to accommodate the learner characteristics (Sheffield, 1997).

As educational technologists, we believe that these expectations can be reached through the application of educational technology. The Internet can be an ideal technological tool for multicultural education. In addition to the enormous amount of information available on the Internet, the Internet has the potential to network and interact with people (Gorski, 1996). The Internet can support several educational ideals consistent with multicultural education: Inclusive education, Collaborative education, and Interactive education (Gorski, 1996)

Designing a Website for Multicultural Education

The website being developed is an example that models multicultural ideals. It is a sample of interactive, inclusive, and collaborative media for multicultural education. The website consists of four parts: discussion forum, meet the children, literacy lesson plans, and research reviews.

Discussion Forum

This website offers a discussion forum, for students to email teachers or other students to ask for more information or clarification on a particular topic. A vast of network of teachers and students around the world and across myriad cultures could share questions and exchange resources on a given topic. According to Garnsey and Garon (1992), the discussion forum, as a form of CMC (Computer-Mediated Communication), solves the constraints of time and space to those geographically dispersed organizations that are looking forward to communicating with each other. It also allows teachers to share resources and discuss their teaching successes and failure, which is an excellent model of collaborative media for multicultural education. This is
sample of the interactive learning environment made possible by the Web. Another use of the discussion forum is to provide an authentic use of language through for communication. Some educational theorists suggest that authentic tasks are very important for students, as they enable students to learn meaningfully and purposefully (Brown, Collins & Duguid, 1989).

Meet the Children

Inclusivity is another important notion in multicultural curriculum transformation (Gorski, 1996). If education is truly to be student-centered, then the experiences, perspectives, and ideas of the students themselves must be brought to the fore. To be “included” in the educational process, students must be given opportunities to have their voices heard and to hear each other’s voices, which are prerequisite to student-student interaction and cooperative learning. The Internet can facilitate this kind of Inclusivity by encouraging teachers and students to participate in virtual global communities with other teachers and students who may be either very culturally similar or different. This web site offers the opportunity to meet Korean children who want to share their experience and writing with other students around the world. Writing samples by the children are included.

Literacy Lesson Plans

The web site describes an innovative multimedia story-writing project with elementary children in an ESL classroom. The children wrote and illustrated multicultural stories and then worked with international graduate students to transform the stories into interactive multimedia stories in three languages. A sample story is included and a variety of lesson plans for literacy development in ESL are provided.

Research Reviews

The web has the potential to greatly expand the breadth and depth of collaborative possibilities of educators (Gorski, 1996). Five research papers are being provided: multicultural education, globalization, literacy development, technology-writing and publishing on the web, and TESOL. In this web site, research findings will be compiled to share resources on multicultural education and tips for teachers on how to make a learning environment effective based on research.

Importance of the Work

The resources on this web site have important implications for educational technologists who wish to make instruction more responsive and effective for learners with diverse backgrounds. The web site should have positive implications for training pre-service and in-service teachers in multiculturalism and provide a resource site for teachers and children.

Knowing Who We Are – Supporting Companion Awareness In Discussion Forums

Kimmo Koivunen
University of Tampere
Department of Computer and Information Sciences/ TAUCHI unit
University of Tampere, Finland
Email: kimmo.koivunen@uta.fi

Abstract: In this paper we describe how learners need awareness information about co-learners in computer-supported collaborative learning systems. Awareness is essential for working collaboratively and for building a learning community. If the learner doesn’t know anything about his/hers co-learners, there can’t be any community, which means that there can’t be any real collaboration either. In this paper we first describe a theoretical background for our research after which we introduce one possible solution to solve the demands for awareness in a Web-based conferencing systems. We also present our initial implementation of awareness support and report experiences from a course using the system.

Introduction

In many cases Web-based learning environments are used asynchronously, which obviously gives freedom of time and place for learners. But when a learner logs into the system, it is very hard for him/her to know if there is someone else present at the same time or even ever have been. Most of these asynchronously used Web-based learning environments include some kind of discussion forum. In these discussions a learner can find co-learners who have made comments and make conclusions that he/she is not alone, but especially co-learners who are only reading comments are quite invisible. Thus learners come visible only through their contributions, which can lead to wrong conclusions about the state of the discussion. Ongoing discussion might even look like a dead discussion because learners are only reading. That is why it is reasonable to give information about their visits to other learners. This information can enhance learner’s awareness of co-learners and their interactions, which are essential especially for collaborative learning (Dillenbourg 1999). It even can be argued that otherwise there will not be any chances to collaborate. This awareness can inform learner that co-learners are interested in each other’s contributions and can be in important role in community building. A learner must receive information, which could include who the other learners are, what they have done and what they are doing now. If learners are aware of who are the ones to collaborate with then it is possible to start building a community for learning. In this paper we consider how the technology can support collaborative learning by providing awareness information (see also Jermann et al. 2001).

First in this paper we describe a theoretical background for the research and after that we introduce one possible solution to solve these demands for awareness in Web-based conferencing systems. We present our implementation and report experiences from our experiment. Finally we make conclusions of the work we have done.

Collaborative learning and community building

Learners’ work and learning in online learning environments can be seen at its best as collaborative learning. Learners are working together and building new knowledge by reflecting their thoughts with others. However, collaborative learning is a difficult concept in practice. According to Dillenbourg (1999), the words ‘collaborative learning’ describe a situation where particular forms of interaction among people are expected to occur. This interaction can trigger specific learning mechanisms and finally lead the participants to learn.

Dillenbourg (1999) classifies four categories in which there are different ways to increase the probability that some type of collaborative interactions will occur. These categories are:
to set up initial conditions,
- to over-specify the 'collaboration' contract with a scenario based on roles,
- to scaffold productive interactions by encompassing interaction rules in the medium, and
- to monitor and regulate the interactions.

With reference to this categorization our work emphasizes the fourth category. Also, as an alternative to the tools for the teacher to monitor the learners, we provide tools for the learners themselves for self-regulation of their interactions. These tools offer information about community's members and their interactions, which can be used by the learner to maintain the awareness of the state of the community. In collaborative processes this information about other learners could really help. Especially in asynchronous learning environments this kind of awareness information would be helpful for interacting with other learners.

Because learners are, in most cases, inside the environment at different times this awareness information would help to keep discussions alive. A learner can check from awareness information if other learners have been inside the system and read their comments. In this way a learner can have more clearly expectations when the discussion is going to continue.

For working collaboratively is also necessary to build some kind of community. Or more clearly, if group of people are working, or in this case learning, collaboratively there is a community. That's why, because communities are everywhere (Wenger 1998). It's important to realize that these communities don't have to agree in issues, which they are dealing. Arguing, as well as discussions, agreeing and so on, is common for the communities.

Informal information about others is also good for community building. It supports especially the social aspect of the community. Nardi et al. (1998) were surprised how well a chat facility supported community building. It was especially its informal and social features that are valuable for community building.

Companion Awareness

Like collaborative learning, awareness is also a notion, which is hard to define precisely. It has lot of different aspects and it can be classified by many different ways (Liechti 2000). Definition of the awareness is depending of the context of the use and also of the characteristics of the system. In this paper we are exploring new opportunities, which the awareness can provide for asynchronous discussion forums.

Gutwin, Stark & Greenberg (1995) have defined a framework of awareness. In this framework they distinguish social, task concept and workspace awareness. Especially they focused on workspace awareness, which is essential for students to learn and work together effectively. Workspace awareness is information, which describes who is participating to the work, where are they, what have they done and what are they doing. Their focus was on the synchronous learning environments but their conclusions about awareness are valid also in the asynchronous environments.

Jermann et al. (2001) have defined another framework, which describes capabilities of tools to support collaborative interaction. In this framework they set awareness features in learners locus of processing. This means that awareness support gives information to the learner, but it depends on the learner how the information is interpreted or understood. Because of that awareness features should be quite simple and the given information should be easy to understand.

Awareness information can help collaborative learning especially in the community building. When a learner knows which other persons belong to the group, he/she can have a feeling of belonging to the community. This belonging strengthens the community and makes interactions easier. The benefits of awareness are more obvious in synchronous systems, but we believe that these benefits are important in asynchronous learning, too. Our focus is to support learners' collaborative work with awareness of their co-learners. In asynchronous collaborative learning systems this awareness information should include the following:

- information which helps to identify co-learners,
- information which supports social aspects of the community, and
- information which shows the usage of the system.

We use the notion, companion awareness, to describe this kind of awareness information.

Dyn3W – Learning environment

In our courses at the University of Tampere we are using Dyn3W learning environment. It is a product of project called CoWoGLe (Conferencing on the Web for Group learning), which have been going since 1996. (Hietala et al.
1997). The system has been in use on several courses and more than 1000 students have been using it over the years.

The main part of our Dyn3W system is a discussion forum. The discussions are threaded (figure 1) and because the system is using frames, it is possible to write a comment and read old comments concurrently. The system keeps record of each user’s usage. It also counts comments. Students are divided in groups and they working in these groups with same assignment.

New awareness features

In our system the learners are working together in small groups and they have to make a decision, which they present to the other groups. Without any awareness about the other group members this group work is difficult, especially the decision-making is hard. That’s why we implemented awareness support for learners. These new awareness features include information about who group members are, what they have done and when they have been inside the system. For learners it is also possible to give an informal description of themselves. This was designed for supporting the informal aspect of communication. It is also one way to support group’s community building, which is important in learning relationships (Wenger 1998).

![Figure 1: View from small group working area](image)

A view from the small group’s working area is shown in figure 1. In the left frame discussion tree is shown. Above that there is the button bar, which includes a button for the awareness information. This awareness information is shown in the right frame, which normally is used for reading comments from the discussion and writing new comments to the discussion.

In our implementation the learner can see him/herself as one of the members on the list of the group. Another way in the implementation could be that he/she is removed form lists and information is only about other group members. In this case it is more difficult to learner compare him/herself to others. Showing the current user also in those group listings makes it clearer that the user is a member of the group. He/she can see that he/she is in the same position with others. Also comparing oneself to others comes very easy (on right in figure 2).
We hope that this would encourage learners to work harder. Because they can easily see how much work other group members have done, they might want to do likewise. Of course this can also lead learner to be lazy, because he/she is not only one. This problem could be solved with forced requirements, which seem to be good way to get discussion going (Sorenssen & Takle 2001).

The awareness features included also information about group members' presence in the system. This is implemented by telling which time each group member has logged in and out of the system (on left in figure 2). It could be implemented also so that system just tells who is inside and who is outside the system. But we wanted to show learners more detailed information about each group member's visits to the system.

**Experiment and results**

Dyn3W- system with the new features was in use on Computer-Aided Instruction course at Spring 2001. The course had 74 participants. In this course, which includes also lectures, exercises and two group projects, the assignment for working in Dyn3W- system was to collaboratively produce a short description for a good online course. For that students were randomly divided into eight groups. Four of these groups had the awareness support and four did not have this support in the conferencing system. This means there were 36 learners with support and 38 without. Because of that, we can find out different groups' usage of the system and compare if there is any difference e.g. in discussion activity. Participants used the system for a quite short period, which lasted only 4 weeks.

These new awareness features weren't introduced or explained to the learners during lectures or exercises. We did this because we wanted to find out if the users could find these tools by themselves and how they would be using those tools. In this way we can explore if learners find ways to use them and how many times they are using them. Introducing these tools just for part of participants would also be quite difficult. Introduction would also lead learners to use tools in a particular way that the teacher is thinking to use it.

As we can see in Table 1, the new awareness did not encourage our students to produce more comments than in the groups without the features (6.8 < 8.2). However, if we look a little bit closer to the data, we can find an interesting issue. It was compulsory for all participants to produce at least one comment (new course suggestion) in the group. If we consider those who produced more than only this one compulsory comment, we find that there were more students who stayed and participated in the discussions in the awareness support groups than in those without the support (29 > 28). In groups without the awareness features 26.3% of learners made just that required comment, but in groups with the awareness features the same percentage was only 19.4. This gives a weak evidence for the
usefulness of the awareness tools. Learners with the features also had more sessions than learners without the features.

</tbody>
</table>

Table 1: Comparing the two learner groups

Most of the learners used the new awareness features at least once (Table 2). This means that most of the learners found these features easily. Most of them were using all of the features. Many learners liked to read other learners self-descriptions but they didn't give a description of themselves. As we see in Table 1, learners using the awareness features had 16.5 sessions by average and they used awareness support during 4 different sessions (Table 2).

| Used the awareness features at least once | 33 learners |
| Read other users descriptions of themselves | 25 |
| Wrote description of themselves | 5 |
| Were interested in the "presence" information | 29 |
| Were interested in the number of posts | 29 |
| Sessions where using awareness by average | 4 sessions |

Table 2: Usage of the awareness features

Conclusions

According to the preliminary results we got from experiment it's quite fair to say that learners were at least very interested in getting companion awareness information. The fact that learners did use awareness features quite often but not in every session, supports that conclusion.

Participants took part in the discussions as much as it has been common in this course in earlier years. So the awareness features didn't have effect for participation in way we were expecting. Duration of the online exercise might also have effects. Four weeks period is quite short, which makes the learners focusing to the task and leaving social aspects to background. On our course learners could also meet other learners at the lectures twice a week, on the campus site and so on, which probably effected also to the need of awareness information. The awareness features can be more valuable for an online course where learners are physically distributed.

Typically on every course, traditional or online, there are learners that don't want to do more than they have to. We got weak evidence that with the awareness support for the learners we can downsize the number of this kind of behavior of learners. Somehow the awareness features seemed to get more learners to be involved to the work of community. This might mean that learners are more motivated for the course and therefore are working harder, which would hopefully lead to the better grades and learning.

We also found out that learners are interested in all kind of awareness information, but they are not ready to take extra effort for making others aware about themselves. This can be seen from the interest of other learners' descriptions. Somehow it's surprising that the learners didn't make a self-description after they have read other learners self-descriptions. Nardi et al. (1998) have made same kind of observation with personal Web pages in an online course.

Future work

In the near future we are going to rearrange the experiment we have discussed in this paper. Especially we want to get more evidence for the finding that those learners with the awareness features were more active than was
compulsory. We are also going to make some improvements to our system. We are going to highlight buttons for learner self-descriptions after the description have been done. We hope that this way the learners will not get tired with this feature, because now they can know from the button if their co-learners have made their self-description. We are also considering ways to encourage learners to writing their own descriptions.

It is also possible to give learners more or even better awareness information. One possible way to do that would be information about the reading times and the readers of each posting (along the lines of the BSCW system (Appelt & Mambrey 1999)). This means that learners should be able to see who have read their postings. So if learner makes a new posting, he/she can check later who has read it or hasn’t read it. In this way learner can be more aware about ongoing discussion. In this case questions about privacy have to be considered too. Is it fair to the learners to provide so detailed information about their usage of the system for their co-learners? If it is done openly, it might also encourage learners to use the system more and hopefully in the meantime learn more in collaboration with others. We are planning to include these awareness features into our discussion forum.

In our experiment there were also peer groups without awareness support. If we in the future compare more carefully these groups with those with awareness support, we can maybe find out more detailed knowledge of usefulness of supporting awareness. A problem with that kind of analysis is the short time of usage of Dyn3W system on that specific course. The awareness features are probably more useful in longer lasting usage of online learning environment. One possible way to get analysis little bit further is to evaluate the quality of different groups’ proposals and find out if there is any difference and what might be the reasons for them. This is one of the issues that we are planning to focus in our future research.

Abstract: The design rationale for the development of an exemplary, flexible online course for making accessible online courses is described. We developed the course by adopting the roles of content expert and instructional designer. The course has a dual purpose; the assessment for postgraduate students provides a guide to learning for academic staff development. The design and development process included the formulation of learning outcomes, assessment criteria and strategies, learning methods, and the alignment of these. The learning strategies included a variation of the cognitive apprenticeship model that was refined following feedback from prototype face-to-face workshops. Learner-centred design is fundamental and includes: high contrast text and background; no unnecessary graphics or icons; tips for people using assistive technology; avoiding the use of PDF; direct links to other course areas; text transcript for online videos; and easy access to resources for learning activities.

Project Initiation and Rationale

The production of guidelines for making online courses accessible (Pearson and Koppi, 2001), lead to considerations of developing an online course for making accessible online courses. Because the authors are at different universities, in different fields with different ‘clients’, the nature of the course had to be negotiated. Pearson (at the University of Teesside, UK) teaches postgraduate students and the desired accessibility module would be part of an MSc in Multimedia Design. Koppi (at the University of New South Wales, Australia) is involved with academic staff development and the course would have to help teaching staff to produce their own accessible online courses (using WebCT at UNSW).

The project development proposal had to include a rationale stating that the intended course would have the dual purpose of an MSc component and a staff development purpose. This was to prove problematic, particularly where assessment was concerned. The project proposal was based on constructivist learning principles and was structured to include learning activities, dialogue and collaboration, and student support. We decided to adopt the roles of content expert (Pearson) and instructional designer (Koppi) to help us include the essential perspectives in courseware development. The structure of this paper describing the design and development of the course is based on an instructional design plan.

We realised that the course itself would have to be an exemplar of accessible course design. We would have to ensure that it would be accessible to people with disabilities. We intended to employ the services of an experienced student who is blind, and is a regular Internet user, to assist us with identifying the capabilities of assistive technologies, and with checking the accessibility of the course. We also intended to use the checking tools provided by Bobby (CAST, 2001), DreamWeaver 4, and our own Guidelines (Pearson and Koppi, 2001) to check for accessibility.
**Formulation of Learning Outcomes**

Following instructional design principles (Biggs, 1999a and b), the aims, objectives and learning outcomes were formulated first, and the learning outcomes, which are concerned with what the student will be able to, are given as follows.

"On successful completion of this module the student will be able to:
1. Discuss the issues relevant to access for people with disabilities to online learning.
2. Demonstrate skills in the use of relevant guidelines and accessibility checking mechanisms.
3. Describe the use and application of assistive technologies.
4. Describe the needs of the learner in the design of accessible online courseware.
5. Demonstrate skills in the design and development of accessible and inclusive online courseware.
6. Analyse barriers to accessibility in existing web sites and online courses."

**Assessment Criteria**

The assessment criteria are concerned with measuring how well the students have achieved the learning outcomes; they were formulated for each learning activity designed to produce the desired learning outcomes. For example, for the learning outcome concerned with the task investigating the guidelines based on those developed by the Web Accessibility Initiative (WAI), part of the World Wide Web Consortium (W3C), the assessment criteria together with relevant information are given as:

"If you are being assessed for this course, your portfolio contribution for this activity will be assessed according to the following criteria. If you are carrying out this task out of interest or for your personal development, the criteria can be used as a checklist for your own learning.
1. The extent to which you have considered the purpose and the extent of the activities of W3C and WAI.
2. Your analysis if the applicability of W3C guidelines for accessible web site design to the average non-technical academic developer.
3. Evidence of research and understanding of the nature of other guidelines.
4. Quality of the overall presentation and coherence of the posting and additional links.
5. The quality and coherence of your contribution to the discussion of this topic.
Marked out of 100% with 20% for each element."

As indicated above, this online course has a dual purpose (part of a postgraduate degree and for staff development), and so the assessment criteria can be used in different ways. The criteria can be used for summative assessment (portfolio) in the case of the students, and as a learning guide in the case of teaching staff learning about accessibility. The students can also use them as a learning guide because the assessment criteria are provided with each learning task.

**Assessment Strategy**

**Types of Assessment**

The assessment strategy is concerned with the methods of assessment that are best suited to the students demonstrating that they have achieved the learning outcomes. There are many ways of assessing learning and McLoughlin and Luca (2001) note that there are three types of assessment:
- **Cognitive**: thinking, knowledge, application and understanding of principles, concepts
- **Performance**: demonstration of skills and abilities, complex task performance
- **Portfolios**: evidence of complete student record, tasks, achievement, examples of work etc.

Of course, these three types are not exclusive, e.g., a portfolio would include evidence of cognitive and performance attainment. For academic staff undergoing staff development in inclusive courseware design, and for postgraduate students learning about courseware design, the most appropriate types of assessment would be...
performance and portfolios since we would want to see practical examples of work as evidence of learning and application of inclusive and accessible principles.

The portfolio is used as half of the assessment and is described as follows.

“You should develop a portfolio by posting to the Student Presentations area or your personal topic area in the discussion forum, to demonstrate understanding of issues related to disability, including:
1. The Disability Discrimination Acts and their effect on education and online learning.
2. Review of current guidelines and their usefulness for academic developers.
4. Accessibility checking tools, their use and application, reviews of good/bad examples of websites.
5. Design methods and tools for creating accessible documents and courses.
This assessment will take place throughout the module and will be directly linked to the activities you undertake through the course.”

The other half of the assessment is concerned with the students or staff either (a) creating or modifying an accessible and inclusive course based on their own subject expertise, or (b) redesigning a given course (especially prepared from common practices) which does not meet accessibility requirements. Participants have the option of working in groups or as individuals in carrying out the tasks.

Authentic Assessment

In addition to the learning outcomes, assessment criteria and assessment strategies being aligned, the assessment tasks should also be authentic. Herrington and Herrington (1998) in their review of authentic assessment provide descriptors such as: situated, practical, realistic, performance-based, real-world, and ill-structured. The use of real-world learning environments enables the same activity to be used for learning and assessment (Herrington and Oliver, 2000). For example, the assessment of how well teachers are able to design and develop an accessible online course or their redesign of an inaccessible course, as described above.

In the real world, work is often collaborative in nature and authentic tasks should include collaborative activities wherever possible (as in this course). If well designed, collaborative work can enhance the learning experience and the social negotiation that promotes higher order thinking (Herrington and Oliver, 1999). In the course, discussion topics are used to facilitate collaboration and the presentation of alternative viewpoints.

Learning and Teaching Strategy

The learning and teaching strategy is concerned with the methods will best help students achieve the learning outcomes. Having formulated the learning outcomes and assessment strategy and criteria, it follows that the learning tasks should be considered and that they should all be in alignment. This section presents a rationale for the learning tasks employed.

Cognitive apprenticeship model

The cognitive apprenticeship approach (Brandt et al., 1993), when coupled with participation in the community of practice (Lave and Wenger, 1991) and authentic problem-based learning (Savery and Duffy, 1995; Grabinger and Dunlap, 2000), can provide an authentic situated learning experience that bridges the gap between abstract theory and effective practice (Herrington and Oliver, 2000). With respect to designing accessible learning environments, the intention is for the teachers to apply the theory in their everyday practice and not to treat it only in the abstract. Learning, online or otherwise, can be facilitated by the use of scaffolding (support) in a social constructivist setting (Roehler and Cantlon, 1997).

We decided to adapt the five stages of the cognitive apprenticeship model (Brandt et al., 1993) as follows.
**Phase 1** We elected to present the expert perspective through an interview (Koppi interviewed Pearson) which was filmed and converted to streaming video. The five major issues (as identified in the learning outcomes) and expert considerations were discussed (Pearson and Koppi, 2002). The video sets the scene for the five learning tasks corresponding to the first five learning outcomes.

**Phase 2** Working in groups, the participants carry out the learning activities and discuss their findings and conclusions.

**Phase 3** As an authentic activity, the participants apply what they have learned to the design and construction of their own online learning environment (e.g., using WebCT) or to the redesign of an existing problematic one already prepared by us.

**Phase 4** The learners continue developing their websites in their own time and check that their sites conform to acceptable standards (e.g. by using the Bobby and DreamWeaver software). Postgraduate students carry out the assessment already detailed – redesign of inaccessible course or design/re-design a proposal for their own course or web site.

**Phase 5** The learners may each reflect on what they have learned and describe general principles for developing accessible online learning environments. Students illustrate their learning by creating a portfolio of their accessible designs and implementations that contribute to their assessment. Academic staff could organise and facilitate a workshop in their own department or school.

**Face-to-Face Workshop Prototypes**

We developed face-to-face workshops on accessibility for academic staff, with the intention of using the workshop tasks as prototypes for the online tasks. The workshops enabled us to see how the learning tasks worked, how long they took, what the problems were, and to obtain feedback from the participants. We modelled the workshop along the lines of the online course: orientation introduction, activities, reporting back, with support from the workshop facilitator. We were in effect doing evaluation of the intended online tasks in advance.

The results of the workshop experience enabled us to refine activities for the online course, mainly by adding more support and tasks to provide a background and orientation to the issues of learner-centred design. We also realised how much more valuable an online course can be than an ephemeral face-to-face workshop which disappears without visible trace. The online course can be revisited and re-examined after further learning or application of learning has occurred. Fleeting ideas in a workshop, too soon gone because of the pace, can be explored in the online course. The advantages of face-to-face though cannot be denied – the time commitment is made and colleagues are there on hand for immediate discussion, however brief. It seems that commitment to an online course can be problematic for busy people because it is too easy not to set the time aside (Forsyth, 2001).

We also utilised the services of Darren Fittler, a law student who is blind, and an experienced Internet user. This proved to be a highly engaging time for the workshop participants. Darren was a first-time user of WebCT and went through his allotted tasks (of which he had no prior information), speaking his thoughts out loud, and that gave a powerful message with respect to learner-centred design. We felt we had to capture that and incorporate it into the online course. He was later videoed going through it all again in a studio setting. If we had not had the experience of the face-to-face workshop with Darren we would probably not have thought of including him online.

**Multipurpose Course Design**

The issue of the dual purpose of the online course (part of a postgraduate degree, and staff development), and its effect on the inclusion of assessment strategies, was resolved essentially by giving the assessment criteria different purposes. For academic staff, doing the course out of interest or personal development, the assessment criteria can be used simply as a guide to learning. This obviated having to develop two separate courses, one with and one without assessment. Extra instructions and clarification had to be repeated for every activity page on the website because the course can be dipped into at any place by staff and being confronted with unexpected assessment may prove a barrier to engagement.
Design Features of the Online Course

Since learner-centred design is a core concern of the online course, some of those design features are noted here.

- The Home page has text and icon (with alt-tags) links to all the important elements of the course.
- High contrast text and background are used throughout, and no unnecessary graphics or icons are used.
- On the Home page there are tips for accessibility, e.g., for people using a screen reader to hide the left navigation bar which adds unnecessary complexity to the page.
- The tip also includes a link to downloading the Adobe Acrobat Reader 5 to enable suitably formatted PDF documents to be read by a screen reader.
- The use of PDF has been avoided wherever possible, or alternative formats have been provided.
- The Welcome page provides tutor contact details, describes the course, its rationale, the activities, assessment portfolio, and invites constant feedback/evaluation of the course.
- The aims, objectives and learning outcomes are visible from the Home page.
- A link to other parts of the course is provided wherever they are mentioned, and that link opens in a new window to enable easy return (closing the window).
- Links are provided directly to any particular discussion topic rather than just to the discussion area which would require further searching to find the specific relevant topic.
- A schedule is provided of tasks, their content, deliverables (particularly if the course is assessable) and an indication of how much time should be allocated to each task. This time allocation is a suggestion only in that personal interests and different learning styles will result in different times being spent on the tasks.
- An orientation activity is provided for easing new online learners into the environment, and to enable course participants to meet each other and to comment on each other's interests. Practice is also provided in uploading a file to the student presentation area, with tutor contact details immediately to hand in case of difficulties.
- Each of the activities is developed as self-contained (to minimise searching other documents for relevant information) with introduction, task, reporting, discussing, assessment criteria (for those being assessed), and resources being provided.
- A direct link to assessment is also provided on the Home page.
- A link to resources, including links to relevant free software downloads, is available from the Home page.
- The videos include either subtitles or a text transcript.

Web Accessibility Initiative (WAI) http://www.w3.org/WAI/
1. Introduction

There is a growing tendency to strive for integration of individual and social dimensions in the new learning environment settings where technology is used as a tool for organising learning. Computer Support for Collaborative Learning (CSCL) is an emerging area of research when using Web-based learning environments in education. It represents a departure from previous work in instructional technology where learning was seen as an individual phenomenon. Many current learning theories connected to CSCL embrace a view of learning as a largely social phenomenon. Social interaction is seen to be a paramount site for the development and practice of cognition. One might expect the group to perform better than individuals on various challenging tasks like learning, knowledge creation, creativity, and problem solving. (Solomon 1993; Levine et.al. 1993; Scardamalia & Bereiter 1994; Kirschner & Whitson 1997). Collaborative learning can here be defined as a process through which a group of learners construct knowledge for its members and for itself as a learning community. It is typical of collaborative learning that learners have an inherent and spontaneous motive for collaborate, that learners determine and plan their own learning process, and learning contents are tailored in that learning community. Learning is co-operative and based on interaction with others, and it is evaluated on a self-evaluation basis. (see Korhonen 2001.) Learners thus have the possibility to study and apply issues closely related to their life situations and contexts flexibly (cf. Brown, Collins & Duguid 1989; Lave 1988) Structured and formal teaching and learning is replaced with a learning environment constructed by group of learners, in where they...
are able to set their learning goals collectively and share their responsibility to follow the learning paths to meet these goals.

There are some encouraging research findings of group discussions or problem-solving activities in collaborative learning settings which give a support on the use of asynchronous group discussions in CSCL environment. Benefits of group discussion actions brought to learning are e.g. increased motivation, deeper understanding of the concepts and an increased willingness to tackle difficult questions that learners cannot answer alone (Weir 1992). Participants who solved problems through computer supported group discussion were more satisfied with the learning process and virtual groups tend to be more task oriented than face-to-face groups. Computer conferencing is giving flexibility to the communication. (Jonassen & Il Kwon 2001.) Group discussions brought in a case-based learning environment showed also that students who worked in groups performed significantly better that those who worked alone on the analysis and alternatives tasks. Participants who worked in groups liked their method also significantly better than those who worked alone and felt they have learned more working in a group. (Flynn & Klein 2001). The primary disadvantage that has been identified in recent research is the lack of nonverbal cues and the fact that in a virtual group discussion it is more difficult to reach group consensus. Some of the students might complain also about the extra time and effort needed for written argumentation. (see Jonassen & Kwon 2001.) Computer-mediated communication appears to support cognitive development of participants in many ways but educators need more information how to foster student development in general, and to enhance teaching and learning in particular in CSCL environments.

Central to the implementation of group discussion settings mentioned above is the organization of learning. There is some evidence that the more students are coached and instructed in their systematic and reflective use of computer supported communication, the more varied and extensive the collaboration will be (Admiraal et.al. 1997). The strength of group discussion setting in the collaborative learning environment lies in its members' diversity, with each member should contribute his or her knowledge and competence into the collective action (Sharan & Sharan 1994; Korhonen 2001). The purpose of this presentation is to analyse two different kind of
cases where the discussion groups have been brought into CSCL setting. The analysis and interpretations of the discussion groups are intended to imply how group investigation based or on the other hand freely organized discussion group influence of group interaction in CSCL environment.

2. Two Cases under Examination

The group discussion cases evaluated here are carried through a WebCT-based network learning environment. The CSCL environment is serving as a basis for sharing material and information, discussions and publishing written documents in Web. In these cases learning is not only virtual; it also involves contact teaching as orientation or group work under a teacher's supervision.

In the first case the use of the Web discussion group is based on certain co-operative group method brought into CSCL environment. The group method chosen is the Group Investigation method developed by Sharan & Sharan (1992; 1994). Group discussion is based upon research-like learning process and consensus building through cooperation by group members. The group of students attending this integrated Web-based course is consisting of 28 Finnish education science and adult education students in University of Tampere. The Group Investigation period in Web-based learning environment is bringing an interesting addition to the traditional seminar work, which is carried out in face-to-face meetings. The character of Group Investigation lies in the integration of four features: investigation, interaction, interpretation, and intrinsic motivation. Investigating in groups calls for students to use their interpersonal communication and planning skills, reflect and integrate their findings collectively and present their findings to others as well. (Sharan & Sharan 1992). These basic co-operative features of the group method are combined in the six stages of the model (Sharan & Sharan 1994):

- Stage 1: Students determine subtopics and organize into research groups.
- Stage 2: Groups plan their investigations.
- Stage 3: Groups carry out their investigations.
- Stage 4: Groups plan their presentations.
- Stage 5: Groups make their presentations.
Group Investigation method suits for small group of learners, who have complementary skills and have a common learning goal to reach for. The goal of the Group Investigation is to combine social interaction and communal problem solving to a research like process (Vahtivuori, Wager & Passi 1999). This method is quite simple and straightforward for implementation, so it doesn't require a long careful orientation. This kind of instructional co-operative method seems to work particularly well for Higher Education students of theoretical science study modules.

In the second case learning also involves contact teaching as orientation and small group work under a mentor's supervision. However, the network discussion group is organized much more freely. The organization of groups is based on certain theoretical discussion themes. The discussion groups are working as knowledge construction areas where the goal of the discussion is to share the knowledge with others and to reflect the findings. The group of students attending this network-based courses is consisting of 22 adult nursing science students in Open University in Institute of Extension Studies in Tampere. The requirements in this network courses is to do several written assignments: like analysis of network discussion themes and write a written home assignment. The role of the virtual discussion forum is to be a basis for all the written assignments in the study period.

The both of the research groups construct a personal learning diary. These authentic learning diaries of the learners are composing the central research data. So the situations are analyzed qualitatively. The main research question in this case is to try to find through these discussion group cases some evidence on how group's movement toward reaching a conclusion is carried out in different kind of group discussion settings. Is the group interaction and learners' experiences of interpersonal interactions different when there is certain cooperational method utilized and is the quality of outcome better or worse in that case?

The analysis of the research material is carried out during the winter 2001 -2002 and will be potentially reported in the coming ED-MEDIA 2002 conference in June, 2002.

{kritzenberger, herczeg}@imis.mu-luebeck.de

Abstract. The development of web-based courses for virtual universities very often starts from a paper-based tradition of teaching and learning. Web-based learning environments, however, have an added-value by the potential of hypermedia, multimedia, interactivity, cooperation and collaboration, mediated by digital media with different features distinguishing contexts for presentation of content. Currently, there exists no adequate model covering media as distinguishing contextual aspects for web-based learning environments. This paper presents a framework to deal with media features as varying contexts during the development of learning environments.

1 Introduction

The production of web-based courses often start from a paper-based tradition of teaching and learning with content authors writing a kind of book, which is subsequently the basis for a continuous media production process considering media features as distinguishing contexts. Therefore, the production of web-based learning material does not only mean the transfer of and adaptation from one medium to another one, but also an integration into an adequate media production process, where media features change contexts for design. As we see the development of web-based courses as equivalent in many aspects to software development processes we refer to ISO 13407 as a reference model for user centered design processes, which focus on understanding user contexts. The importance of contexts have already been recognized in many other areas (see for example Suchman 1987). This paper is based on experience of the authors in the production of web-based courses, in the design of user-adequate learning spaces and in the support of the design process. The IMIS is involved in a national project called "Distance Education in Medical Computer Science" (started in January 1999) which aims at providing a complete course of studies for the specialization of students in medical computer science offered at a virtual university (Hagen, Germany) (Kritzenberger/Hartwig/Herczeg 2001; Kritzenberger/Herczeg 2001).

2 Media Contexts in a User-Centered Production Process

The stages of media production (writing a book, transmission of the book into hypertext, hypertext functions, multimedia course, interactive computer-based training, cooperative learning) provide different contexts for thinking about media design for learning environments integrated in one process model of media production (figure 1), covering media features in cyclic sub-processes (similar to the spiral model for the user-centered software development processes as specified in ISO 13407). Furthermore, in the development of web-based courses we have to distinguish several problem areas for the media development process: Domain knowledge selection, teaching model, media features, interactivity, communication and collaboration. Most of the requirements come from the overriding demands of the teaching model. It is the main frame for specification of hypermedia, and has a secondary effect on framing the multimedia use and interactivity. For the pedagogic conception of interaction the main focus has to be on the learner's cognitive operations and information processing procedures. The decision is also the embedding of hypermedia, media use and interactivity in the overall learning environment. These requirements have to be made more concrete in the media design and is subject to discussion between content authors, media designers, pedagogic experts and several other specialists. That is, the case is not to enhance the hypertext with time-based multimedia like audio, video or animations etc.. The critical aspect of multimedia design is to use it for a more precise presentation of facts wherever it seems to be adequate, e.g. as a more concrete way of explaining processes, which otherwise would be too complicated to be explained properly and therefore could otherwise hardly be understood by the learners. For example, simulations can help to demonstrate how time-based actions follow each others in a complex process to be explained in the subject domain. In this stage of development it is helpful to analyze the kinds of knowledge involved in
order to deduce consequences for presentation. Furthermore, there is a larger organizational context of teaching and learning, where communication and collaboration environments are applied. We have also to understand the use of the multimedia and interactive learning environments in this larger context of communication and collaboration processes of the virtual university or other institutions where the web-course will be offered.

Conclusions
The model proposed in figure 1 is capable to deal with different media features separately and reflect them as contexts of learning. The model also shows an integration of the interdependence of human-centered design activities as specified in ISO 13407. For further work, this model has to be refined as a generic model for dealing with media contexts in the development of web-based learning environments in order to improve their development process and by this also their usability.

Abstract. Learning is an active, constructive and collaborative process, where people construct knowledge from their experiences in the world. People construct new knowledge with particular effectiveness when they engage in constructing personally meaningful products, that is meaningful to themselves or to others around them. The construction of knowledge from experiences in the world seems to be especially important in childhood learning, as children need to learn through their senses and through physical activity. Unfortunately, for school children there are few learning situations where senses and physical activity is involved. This is partly due to the nature of the concepts to be learned and partly to the lack of manipulative learning material. This contribution introduces a mixed reality environment as a collaborative and constructive learning space for elementary school children. During recent teaching experiments in an elementary school the children created their own mixed reality environment which served from a scientific point of view for a semiotic-based understanding for the creation and usage of physical and digital media bringing together arts and computer science.

1 Introduction

Education in the media age means to develop media competence and a deeper understanding of media characteristics starting from kindergarten age to high school education. The learning goal is to understand the design as well as the use of the media and also to understand the essence and nature of specific media.

Starting from these learning goals the authors are involved in a project called ArtDeCom ("Theory and Practice of Integrating Education and Training in Arts and Computer Science"). We try bringing together education in the two usually separated disciplines of arts and computer science in school on several levels of education. Pupils should be given an opportunity to explore the relationships of the two disciplines with adequate tools and learning goals for their respective age and learner level. The project is funded by the German "Bund-Länder Commission for Educational Planning and Research Promotion" (BLK) within the general funding program "Culture in the Media Age". It aims at investigating teaching material and situation for a curriculum definition for integrating education in arts and computer science on all educational levels. The IMIS is cooperating with the Muthesius Academy of Arts, Design and Architecture and with the Institute of Art History of the Christian-Albrechts-University in Kiel (Germany) to develop curricular elements for an integrated education of arts and computer science.

This situation is the background for the integrated lessons of arts and computer science in an elementary school in Luebeck (Germany). The teaching attempt is in the 3rd class level of an elementary school for children with an age of 8-9. During several lessons the children work in design projects developing their own mixed reality environment, within which they later perform an interactive musical revue. The children themselves develop the scenes of the mixed reality environment working in groups and using adequate software tools as well as real world materials. Collaborative and constructive learning is practiced permanently during the design process as well as during interaction with the hybrid environments of the mixed reality scenery.

A key focus of our research refers to cross-settings of ways of thinking in arts and in computer science. We think that mixed reality environments are a perfect learning space that enables children to explore concepts from both disciplines in an intuitive way.

2 Collaborative and Constructive Learning

Constructive learning theory addresses learning as an active process, in which people actively construct knowledge from their experiences in the world. People construct new knowledge with particular effectiveness when they engage in constructing personally meaningful products, which are meaningful to themselves or to others around them. Furthermore, it is important that the learning environment is authentic and situated in a real-life situation. Learners must get an opportunity to build multiple contexts and perspectives in a social context. Numerous examples have been given in academic context.
The construction of knowledge from experiences in the world seems to be especially important in childhood learning, as children need to learn through their senses and through physical activity. Today's kindergartens and playgrounds are full of physical objects and physical activity. But as children move on through elementary school and into secondary school, they encounter fewer learning situations where senses and physical activity is involved. This is partly due to the nature of the concepts to be learned. They are very difficult to explore with the senses when manipulative learning material is not available. One reason is that many abstract concepts seem to be very difficult (if not impossible) to explore with physical media. For example, traditional physical media generally do not support children understanding the behavior of dynamic systems or how patterns arise through dynamic interactions among component parts. Such concepts are typically taught through more formal methods, involving abstract mathematical formalisms. Unfortunately, many students have severe problems with this approach, and thus never develop a deep understanding of these concepts (Resnick 1998).

With this background in mind Resnick (Resnick 1998) has created a new generation of computationally enhanced manipulative materials, called "digital manipulatives", developed at the MIT Media Lab. They expand the range of concepts that children (and adults) can explore through direct manipulation of physical objects. They aim to enable children to continue to learn concepts with "kindergarten approach" even as they grow older. As children build and experiment with these manipulative materials, they form mental models and develop deeper understanding of the concepts they enact with. Children continue to learn new concepts with a "kindergarten approach". Resnick assumes that children learn with digital manipulatives concepts that were previously considered "too advanced" for them.

There are several other approaches with physical and tangible (graspable and touchable objects) interaction, for example MIT’s KidsRoom (Bobick et al. 2000), Triangles and 'strings' (Gorbet et al. 1998), Curlybot (Frei et al. 1999); StoryMat (Ryokai/Cassel 1999) in order to enhance collaboration among learners and enable constructive learning experiences for children.

Furthermore, several design projects with children have shown positive effects on learning and deep understanding (Alborzi et al. 2000; Druin/Perlin 1994; Stanton et al. 2001). In these projects children create external artifacts, like animate stories, video games, kinetic sculptures, models, simulations and so on, which they share and discuss with others. These artifacts provide rich opportunities for learning. As children are involved as active participants, they have a greater sense of control over the learning process. As they design artifacts in group work, they experience pluralistic thinking, multiple strategies and solutions. By the way they need to think about how other people will understand and use their constructions. Furthermore, design projects are mostly interdisciplinary and therefore bring together concepts from different disciplines.

3 Mixed Reality Environments as Learning Spaces

In our approach to constructive learning we use a mixed reality environment as a collaborative and constructive learning space for children. As we have discussed in the previous chapter, in early elementary classrooms children need manipulative material to initiate learning processes, as they allow exploration with the senses and therefore enable physical experience for the learner. They allow children to explore concepts by interaction and with their senses and therefore allow to build and to correct mental models and a deeper understanding of the underlying domain.

In mixed reality environments real world and virtual world objects are presented together on a single display. Mixed Reality techniques have proven valuable in single user applications. For example in other contexts single user mixed reality interfaces have been developed for computer aided instruction (Feiner/McIntyre/Seligmann 1993) and for medical visualization (Bajura/Fuchs/Ohbuchi 1992). These applications have shown that mixed reality interfaces can enable a person to interact with the real world in ways, which were never possible before. However, there has been less research on collaborative applications (Billinghurst/Kato 1999) or on interaction of children with mixed reality environments (www.animax.de) or even multi-user mixed reality environments and their use as learning spaces.

3.1 Design of Mixed Reality Environments

The mixed reality environments used in our lessons are designed by the children themselves in collaborative design projects. In the beginning the class is divided into groups, where each group works out a project development plan. It includes a story, the material to be used, the function of the computer and its connections and extensions to physical space. Afterwards there is a phase of creating, collecting and arranging objects for the mixed reality environment. These objects can either be of digital or of physical nature. Various materials for scenery creation are used, like wires and papier-maché (see figure 1). During the development process the pupils are acquainted with the hardware and software to be used.

Children collaboratively create their own mixed reality environment. During this working process the children get involved as active participants creating something meaningful to themselves and to others.
Furthermore, during the working process the children do not only create an animation for the digital world, but they also create the digital world. In our project they simply use a LEGO Cam for that task and LEGO MindStorms Vision Command to program the interactive sequences of certain picture recognition sequences (see figure 2).

3.2 Scenario: The "World of Dragons" music revue in a mixed reality environment

Figure 3 shows a sketch of the collaborative mixed reality environment, which was designed (as described in Chapter 3.1) by the children for a music revue "World of Dragons". It consists of an animation, which shows a wild landscape with mountains, trees, a watercourse, an active volcano, a cave and several moving dragons. On the stage within the physical world, there are several trees which have been made from the same material and look exactly like the trees in the animation. Between the projection wall and the video animation the children move and dance on the stage. They wear differently colored dragon costumes and dance to the music of Sergey Prokofjew ("Romeo and Juliet", "The Montagnes and Capulets"). The rhythm of the music as well as the narrative structures of the animation impose a certain timing of the acoustic and body expression.
Interactive music revue

By their movements and by the colors of their costumes the children activate different sounds in the mixed reality environment. There are also other sounds coming from objects in the mixed reality environment, like the blowing of the wind, the rolling of thunder, the volcanic eruption, the sound of an avalanche, the shouting of dragons, as well as the recurring sound of a stumbling little dragon.

3.3 How children learn from mixed reality environments

The learning experience of the children can be interpreted on several levels. On a concrete level of interpretation, children learn about concepts and methods in both disciplines, in arts and in computer science (see figure 4).

In an active hybrid environment the activities of the children ground in a physical world. They are engaged in the manual development of the "landscape". They create and realize the objects, which are used for the animation. They act and dance on the stage and interact with the animation by their movements and they influence the behavior of the computer program with signs like the color of their costumes. With iconic programming the learners bridge the gap between the physical world with its multiple meanings and interpretations and the abstract world of models and algorithms in computer science. Furthermore, an adequate tool is needed to realize programming experience for children. For our purposes we found LEGO MindStorms, Robotic Invention System and Vision Command fitting perfectly as a programming environment for the purposes of our project.

The most interesting aspect of children’s learning experiences in mixed reality environments is of semiotic nature and can be explained with the "teridentity relation" (x=y=z) of Charles Sanders Peirce.
Whereas in traditional ways of teaching only separated areas are interpreted from a semiotic point of view, in our form of transdisciplinary teaching we try to relate all possible signs to each other. It does not matter, whether these signs are of iconic nature, or if they are indices, symbols, individual events and states, or habits of predictive / relational, propositional or argumentative nature.

If we interpret the learning experiences of the children in a more systematic and semiotic way, we get the following situation and interpretations. According to Peirce (Hartshorne/Weiss/Burks 1997) there are 10 possible kinds of signs, where Peirce endeavored to construct a theory of all possible natural and conventional signs, whether simple or complex. This theory is helpful to explain how different levels of interpretation and learning experience are related to each other. We do not want to classify the elements of the transdisciplinary learning environment according to these 10 classes of Pierce, because this conclusion would neglect a lot and shift the focus to the theory. Instead we would like to focus to very important practical aspects:

- experience in design and creation of the narrative story; the dragons mirror the fascination and the anger of the world of the dragons as well as the kind of relationships between the children and their appraisals
- experience of the relationship to the body, to corporeality and being touched by others, especially children of the other sex
- experience of elements of mimic and dancing expressions (which exists independently of verbal expressions)
- empathy in music and rhythm, with its attributes like loud and soft, fast and slow, pretty and grave
- experience of the quality of material during the creation of the landscape (which is either light or heavy, hard or soft, dry or slippery) and examination of the shaping of the three dimensions of the room
- experience of the pictorial nature and modelling process during the creation of the digital animation, when single picture sequences are constructed from gradually changing the real world models
- identification of characteristic sounds and their integration into the narrative and expressive dance story of the music revue
- experience in abstract information processing for conception and development of the picture recognition program with LEGO-RIS Vision Command
- reflection on the different relationships of boys and girls to dancing as well as to computer technology
- experience on how attribute of objects in the real world (like colour, movement, position in the real world space) cause reactions in the virtual world, that is on the states and effects of the computer program

4 Conclusions

In our teaching attempt we found that mixed reality environments are a very promising learning space for a constructive and collaborative learning of children. The mixed reality environment meets all requirements for a constructive learning space for children, like learning through senses and physical activity using digital manipulatives.

In designing and in working with a mixed reality environment, the children construct a configuration of the world instead of a describing knowledge. They do this by individually creating and constructing the world and by subsequently freely interpreting their self-created world. During the performance of the music revue the children experience a singular event. However, for every event numerous interpretations are possible. By interpreting the world the children do not create an analytical but an intuitive understanding. The children are engaged in the world of constructing the objects, in the world of programming and in the world of behavior. They write programs and they control the computer program with their behavior (dancing, movements, colors of their costumes etc.). By this the children become...
themselves variables in the computer program when acting in the world of the musical revue. They act themselves as signs with different states and effects on each other as well as on the elements of the real and the virtual world.

Further research will explore the use of other computer-based learning environments as tools and environments for trans-disciplinary teaching and understanding in the field of arts and computer sciences. The research will be done on different levels of education and age.

SCHEDULING AND MONITORING DYNAMIC LEARNING OBJECTS ON THE WEB

J.J. KUISMA, J.A. WATSON

NTP Information Solutions Ltd, University of Huddersfield

1. ABSTRACT

Next generation web Learning Management Systems (LMS) will deliver courses built from small reusable learning objects and use systems to tailor curricula so that the learning needs of each individual student can be met in an automated and cost effective way. Web based Intelligent Tutoring Systems (ITS) aimed at compensating for the absence of a human tutor have to date mostly concentrated on providing assistance in a particular subject domain and not focussed on the problem of utilising content represented as learning objects across multiple subject domains. This paper describes the creation of a non-dictatorial tutoring system that employs a 'learning navigator' to help trainees visualise the best path through assignable units extracted from a learning repository. The system takes a unique approach to deliver personalised learning by taking advantage of the SCORM specification and storing content as Sharable Content Objects (SCOs), and therefore enabling the use of existing and third party content.

2. PARTNERS

This paper discusses a collaborative project between NTP Information Solutions (NTPIS) and the University of Huddersfield that has been set up to investigate different ways to enhance web based learning environments. NTP Group is one of the largest multi-occupational training providers in the UK Serving 25,000 trainees throughout the UK. Together with the four other companies in the NTP Group, NTPIS delivers a range of management, training and consultancy services for UK enterprises. A key part of the company's strategy is to provide e-training solutions directly to the work place across diverse sectors. At NTPIS creative designers use authoring tools such as Trivantis Lectora and Macromedia Flash to produce learning applications in the form of Sharable Content Objects (SCOs) that are then delivered as courses through a Learning Management System (LMS). This method follows the SCORM standard that facilitates interoperability of learning content between systems. The University of Huddersfield has a track history of research into the monitoring and scheduling of Computer Based Training (CBT) applications delivered over the Internet and delivers several of its MSc courses using the Blackboard LMS. Both organisations are aware of the low completion rates associated with e-Learning and are seeking ways to combat this by enhancing LMSs.

3. OVERALL VISION AND GOALS

NTPIS wish to develop a total Internet/intranet training solution for their customers. This includes developing the next generation of their LMS to include tutoring and guidance. Their vision is to provide a one-stop shop that will help their customers to grow, by the use of improved management information systems and by investing in it's most valuable capital; the employees and their knowledge. The next generation LMS will not just provide a training delivery platform but also act as the central point of access for getting help and advice. An agent will be integrated into the LMS that will contain a level of intelligence to answer trainee's questions and be able to direct trainees to the resources that they need. It will monitor activities and determine common learning and browsing patterns and suggest the best approach for each individual user based upon their profile.

This paper focuses on the problem of delivering personalised training for the individuals in a manner that matches the requirements of industry. It describes a system that uses a generic domain knowledge model and reusable-learning objects to provide cost-effective way to provide individualised learning experiences. The learning objects are authored to comply with the Sharable Content Object Reference Model (SCORM) specification to provide the interoperability across the LMS and content vendors. The system extends the SCORM by mapping the Sharable Content Objects (SCO) to the learning outcomes in the system's knowledge model. Small reusable SCOs are published in the data repository and combined dynamically, at runtime. The system provides guidance to trainees by suggesting appropriate learning paths through the content and gives information about the relevancy of SCOs depending on the profile of the trainee and their individual circumstances.
4. BACKGROUND

The use of e-learning has increased enormously during the last few years and even the most modest estimations predict huge growth in the future. The main reasons for this have been based on the Martini principle of delivering training anytime and anywhere, giving cost savings on the reduced off-site time, travel and accommodation expenses and trainer costs. However, a disadvantage of this approach is that e-learning can often lead to an isolated experience and not deliver sufficient tutoring or guidance. This factor has often been linked to poor completion rates for online courses. In a traditional classroom scenario training tends to be pitched to the average level of the people attending the class. This level may not suit all and training individually can, sometimes, provide an advantage if training is tailored to an individual’s specific needs. CBT and e-learning provides direct access to each individual being trained and should, in theory, be superior to the broadcasting methodology used in the traditional classroom if mechanisms can be put in place to provide an individualised experience. However, the benefits of this have not yet been exploited. Regardless of the fact that the training is done individually and at any time the trainee prefers, the delivered training content is still static for the trainee. The same limitation applies to the majority of hypermedia, as web content is often the same static information presented to each reader (Brusilovsky 2001). Academic research has delivered some pedagogically valid systems that pitch the level of training into the level of the trainee but they have been bespoke applications for a certain knowledge domain (Mullier et al. 2001). Also, the industry has developed several generic domain user modelling systems (Kobsa 2001) but nothing focussed purely on training and education. NTPIS require a system that can tailor content extracted from a repository of re-usable SCOs to a large diverse audience. To provide a cost effective solution for the enterprise the content has to be authored for the industry standards so that it can be reused and interchanged across the platforms.

The Advanced Distance Learning (ADL) is an initiative from the US Department of Defense (DoD), which is aimed for promoting the co-operation, between government, academia and business to develop e-learning standardisation. This initiative has resulted in actions that have delivered the Sharable Content Object Reference Model (SCORM), which is currently on version 1.2. The SCORM defines a web-based learning “Aggregation Model” and “Run-time Environment” (RTE) for learning objects. The aggregation model specifies how to aggregate the resources into the structured learning content. The RTE defines the common language and data model for the communication between the LMS and the content. This enables the true interoperability between the content and LMSs developed by the different vendors. SCORM has been the specification that has brought together pieces of the learning specifications made by other organisations, like Aviation Industry CBT Committee (AICC), Alliance of Remote Instructional Authoring & Distribution Networks for Europe (ARIADNE) and the Institute of Electrical Electronics Engineering (IEEE) Learning Technology Standards Committee (LTSC). NTPIS has recognised the advantages offered by following official open standards, and developed it’s infrastructure to implement the SCORM 1.2 specification. The ADL initiative envisions use of the training content to be developed as small reusable Sharable Content Objects (SCO), which could be stored in a repository used in various different courses. The first versions of the SCORM specification have already been well adopted by the industry and implemented in most of the leading LMSs. ADL takes the vision of interoperability and re-usability further, in it’s long range vision; once the SCO are commonly available they can be assemble in the real time, on demand and then delivered to learners. (ADL SCORM 2001).

This research has developed the system that implements dynamic scheduling by associating SCOs with the data of its learning outcomes and by developing the dynamical routing engine that can suggest to the trainee the different learning paths that can be taken to achieve the same learning objectives.

5. SYSTEM ARCHITECTURE

NTPIS have developed a web based LMS that acts as the infrastructure for delivering, managing and monitoring training in the work place. The system contains various interfaces that allow course authors, tutors, managers and trainees to create a customisable training portal that displays the user with the menus and menu-items based on the given rights. When trainees access this system they are presented with a menu showing the courses that they are enrolled on, where they are up to and what they need to do next. Content is developed using authoring tools, such as Trivantis Lectora and Macromedia Flash, in the form of SCOs and submitted into a learning repository using the Lesson Management Interface. A training manager uses the Course Management Interface to create courses by defining paths between the SCOs that are present in the repository. Work completed so far has focussed on...
extending these interfaces and including a 3rd interface; the Learning Navigator Interface. The objective of the Learning Navigator is to provide a graphical way to visualise the contents of the learning repository and the structure of the course the student is following. The interface allows the trainee to not only see the SCOs that form part of the course that they are enrolled on, but also any other relevant SCOs. The trainee can also view several different paths through to SCOs ranging from how the course was originally authored to what the system considers is the best path for the user to take in their particular situation.

5.1 THE LESSON MANAGEMENT INTERFACE

The lesson management interface (Fig. 1) is an access point to the learning object repository and provides the tools necessary for editing and registering SCOs into the system. The SCORM Aggregation Model defines the basic SCO information, such as name, description and keywords. We have extended this information by assigning the SCO with weighted learning outcomes (skills). These learning outcomes are predefined in the system and have been related to each other in a hierarchy, which consists of skills categories in a tree type structure.

5.2 THE COURSE MANAGEMENT INTERFACE

The course management interface (Fig. 2) is used to create courses from SCOs in the repository. Courses are assigned with learning outcomes that are expected to be achieved by taking a course. Like the skills associated into the SCOs, these outcomes are mapped to the same skill hierarchy. Course tutor uses his expertise to use learning repository to combine linear series of SCOs that fulfil these learning outcomes. This forms a basic course structure and is called a default Learning Path.

5.3 LEARNING NAVIGATOR

The Learning Navigator (Fig. 3) is an interface that is used by the trainee when proceeding through the courseware. It presents the trainee with the course structure that consists of Stage SCOs and Proximate SCOs. The stage SCO is a learning object that has been authored to be part of the course. The Proximate SCOs are dynamically pulled out from the learning object repository and recommended for the trainee, based on the skill relations that are assigned to the Stage SCOs and what is the trainee’s knowledge on the those skills. In addition, it presents the Learning Path recommendations made by the Routing Engine.

The example demonstrated above in figure 3 is part of a course on “Protecting individuals form abusive behaviour”. There are three stage SCOs, from which each has been grouped together with the additional Proximate SCOs. If the path viewed had been the default path (original path authored by the training manager) the path would be a straight line. However, the path deviates from this and shows a path that has been chosen by the Routing Engine. The Learning Navigator is also a trainee’s tool to get all the necessary information about the course structure and it’s different entities. This information can be divided in to two parts, the visual data and the text-based data. The text-based data is mainly
displayed in roll-over popup windows and contains detailed information about the SCOs, Skills, and course outcomes (e.g. Name, description etc). The visual data can be listed as:

- Stage SCOs
- Proximate SCOs
- Course learning outcomes
- Proximate SCO relations to Stage SCO
- Relevancy of the SCO (Which depends on the:)
  - Trainee level of the SCOs (Skills associated for the SCOs)
  - SCO relevancy towards learning outcomes (Mapped using skills hierarchy).
  - SCO relevancy towards the Stage SCO (Mapped using skills hierarchy)
- Different Paths with the order of the SCOs
- Current course position

5.4 ROUTING ENGINE

The decisions made by the Routing Engine follow loosely the framework used by Karagianidis et al (2001a). This defines the layered structure for the evaluation for adaptive and personalised learning services, which uses two distinct high level processes; Interaction Assessment and Adaptation Decision Making. The Interaction Assessment phase makes the high-level conclusions from the learner’s interactions during their learning. These conclusions are analysed by the Adaptation Decision Making component, which personalises the content for the trainee. The NTP Routing Engine (Fig. 4) applies this framework in the manner that complies with the requirements of the SCORM specification. The Interaction assessment has been implemented in the SCO Performance Assessment (SPA) module. This component makes conclusions based on the communication interchange using the SCORM RTE, rather than monitoring low-level events such as keystrokes and mouse clicks. Conclusions such as "The trainee 'Mike' has achieved 47% level on the 'Protecting individuals from abuse' skill", are based on trainee’s prior knowledge and analysis of SCORM data model items lesson_status, score and interactions collection. The benefit of this approach is that the learning content can be authored to the SCORM standard and all objects in the repository, whatever their subject domain, can be scheduled by the system. Some limited extensions to the SCORM standard had to be made so that SCOs could be linked to specific skills. Karagianidis’ Adaptation Decision Making component is implemented in the Pathway Generator (PG) module. This module passes the information about the Stage SCOs, Proximate SCOs and Pathways to the Learning Navigator. The possible paths could include:

- **Original** One that was authored
- **Generic** With SCOs that will generate widest range of knowledge
- **Fastest** Based on time taken by the previous uses
- **Suggested** Contains SCOs that best fit the users performance and entry profile
- **Popular** Based on what paths have previous users selected

The PG recommends new paths by assessing how relevant SCOs are to the learning outcomes of the course and the Stage SCOs. These relevancies are counted by taking the sum of the linked skill elements, which are counted by dividing the amount of the skill association percentage (A) by the trainee’s knowledge level on the skill (K). Each type of elements has a factor (f) that can be used to adjust the importance of the different type of relationships. Following formula is used to count the Proximate SCO relevancies. The Stage SCO relevancies ignore the last sum, which represents the Proximate SCO skills that are linked to a specific Stage SCO.

\[ R_{ps} = \sum_{\text{all skills}} \left( f_{a} \frac{A_{ps}}{K} \right) + \sum_{\text{linked to goals}} \left( f_{l} \frac{A_{g}}{K} \right) + \sum_{\text{linked to stage SCOs}} \left( f_{l2s} \frac{A_{ls}}{K} \right) \]
5.5 IMPLEMENTATION ARCHITECTURE

The system has been implemented using a client side Java Applet as the SCORM API and the Learning Navigator, providing the graphical user interface and interactivity required by the Learning Navigator. The functionality of the Routing Engine and all database access was left on the server side Java Servlet, implementing a scalable distributed client-server framework (figure 5). Even though there are other technologies to implement the required system (Sherman 2000), this framework was chosen because of the following benefits:

- Java Applet can be used to implement high quality interactive graphical interface
- Faster response times compared to http-CGI architecture
- Logical functionality mainly in the server side minimises the download size of applet.
- Distributed architecture provides better scalability and maintainability

Figure 5: The implementation architecture

6. VALIDATION

The proposed system will be validated and analysis will be made whether the pedagogical benefits match the estimations and if the logic of the system is suggesting better paths for the user. The intention is to follow the same validation process as Karagiannidis, Sampson and Brusilovsky (2001b). Validation will focus on three areas

- Overall success towards increased learning i.e. comparison with and without the Learning Navigator facility.
- Whether the SPA module can provide enough information to the pathway generator such that useful decisions can be made.
- Success of Proximate SCO and pathway recommendations of the Pathway generator

The granularity of the adaptation is dependent on the size of learning objects and the effect of this will need to be examined. In addition, we will need to measure how much users experience is affected when presented with SCOs that contain various different navigation panels and graphical user interfaces. This
can be avoided by the use of standard template, but when SCOs from various sources are used, the outcome might be disturbing. ADL envisions including the templates to the scope of future versions of SCORM.

7. CONCLUSION

This paper has discussed how a LMS can be extended to provide individualised tuition. There is little doubt that a relevant individualised experience should lead to an enhanced training experience. B learning is an ideal vehicle for deployment of individualised training because it provides direct access to each individual. We have demonstrated how courses can be represented as small discrete re-usable objects, stored in a learning repository, retrieved, and allocated dynamically at runtime. The e-Learning industry requires a cost effective solution of using existing/3rd party content and standard authoring tools to develop content. In addition, e-learning specifications, such as SCORM, should be used to provide interoperability between systems. At its current version SCORM requires slight extension to provide mechanism for delivering individualised training. Mapping the SCOs into a LMS skills architecture enables the PG to recommend learning objects outside the original linear course structure on the basis of their relevancy. Still, the analysis of the users interactions inside a SCO does not reflect towards a specific skill, but towards all skills associated in the SCO. The continued proliferation of e-learning solutions and the increasing number of trainees using LMSs means that the functions, which this project has provided could play an essential role in increasing learning effectiveness in the workplace.

We have demonstrated how courses can be represented as small discrete re-usable SCOs, stored in a learning repository, retrieved, and allocated dynamically at runtime.

Writing-4-Sharing—A Web-based Writing Support System

Kung, Shiao-Chuan & Liang, Ting-Wen
Wenzao Ursuline College of Languages
National Sun Yat-Sen University
Kaohsiung, Taiwan

Introduction

This paper describes a web-based application that facilitates the meeting of pedagogical goals of process-oriented communicative writing. It supports the teaching strategies used in an EFL (English as a Foreign Language) writing class and allows the construction of electronic portfolios. The system allows uploading and exchange of electronic files through the World Wide Web and performs administrative tasks. It makes possible the smooth completion of collaborative writing, process writing and peer reviewing activities, all essential components of the curriculum of this writing course.

Rationale

The "Writing-4-Sharing" system was developed in response to a dire need to manage the sizeable numbers of papers in large writing classes efficiently. One of the difficulties encountered by teachers of writing in Asia is the large number of students in a class. It is not uncommon for an EFL teacher to be facing classes of 30 to 50 students. While collaborative writing, drafting and revising, and peer reviewing are techniques that are frequently used in writing classes, they require that the teacher keep track of all the papers and all the changing team members of each assignment, thus burdening the teacher with menial record-keeping tasks. A system that can track assignments, assign grades to all the members of a team and publish the students' work in an electronic space where all the students can view each other's work and the corrections made by the teacher can support the teaching strategies mentioned and reduce the number of administrative tasks that the teacher needs to perform.

Description of the System

"Writing-4-Sharing" was created at the Wenzao Ursuline College of Languages in Taiwan and is currently being used in a freshman level writing class of English majors. The system allows students to submit drafts and completed assignments through the World Wide Web and the teacher to download them, point out the locations of the errors and send the corrections back also by uploading the papers onto the Web. This cycle can be repeated as many times as drafts are required. The teacher can therefore electronically monitor individual or group writing processes from the brainstorming phase to the final draft. The system also enables students to see each other's papers, thus facilitating collaborative writing and peer editing as well as viewing of the comments offered by the teacher to all the papers. In addition, the program tracks the papers submitted by every student and keeps record of all the grades.
After logging in, students are shown a personalized screen from which they can choose to view announcements, participate in discussions, view their portfolios, consult online resources, upload or download assignments, or check feedback given by a peer reviewer or the teacher.

The teacher's interface allows her to post announcements or course materials. She can also start discussion threads or recommend valuable online resources.

The program allows the teacher to see groupings of papers submitted by student name or by project name. She can download the papers and use features of Microsoft Word such as underlining, commenting, or coloring to mark places in it where correction is needed. When the errors have been marked, she can upload the papers back onto the Web next to the original paper. The system automatically renames each file when it is uploaded or downloaded according to a numerical scheme so that there are no problems with multiple copies of the same file name.

"Writing-4-Sharing" also allows the teacher to assign students to work individually or as a team. She can assign students to different groups so that students can collaborate on different projects with different partners. When a grade is given, it gets posted to all the members of the team. The teacher can also assign students to peer review each other's papers or to view model papers without making additional paper copies.

Using Technology and Constructivism in Business Law:
First Year Lessons

Richard G. Kunkel, J.D.
Department of Legal Studies in Business
University of St. Thomas, St. Paul, Minnesota
United States
rgkunkel@stthomas.edu

Abstract: Converting to new teaching methods incorporating technology and constructivist principles can be a daunting challenge for professors and students alike. This paper will present the author’s experiences in applying technology and constructivism to teach Legal Studies in Business. Students worked on realistic business problems that required them to conduct online legal research in an assigned U.S. state. The students used WebCT to post research results online; summarize and discuss the law, and collaborate with fellow students to reach solutions. The conversion to these new methods introduced several new layers of complexity to the teaching and learning process, including use of legal research techniques, bulletin boards, and new ways of evaluating student performance. Several strategies have been developed for easing the transition for new users of these technologies, and for enhancing the author’s second year of teaching with this method.

Constructivist learning principles call for teaching methods that are problem-based, realistic, ill-structured, and invite consideration of solutions from multiple perspectives (Dunlap 1999). The emergence of substantial legal information online has created new opportunities for problem-based learning about real-life situations by using the Internet research tools available in the real world.

The most distinct feature of the Legal Studies in Business environment is that applicable legal rules vary widely from one jurisdiction to another (unlike laws of physics, chemistry or other disciplines). Thus, business law provides a unique context for using multiple perspectives to engage in problem-based learning.

To capitalize on this opportunity, the author assigned each student to a specific U.S. state, and required the students to conduct online legal research in the assigned state to solve a realistic business problem. The students also were assigned to a group of four fellow students. Using a WebCT bulletin board, the group was required to collaborate to reach a group solution the business problem, even though the legal rules varied in the students’ assigned states. This process required students to analyze and synthesize the rules of law, and to deal with the complexity that is a part of the real world legal environment. Making the transition to this teaching method presented several challenges for students and the instructor.

Complexity.

This method introduced a much higher degree of complexity for students compared to traditional lecture environments. Students were challenged to learn how to use the Internet tools for research, how to use the Lexis -Nexis legal research database, how find legal information online, how to read and analyze cases competently, how to reconcile conflicting rules of law in multiple states, how to use WebCT, and how to collaborate effectively online. For many students, dealing with the added complexity in one or more of these areas was a difficult obstacle that interfered with learning. During this inaugural course, insufficient support materials were provided to prepare students for this adjustment and to lessen complexity. In the future, significant explanatory materials (e.g. “How to Read a Case”, “How to Handle Information in Lexis -Nexis”) must be provided.

Ambiguity.
In our educational culture students expect and prefer specific information about course assignments and their weight in grading from the opening days of the course. In preparing the first attempt of this new teaching method, it was difficult to predict student performance on problem-based learning, and thus difficult to state a specific number or problems or their relative weight. Two choices were possible. Be specific and lose flexibility to make adjustments as needed based on student performance, or be ambiguous, thereby maximizing flexibility but increasing student uncertainty.

In this first effort, the number and weight of the assignments was left ambiguous. Students were asked to trust the instructor’s judgment that the number of assignments would be reasonable based on their performance and that the relative weight of assignments would be adjusted at the end of the semester as fairness dictated. Many students struggled with this ambiguity regarding their workload and grading to a surprising degree. For some students it interfered with course performance.

To reduce ambiguity, instructors should be as specific as possible while retaining some flexibility. One approach would be to split the syllabus into two parts: a first part with specific numbers of assignments and grading, and a second part that will be pursued and adjusted if student performance permits.

Clarity of Instructions.

Constructivist principles hold that problems should be ill-structured and that learners’ have a high degree of autonomy. Accordingly, few restrictions were placed on how students organized the work of their groups and the form their responses should take. Instructions were general and often given verbally in class.

Students and groups that struggled in their performance often cited the “lack of instructions” or “misunderstanding” of instructions as a reason for their poor performance. Students expect specifics on what, where, when and how to perform, and several groups had difficulty exercising their autonomy in this area. Confronted with the challenge of problem-based learning, some groups appeared to use lack of specific instructions as a “cop out” for poor performance. Specific and clear written instructions should be given early in the course to set patterns for performance, and learner autonomy can be increased as the semester progresses.

Workload and Feedback.

This approach requires the instructor to assess a large volume of messages and legal information posted in WebCT. The method requires good methods for evaluating student posting, keeping adequate records and posting feedback to students. Disciplined, consistent attention to the WebCT bulletin board is essential. Students found it difficult to move forward on further assignments until sufficient feedback was received. A lack of timely feedback was a strong source of student frustration. Consistent and timely assessment is an essential component of the method.

Interface Design, Functionality and Course Evaluation Quality Assurance for A General Education Course at the University of California, Davis

Abstract

This paper discussed how a Mediaworks online course was checked for quality assurance focusing on interface design, features, functionalities and performance. Recommendations to improve QA practice concluded the paper.

Interface Design Features with Implications to Learning

Moby course development uses a familiar interface. The main LOGIN screen contains an embedded watermark of the UCDAVIS logo as a main background and two boxes where users input their username and password. The Main Page contains two main frames which divides the course’s contents and the Home Page Menu. The entire course is organized with the Lecture Menu, My Personal Information, E-mail Your TA, Review My Notes, Course Management, Paper Interactions, Administration and Acknowledgment information on the left side. The right side merely contained directions to click on course links. The Lecture Menu contained all 24 lecture modules supplemented with information about the course organization on the right. The screen frame is divided into four movable frame sections. The upper left section is the graphics page. The lower left is the lecture page where all lecture files are displayed. The upper right contains the module number while the lower left contains the lecture titles, sublectures, slides and graphic titles.

The Moby course generator templates allows designing course content in a variety of combinations. For Anthropology 15, content was presented using a combination of highly text-based lecture presentation with simultaneous audio version of the text. While this choice of mixing media method worked well for handicapped users, this arrangement is found (Hannafin and Hooper 1989) to place a huge cognitive load on the learner who have to simultaneously process two modalities e.g. sight and auditory, for the same information. Still another feature worth mentioning is the way information were grouped together in a screen by screen instance. The typical interface has a whole screen filled with a dense amount of text forcing users to read all lectures from the screen. A dense screen forces users to stare at the screen for long periods of time (Aspillaga 1996) and puts a big load on the user’s eyes. This is a feature that could be simplified if main points were bulleted. This could be complemented with an option for downloading and printing a PDF version of the same lectures eventually allowing users to read from printed text. The typical Moby generated course navigation options for the hypertext menu have been placed on the right side. Interface design research (Tullis 1997) on hypertext branching recommends left side positioning of navigation branching for ease, consistency and predictability. Screen by screen viewing for each lecture modules revealed a need for the eyes to move around the various information-filled frames detracting the user further from making a coherent sense of all information (Verdi 1985). Even if the basic usability design requirements were not met by the course, the design choice was consistent until the last screen. The navigation options for all lectures were placed in the same predetermined design location adhering to user-interface design principles of consistency and predictability (Tullis 1997). By using the text with audio combination to present lecture content, the course design fulfilled the W3C requirement for accommodating various users including people with handicap.

Quality Assurance for Anthropology 15

QA Testing of various linkages in the course modules required clicking on all available active links from course lectures to all graphics files. This was a highly important part of the QA testing and was considered of utmost priority over features testing. The graphic file must match the link. When a file mismatch occurred the problem was immediately alerted to the person assigned and was resolved immediately. Features corrections was also ranked in order of importance from highest to lowest priority. An unresolved issue of highest priority would be one which will alter the course organization, the course content and the message being conveyed such as teaching about gorillas and the graphics shows no relation to gorillas, e.g, picture of an urban landscape.

1 Doctor of Curriculum and Instruction, Instructional Systems UCF and Research Analyst, University of California Davis IET Mediaworks, 2 Mediaworks is the Information and Educational Technology arm of UC Davis 3 Moby Course Development is developed in three server environments, the development server, the test server and the production server. The Development Server has a machine name of halfmoon.ucdavis.edu. This server takes care of the code design, development and graphic design in Windows 2000/IIIS system and web server. This server allows limited user-defined security groups (EduTech and Mellon Team) with the write access limited to these same two groups and the Administrators. The Test Server has a machine name of cloudybay.ucdavis.edu. It is a Windows 2000/IIIS system. This is where all data files are loaded and updated during the testing phase. The Production Server named halfmoon.ucdavis.edu is housed at and managed by the UC Davis Data Center. It is a machine with a UNIX box with Solaris 7.0/Apache serving as the system and web server. The procedure sequence starts with the issues log. This log becomes the source of allocating tasks among members of the development team. The team leader then assigned tasks based on this log. The team leader by e-mail, that the code is working. If more work was required the programmer would likewise be notified. Recommendations to improve QA practice concluded the paper.

More suited to people with a auditory and visual handicap.

Hypertext linkages within Lecture Modules are located on the right side of the 4 frame lecture page screen

World Wide Web Consortium is a consortium that develops, recommends and standardizes and disseminates information related to web technologies.

91088
There was a major drawback to doing quality assurance testing for the online course within a very limited time. First, the quality of the product is not assured. Technical glitches may still be undetected and can pose serious problems to the course. Second, depending on the severity of the problem, the course may require redesign and redevelopment which can cause severe drain on the development team's resources in terms of time, human, and equipment. In addition there is also the added pressure imposed on the morale of the entire members of the team who have to go through the whole project cycle. Quality assurance in an online course delivery is a lot more complex than traditional format because rules are not fixed and clear-cut and standards are evolving. The basis of comparison for both formats are totally different. In the traditional method we have a human imparting the knowledge. In a computer-mediated course the human is replaced by a machine. While course content remain unchanged the criteria for evaluating one against the other can be approached in various combinations and in many different ways.

Acknowledgments

The online version of Anthropology 15 was developed in collaboration between the content provider, Dr. Alexander Harcourt and Mediaworks, the central media unit in the UCDavis campus using a content delivery system called Moby and the campus portal, MyUCDavis. Acknowledgments are due to Prof. Harry Matthews for infrastructural information on Moby online course development and Dr. Barbara Sommer for course evaluation information. Special thanks are due to the Andrew W. Mellon Foundation who provided the grant to support the Mellon project.

Applying Knowledge Map to Intelligent Agents in Problem Solving Systems

Rita Kuo*, Maiga Chang*, Da-Xian Dong*, Kun-Yuan Yang*, and Jia-Sheng Heh*
Dept. of Information and Computer Engineering*, Center for Teacher Education+
Chung-Yuan Christian University
Taiwan

jsheh@cycso1.ice.cycu.edu.tw

Abstract: According to the four steps of problem solving proposed by Marshall in 1995, a knowledge structure is designed based on the Concept Map and the Concept Schema, which is so-called Knowledge Map. Knowledge Hierarchy derived from Hierarchy Map of Concept Map can be used to indicate the relationships among concepts, whereas Concept Schema represents the information of the corresponding concept. After the Knowledge Map is well analyzed and designed, three functions for manipulating knowledge in problem-solving systems, such as matching operation, locating operation and loading operation are considered. And finally an intelligent agent within Knowledge Map to accomplish problem-solving steps is implemented to providing assistances for students in distance learning environment.

Introduction

After the invention of computer, some interactive programs, called CAI Systems (Computer-Assisted Instruction Systems), are developed for help students learning. There are many previous researches from building a proper problem-solving system for students to solving a common problem by using computer system (Mayer 1992), such as four steps for solving mathematic problems (Polya 1965), seven stages of problem solving for science experiments (AUP 86), and so on. Another interesting research issue in CAI Systems is Intelligent Agent. Some Intelligent Agents are used for helping students doing science experiments in V.E.E. (Virtual Experiment Environment) (Huang et al. 1999; Kuo et al. 2001); the others are used to diagnose students' learning status in problem solving systems (Chang et al. 1999; Heh 1999; Chang et al. 2000). In this paper, an Intelligent Agent is designed with a kind of knowledge structure, Knowledge Map, to help student solving problems.

Using Knowledge Map for Solving Problems in Intelligent Agent

This paper proposes a new knowledge structure used for problem solving called Knowledge Map. The idea of Knowledge Map comes from Concept Map and Concept Schema. An example of Knowledge Map for partial domain of Physics is shown in (Fig. 1). The gray blocks are the original Concept Map and are drawn as a Concept Hierarchy, which comes from the idea of hierarchical Concept Map. For example, the concept, “Motion with Constant Velocity,” is one type of “1-Dimensional Motion.” The correspondence of white block to the gray one is the Concept Schema, which comes from the definition of schema in (Gagne et al. 1993) for presenting natural categories, events and text of a concept. Take “Motion with Constant Acceleration” for example, it has its own definition “acceleration is constant” and the physics formula “rule $v_t = v_0 + at$”.

After constructing the Knowledge Map, some operations for manipulating knowledge in problem solving systems have to be designed in an Intelligent Agent: 1. Search-Operation; 2. Locate-Operation: finding what concepts should be accessed; 3. Load-Operation: loading contents in concept schema into the short-term memory. To use the Knowledge Map for Solving Problem, this paper follows four problem-solving steps extended by four types of knowledge schemas (Marshall 1995; Cheng et al. 2001). In (Fig. 2), a problem loaded into a Problem Solving system. This problem is processed through four steps:

1. problem identification: loading problem into problem solving system and using knowledge map to construct Knowledge Object Schema (KOS).
2. problem elaboration: elaborating the KOS.
3. problem planning: translating KOS to Problem-Planning Schema (PPS) and using knowledge map to do problem solving plan.
4. problem execution: using PPS to get the answer and produce results.

All these steps get knowledge from knowledge base in long-term memory and produce different schemas stored in short-term memory.

Fig. 1 Knowledge Structure - Knowledge Map

Fig. 2 Flow Chart of Problem Solving Agent

Conclusion

This paper proposes a new knowledge structure for problem solving called Knowledge Map constructed by Concept Hierarchy and Concept Schema. Concept Hierarchy indicates the relations between concepts and Concept Schema stores concept-related information. This paper also shows the four steps of problem-solving and designs three operations for manipulating knowledge on Knowledge Map. With these operations, Knowledge Object Schema and Problem-Planning Schema are created to complete the whole problem solving process and help Problem Executor to generate results. The feature work of this paper is to change Knowledge Map to reticular one, increase (or insert) knowledge automatically, and construct Knowledge Map from natural language.

Using Digital Terrestrial Broadcasting in Schools

Haruo Kurokami (kurokami@mbc.sphere.ne.jp)

Abstract: Digital terrestrial broadcasting is going to be introduced into Japan and there may be some possibility that it can be used for educational purposes in schools. We conducted an experiment to try DTB collaborative learning in three elementary schools. Students in these schools watched TV as the main content of DTB and then received information from other schools from data pages. Interviews of teachers and a questionnaire to the children revealed that it is interesting to use DTB as a learning tool but there are still some problems to be solved.

Digital terrestrial broadcasting (DTB) is going to be introduced into Japan and there may be some possibility that it can be used for educational purposes in schools. We tried to explore the possibility of using DTB in schools using them as a tool of collaborative learning in three classrooms.

1. Purposes and Framework of the Experiment

The purposes of this study was to develop a method to design multimedia contents on data broadcasting, to try the interactive function of DTB, and to make a list of necessary conditions as to learning using DTB. We chose three elementary schools for our experiment; the Attached Elementary School to the Faculty of Education of Kanazawa University, Meisei Elementary School, and Takahama Elementary School. Each school has an excellent IT teacher who leads other teachers. Attached elementary school is in the suburbs of Kanazawa city, Meisei elementary school is in the middle of Kanazawa city, and Takahama Elementary School is in a country area near Kanazawa city. Every school has a river near by and has an integrated curriculum for environmental learning in the sixth grade.

2. Outline of Implementation

Students in each school watch shows as the main content. The shows are from a series of TV programs named “The only one earth,” which deals with various environmental issues for fifth and sixth graders in Japan. Collaborative learning with this series had already been tried and the results were analyzed (Kurokami, 1998, 2000). We were allowed by NHK to use this series for our project. We picked up two shows about “water” because topics of learning in the project schools are about water; river, water pollution, water insects, water usage, and so on.

After watching TV, students learn in depth about issues in the show deeply for their area. Sometimes they go to a field or a river outside of school and investigate the number of insects, the extent of water pollution and the way to clean up water. Afterwards, they make a multimedia data broadcast to be aired with the next main show.

The curriculum for environmental learning started at the beginning of sixth year. In the spring term, each class learned about environmental issues independently. After the summer vacation, they started learning about the environment collaboratively. We conducted DTB learning three times during this period. The main show of the first DTB was “Water and Human Life” and the content of the data broadcast was a self-introduction. They identified relationships between various phenomenon and human activities and watched the self-introductions from the other schools. The self-introductions contain photographs of schools, students and teachers, and texts about their learning
activities. The second DTB was on Oct. 26, 2000. Topics of the main broadcast were about the ways to clean up water. Children of the Attached Elementary School visited Sai river and filmed their activities. From this, they edited 17 short movies out of their original digital videotapes. Meisei Elementary School contributed two short movies to the data broadcast. These movies became the main resource of the digital broadcast. The last broadcast for the children was to exchange comments with each other by way of a data-broadcast using up-link to the broadcasting center.

3. Result and Conclusions.

We conducted formal interviews with teachers three times during the experiment and conducted a questionnaire to the children after the period of the project. Answers from the questionnaire were as follows:
- It was very interesting to find out about the activities at the other schools.
- I would like to know more about the other schools.
- Watching the shows and the data was very interesting.

From this, we can think that most students were interested in the collaboration with DTB.

On the other hand, teachers said that it was very difficult to control the stream of learning. One of the reasons is the delay in seeing the data. Data sent from each school is connected to the show of previous broadcast. Therefore children have to watch the next show first before they can see this data, which is downloaded to each school behind the main show. It might be a little confusing for children. The other problems cited by teachers are as follows:
- Lack of data cache: The system we used had no cache for the main content at all. We could not stop the TV nor re-watch it. Also we could not cache content of the data. Each show was 15 minutes long and watching data from the other schools took more than 30 minutes. A lesson in Japan is 45 minutes. Therefore, there was not enough time to think nor discuss topics from the show or the data. It is necessary to add a cache device to the system.
- Difficulty of BML editor: Children can write up their data using Broadcast Markup Language (BML) editor, but operation of the BML editor is not easy to understand. Sometimes using the BML editor was confusing for some students who has knowledge of HTML. BML editor has to be come more user friendly.
- Screen operation: The most confusing thing for children was that a mouse could not be used for the data broadcast. It is designed to be manipulated by remote control. Therefore children needed to be familiar with the screen and the movement of DTB.
- Time for editing: Children have to film and take pictures of their learning activities. Then they have to integrate these materials into a series of document. However, it is time consuming for the children to edit their own film and pictures into a multimedia broadcast of DTB. It was educational for children to carry out this activity, but it took too much time. A more flexible curriculum and time schedule are necessary.
- Limited size of movie file: In the regulations about DTB, each component on a data page cannot be over 1 MB. As the size of some movies from schools was more than the limitation, we ourselves put the big movies on the HDD of each television set and linked them to the data pages. Therefore, we need to increase the limitation of bytes. School children are increasingly making digital movie at school as a learning activity, so they need to be able to present all of their data.
- Privacy policy: People who could watch the DTB were strictly limited in this experiment, because there were only three sets on which to watch it in the Hokusiku area. Therefore, we could publish private information in the broadcasts. When this is launched on a full-scale, we would have to hide this information. The problem of privacy policy will occur at that time. If we use DTB for collaborative learning, we would need communication channel to exchange private information.

We think there is a huge possibility for using DTB as a learning tool in the future. These results will be useful for our next experiment.

Abstract: Through the Preparing Tomorrow’s Teachers to Use Technology (PT3) project, online distance courses in College of Education at New Mexico State University (NMSU) have become an essential component of the Teacher Education Program. Pre-service teachers have been engaged in the process of learning with and about technology. The main purpose of this study is to describe and analyze College of Education students’ beliefs, expectations, and attitudes toward online learning. This is a qualitative ongoing case study. Through purposive sampling techniques, twenty-one students from six different online graduate courses in the College of Education were selected as participants. Videotaped interviews have been conducted to explore and evaluate students’ reflections toward online learning in its natural environment. This study is exploratory in order to allow insights to emerge from a recursive data analysis process. The variables in the site of the research are highly complex and extensive. The research data is very context dependent and needs to be collected in its natural environment without controls and manipulations.

Overview of the Study

Over the past few years, online distance education has been explosively popular with College of Education students at New Mexico State University (NMSU). The Preparing Tomorrow’s Teachers to Use Technology (PT3) project has been helping faculty integrate online learning environments into their courses. As a result, the College is dealing with the enormous growth of the electronic learning environments, which has encouraged the University to open its door to learn and teach in virtual milieus where students and professors can communicate with each other electronically. With the rapid growth and increasing accessibility of the Web, many professors are now offering various types of online-based courses, ranging from partially online to completely online, to their students. Email, electronic conferencing, synchronous and/or asynchronous chat and electronic bulletin boards have been used to enhance many classes in the College of Education. With the use of virtual learning milieus as a supplement to on-campus classes as well as in online classes, there is no doubt that the traditional classrooms are no longer bound by time and space in the College of Education.

When used appropriately online distance education can provide increasing numbers of convenient and relatively inexpensive learning and studying environments; it also has the potential to support real-world experiences to not only faculty but also students at NMSU. The College of Education has invested heavily in WebCT as a virtual learning environment. Since WebCT has provided new opportunities to use the Web as a medium for instruction, many courses and programs in the College of Education have been rapidly changing to keep pace with the use of WebCT.

WebCT is a unique educational delivery system. The use of WebCT, however, as a delivery medium in the academic setting in the College has started to change students’ roles and learning strategies. Unlike traditional education, WebCT as an instructional tool has started to make College of Education students take responsibility for their own learning at their own pace in their own space. Learning with
WebCT has also put students at the center of their learning process. Professors are embracing WebCT into their curriculum both for online instruction and to supplement traditional education by incorporating new ways of accessing, delivering, exchanging and sharing information with their students whose beliefs, expectations and attitudes toward online learning have become an important tool for addressing problems, which may arise in implementing online tools.

Technology Integration into Learning Environment

WebCT by itself is just an electronic data source for the students. Like the use of any other educational media, designing WebCT as an instructional tool must be based on instructional theories, design models, and strategies. Since information can be sent though WebCT quickly, students may need to carefully redesign and revolutionize their new roles around online learning, methods, techniques and strategies in interactive and collaborative virtual learning activities.

This study has taken a grounded theory approach to allow the researchers to explore and discover the students' reflections toward online teaching for two reasons. First, increasingly academic institutions are beginning to offer graduate level teacher education courses online. Secondly, online learning opportunities and students' beliefs, expectations and attitudes toward online learning are relatively new phenomena. Students' reflections, however, toward online learning need to be more clearly defined, examined and/or analyzed to integrate and implement this technology into the curriculum efficiently. However, there is a lack of theoretical or empirical research on this topic (Wills & Becht 1997, Mendels 1998, Valenta et al 2001).

The main purpose of this study is to examine College of Education students' beliefs, expectations and attitudes toward online learning in higher education settings. Before entering the study, the researchers tend to analyze the research data inductively rather than to prove or disprove a hypothesis. The main focus in this study is: 1) to investigate and understand the insider's views toward teaching online courses in different subject areas, and 2) to expound on this study participants' perspectives and interpretations rather than researcher imposed categories.

Research Design

Participants and Setting

The purpose of this study is to investigate the students' beliefs, expectations and attitudes toward a particular phenomenon of online learning in different subject area experiences. During the 2001-2002 school year, research was conducted within the College of Education at New Mexico State University, a mediumsized research university in the Southwest. The College of Education has been offering classes online (in various degrees, i.e. enhanced or completely online) approximately four years.

The students in the College of Education were chosen for three major reasons: First, many members of the current students have been strongly interested in using the web as an instructional tool to make possible communication between regular class sessions (Baptiste & Kurubacak 2002). Each week students would post their assignments and any questions, concerns, or ideas online. The students could read, receive, post, exchange and/or share information on the discussion topics of each week before and after class. Sometimes students would email the course professor's account directly, when they had particular questions, suggestions and/or comments any time. Second, the most of course curriculums in the College of Education have included both computer-based learning activities into classroom and web-based learning activities, WebCT has been used for posting the students' messages and papers via email and electronic bulletin board. Finally, the majority of students in this study have been considering the idea of taking courses completely online in the near future and some of them are already taking courses online.

Twenty-one students from six different online classes in Teacher Education Program at the College of Education were identified for the interviews according to their willingness to participate the study. Four of these twenty-one students were male and seventeen of the participants were female in this research.
Data Collection

This study utilized qualitative data to provide detailed information to the researchers for analysis. Video and audio type taped interviews have been the instruments in this study. Therefore, the open-ended interview questions are designed to collect and analyze data on the students' beliefs, expectations and attitudes toward online learning in different subject areas. Each interview's questions were developed and modified according to investigating the focus of this study.

The researchers allowed the participants from the six different online courses in Teacher Education Program, as groups, to set the interview dates and locations themselves. Face-to-face interviews were held with all six groups in the College of Education building. Each interview lasted approximately 45 minutes in length. Although all interviews were video and audio recorded, the researchers wrote notes that summarized the major points of each session.

Researchers have been following a careful data management process to ensure high-quality accessible data and documentation of data collected. For these reasons, the researchers regularly recorded and systematically stored qualitative data on computers and videocassettes. The data has been indexed for easy and consistent retrieval.

Data Analysis

The analysis of the students' beliefs, expectations and attitudes toward online learning on the different subject areas is an ongoing process, that began at the end of the Fall 2001 semester and will continue through the final written report. The data analysis process in this study is analytic and recursive to inform further decisions on data being collected. It also is restructured, flexible and open to the discussions with the stakeholders and reviews of related literature.

During the data analysis procedure, the researchers briefly followed these steps given in a logical order: 1) transcribed each video and audio type cassettes, and 2) identified patterns and themes. After transcribing the cassettes and identifying patterns and themes, the researchers triangulated the qualitative data and reported the results in descriptive and narrative form together.

Discussions and Interpretations

Content analysis of this study indicated that students have both positive and negative beliefs, expectations and attitudes toward online learning. Among the students' positive reflections in this study were that online courses could provide not only enhanced flexibility, but also student convenience and access to updated course information. Among some of the negative reflections that students reported about their experiences with online learning was decreased human interaction and collaboration as well as the increase in students' course work. The lack of technical support and knowledge about technology seems to be major problems for the students in this online learning environment.

Positive Students' Beliefs, Expectations and Attitudes toward Online Learning

The participants in this study learned best when they developed positive attitudes toward virtual learning environments. These positive attitudes motivated them to solve a problem, accomplish a task, set specific goals, work with others and informational resources during the learning process. However, it took time for these students to adopt a positive attitude towards online learning. The twenty-one interviewees in this study could eliminate their possible biases toward online learning when the instructors were aware of which WebCT methodologies and techniques affected their beliefs, expectations, and attitudes.

Therefore, the structure of any online course must involve determining the overall instructional approach, the theoretical and educational basis for that approach, potential strategies, methods, and instructional activities (Bannan & Milheim 1997). The participants in this study especially emphasized that they enjoyed working within the virtual environment because of enhanced flexibility, convenient course scheduling, and round-the-clock access to course related information.
Flexibility and Convenience

The participants in this study were working full time or part time while earning their master or doctorate degrees in the College of Education. The majority of students had to commute at least one hour to the campus everyday. What was most important to students in this study was that online distance education not only provided flexible time management, but also allowed them to save on travel time.

All of the interviewed students in this study stated that they could work anywhere at their own pace. Monica pointed out, “It’s comfortable for me to study at home, especially after the children go to the beds...but you have to discipline yourself, otherwise you can easily focus on doing housework rather than doing your assignments in your cozy study place” However, the participants in this study were also aware that it required high self-discipline and self-confidence. Robert stated, “I would like to study at home, however, you have to firmly arrange your schedule... to take the class online is different from...to attend the class on the campus...Also you can raise your voice online to ask a help when you need. It’s not easy every time...sometimes I feel I am the goofiest student in the class [laughing]...WebCT-based course requires self-discipline. It is easy to be frustrated and drop out.” Robert was not the only participant who felt that the online learning environment was different from face-to-face class settings. Nineteen of the other participants also agreed with Robert’s viewpoint on virtual learning milieus; “students roles and responsibilities in online classes were not the same as their positions and tasks in a traditional face-to-face course”.

Access the Course Online

Twenty-one interviewees highlighted that they could find useful information about the course and course work in their virtual class. These participants also pointed out that they regularly accessed WebCT to get online course information throughout the semester. All participants in this study indicated that they enjoyed reading about the course and assignments. One of them, Juanita, made her statement on this issue: “you can read the instructor’s messages before coming to class...I had a hard copy syllabus, but I always check the online one, if she [the instructor] changes the schedule or announce new activities.... I can learn new information very promptly, it is helpful.” Juanita had significant previous experience taking WebCT classes and did not lack self-confidence. She regularly accessed the course web page from work because her work place provided a faster modem.

Of twenty-one participants, the majority pointed out that they would like to read the assignments posted by the other students in their classes. John stated: “[I] always read the posted assignments...especially before the class...I am amazed...the people focus on different details on the assignments...sometimes I have never ever thought these details.” John also highlighted that “[it] was very difficult to express himself or herself sufficiently...like at the face-to-face class.” However, the majority of the interviewees in this study reflected their anxiety about the online assignments and other posting messages. Tim expressed the following statement: “[it’s] kind of weird; because everybody can read you...not only the instructor.” The participants in this study felt that they were more motivated to work hard on their assignments, because the professor and other students would be reading them.

Negative Students’ Beliefs, Expectations and Attitudes toward Online Learning

There were three main barriers for the students in this study to learn with online environment: 1) technological problems, 2) lack of technical support, and 3) lack of knowledge about technology. The students in this study sometimes had difficulties accessing the online course. John stated: “[It’s] frustrating to have problems, it’s frustrating not to find the solution, and not to fix it.” The lack of accessibility to the online course created negative reflections toward virtual learning milieus.

This study indicates that students are more successful online when they are trained on online learning and have regular technical support. Students must be encouraged and motivated to take full advantage of online learning milieus.

Limited Interaction and Collaboration Online

Interviewed students indicated that they did not have enough information about online learning and their changing roles in electronic learning settings. Kim stated, “[I] always miss the class online, thus it
is very hard for me to catch up... At the beginning of the semester, I had no idea about how I could access the course WebCT site, it took nearly over three weeks to learn, it is really heart breaking." Thus, they did not successfully nor actively interact with other students, faculty, and online educational resources. Also, the majority of the participants in this study stated that they needed to learn the skills of online communication. John pointed out, "[Maybe] another form of communication is needed online. WebCT courses require high-level self-discipline as well. You have to logon regularly the course."

There were many comments that specifically addressed the lack of collaboration in online learning. Tim expressed his feelings about online collaboration, "[Online] communication is not like to communicate somebody else in person. WebCT is not for me to talk with other. I always prefer to interact my friends face-to-face. It's warm and comfortable. You cannot get feedback promptly online. You have to always be careful whether somebody else answers you or not." When the interviewed students communicated with each other on WebCT, the students were not able to reflect on their experiences and fix their learning problems. The participants in this study, however, indicated that a majority of students in College of Education when lacking knowledge and experience with online environments tend to generate a lack of confidence when communicating online. The learning strategies, methods, and activities in online learning setting are different from face-to-face courses. Uncertainty creates curiosity, anxiety, and conflict in these students who have low comfort levels with using online technology. As a result, the students were less eager to participate in online learning. While virtual learning settings might be helpful in achieving vital educational goals, faculty members suggest that face-to-face communications are important to promote effective social interactions among students and between students and faculty.

The majority of the interviewed students preferred face-to-face class interactions. They also pointed out that their age, gender, personality, and cultural backgrounds highly affected their participation and contributions in various educational settings. Juanita strongly stated, "I am better at face-to-face communication in person than at communicating online. I would like to observe the mimics, gestures and body languages when talking with someone. I have to see the eyes when I am communicating with her/him." Like Juanita, John (another participant) made few comments to the online course. He acknowledged that the variety cultural backgrounds of the students could support effective communication, but the face-to-face communication was more valuable and helpful than online interaction.

In addition, the online learning, communicating, and writing skills of students could be major barriers to interactive online learning. Kim highlighted that "[special] 1 learning skills are needed for taking a WebCT class...for example writing is not easy for me...I don't enjoy typing the keyboard to do my assignments...It takes too much time for me to type, and it is not fun...It is easy for me to speak in person." Like Kim, Tim stated, "[Reading] on screen is very difficult...I have to printout each screen to get the real his/her point of view" Juanita, like Kim, also expressed similar feelings about studying online, "[I] am one of the slower, and it takes all my time to write something for the class...I don't like it." When an online learning environment has cross-cultural communication and uses a systematic approach to deliver content, online students can connect theory and practice as well as have more in depth reflection in the construction of knowledge.

**Overwhelmed Course Work**

The majority of the participants in this study felt more time was spent on the WebCT class than in regular classroom. Jane loudly expressed her feelings with the statement, "[I] did have to work very hard for the online class...I strongly feel online courses required more work." All of students in this study pointed out that they often times felt overloaded with information in their online classes and that virtual learning environments required more work. The majority of the participants in this study, like Jane, expressed their feelings of being overwhelmed by not only the quality but also the quantity of contributions of the instructor and other students. Kim pointed out, "[I] feel I cannot write and think at a high level like the others in the class...I think it's depend on the course content, but I lost my concentration on the coursework..." One of the most challenging aspects in implementing an online learning in higher education can be the structure and instructional strategies of the course content.
Conclusions

The body of the research literature dealing with students' beliefs, expectations and attitudes toward virtual learning milieus is small, but growing (Valenta et al. 2001). Online learning in higher education is a recent phenomenon, which requires more research as well. The use of virtual learning environments is gradually shifting, so it is necessary to keep pace with improvement on the learning process. The use of online communication in academic settings is increasing rapidly and has become a vital issue studied. This study shows that the key points of online learning are to offer online learning techniques and to provide reliable and regular technical support. In addition, encouraging and motivating students to take advantages of virtual learning as an educational tool is also a necessary measure to insure effective utilization of the online learning milieu.

An essential step in integrating online learning environments productively in higher education is starting with an explicit definition of the educational role of online learning and understanding the changing roles of students in virtual milieus. Integrating online learning into learning can lead the College of Education to adapt changing roles, needs, interests, and concerns. Students are, doubtlessly, one of the most important components in online teaching. On the other hand, the roles of students have been changing dramatically in virtual learning milieus; their needs, concerns and roles vary substantially from face-to-face educational settings. The major problem is that many students do not understand their responsibility to be active contributors of learning in the virtual milieu and that the professor's role is to be a facilitator and a mentor. Therefore, not only must students be trained how to instigate and contribute as online participants on WebCT, but they must also acquire good online learning skills and strategies before taking a WebCT based course.

To create a successful collaborative online learning environment, group or cooperative learning must be emphasized among students, and between students and professors. Virtual collaboration, which covers active participation and interaction, are essential experiences that students should have. Thus, WebCT must organize and structure online interaction among students, professors, experts from the outside, and/or global online resources with fewer time and space limitations. Online learning must also encourage and engage students to work together during learning activities. Conversely, promoting and maximizing group work and collaborative learning in a virtual environment is not easy. It is also difficult to identify social presence, authentic tasks, and cognitive strategies such as taking ownership of a task whose cognitive challenges are consistent with the cognitive demands of the design environment. This environment must support knowledge construction and idea sharing. This virtual learning setting must also enable students to continue work on their own tasks.

The overall teaching atmosphere in College of Education is highly academic and professional. Nevertheless, lack of online learning experiences and computing skills affect students' beliefs, expectations and attitudes toward online learning. The major challenge facing students is learning how to restructure their learning styles (through the use of online learning for better utilization of current resources) and how to implement improvements in online learning milieus. The delivery of courses via virtual learning environments requires training students in ways that maximize and allow them to further adapt their educational strategies. Thus, it is an essential issue to provide excellent training and technical support for higher education students.

Abstract: In this paper, we describe the development of an adaptive multimedia learning environment that utilises multimedia presentation techniques in its interface while still providing Internet connectivity for management and delivery purposes. The system supports the WWW as its addressing space but uses the local client areas to store media items expensive in terms of delivery time. Learning objects that provide frameworks for tasks and other summative assessment activities are stored on a server and delivered when required. The system supports link annotations in its adaptivity and employs an overlay student model with stereotyping when accessing the course content.

Keywords: Educational multimedia, Adaptive Systems, Dynamic course generation, Student profiles.

1. Introduction

Large classes of students with different cultural and academic needs, coupled with the large range of individual approaches needed to deal with some of student learning issues raised above, have created problems for institutions catering for large numbers of students. A direction that a number of academic institutions have pursued is to place course materials in an on-line format. These materials can either replace pre-existing lectures/tutorials, or supplement it. Needless to say, a great variety of educational materials exist for possible reuse within the public domain and are available via their Universal Resource Locator (URL).

As has been pointed out [17, 18], the World Wide Web (WWW) provides a vehicle for the development of a learning environment with teaching structured towards the development of lifelong learning skills, and catering for the expectations and learning styles of students with a wide range of backgrounds. Early Australian examples of the use of the WWW in IT education abound. Boalch [3] provides an examination of the use of the WWW as a support medium for the delivery of a first year unit in Information Systems at Curtin University. He provides an evaluation of site utilisation and user feedback in the case where subject information and course details were provided on the WWW for students.

The Eklunds [8] examine the use of the WWW to supplement traditional IT teaching. They provide case studies of two examples of the re-structuring of traditional forms of IT course for Web-delivery. Jones [11] of Central Queensland University gives details of case study involving the design, presentation and evaluation of an undergraduate unit in Systems Administration taught completely via the WWW to on-campus and distance students.

However these and many newer systems that have been developed, rely on the low-level concept of interactivity (derived from a distance education paradigm) as the relationship between an individual student and text, and fail to use the technological interactivity, which is available. Common online learning environments often fail to maximise the potential of current multimedia resources. While the value of HTML pages and threaded discussions is acknowledged, they do not display the ability to adapt teaching material for the needs of individual students.

Multimedia objects within learning environments, provide a possible enhancement to the presentation of our on-line materials. Ricketts [16] describe the successful use of a hybrid CD/WWW presentation of course materials delivered in distributed mode where multimedia elements were provided on CD. The Herringtons [9] describe the benefits of multimedia within authentic assessment used in a teacher pre-service course. Looi et al [13] describe a collaborative WWW based system that provides for on-line communication and collaboration in the creation of multimedia artefacts for the WWW.
Further, Jonassen et al. [10] take the position that the true worth of multimedia and hypermedia might be obtained through the learner constructing knowledge via the use technology, rather than as a mode of delivery. Although the authors agree that the creation of multimedia and hypermedia artefacts is a powerful mechanism for individual learning, we do not discount the learning benefits attributed to the construction of different media views of content; we would argue that more individual learning styles could be accommodated.

Our view then of a learning environment is a domain populated with instructional items, presented as either multimedia or hypermedia objects with some addressing mechanism. This address might be a URL, or a directory path to a locally stored object. We use the term object to conform to the IEEE Learning Technology Standards Committee specification [7] for learning objects and further, agree with Wiley’s [20] interpretation as ‘any digital resource that can be reused to support learning’.

2. **Adaptive Teaching**

Various researchers who have experimented with adaptive teaching on the WWW have used techniques and principles derived from Intelligent Tutoring Systems (ITS) and particularly Anderson’s rule based cognitive modelling [1]. Others have used Adaptive Navigation Support [4] to provide adaptive navigation through hypertext pages and thus developed adaptive textbooks for the tutoring, particularly, of software applications [4].

ITS and hypertext/hypermedia architectures provide different means of access to the educational materials contained within the knowledge domain. Hypermedia systems employ referential links that enable users to typically follow non-sequential paths; organisational links (eg hierarchical) do provide some structuring that maps the expert’s view of the domain. The pedagogical module of the ITS, provides information about the teaching process; this is non-existent in unstructured hypermedia systems and the user is generally free to explore the domain.

Adaptive systems couple the course model with a student model to provide adaptive navigation support. An adaptive system that makes available specific content (adaptive presentation) [4] provides students with a format of the new knowledge and skills appropriate to the students’ level of understanding. Alternately, the system might provide links to appropriate content (link level adaption) [4]. Some systems also employ stereotyping within their student modelling structure. This appears to be an appropriate technique where distinct student groups with similar characteristics can be identified. However, any system based on stereotypes and preferences should be observable and thus editable by the user [12].

This paper presents techniques that are being developed to provide adaptivity within an introductory multimedia course¹, the aim of which is to provide the foundational knowledge and skills required to create and utilise a range of media items within multimedia presentations. The students undertaking the course come with a diverse range of knowledge and skills. The prototype developed is referred to as an Adaptive Multimedia Learning Environment (AMLE).

3. **Implementation of AMLE**

AMLE is essentially a collection of multimedia and hypermedia learning objects that are tagged with and address or path that enables the system to locate it. Learning objects, irrespective of their form and functionality, can then exist on remote servers, or indeed as local files. Our architecture is based upon a concept which has associated documents similar to [15]. Concepts can vary in presentation and can have hypertext/hypermedia links embedded within them; concepts are further grouped into sessions.

a. **AMLE’s Architecture**

Two major decisions were undertaken in the early development of the prototype; firstly, to ensure that our items were consistent, we decided to use Adobe Acrobat pdf files as the default format; every concept has a

version in this format. Associative links within these files can address the WWW in total, as well as the local file space. A player called a concept viewer to display concepts in this format, has been created.

The second decision taken was to keep media rich items on the local file system. The rationale for this was that the course offered initially would be administered each semester and the concepts would be static over this period; the time taken to deliver these materials would be greatly reduced. However, these still could be accessed through their URL if they existed on a server.

We have created an event driven interface (client) with Macromedia Director that provides hypermedia functionality, and a range of concept viewers to support different media formats. The main interface of the client connects to a remote server and accesses data defining both the course domain and the student profiling information. Thus, media files that constitute concepts and related activities are stored locally but administered over the WWW.

This WWW connectivity then provides the facility to monitor student usage and register assessment items. Lecturers/tutors interact with the course and student model through a standard WWW browser. Other learning objects that document assessment tasks and/or other course information are stored on the server side and accessed through either a WWW browser, or the main interface.

We have developed this multimedia learning system using Macromedia Director, ColdFusion, HTML and CGI Perl script that allow rapid prototyping; our main interface exists as a run time version while some tools and other applications can exist as source code. This is of significance in the initial course on offer because students can create multimedia artefacts that can be inserted directly into their workspace.

**b. Interface details**

The main interface provided for students to access the learning materials can be classified as a hybrid browser. It takes advantage of the multimedia development environment and enables a range of concept players to be used depending on content availability and student preference. These range from a concept being displayed as text formatted with HTML tags, to a concept being displayed as an acrobat pdf file, containing both textual and graphical information. Video and audio formats can be utilised, along with appropriate animations. A range of other appropriate tools is provided in the interface to enhance the learning environment. For example, on-line tutorial groups can be established with the ability to discuss particular content-based issues.

The main interface is a windows environment that initially provides authenticated logging on/off facilities. Once identified and registered, the user is provided with the current session, or the pre-test for that session if that is the first time that the student has accessed that session. From there, individual concepts can be accessed through a session player. Sessions are groupings of concepts and tasks that the domain expert has predefined for the course. This would correspond to the content provided in a weekly lecture(s) and associated tutorial/practical activities.

It has been argued that link annotation [6] provides the user with extra information about the content available, enabling a more informed decision. Annotations are employed within the session viewer to indicate the content that a mouse click will provide. Where the system can infer that the student knows the concept or can perform the task, the session viewer is annotated accordingly. Links are not hidden so that the student is still able to follow it for revisional purposes.

**c. Domain knowledge**

Our course model is organised hierarchically into courses, sessions, concepts and documents. Sessions have been defined from concepts; sessions can have any number of concepts but a concept can only appear once within any session of a course. A concept consists of many documents; a document can be the content of a concept, its objective or some practical activity.
Our implementation is supportive of other possible domains of knowledge; the delivery system then is content independent. Tools for both the generation and subsequent use of the system have been investigated and an on-line database supporting both the student and course models, has been established. The placement of content into small modules, provides a mechanism for the flexible reuse. The course metadata is stored on a remote server along with the student profile information. We utilise an overlay model [5] and allow WWW access to this information.

To accommodate a range of students at various levels in their programmes, we pre-test at the session level. Another alternative considered and still to be investigated, might be to pre-test at the course level and infer knowledge from the results. For the practical components, students might be able to demonstrate the possession of some particular skills; this then needs to be handled manually and/or electronically.

The content of the delivery system is relatively static; that is, the teaching components that are delivered through a range of players accommodating text, pdf modules, video, audio, animations, etc. and any other media format that might become available in the future, are stored at the client side. The components of the delivery system involving the course structure and assessment pieces, student profiles and assessment results, data of those on-line, are stored on the server side.

Assessment at the concept level is based on a competency model; an evaluation is made of a student’s understanding of a concept through questioning. Mastery of these randomly selected questions is reflected in the student profile that drives the adaptivity within the system. Where a concept is a skill or task, students may be asked to do something and have it registered manually; for example, the concept might be the scanning of an image. The concept might be demonstrated and the student asked to perform the task; completion of this task is manually registered. We distribute weekly tasks and longer summative assignments etc. through a server when required.

d. Instructional design

The hypertext/hypermedia learning environment constructed allows the instructor to employ a range of instructional methodologies. Constructivist principles underpin the environment and are supported; students create multimedia artefacts and place them into their workspace (or on the WWW), search out content, and satisfy authentic tasks. These in total, provide the macro level scaffolding [2] that allow the students to use particular content in different, albeit overlapping, contexts.

We are developing tools (search engine, glossary, concept map) to enable the user to search and access concepts directly as required. As students become more familiar with the environment, the instructional strategies may vary; for example, more problem based learning activities could be introduced. These activities might relate to the construction of multimedia artefacts, the acquisition of some understanding, or the establishment of a reasoned point of view with regards some ethical issue like copyright.

Student/student and tutor/student interactions are being established via online discussion groups which have the potential to support collaborative learning. This could be tutorial discussion groups with a number of their peers currently logged on addressing some weekly task. The number participating in these discussion groups is 4 by default; however, this is a system parameter and can be changed. Students are initially allocated on a first in, first allocated basis but any part of the student profile could be used for this purpose.

e. Student and course administration

An on-line instructional management system has been constructed to establish courses based on concepts and sessions. An 'Administration Tool', enables course coordinators to create particular courses and direct content at particular groups. We have the potential to administer concurrent versions of a course directed at particular groups.

Lecturers and tutors have WWW access to our student model. Lectures can add/delete a tutorial group, add a new student, search for existing student, and update student's detail such as tutorial scores, assignment scores and exam scores. Tutors have access to update and search facilities of students' tutorial and assignment details.
AML uses and maintains student profiles that contain a summary of the student's competencies and other preference information. The coupling of the course model with the student profile has the potential to allow students to proceed at their own rate through the learning material. Further, the management system enables tutors to enter marks electronically and subsequently manage the assessment components of the course. Reporting mechanisms then cope with student, tutor and course co-ordinator requirements.

4. Current and Future Work

Our major concern has been to provide adaptivity and interactivity for our students since we recognise that our students' backgrounds and cultures contain a wide range of learning styles and expectations. We have used the on-line management components of the proposed system to maintain the assessment profiles of current students. However, the web-based materials that have been used thus far have not provided us with the granularity at the concept level to enable adaptive technologies. To this end, we have created a range of prototypes with varying interfaces to access the course model, and a number of players to display the content. These will be trialled with students in the near future.

A range of tools including tutorial chat facilities, notebooks and email, are provided in the interface for the users to take advantage of. Further work will involve the pre-testing of students and the full utilisation of student preference data collected.

The range of questions and question types that are randomly presented and marked by the system are a topic of current investigation. Results from these form the basis of the student's competency model and the subsequent adaptivity. Tutors are able to enter marks directly into the student competency profile for tasks where the competency for a concept can be demonstrated. The student's competency profile is further enhanced by an assessment profile that includes summative activities that could extend over a number of sessions. Both profiles are available to the students through a WWW browser interface that displays their current competency and assessment states.

A number of instructional methodologies and educational activities underpinned by a constructivist philosophy are being explored. So too are the different tools that will be available within the interface; for example, an online helpdesk that simulates a tutorial helpdesk situation where students pose questions to tutors who are currently on line

5. Conclusion

We are developing components of a multimedia learning environment that we feel have the potential to enhance on-line learning. The system presents course materials as concepts and adapts to prior knowledge through the use of link annotation. We have also introduced stereotypes into the overlay student model and have coupled this to different content presentations. Students can also specify the type of media presentation they prefer to use within the concept viewer. A range of other tools like search engines, indexes, helpdesk, tutorial groupings etc. will allow the lecturer to employ a range of instructional methodologies to satisfy the requirement of the course.

The dynamic components of the learning environment i.e. assessment, course structure, and other instructional artefacts, are stored on a remote server and are accessed through the WWW. Tutors have convenient on-line access to student groupings to enable marks entry.

We utilise two forms of assessment; namely formative assessment that includes the mastery (or competency) of particular concepts or skills conducted generally at a weekly level, and summative assessment that necessitates the use a range of knowledge/skills in its satisfactory completion. These are recorded within the overlay model of the student profile. Student preferences and settings, along with marks etc that make up the assessment profile of the students model, are available to the student for perusal and alteration.

Abstract: The E-Education and Research Unit (www.cs. hut. fi/ itlab) has provided multiformat eLearning courses since spring 2000. The eLearning platforms underpinning these programs are WebCT (www.webct.com) and Edulink (www.edusolutions. fi). In autumn 2001 the Education Unit launched its first fully Internet-based courses using the investigative learning theory as a background theory and applying the well-known 7-Step Model of the Problem-based learning. The 7-Step Model was supplemented with orientation module which included personal assignments such as setting own learning objectives and selecting the methods to reach them. Mediamaisteri LTD's (www.mediamaisteri.com) eEvaluation tool was selected for self-evaluation. Two studies are in process concerning these courses: adults' comprehension of ICT as a tool of developing and creating their own expertise are examined as well as the development of critical thinking as the manifestation of the students' epistemological autonomy.

Working with the 7-Step Approach on the eLearning Platform

The E-Education and Research Unit (www.cs. hut. fi/ itlab) has provided multiformat eLearning courses since spring 2000. The eLearning platforms underpinning these programs are WebCT (www.webct.com) and Edulink (www.edusolutions. fi). In autumn 2001 the Education Unit launched its first fully Internet-based courses using the investigative learning theory as a background theory and applying the well-known 7-Step Model of the Problem-based learning. The focus of the 7-Step Model is in rational, individual problem solving and information gathering which proceeds step by step. The steps of the model are clarification of terms associated with the case, determining the problem, analyzing through brainstorming, constructing an explanatory model to describe the phenomenon, formulating learning objectives, information gathering by self study and application and evaluation of knowledge. (Schmidt 1983.) The method trains to solve problems in groups, problems of which one have no previous knowledge or information.

The eLearning courses lasted from August to December 2001, accounting for 2 or 3 credits. Some 60 students completed these courses. The 7-Steps Model was supplemented with orientation module which included personal assignments such as setting own learning objectives and selecting the methods to reach them. Mediamaisteri Ltd's (www.mediamaisteri.com) eEvaluation tool was selected for self-evaluation.

The groups organized themselves independently, with each student joining a group that had targets closely matching his/her own. After an orientation session, each group was given a case-study and the general discussion forum provided by the Edulink platform was closed. In line with the 7-Step Model, the groups elected a chairman and a secretary at the very beginning. The teacher's role was to support the students and the group as and when required. Group work proceeded independently and the tutors played their planned guiding role. Technical support and the tutors of the groups monitored the step-by-step progress and the completion of the individual learning tasks while also providing related guidance and feedback.

The Studies and the Preliminary Results

The main issue addressed by Mrs. Inkeri Laaksonen's Master's Thesis is to clarify adults' comprehension of Information and Communication Technology as a tool of developing and creating their own
expertise. Another issue that the thesis addresses is how adult students perceive their own expertise and whether the learning culture changes as it moves towards eLearning. The target group is adult learners who are studying Master’s Degree in Computer Science while being employed on full-time bases. The qualitative basis, and the basis for the research methodology of the thesis, is existential phenomenology. The research method applied is Colaizzi’s method of phenomenological psychology (Lehtovaara 1995; Valle & Halling 1989, 41–59).

The method selected for gathering material for the thesis was written stories. The preliminary results of the thesis indicate that group work on the Internet was perceived to be easier than conventional face-to-face group work, and that shy or quiet students could make themselves heard more easily over the Internet: “Discussion forums of eLearning platform have helped me take other people’s opinions into account”, “Group work is much freer over the Internet than in face-to-face groups”. On the other hand, the eLearning culture is taking its first steps, and this is reflected in the stories. ICT plays a large role for some of the writers: “ICT has played a very large role in developing my expertise”, “Without doubt the Internet is a natural place for most people to develop themselves, seek information and keep in touch”. Some writers miss social interaction: “All of us want to talk with other people about other topics besides work or school every now and then, but on the Internet that kind of small-talk is impossible and therefore getting to know someone else is impossible in that environment”. The ease of searching for and finding information on the Internet in the course of developing one’s expertise was underscored in the stories, although critical inspection of the authenticity of the information was regarded as a problem: “I think that faced with today’s information overload, filtering out correct and useful information from incorrect and useless information has become a key issue”.

Facilitating autonomy could be regarded as a broad principle in the philosophy of education, which can be carried out in different learning environments and with learners of different ages. Autonomy has become a part of distance education as study modes in adult education have developed. The aim of Mrs. Tiina Front’s doctoral thesis is to specify the concepts and conceptions of the learner’s autonomy and of open learning environments, especially eLearning environments. The main goal is to define the criteria or dimensions that could be used to analyze the development of the student’s autonomy and the roles of support, interaction and distance in this developing process. The learner’s autonomy is defined here as the autonomy of action and autonomy of thinking (Launis 1994), on the one hand, and the epistemological autonomy and trans-situational autonomy, on the other hand (Candy 1991). The development of critical thinking is the manifestation of epistemological autonomy, which is the focus here. Garrison et al. (2000) describe the development of critical thinking in the practical inquiry model.

The data gathered from the eCourses at the Helsinki University of Technology will be coded and analyzed according to the four categories derived from the cognitive presence descriptors (Garrison et al. 2001). The results will show how the 7-Step model supports the development of critical thinking in terms of increasing the learner’s autonomy. The preliminary results are presented in ED-Media.

Helping Teachers COPE with Student Performance Data: 
An Interactive Assessment Database Tool

Abstract: Project COPE (Computer Organized Physical Education) is a data management system designed to help teachers productively deal with the inordinate amount of assessment data they encounter. When teachers collect performance data on paper based forms it is difficult for them to use the information efficiently. Project COPE involves the use of a computerized data management system coupled with hand held recording units to record and organize information about student performance. This technology is useful in all educational settings including the classroom and the gymnasium.

Introduction

Project COPE (Computer Organized Physical Education) began as a data management system to help elementary physical education teachers productively deal with the inordinate amount of assessment data they encounter in teaching (Lambdin, 1997). Elementary physical education teachers often teach 300-600 students and have contact with the same students over a five to seven year period from kindergarten to fifth or sixth grade. However, information about student needs often is not passed on from year to year in usable formats because of the overwhelming number of students and difficulty in organizing the huge amount of data. When teachers collect performance data on paper forms it is difficult to use them efficiently. It is very time consuming for teachers to transfer data from paper to computer systems after class is over. This causes teachers either to spend a great deal of time doing paperwork or to give up attempts at tracking student progress. Because the cost to benefit ratio of data recording is so high, teachers often have chosen to collect only the simplest data on student learning (test scores). The data often are used for the sole purpose of calculating a grade for the report card and then discarded when a new year and new grade book are started. Given the difficulty of recording and manipulating student data, the teacher's memory has been considered the best device for identifying student needs when planning for instruction.

Dynamic Data Management System Components

Project COPE uses a database created in FileMaker Pro to organize the data, and hand held units to aid in one step data entry. The use of PDAs (Personal Digital Assistant) allows direct data input during class activities rather than having to transpose from teacher notes. When dealing with hundreds of students and scores of objectives this direct entry option is crucial. Just as hand held units are used by clerks in stores and meter readers on the streets, teachers across the country are beginning to use PDAs to provide for efficient assessment data entry during teaching and learning activities.
The current system has been developed so that it could be used in any content area. There are six main functions in Project COPE. They are Students, Assessments, Individual Data, Class Summary, Help Data, Mastery Data, and Reports. Using the various features supplied with the Project COPE templates, teachers identify which grades, classes, and semesters they are teaching. If necessary, teachers can create new grades or a new class with ease within the program. After initial setup the teacher is able to assign three or four objectives to assess on any given day. This information is then exported from the desktop computer to the personal hand held device using Filemaker Pro Mobile. Teachers enter data for students on the various objectives using the hand held device during their teaching. After data are entered in the PDA, the sync capabilities of the PDA transfer the collected data from the hand held device to a computer. Using the find, sort, and script capabilities of the database teachers are able to easily determine which students have mastered each objective and who still needs additional help. The organization of information in this way is invaluable in making instructional and lesson planning decisions. Another advantage of utilizing Project COPE in classroom teaching is that feedback information can be printed out in customized report cards which indicate specific individual mastery of learning objectives rather than just a letter grade. This enables complete and useful information about learning and performance to be viewed by students' and their parents. Finally, summary information for use in program evaluation can easily be compiled.

Conclusion

The impact of the use of dynamic and interactive systems such as Project COPE is enormous. The general system is equally useful in recording emergent reading characteristics, use of problem solving mathematical strategies, performance characteristics for mature throwing and catching, and the exhibition of pro-social behaviors. Teachers are able to efficiently record data, easily manage data and effectively use the information to individualize instruction and monitor the success of their own teaching. Students receive the benefit of appropriately targeted instruction. Parents receive specific information about their children's learning needs and teachers and administrators are able to obtain often elusive summary data on program impact. If knowledge is power, Project COPE provides teachers, students, parents and administrators with increased power in learning environments.

Hard Choices for Individual Situations by Bruce Landon, Ph.D.

Overview

The Decision Dinner - a parable about the weighted average decision strategy
by Bruce Landon and Nancy

The novelty of the proposed decision process can be illustrated by a parable about a small group of decision makers and relating it back to the online learning product selection situation. First, assume the task of selecting a restaurant for a board of directors' first dinner in a new city. Also imagine that this dinner is pretty important, perhaps not quite as important as the Nixon dinner in China, but a dinner of consequence, nonetheless. The first steps in the process would be to scan the available resources to see which restaurants (like product providers) are available and then to proceed to get menus (lists of the features available in each provider's product). The menu information could be augmented with reviews of the items on the menu but this would still not be enough. What the decision making group needs to know is what kind of items the members of the board actually like to have for dinner, i.e. which menu items are important to them. So the group decides to collect some more information by sending out a stakeholder survey to find out what each of the board members enjoys for dinner.

To construct this survey, the decision making group had to make a short list of restaurants (product providers) and from their menus make a short list of the most promising items (important features) because the board members would have never responded to a survey that was as long as all of the menus from every restaurant. The group sent out its survey and analyzed the results to calculate the importance weighting for each of the dinner menu items. Knowing the consequences of making a mistake on selecting a restaurant for both the decision makers and the board of directors, they elect to use the most rational decision making strategy known: the weighted averaging strategy.

To be able to use this strategy, the decision makers will have to find out how suitable the menu items actually are. So they have dinner at each of the restaurants to taste and judge the quality for themselves. Not only do they have to carefully taste the suitably of the menu items (features) but they must rate each one on a consistent scale so that the scores can be used in the weighted average strategy. They decide to all use a scale where 0 means awful and 10 means wonderful on suitability rating forms used when they go to the restaurants. Then night after night, dinner after dinner, they evaluate the suitability of each of the short listed restaurants on all of the important menu items. Finally using the board members' weights for each menu item and the decision makers' suitability scores for each menu item at each restaurant, they calculate the winner from the data collected.

The winning restaurant is the one that has the highest average score when the menu item weights are multiplied by the menu item suitability scores. The decision makers make the reservations with the winning restaurant and the board of directors proceeds to have a great dinner. The board of directors was impressed by the rationality of the group of decision makers but in truth they were more impressed by the dinner after which they voted to give bonuses to the decision makers and all live happily ever after.

Selecting an online educational delivery application is analogous to selecting the restaurant in the parable above. The members of the board of directors are analogous to the stakeholders who will be impacted by the selected product i.e. the students, faculty, staff, and administrators. If the consequences of making an error and selecting the wrong product were not important there would be no need to be so rational as to use the weighted average decision strategy and the group of decision makers could use a less rational process. When the consequences are important such as in the assigning of course grades then a very similar rational process is most often used called weighted averaging grading.

This chapter will focus on faculty use of a decision-making process for complex situations. The analysis part of the process describes and compares course management software focusing on: technical specifications, instructional design values, tools and features, ease of use, and standards compliance. The extensive comparisons provide faculty with side-by-side product feature descriptions. The decision-making focus of the chapter and of the companion site is on supporting a detailed rational decision process for selecting course management software. This decision process uses a grading style model familiar to educators that compensates for the cognitive illusions and limitations of decision makers to achieve a transparent decision process for selecting the "best" application for each local situation. The current site obviously meets needs for decision-making support as evidenced by 16k visitors a month to the site. By the fall of 2002, there will be similar decision-making supports available which will focus on student services, teaching technologies and online education policies.

Introduction

Faculty make decisions every day and most of them are informal choices about what looks good on the menu for lunch. Sometimes, faculty make quite formal and rational decisions about which student gets an A and which student gets an F. A strategy of weighted averaging. The way in which decisions are made often reflects the importance of the decision
and the situation as well as the decision maker. The research in psychology over the last few decades has illuminated some of the strengths and weaknesses in the way that people make decisions with the important finding that in many situations people are less than rational decision makers. When a person is overloaded with information or under time pressure then their decision-making can be quite compromised and they seem to use “rules of thumb” to make a decision. The case of selecting an online educational delivery system is examined from this perspective in this chapter. First the difficulties facing the decision maker are addressed and then a remedy is demonstrated to show how decision-making can be assisted to prevent the decision process from being compromised by these “rules of thumb” using a web tool for comparative analysis.

Why choices are difficult

Too many products

The situation is reminiscent of the early automobile industry when there were over a hundred automakers. Like the early auto industry many other competitors will not survive in the long run. The current front-runners: WebCT and BlackBoard started out as small almost personal projects a few years ago and are now multi-million dollar enterprises that span the global education marketplace. There may well be others out the current products that will evolve into the major brands of tomorrow as the market matures. The point of this analogy is that selecting a learning management system is much more complicated than selecting a new car, in part, because there are so many competing models. There are over 100 products in this marketplace that range from relatively simple limited function applications like WebBoard which just provides threaded discussions and chat to complex enterprise wide learning systems that link to backend databases and administrative data systems used by colleges and universities. Previously in 1997, I had attempted to characterize these products as components or suites by this categorization turned out not to be useful because there were so many variations from product to product he became difficult to classify new products. Also, the products in this marketplace evolve quite rapidly with a new model or version almost every year, like automobiles. So to deal with this rapidly changing market it seems better to characterize products in terms of the features that they provide.

Too many product features

The feature and tools are organized in terms of the group that they are most likely to be interested in them: Learners, Learner Supporters and Technical Administrators. These major groupings are further divided into subtypes of features/tools and finally into the individual features of the product. This schema has grown over the years and the language has changed as well so that some of the terms have been replaces in common usage by other terms as in the case of Newsgroup being supplanted by the term discussion or forum. A glossary of terms provides some help for those who are unfamiliar with this area (http://www.c2t2.ca/landonline/glossary.html), but the fundamental problem is that there too many features/tool about too many products to keep track of easily (products * features = 3474 facts) especially to keep track of in your head. The most frequent problem in making good decisions in this kind of situation is that of forgetting or omitting some important part of the problem when making the decision. Often we are overly optimistic about how big a decision problem we can do “in out head.”

Too little working memory in decision-makers

Nobel laureate, Herbert Simon (1979) characterized the human decision making capacity as having “Bounded Rationality” (also see Gigerenzer & Selten, 2001). When people face decisions they operate within the bounds or capacities of the human mind. They are limited by fallible perceptions, wandering attention, faulty memories, and fluctuating information-processing abilities. People don’t optimize, but instead resort to simplifying rules of thumb in order to proceed with their decision-making. These limitations have been investigated for decades with the repeated finding that working memory limitations play a major role in limiting the ability to make rational decisions.

The notion of limited memory was articulated well by George Miller (1953) as the magical number seven plus or minus two “things” that you hold in your mind at once while working on a problem (presumably due to a phonological loop process, Baddeley 1986, cited in Anderson 2000). This limited working memory is a profound handicap for a rational decision maker because when one works with ideas in the head then one is moving them around sort of like a juggler. When there are too many “things” then some of them will get dropped or set aside from consideration in the decision-making. Stated in another way, decision-making becomes more difficult as the number of things to consider increases and quickly reaches a point of overloading working memory.

When facing difficult decisions, people encounter overload and then they resort to ways of coping that involve cognitive shortcuts. When overloaded, they are more susceptible to cognitive illusions (Kahneman and Tversky, 1996). Cognitive illusions are similar to perceptual illusions in that they stem from the fact that in both types of illusions the person can focus only on a small part of the situation at one time. In the case of perceptual illusions this is because the fovea of the eye that sees fine detail encodes only a small segment of the spatial panorama at each fixation. In the case of cognitive illusions this is largely because the conscious working memory can hold only a few “things” and the rest must be inferred or extrapolated in ways that are sometimes biased. In both types of illusions the person is not necessarily aware of any “illusion” at all and may believe that they are “seeing everything correctly.”
Too many Cognitive Illusions in Decision-Making

The discrepancies associated with cognitive illusions may be seen a little more clearly in contrast to an idealized rational decision process. In the idealized process, one starts by selecting relevant features/criteria and then assigning an importance weighting to each of those features. Next one evaluates each choice option on each of those important features and assigns a suitability score. Finally one makes the rational decision to choose the option with the highest weighted average suitability score (the average of the weights for a feature multiplied by the feature's suitability score). Choosing the option with the best score is the rational decision (Keeney and Raiffa, 1976 as cited in Roe, Busemeyer and Townsend, 2001). With only a couple of optional choices and a few important features it is likely the limitations of working memory would be overwhelmed even if one were able to do the mental multiplication part. When one is overwhelmed by the size and complexity of the decision situation then one is susceptible to a host of cognitive illusions. A few of the major ones are: Availability Heuristic, Representativeness Heuristic, Hindsight Bias, Gambler's Fallacy, the Framing Effect, Similarity Effect, Decoy Effects, and Overconfidence Effect. When the decision situation is simple and small, on the other hand, most people can and do make good judgments unaffected by these cognitive illusions.

The Availability Heuristic investigated by Tversky and Kahneman (1973) is a powerful cognitive distortion. Essentially, it is captured by the by the saying, "out of sight - out of mind." It turns out that the believing the truth of a piece of information is related to the ease of recall. If something does not easily come to mind then the inference is that it must not be true (Begg, Amour and Kerr, 1985). Unfortunately, the ease of recall is affected by circumstances that have nothing to do with the truth of the information such as the vividness of the information and the number of times it has been repeated. The power of the Availability Heuristic is not lost on those who repeatedly advertise on radio and television.

Another powerful cognitive illusion is the Representativeness Heuristic (Kahneman and Tversky, 1973). The illusion is that if something looks like one of those then it must be one of those in spite of relevant base rate information to the contrary. Common versions of this are "you can tell a book by its cover" and "if it looks good then it works well." These rules of thumb leave out the base rate information such as about how likely it is for a random book to be a good read. The cognitive illusion is to be unable to process additional information about the likelihood of an event given the overwhelming impact of how it looks on the surface.

The Hindsight Bias is the tendency to believe, after the fact, that one would have foreseen a particular event (Fischhoff, 1982 as sited in Galotti, 1999). This has also been referred to as the "I-knew-it-all-along-phenomenon" that inflate self-esteem and feelings of overconfidence in one's predictive abilities. The notion is that hindsight is always 20-20, but in reality, many events like the weather are still uncertain predictions before the fact.

There is an entire industry built on the cognitive illusion of the Gambler's Fallacy. This is the popular illusion of believing that in a game of chance that the more you loose the greater your chance of winning (Tversky and Kahneman, 1971). The truth is that the odds of winning stay the same. The illusion is belief that the law of large numbers applies in the situation of small numbers and that there would necessarily be some balance in the situation of a specific gambler. This shows up as the gambler's belief that in a fair game of chance after you have lost for a while it becomes more and more likely that it is your turn to win. Other forms of this can occur in committees who believe that after a string of poor decisions it is their turn to get lucky in picking a good vendor or whatever has been the focus of their decision-making.

The Framing Effect refers to the impact of the context on the decision. People tend to avoid risks that are described in terms of benefits, but tend to take the same risks that are described in terms of loss (Tversky and Kahneman, 1981). This is reminiscent of the rule of thumb: win - stay, lose - shift. The illusion is that the value of losses is greater than the value of gains when mathematically they are equal. This misinterpretation of the importance of risk can bias the importance weighting of features and thus bias the decision process.

Similarity Effects (Tversky, 1972) and Decoy Effects (Roe et al, 2001) are both products of confusion. When a new option is added to a choice set that is similar to one of the existing options the original option is less likely to be chosen because this effect sort of divides the mind share like a similar product can divide the market share. The Decoy Effect is a special case of the Similarity Effect where a range decoy that is more extreme than the original choice set dramatically reduces the choice likelihood of nearby options (Roe, 1999). In effect, the extreme decoy sabotages the nearby options by altering their context.

Decision Deadlines can also influence the role of Cognitive Illusions. When deadlines are quite short the decision maker tends to rely more on fewer pieces of information. In effect the working memory is further limited by time pressure. Roe's (1999) analysis suggests that the option chosen under time pressure is simply the one that is the current focus of attention when time runs out. With longer decision deadlines the more subtle similarity effects exert more influence. Longer decision timelines in the context of face-to-face group decision making tend to be associated with more extreme decisions due to attitude polarization (Moscovici and Zavalloni, 1969). It is rarely the case that truth wins in the group decision-making situation (White, 1993 as cited in Myers and Spencer 2001).

Overconfidence is a paradoxical Cognitive Illusion in that it is the illusion that one has no cognitive illusions and that one's decisions are without bias. Kahneman and Tversky (1996) have found a replicated tendency for people to be more confident
than is warranted by the evidence and to overestimate the accuracy of their beliefs. This overconfidence extends to eyewitnesses testimony where Loftus (1979) has found that the witness’s confidence in their testimony to be unrelated to accuracy of their testimony. This overconfidence has the side effect of enhancing personal self-esteem and thereby contributing to resistance to being influenced otherwise i.e. stubbornness.

In summary, there are many mental obstacles for those who would be rational decision makers. Many of these Cognitive Illusions stem from the limitations of working memory. These are the same limitations that cause people to not be able to remember long strings numbers like international telephone numbers. Because large and complex decisions situations are beyond the capacity of working memory, people resort to rule of thumb strategies to do the best they can. In such overwhelming situations Cognitive Illusions bias judgments and compromise decision-making.

Making the decision situation smaller and simpler can circumvent these obstacles. Dividing up a complex decision into several small and simpler decisions keeps the load on working memory within normal capacity and then decision makers can be quite rational in making good decisions.

Donald Norman (1999) has made the case that human-computer interactions can and should be designed to take account of normal human fallible perceptions, wandering attention, faulty memories, and fluctuating information-processing abilities. With good design of decision-making processes that keep the in-the-head part small and simple, a system can be optimized to enable quality decision-making. The normative weighted averaging strategy can be easily divided up into small and simple component parts and then later recombined (outside-of-the-head) into a rational decision process that leads to the “best option.” There is a powerful decision-making synergy in combining the focused judgmental prowess of people with the memory and computational prowess of computers.

**How people normally Make Decisions: The 5 Basic Strategies**

There are five basic decisions strategies (Payne & Bettman, 2001) for choosing among options (products, services etc.) based on features or aspects of the options. All of these five strategies are compromised by the reality that the set of options is limited to those known to the decision-maker and the “best” option may be simply missed in the whole process. While the names of these strategies on may be unfamiliar is quite likely that everyone has used all of the following strategies at one time or another:

- **Lexicographic strategy** (aka one reason, pick the best)
- **Elimination by aspect strategy** (aka pick the last)
- **Satisficing strategy** (aka Bounded Rationality Model)
- **Equal weight strategy** (aka scoring strategy)
- **Weighted averaging strategy** (aka weighted adding strategy, grading model)

The Lexicographic strategy involves two steps: selecting the most important feature and then picking the product from all of the options that is best on that one feature. There is no requirement for the features to be expressed as numbers. If there is a tie then the decision maker simply repeats the process on the second most important feature. This non-compensatory strategy does not allow for some features of an option to make up for other less adequate features. The only involvement of a second feature is in the case of a tie that is broken by considering the next most important feature and selecting the option that is best on that feature.

The elimination by aspect strategy is a simple screening strategy involving two steps: setting the requirements for each of the features and then eliminating options one at a time which do not meet any one of the requirements. The decision maker examines the features of each option one by one and the option is eliminated as soon as a feature is found that does not meet the requirements. This popular strategy does not need for the features requirements be expressed as numbers and is easy-to-use. The elimination by aspect is a non-compensatory strategy so that once an option is rejected on any feature that option is eliminated from further consideration. This strategy does not necessarily result in a single best option since more than one option may pass on all of the requirements. Including any features that are irrelevant or biased in favor of one of the options compromises this process.

The Satisficing strategy (Simon, 1955 cited in Gigerenzer and Selten, 2001) is more psychologically developed model of sequential decision-making that includes setting requirement cutoff levels for each feature. An option is examined until it fails to meet one of the cutoff levels then it is rejected and the next option is considered. The first option that passes on all of the features is selected. If none of the options pass all of the cutoff requirements, then the requirements are reduced to new lower cutoff levels and the process is repeated. The satisficing strategy is non-compensatory and effected by the order in which the options are presented as well as the aspiration level of the initial cutoff requirements.

The Equal weight strategy is comprehensive and considers all of the features on all of the options. The suitability values of one (passed) or zero (failed) are assigned to each to each feature on each option. The total suitability score for each option is the simple sum of the feature suitability values for that option (all features are weighted equally). The option with the highest sum of the values is selected. This strategy is directly analogous to multiple choice test scoring where correct answers are awarded one, wrong answers are awarded zero, and the highest sum score identifies (selects) the best student.
on the test. This compensatory numeric strategy enables some features assigned one's to compensate for other features that were assigned zero's. This strategy is more useful when there are many features because there is less risk of a tie for best score.

The Weighted averaging strategy is a more complex version of the simple sum score model where each feature is also assigned an importance weighing. This idea implies that the decision maker is willing to make trade-offs to arrive at the selected option. The process involves five steps: (1) setting the importance weights for each of the features, (2) for each option then determining the numerical suitability value for every feature, (3) multiplying the feature suitability value times the feature weight, (4) then summing these weighted features subscores into an option total score, and (5) finally selecting the option with the highest average score. The averaging of the weighted option total scores simply returns the scores to the scaling metric of the feature suitability value units (which are often on a rating scale such as 1=poor to 9=excellent). This strategy is directly analogous to the grading model where different parts of the grade are weighted differentially (or subsections of an exam are weighted differentially) to arrive at the final mark. The weighted averaging strategy is compensatory in two ways: high scores on one feature compensate for low scores on another feature and a lower importance weight on one feature is compensated for by a higher importance weight on another feature. This strategy is less likely to result in ties between options than is the equal weight strategy when using a relatively small number of features. Furthermore, the weighted averaging strategy is considered the normatively rational decision process because it uses all of the information available in a consistent manner to arrive at a selection. This model is similar to the multiple linear regression model used in statistical analyses and suffers from some of the same shortcomings, most notably it is compromised when irrelevant features are used and when unreliable suitability values are used.

Decision makers often make use of combinations of the above strategies. In combined strategies the decision is made in phases. The initial phase is often to screen out some of the potential options in order to reduce the complexity of the situation to as short list of options. This phase is followed by a more thorough consideration phase to select the best option from a short-list of candidate options. The primary reason that everyone does not use the weighted averaging strategy all the time for all decisions is because it would be too mentally difficult and too time consuming. Other strategies are heuristic attempts to make good decisions with less effort and in less time and sometimes they seem to work well enough.

Idealized decision-making process for comparison

Selecting an online educational delivery application is a high-stakes gamble that can impact the future prosperity of an educational institution. The weighted averaging strategy is ideal decision-making process because it is considered to be the only normatively rational decision process. In its most rational form every possible product option would be considered on every possible feature — nothing would be left out. The process involves the five steps: (1) setting the importance weights for each of the features, (2) determining the numerical suitability value for every feature of every product option, (3) multiplying the feature suitability value times the feature weight, (4) then summing these weighted features subscores into a product option total score, and (5) finally selecting the product option with the highest average score from among all of the possible product options. In this ideal there are three major difficulties: discovering every possible product option in a dynamic expanding market, accurately determining the importance weightings of each of the features, and accurately determining the suitability of each feature on every product. The practical difficulty is simply not having sufficient time and resources to carry out the process. The recommended process is below intended to approximate this ideal strategy within the practical limitations of time and resources.

Tailoring decision processes to Individual Situations by involving the stakeholders

The ultimate success of a decision process in addition to making a good decision is that others, the stakeholders, cooperate with the decision makers and carry out the decision and implement the chosen alternative. Tetlock (1983 as cited in Gigerenzer 2001) has studied the social aspects of rationality and proposed three social goals that are important for maintaining this cooperation. The first social goal is that decisions are made in a transparent way that is understandable and predictable. The second social goal is fairness where the decisions are made in a way that does not violate the expectations of people. The third social goal is where decisions are made in an accountable way that can be justified and defended in public. Decisions, which meet all three of these social goals, are more likely to pave the way for the acceptance by the stakeholders of the eventual decision to select a particular product over the competition.

One direct way of accomplishing these goals is to involve the stakeholders in the overall decision process. Including several of the stakeholders on the decision-making or decision-recommending committee often does this. The common difficulty with this approach is that there are many times more stakeholders than there are members on the committee. By dividing up the decision-making tasks it is possible to meaningfully involve more stakeholders and still keep the decision-making committee to a workable size. There are a couple of obvious groups of stakeholders: the student learners and the faculty who will be using the selected system to deliver online courses or use it to deliver the online portion of blended regular courses. In many institutions there will also be other stakeholders who will be interested in some involvement in the decision process. Other obvious stakeholders are the systems and computing personnel who would be doing the technical administration of the Learning Management System if it is not hosted from the vendor’s site. Also, there may be a myriad of learner support services from the registrar to instructional design personnel to the library and disabled student services personnel who all have a stake in the decision process.
well have political role to making their priorities felt in such an important institutional decision. One recommended approach
is to involve some of the stakeholders in deciding the importance of specific product features and also involving the more
technical expert stakeholders in judging the suitability a specific feature in a particular product.

When the initial importance weightings of the product features for the comparative analysis site were developed there were
many differences of opinion among the experts involved in the peer review committee. These differences were worked out
and consensus was achieved by using a couple of face-to-face meetings followed a nominal group process similar to the
Delphi process (Delbecq, Van deVen and Gustafson 1975). After people met and had an opportunity to talk about what they
thought was important and why, they were then asked to provide importance ratings for the specific features. These ratings
were simply averaged to provide a mathematical consensus without resorting to additional face-to-face meetings. The
resulting averages were also sent back to the peer review committee by email with requests for further comments if members
had strong feelings that there was an error anywhere. These requests produced some new ratings that were again averaged
and circulated again for comment and revision. It took only a couple of rounds of this nominal group process to produce a
consensus on the feature weights. This consensus was in part because the process was transparent, fair, and accountable

Focusing on what is important

Colleges and Universities are hugely different as are institutions of 3,000 students and institutions of 30,000 students.
Historically, much of educational market has been a geographical patchwork of niche markets with some exceptions. In each
institutional situation of there are some considerations that are more important than others. One way to approach the problem
of too many products and too many features is to limit the consideration to only those things that are locally important.
Determining what features are needed in an institutional Learning Management System is often a political process in each
institution that can involve many people. This process is informed by the institutional history of what has worked well and
what has not, as well as expectations about what will be needed in the future. In practice, different institutions and faculty
within those institutions use products in different ways and in more than a few cases some features of a product are never
used. This situation results from the newness of the market and the rapid pace of technological change in recent times. In
this situation the wiser approach would seem to be to focus on what is needed rather than what is offered in the market. The
idea of a needs analysis is not a new idea, but it can be particularly advantageous in selecting a Learning Management
System by informing the process of which product features fit into the institution’s needs and which ones are less needed or
merely duplicate existing institutional systems.

Each institution is unique and that uniqueness can be augmented or diminished by the choice of an institutional Learning
Management System. Sometimes institutional mission and goal statements can provide a guide to which directions to
pursue and sometimes these policy documents play no real role in the decision making of the institution. What is at issue in
the selection of a Learning Management System is the potential commitment to a product that is as far-reaching as the
institutional decision about which word processor application to support. Once the decision is made it will not be easy or
inexpensive to undo that decision. By basing the decision around the unique needs of the specific institution there is a better
chance that decision made will further the success of the institution rather than the opposite.

Thinking in terms of the audiences of users

One way to reduce the complexity of the decision process is to divide the product features into groupings based on the group
of people who are more likely to be involved with those features. In this instance one can think about three different groups
of people: Learners, those who support the learners more or less directly and those who are involved in the technical
administration of the software installation. These three groups do not exhaust the possibilities but provide a starting
viewpoint.

The learners or students are usually the largest group of users. It is useful to consider the Learning Management System
from their perspective since any problems or short comings are going to effect so many people and because many
institutions profess a “learner focus” as part of their mission. However learners are not a homogeneous group and the needs
of “first time users” may well be very different from those of returning successful students.

The Learner Support group includes faculty, teaching assistants, instructional designers, various administrators and others
who’s job it is to help learners to be successful. The titles and descriptions of these roles vary dramatically from situation to
situation

The audience of technical administrators consists of those folks who operate the server as well as those who administer the
authorization or security policies out of sight. In many situations is this audience also includes additional administrators
involved in setting up course shells on the server and arranging for access to registration lists. In general, the technical
administrators operate behind the scenes and are able to access parts of the software system that are not available to
instructors or course developers.
Thinking in terms of product features

Within each of the three audiences the features of the products can be further grouped into clusters of features and this can reduce the complexity further. On the Online Educational Delivery Applications site (http://www.c2t2.ca/landonline/) the following conceptual groupings have been used to provide targeted views for the learners, learner support, and technical administrator audiences respectively:

Learner Tools (for learner audience)
- Web Browsing
- Asynchronous Sharing
- Synchronous Sharing
- Student tools

Support Tools (for learner support audience)
- Course
- Lesson
- Data
- Resource
- Administration
- Help desk

Techlnfo (for technical administrator audience)
- Server Platform
- Client Platform
- Pricing
- Limitations of package
- Extra Considerations

Within each of these conceptual categories there would be a small number of specific application tools or features. Altogether there were 62 such specific features that could be a part of an individual application. The complete listing of application features inside of the above conceptual structure attempts to organize the otherwise overwhelming list of features:

No product had all of the possible features and no institutional situation needed all of the features either. The Online Educational Delivery Applications site was intended to help institutions find products with the features that they need and for vendors of products to be discoverable on the basis of the product functionality in the context of a rapidly developing marketplace. The list of product features also turns out to be a moving target over time as new technologies are incorporated into the evolving applications.

**Product Reviews and Rapid Product Change**

The situation of finding appropriate application candidates is made substantially more difficult by the fact that the products themselves are changing. Most of the products will release a new version one or more times per year and in many situations this “revision” can change the product substantially, especially when the newness comes from a company merger or acquisition. Published product reviews and comparisons quickly become dated in spite of the best of intentions. This dynamism among the vendors is heightened further by technological changes such as the advent of database back-ends on courseware systems that has occurred during the last several months.

In the context of the field of rapidly moving products it is very difficult be base decisions on what is available, but it is still quite feasible to base decisions on what is needed in the individual situation. The institutional context of online learning is changing more slowly than the marketplace and it can be argued that a needs analysis is more valuable than a market analysis in such a situation.

**Screening phase of decision-making based on requirements of Individual Situations**

The elimination by aspect strategy is a screening strategy involving two steps: setting the requirements for each of the features and then eliminating options one at a time which do not meet any of the requirements. To be able to decide which features are important the conventional approach is to conduct some sort of needs analysis of what is required in the institutional setting. This analysis often reveals the uniqueness of the needs of the future users of the online system. At this stage it can be beneficial to involve the stakeholders: students, faculty, student support personnel, and the technical administrators to gain later acceptance of the eventual decision as well as to become aware of needed features that might have been otherwise overlooked. Politically it can be beneficial to even involve representatives from the governing board of the institution when this decision will represent a new pedagogical direction or is expected to involve significant long-term resource commitment.

**Situational Requirements**

Individual situation are both nominally different and substantially different. Sometimes the differences are so large that our tendency to attend to differences makes it seem like some institutions are as different as day and night. While there are a host of differences between institutions there are also some similarities so that examining an example of decision-making can be instructive about similarities in the processes. As the online educational delivery applications have begun to move from the one-size-fits-all mold of the industrial era, they are more adaptable to individual situations but still the applications have different strengths and weaknesses. The ideal of making decisions based on individual local institutional situations is to exploit the synergy of matching the strengths of a product to the specific needs of the specific situation. The uniqueness of local situation can be described in many ways but by using the features of the products as the focus for this description the potential synergy is easier to find and exploit. This involves, for example, translating a local need for better two-way
communication between instructors and students into the importance of the e-mail feature. Likewise the need for orienting
and assisting instructors in how to use an online educational delivery system can be translated into the importance of an
instructor help desk feature. When this feature importance is expressed as an importance weighting then this information
can be utilized in the weighted average decision strategy which combines information about many such attributes into a
overall suitability score as is described in more detail in the example below.

The deciding of which features are more important versus which features are less important based on an analysis of the local
situation goes a long way toward reducing the risk that the chosen application will be accepted by the stakeholders and will
benefit the institution. Including irrelevant features at this stage will bias the process in favor of those applications which have
those irrelevant features so this deciding which features are required is a fundamental part of the overall decision process.
This is a process where the stakeholders, as described above, can help out by being involved in determining which specific
features are important enough to be “needs” rather than “wants.” The elimination by aspect strategy does not require that the
feature requirements be numeric so simply identifying which features are really needed is enough. There are 62 feature
categories on the Online Educational Delivery Applications site and there are undoubtedly some additional ones are critical in
some situations.

The outcome of the deciding which features are important is a Shortlist of important product features. Any product that does
not include all of those features would not meet the needs of the institution and should be screened out of the competitive
options for the final selection. This initial product screening can effectively be done by the elimination by aspect decision-
making strategy. The decision maker examines the features of each option one by one and the option is eliminated as soon
as a needed feature is missing or completely inadequate.

Screening tools on the web

Once the set of needed features has be determined then the Online Educational Delivery Applications site can be used to
identify which applications provide those features so the number of potential options can be reduced to just those that are
likely candidates. By using a page like the above table the decision maker can check the checkbox next to the required
features and then click submit and the returning page will include a list of applications which support those features. Using
that same page the candidates can be further investigated in side-by-side comparisons of feature descriptions. This side by
side comparison may help in further reducing the list of applications to only the appropriate options for the local decision
situation.

Making a Short List of Application Options

Using the web tool described above greatly speeds up this elimination by aspect process for those applications that are
reviewed on the site. The elimination by aspect is a non-compensatory strategy so that once an option is rejected on any
feature that option is eliminated from further consideration. This strategy does not necessarily result in a single best option
since more than one option may pass on all of the requirements. The usual outcome of the elimination by aspect strategy is
to result in a short list of possibly acceptable options that become the narrowed focus for a more discriminating decision
strategy. It may be prudent for comparison purposes to include in the short list any applications that are used by consortia
where the local institution is a member or in the case of community colleges the application that is used by local universities
where the college has special relationships.

Evaluating product suitability as part of the weighted averaging strategy

Evaluating products (or externally hosted product options) can be a very large task. The greater the number of products and
the greater the number of important features multiplies quickly into a potentially overwhelming product research task. This
task can be partially shifted to the vendors by structuring a competition among the likely candidates where they are invited to
bring the information to the decision makers rather than the decision makers seeking out the vendors and trying to find out
the most current product information. The market has matured enough so that most vendors are capable of responding to a
request for proposal (RFP) to supply the desired product functionality. Many institutions already have RFP procedures but
may never have used them for a situation as complex as selecting an online educational delivery application.

Inviting the shortlist of vendors to competitive presentations/proposals (RFP model)

The RFP model has been described for web software acquisition recently (http://www.technologynews.net/rfp/infotech_rfp.doc) as a necessary part of the decision process.
The RFP model offers several advantages over less formal product selection processes including: all vendors get the same
information and have a fair opportunity to compete while the decision makers get a proposal document that can be used to
assess both the vendor interest and competence. Local procedures may vary but in general a useful RFP should include the
following sections (according to the info-tech research group at http://www.technologynews.net/rfp):

1) Executive Summary
2) Reasons for the online educational delivery application so vendors can understand local situation
3) Explanation of the vendor selection process (the elimination by aspect strategy as above)
4) Explanation of the proposal evaluation process (the weighted average scoring as above)
5) Description of the decision-making team
6) Description of in-house resources that will also be used in the online educational delivery
7) Background Information about the institution and the competition
8) Time line for the vendor's deliverables
9) Penalties for missing deadlines
10) The Specifications including short, medium and long-term specification lists and descriptions
11) General terms and conditions for the institutional agreements
12) Special terms and conditions such as the number of references required, legal requirements etc.

The RFP would be sent to the short list of possible vendors. The vendors will likely have questions as they prepare their proposals so it is useful to have a designated contact person who can supply consistent clarifying information to all of the vendors' requests for information. When the proposals are received there is often another round of elimination by aspect strategy to determine which proposals are in the competitive range. The US Department of Defense (http://web.deskbook.osd.mil/reflib/mfarsups/072ua/009/072ua009doc.htm) further advises that a proposal may be considered outside of the competitive range if (1) it does not address the essential requirements, (2) has a substantial technical drawback the would essentially require a new proposal to fix, or (3) the proposal contains major deficiencies, omissions, or out-of-line costs. They also advise that these proposals are part of a negotiation process and at the end of negotiations, the competitive vendors should be provided with one additional final opportunity to submit a revision known as the “best and final offer.”

The RFP method is a time-consuming and involving process both for the institution and for the potential vendors that can be used to produce a fair vendor competition where the best candidate is selected and the social goals of rational decision-making are accomplished. The Online Educational Delivery Application site provides web tool support for the Weighted Averaging Strategy calculation part of the of decision-making. This decision engine tool is little more than an automated score sheet that combines the feature importance and the feature suitability scores into an appropriate total product score. The tool does however enable the decision-makers to use the most rational strategy of decision-making, which would be impossible to do in one’s head. The following example illustrates the decision engine web tool using two vendors (WebCT and BlackBoard) with three features (accessibility for persons with disabilities, student help, and instructor help).

Quantifying feature importance in Individual situations
For the purposes of this example let us assume that our institution is part of the Consortium that is offering us the opportunity to use either WebCT or BlackBoard for our existing system. Further lesson soon that there are only three important issues: meeting the 508 accessibility regulations so that federal funding is not jeopardize, meeting the help desk requirements of our students, and meeting the help desk requirements of our faculty. We could use the default importance weightings from the site that are 1.0 for accessibility, 1.2 for student support, and 0.8 for instructor support but it would be better to tailor the importance weighting to our institutional setting. So for this example let us assume that we did some campus wide information meetings and formed an advisory committee of interested stakeholders.

Potential of involving stakeholders in setting weights
Then with the help of our stakeholders we put together a little three-item telephone survey of a random sample students and a random sample of instructors. The results of our little survey were importance ratings of 9 for the accessibility item, 7 for the student support item, and 6 for the instructor support item. Those numbers can be just entered into the web Decision Table form because the form to produce the importance weights normalizes the numbers before they are used.

Judging product feature suitability to local situation
Different persons can make the suitability judgments than were involved in the setting of the importance weights. In this example we could conceivably involve the members of our advisory committee to nominate from among themselves a task group who have experience with our existing system and are willing to spend a week working with WebCT and a week working with BlackBoard to specifically evaluate the accessibility, the student help desk, and the instructor help desk. Further our task group could also get others to help with their evaluation as they chose with the only caveat that at least two persons with disabilities be involved in checking out the accessibility aspects of the two products.

If we had allowed more time it might have been possible conduct a request for proposals and have representatives from the two vendors provide information and trial facilities to the task group to make their hands-on experience come to them. After a week the task group meets with the advisory committee and presents their considered judgments, which are averaged to make them more reliable. Their judgment of the suitability of the accessibility for WebCT is 7, for BlackBoard is 8, and for the status quo is 2 on a scale of 1 to 9. Their judgment of the suitability of student support for WebCT is 8, for BlackBoard is 6, and for the status quo is 6, and for the status quo is 4. Lastly, their judgment of the suitability of instructor support for WebCT is 8, for BlackBoard is 6, and for the status quo is 3. Now this is where the doing it in your head is overwhelming with normalizing three numbers to an average weight of 1.0, then multiplying nine pairs of numbers and then averaging three columns to arrive at the winning Weighted Average Score of 7.59 for WebCT followed by runner up BlackBoard with a Weighted Average Score of 7.45 which is well ahead of the status quo at 2.9 socore.
**Demonstration model of the Comparative Analysis Decision Table with Three Options**

(Insert table similar to the one below adapted from http://www.c2t2.ca/landonline/option4.asp)

**Instructions:**
To compare applications A and B just enter your ratings for each criteria into the boxes in the column and then press Score. Be sure to enter a rating or a 0 (for skipping a criteria) for each of the criteria so that the score can be computed.

<table>
<thead>
<tr>
<th>Importance Weighting</th>
<th>Evaluation Criteria Name</th>
<th>A (WebCT)</th>
<th>B (BlackBoard)</th>
<th>Status Quo</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>Accessibility</td>
<td>7</td>
<td>8</td>
<td>2</td>

<td>8</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>Instructor support</td>
<td>8</td>
<td>6</td>
<td>3</td>
</tr>
</tbody>
</table>

**Weighted Average Scores**

- WebCT: 7.59
- BlackBoard: 7.45
- Status Quo: 2.9

*NaN - Not a Number error results from a empty rating box in the column

**Rechecking by doing Sensitivity Analyses**

One of the benefits of using a computerized process is easy to have the machine perform calculations again. The results in the decision table can be recalculated after tweaking the numbers to see if it makes any difference in which one is the winner. The adjusting and recalculating can be done on the basis of the know variability of the numbers involved to get a better idea of the stability of the solution. In the present example lets say we were curious to see if WebCT would still be the winner if the average instructor support rating were one unit lower so we can try a rating of 7 in place of the original 8 and then score the whole table again. In this case the change of a rating from a 8 to a 7 would in fact change the winner to BlackBoard because the Weighted Average Score for WebCT would drop to 7.32 which is lower than BlackBoard. The point of doing a bit of rechecking is that it can become clear as in this case that the products are so close that the small changes in the judgments would change the outcome.

The other rechecking that can be done is to examine if the outcome would change if the importance weights had been a little different. In the present example if the importance weight for accessibility were changed to 90 from 9 to examine a 10 fold increase in the importance of accessibility then BlackBoard would be the winner with a weighted average score of 7.88 compared to WebCT with a score of 7.13. Notice in both of these instances of rechecking the status quo never wins so one reasonable conclusion from this is that our institution should prepare for a change from the status quo as at least that much is quite clearly an outcome of this decision process.

**Summary and checklist**

The main reason for getting so involved in the decision of which learning management system is the best for an institution to select is that this is a very important decision. Normally when people make a decision or even groups of people make a decision they do not make a rational decision. Only when the judgments that people make are quite small and simple can they avoid cognitive illusions and biases. Fortunately this kind of product selection decision can be divided up into many smaller decisions that can then be recombined into a weighted averaging decision-making strategy that approximates true rationality. The trade-off is suggested to first use an elimination by aspect strategy to arrive at a short list of competitive products worth considering and then do a more detailed weighted averaging strategy to find out which one has the best score. After that the decision table can be further investigated by doing sensitivity analyses to find out how stable the
selection of the winner turned out to be. Using the web tools on the site developed for this decision-making can facilitate this process:
http://www.c2t2.ca/landonline

The online educational deliver application decision checklist:

1) First decide what features are important in the local situation
2) Screen options out based on feature criteria using web tools
3) Making a shortlist of product and features required
4) Optional Request For Proposals (RFP) from vendors on the shortlist
5) Judging the importance of features and assigning feature weights
6) Evaluating the product features for each of the shortlist candidates
7) Using the Comparative Analysis Decision Engine Tool to pick a winner
8) Rechecking your work with sensitivity analyses
9) Communicating how the decision was made to stakeholders

ABSTRACT
The aim of the ECIC project is the dissemination of participative methods of organizational development originating from Scandinavian countries to other European countries. To support this process we developed a hypertextual learning system. Because of the heterogeneous target group and the ill-structured domains of ECIC detailed usability testing is necessary. First tentative results indicate that graphical overview maps play an important role and interactive examples are very motivating.

KEYWORDS: hypermedia application, usability, interactivity, navigation

INTRODUCTION
The aim of the European Continuous Improvement Circles Project (ECIC) is to disseminate participative methods of organizational development originating from Scandinavian countries to the rest of Europe. Examples for such methods are improvement circles where people come together to discuss a given topic, for instance implications of new information technology for their workplace. A facilitator guides this discussion process in order to attain agreed goals.

Manuals on paper can give an introduction into such methods but sometimes they lack the capability to convey the complex nature of such approaches. More interactive forms of representation like hypermedia are probably more appropriate for participative methods. In addition, the ECIC project consisted of several fairly similar methods strongly related to each other. Therefore, we decided that a hypertext-based learning system might be a viable form of introducing this topic to European countries not acquainted with such approaches. The potential learners of the ECIC methodologies are representatives of business administration or Civil Service who often do not hold academic degrees. The ECIC learning system has to be adapted to the needs of this user group. A thorough evaluation of the learning systems is, therefore, necessary. The methods of ECIC can be seen as an ill-structured domain [1], therefore it is the main interest of our usability study to verify the structural representation and the user interface supporting the interpretations of the learner as an ongoing process.

EVALUATION METHODS
The evaluation has several aims. The most important one is to find out how users navigated the learning system. The ECIC methodologies are quite similar to each other and influence each other in their development. Users should, therefore, get extensive information about the structure of the material to be able to see similarities and differences of the different approaches. In this context, several aspects are interesting. The learning system contains several pages with graphical overviews. We wanted to know whether spatial visualization of information is effectively realized in our program. Dee-Lucas [6] assumes that spatial visualization is especially important for these learners who compare the target content and generate relationships that are not explicit in the text. Tosca [4] points out that the relevance of links is the result of an ongoing interpretation process by the learner. To get information about this process, we analyze whether users prefer some types of links above others and which links are more understandable than others. We are also interested in how long learners examine single pages or nodes.

The ECIC learning system tries to present the information in an interactive way. One of our questions is whether users are motivated by interactive examples or not. If they engage in working with interactive examples for an extended period of time this might be an indicator for the attractiveness for such pages. An important variable is also whether texts are clear and understandable. A final question is what users keep in mind when they have finished using the learning system and if their recollection is based on specific representations in the program.

There are several methods of evaluating computer software [3][5]. We chose a combination of thinking aloud protocols and software logging. The thinking aloud protocols are supposed to convey data about users' attitudes towards the learning system and the motivation for their behavior. We have formulated several short questions, which are based on our research interests formulated above. Users are asked to keep these questions in mind while they work to focus their utterances. It is well-known that thinking
aloud protocols are a fairly disruptive form of investigation. Nevertheless, we find that this method conveys information, which cannot be obtained otherwise, like, e.g. learners' motivation for using or not using specific links or graphical overview maps. In order to interpret correctly if a user stays at the same topic during a long time, it is important to know whether the user finds the topic very interesting or very confusing.

We also developed a monitoring tool to log the users' actions. This tool creates a log-file with information about the duration of a session, the exact time when a page is accessed or left and the object, which is used to leave a page.

![Diagram](image)

Figure 1: Navigational Graph of the first 33 moves, users' moves start at "Contents", the moves are shown by the ascending numbers next to the directed arrows; "Map" is a graphical overview map, "Contents" is the main content of ECIC learning system, "T_A" to "T_D" stand for theme A to theme D which represent four different topics of ECIC.

From these data we can infer whether users traverse the document hierarchically or in a sequential way and whether they visited the graphical overviews or maps to a large extent. The monitoring tool also provides information about how long users visit a specific node. Based on this information, a directed graph can be constructed showing the moves of the user (Fig. 1). McEneaney uses similar graphs to visualize users' behavior [2].

If analysis of users' behavior is only based on navigational log-files, wrong conclusions could be drawn. Both methods – thinking aloud protocols and software logging – are supposed to complement one another to give a more comprehensive view of learners' behavior.

RESULTS

So far, we have tested two persons who worked with the ECIC learning system. Those tests were very extensive and yielded a large amount of data. During the test we also investigated whether the test procedure we developed was viable or not. We realized, for example, that asking the users too many questions during the test was rather disruptive. One (tentative) result of our evaluation is that the graphical overviews played an important role for the subjects, although one of the two persons also employed a sequential mode of browsing to a large extent. For both subjects, it was difficult at first to adapt to the hypertextual form of organization of information. As expected, users spend very much time examining pages with complex information. But Interactive examples engage users' attention even when they do not convey very much information. One user mentioned that some of the interactive examples in the learning system gave him a more vivid impression of the method described. After the test we asked the users to write down the most salient information they kept in mind. One of the subjects drew a graphical map resembling the overview map in the program. The same person used the graphical overview map of the ECIC learning system very frequently.
CONCLUSION
The evaluation of the ECIC learning system is an ongoing process. So far, we have data from two subjects. These data indicate that graphical overviews or maps probably play an important role for learner navigation. We intend to investigate several more subjects to get more representative results. Furthermore, we want to develop a more systematic method of analysis for the thinking aloud protocols and for the directed graphs representing the learners' paths through the document.

Abstract: When it comes to understanding and using information technology, today’s pre-service education students often know more about technology than their college professors or their field-based teachers in K-12 classrooms. University and K-12 faculty members, on the other hand, know more about teaching and learning than pre-service students and less about technology. By bringing these two groups together as student mentor-faculty pairs, both students and faculty members benefit from the expertise of the other. This panel will describe how the Faculty Mentor Program developed at the University of Vermont (an initiative of the Preparing Tomorrow’s Teachers to Use Technology [PT3] Implementation Grant) brings education students and university faculty together to support new ways of learning for both groups.

Powerful Partnerships

Powerful partnerships can occur when college students are given an opportunity to teach their teachers. By facilitating student mentor-faculty pairs, new relationships are established, new skills are acquired and modeled, coursework is reinforced by practical experience, and student knowledge is tapped and utilized. When the roles are reversed, when the learner is given an opportunity to become the teacher, both sides gain.

To prepare teachers to work in tomorrow’s classrooms, education students must be engaged in a program that allows them to learn not only the skills to use technology effectively but also the ability to integrate information technology to improve student learning. Part of the pre-service teacher’s professional preparation should include a teacher education faculty who are not only skilled in using technology systems and software but model effective use of technology as a standard component of coursework (National 2000). Pre-service teachers typically are exposed to at least one course in information technology during their preparatory program. Through this course, students either learn new technology skills and applications or reinforce existing skills. It is less common, however, that teacher education programs have faculty who are modeling the effective integration of computer technology. Without these role models, pre-service teachers are less likely to use technology in their own teaching (Beisser 2000). National educational technology standards recommend that pre-service teachers know how to use and integrate technology, both for instructional and professional purposes (National 2000). In effect, pre-service teachers are being asked to meet standards that are seldom modeled and that their college teachers and in-service cooperating teachers often fail to meet themselves.

Because college students often have or acquire information technology skills through coursework, their knowledge can be tapped to support college and in-service faculty. “Using graduate students to mentor college of education faculty has been shown to be an effective technique for integrating technology into the coursework of pre-service teachers” (Beisser 1997). When graduate students are unavailable, undergraduate students have also been an effective option (Beisser 1997).
Faculty Mentor Program

Recognizing the need to promote and support the use of information technology in its educational program, the College of Education and Social Services at the University of Vermont (UVM) initiated a Faculty Mentor Program in the Spring semester of 2001 as part of the Preparing Tomorrow's Teachers to Use Technology (PT3) Implementation Grant. The Faculty Mentor Program was created to help education faculty (both within and outside UVM) strengthen technology skills and to increase the integration of information technology in college coursework. Undergraduate education students were paired with K-16 faculty members to accomplish a set of goals established by the faculty member, the student mentor and a PT3 grant team member. Initially, three University faculty and one K-12 faculty member volunteered to work with undergraduate students. In the Fall semester of 2001, five University faculty members established student mentor partnerships and additional support was extended to three, in-service K-12 faculty members working with pre-service teachers. In the Spring semester of 2002, the number of student mentor-faculty pairs is anticipated to increase to twenty.

Both students and faculty benefit from this relationship. Students elect to earn $10/hour or college credit for their work. Within UVM, education faculty members have worked with student mentors to create online course syllabi and resources, develop new online courses, and to improve or enhance courses already in place. With student mentorship, faculty members have learned new software, explored new presentation models, developed online courses using WebCT, and have begun to model the use of information technology in their courses. (Examples may be found at: http://www.uvm.edu/~inquiryb/, http://www.uvm.edu/~litblock/, http://www.uvm.edu/~crathbon/)

Through this experience, students establish a working relationship with their professors, reinforce their own technology skills by becoming the teacher, and participate in discussions with the professor about the rationale and purpose of the materials under construction. In fact, some student mentors have been instrumental in advising faculty members about ways to improve or strengthen course work. These student mentors have become "critical friends" of their professors and both parties have become co-learners.

In the K-12 arena, student mentors have the opportunity to work in a local school district with a classroom teacher and their students. In this partnership, the student mentor may work directly with the classroom teacher to strengthen the teacher's technology skills or with students to integrate technology into the curriculum. Often, the student mentor may be more knowledgeable than the classroom teacher about the use of technology skills. Student mentors have helped K-12 faculty learn how to use presentation software (such as PowerPoint) with middle school students to create science presentations, to introduce basic word processing, keyboarding, and paint program skills to second grade students, to research educational software available in the classroom, and to create web pages for curriculum or classroom projects. In turn, mentor students learn more about the complexities of being a classroom teacher. Here again, mentors and teachers share their knowledge and expertise and mutually contribute to their learning.

Studies have shown that it takes five to six years for teachers to use technology effectively in their teaching (Beisser 2000). Ongoing support therefore is critical to support professional development efforts in information technology. Student mentors can be employed to reinforce concepts and skills learned during PT3 workshops or summer institutes. This continual assistance enables the faculty member to move forward while providing reinforcement for the student mentor as well. Practical applications of technology provide students with models for their future growth as computer-using teachers.

Outcomes

As a result of the Faculty Mentor Program, notable growth has been seen in the use and modeling of information technology. More University faculty members have begun to borrow laptop computers and more time has been devoted to developing new online projects. Without the support of the student mentors, this increase in use and interest would not have been as rapid. Faculty members who are now using technology to support their courses are gaining recognition. As faculty web pages improve, other faculty members become increasingly interested in how technology can improve their course presentations. Students who enroll in courses offered by professors that use technology "spread the word" about the course to other students. This interest, in turn, encourages more faculty members to integrate technology into their coursework and to consider new approaches. Faculty members are beginning to publish online exemplars of student work. This enables the professor to
demonstrate an expectation for student work and, as a result, the standards for student performance have been raised. Some faculty members have begun to archive student work online, allowing the student's work to become a knowledge base for other students. This growth in the use and modeling of information technology has been supported by the efforts of student faculty mentors.

The Faculty Mentor Program provides an opportunity for pre-service teachers to reinforce their skills in information technology. Students establish a collegial relationship with their professors and they gain more confidence in their own abilities. It provides them with practical experiences that they can document and use when seeking employment. Students who work in K-12 classrooms receive the benefits of working directly with students to see how information technology can be used to support learning. In this environment, they learn about different networking systems and infrastructure, educational software, curriculum requirements, school rules on appropriate use, the challenges of out-dated or limited resources, and many information management lessons.

Evolving Strategies

As this program continues, the PT³ grant team will refine its approach and methods to improve and strengthen student mentor-faculty pairs. Expectations and guidelines need to be established for both the student and the faculty. Commitment must be mutual on both sides. Faculty members cannot expect students to produce content for their courses, but they can be active collaborators by soliciting and sharing constructive feedback. Everyone must be an active participant in the learning process. Student mentors are not substitutes for secretarial assistance. Student mentors must learn how to be effective teachers and supporters of information technology integration. With collaboration and support, both parties gain from this partnership.

Overall, both the pre-service teacher and the education faculty benefit from this model. The knowledge and energy that a college student provides is a resource to professors, K-12 faculty and K-12 students. In turn, pre-service teachers gain experience, confidence, and practical application to help prepare them to become tomorrow's teachers.

Panelists

Russell M. Agne, Ph. D., College of Education and Social Services, University of Vermont. (Russell.Agne@uvm.edu). Russell M. Agne is Professor of Education at the University of Vermont with responsibilities in elementary and secondary teacher education. He holds a Ph.D. in science education/curriculum and instruction from The University of Connecticut, a M.S. in earth science education from Syracuse University and a B.S. in Secondary Education-Science from Central Connecticut State College. He has published extensively in journals such as The Science Teacher, The Journal of Teacher Education, American Journal of Physics, Teachers College Record, The School Counselor, Science Education, Phi Delta Kappan, The Journal of Research in Science Teaching. His most recent book, co-authored with John H. Clarke is Interdisciplinary High School Teaching: Strategies for Integrated Learning (1997) published by Allyn and Bacon. Professor Agne has served as PI for more than 20 grants and projects to implement science curriculum through NSF, Exxon Education Foundation, The Apple Computer Foundation, Eisenhower Title II Funds, and Bell Atlantic Foundation. He has been elected a Fellow of The American Association for the Advancement of Science, and currently serves as IHE Representative on the Executive Board of the Vermont Science Teachers Association. He has served as Department Chair of Education at UVM and Associate Dean of its Graduate College.

Adam Deyo, PT³ Graduate Assistant, College of Education and Social Services, University of Vermont. (Adam.Deyo@uvm.edu) Mr. Deyo holds a Bachelor of Science in Early Childhood Education from the University of Vermont and a Level One Teacher Licensure for Kindergarten through Third Grade. He was a Child Development Specialist at the University of Vermont’s Campus Children’s School for two years working with Infants, Toddlers, and Preschoolers. In addition, he mentored two separate groups of student teachers in the classroom throughout their pre-service work with young children each year. Mr. Deyo currently is seeking a M.Ed at the University of Vermont and assists on all aspects of the Preparing Tomorrow’s Teachers to Use Technology Grant in the College of
Education and Social Services. He is also a coordinator for the Vermont Association for the Education of Young Children and a member of the State of Vermont Early Childhood Technology Board.

Sandra A. Lathem M.Ed., PT3 Outreach Coordinator, College of Education and Social Services, University of Vermont. (Sandra.Lathem@uvm.edu) As PT3 Outreach Coordinator, Ms. Lathem recruits and supervises student mentors that work with K-12 faculty in the Burlington and South Burlington School Districts. She supports UVM student mentors to assist them with their knowledge and integration of technology in the K-12 classroom and works with K-12 faculty to set goals and objectives for the student-faculty mentorship. Previously, Ms. Lathem served as the Technology Coordinator for the Addison Northeast Supervisory Union in Bristol, Vermont and has been an educational technologist in Vermont school systems during the last ten years. Formerly, Ms. Lathem was the Executive Director of VITA-Learn, a statewide, non-profit organization supporting information technology integration in Vermont K-12 schools. Ms. Lathem received her Masters of Education in Professional Development, Curriculum and Instruction from the University of Vermont in 1995.

Joyce L. Morris, Ed. D., PT3 Professional Development Coordinator, College of Education and Social Services, University of Vermont. (Joyce.Morris@uvm.edu) Professor Morris is an assistant professor in the Department of Education at the University of Vermont. Her research interests include electronic portfolio construction for assessment and learning and professional development of faculty using technology tools. At the University of Vermont, she has taught undergraduate courses in educational technology, science methodology, portfolio construction, and general education. At the graduate level, she offers courses in using computers in the classroom, web design, telecommunications, and connecting technology to the standards for in-service teachers. Prior to her appointment at the University of Vermont, Professor Morris was a science teacher who integrated technology into her curriculum at a Bronx, N.Y. middle school. She wrote and received a grant from Apple Computer that provided a 22 station, networked classroom in 1989. Using these computers, students created science animations, used computer probes to conduct experiments and record data, published science pictionarys for younger students, and participated in a number of telecommunication projects with TERC.

Teacher-Designed Software for Interactive Linear Equations: Concepts, Interpretive Skills, Applications & Word-Problem Solving

Virginia Lawrence
Department of Curriculum, Teaching & Learning
Ontario Institute for Studies in Education of the University of Toronto
Canada
vlawrence@oise.utoronto.ca

Abstract: No longer just a user of commercial software, the 21st century teacher is a designer of interactive software based on theories of learning. This software, a comprehensive study of straight-line equations, enhances conceptual understanding, sketching, graphic interpretive and word-problem solving skills as well as making connections to real-life and scientific phenomena. Developed using Maple and Hyperstudio, this software of 40 questions actively captures students' visual intelligence and evokes thinking to provide generative responses. Other features include corrective feedback, hide-and-show, scoring, timing and a student output file containing a student's 1st and 2nd responses and revealing any misconceptions held and difficulties encountered.

Introduction

A straight-line equation, the most basic kind of mathematical function, is one of the most unifying ideas in mathematics. It has extensive applications in the world of science, especially physics, business and social science. From my experience as a high school mathematics and science teacher for about 20 years, I have seen how the lack of a conceptual understanding of straight-line equations has hindered students' understanding of science, especially physics. Some difficulties encountered by students include the inability to interpret a graph, to determine its algebraic representation, to verbalize the relationship between the two variables, to sketch a simple line without going through a table of values, or to see the graphical representation associated with an algebraic expression.

Dreyfus & Eisenberg (1982) found that students of low ability had difficulty with the graphical concept of a function. In another study in 1991 they contend that the chief source of difficulty encountered by beginning calculus students is their inability to exploit the visual representations associated with the concept of functions. Vinner and Dreyfus (1989) surveyed 307 college students on their concepts of a function and only 8% of the students made reference to its graphical representation. In fact, many studies investigated students' understanding of graphs of function and concurred that students lack the skill in interpreting graphs and fail to see the connection between the algebra and geometry.

In this computer age when a large quantity of data can be easily represented in different graphical forms, it is vital that students be proficient in the interpretation and extrapolation of graphs to deduce important information and relationships between the variables. Computer technology has freed students from the laborious task of graph plotting with pencil and paper but very often a student is not even aware that he/she has made a mistake in keying in information, resulting in the display of a different graph or function. Thus it is important that students have the conceptual, intuitive and visual understanding of straight-line equations in terms of positive and negative slopes, and y intercepts before embarking on the use of graphing software.

As cited in the Before It's Too Late report (2000), computer technology has not only changed the way we live and the way business is conducted, it has changed the demands of our work force, which calls for students to be equipped with the ability to think and solve problems. Educational reforms all over the world are bringing changes to meet such demands. NCTM (National Council of Teachers in Mathematics Standards) (2000) calls for a shift in emphasis from a curriculum dominated by the memorization of isolated facts to one that emphasizes conceptual understanding, problem-solving, functional relationships, multiple representations and connections, in particular between algebra and geometry, as well as to the real-world and other disciplines. My study of straight-line equations is in response to NCTM's multi-faceted frames of learning.

In Ontario, the New Curriculum, which consists of 4 years of high school compressed from 5, was introduced in 1999. Many topics, including straight-line equations, have been moved from higher to lower grades causing difficulties for many students. A recent report confirms a higher failure rate of our grade 9 and 10 students. ("Poor Math", 2001). Teachers with an increased workload of 6 courses from 5 are also faced with larger class sizes and new-immigrant students of very diverse ethnic backgrounds, languages and learning abilities. Professional developments for teachers and the use of computer technologies in the form of software or the Internet are high on the agenda to support student learning.
Computer Technology and Learning

Douglas Noble (1988, P. 241) has given one of the clearest discussions of the three rationales for the introduction of computer into schools.

"The first focuses on... technological society [which] requires new skills, including computer literacy... second rationale... technology of education: computer-based instruction offers new, effective and efficient ways to present material, to individualize instruction... third rationale focuses on a technology of mind: interactions with computers enhance cognitive skills while offering the possibility for intellectual mindstorms".

According to cognitive theories, computer technologies are cognitive learning tools, which expand human abilities such as memory and processing. Roschelle (1994) regarded technology as a form of inquiry with three functions derived from Dewey for the following:

a. to provide a stable, long-term access to a problematic situation in which the learner can repeatedly replay and reflect.

b. to provide focus and context to identify new features and relationship.

c. to augment ways of acting so that their meaning is more readily available to others.

Many studies have shown that calculators and computer-based materials have enhanced learning. Schwartz (1999) confirms the 5 aspects of mathematical activities, namely, conjecturing & exploring, evaluating & analyzing data, modeling, conceptually grounding manipulative skills, and the deepening of understanding, which can be enhanced by the use of computer technology. In mathematics, before students can create ideas or apply their ideas, they need to have a good grounding of basics, facts and conceptual understanding. Despite all the merits of computer technology, a teacher must use it wisely to ensure effective learning and must give clear instructions and guidance. I am in total agreement with Bland (1996, p.2) who says, "Technology should be used to expand possibilities for students, and to permit them to explore otherwise inaccessible problems. However, it should only be introduced after they understand the mathematical concepts involved, and are able to manually use them in simple problems".

Exploring and conjecturing are stimulating and can even evoke critical thinking for the average and above average students but for the less mathematically inclined, who often fail to discover patterns or conjectures, they feel very lost and frustrated. Mayes's (1992) study concluded that the average students performed better with the use of mathematical software with exploratory and programmable functions, but not the weak students. Recently, constructivism has been met with opposition by parents and educators as indicated in the "Math Wars" brewing in California which called for the adoption of the "three phase approach", namely the direct instruction in skills, the help phase and the self-regulated drill and practice (Becker & Jacob, 1998). Hirsch (1997, p.6) cites, "... only through intelligently directed and repeated practice, leading to fast, automatic recall of math facts, and facility in computation and manipulation can one do well at real-world problem solving".

Brady (1991, p.149) once said, "the best teaching aid is often those designed by the teachers themselves". Thus, I have embarked on this project of designing a CAI software (mainly to serve the mathematically less inclined) with 40 questions that provides lots of practice, at the same time incorporating a multi-faceted frame of learning, delving in depth and width into all the topics related to straight-line equations. The research also examines students' conception or misconceptions of straight-line equations as well as ways of thinking and difficulties encountered in word-problem solving, interpretation of graphs, and scientific applications.

Software Design & Learning Theories

Piaget's and Skinner's Theories. Mellon & Sass (1981) suggest Piaget's developmental theory as a theoretical foundation for CAI. Piaget emphasized the movement of students through sequential stages of cognitive development; each stage builds on the previous one to develop effective learning. Skinner (1938) listed four important tenets about learning, which include a short learning process, reinforcement, immediate feedback and provision of 'stimulus discriminations' for path to success, most of which are incorporated in the design.

Jonassen's Activity Theory. Interactivity has been identified as an important characteristic of the computer environment to the acquisition of deep learning. According to Jonassen and Rohrer-Murphy (1999), Activity Theory posits that conscious learning emerges from activity or performance. This software is designed with a high degree of interactivity, constantly asking the student what to do next and leading her through a continual process of interpreting, judging, constructing, applying concepts, translating modes of representation, and reinforcing algorithmic skills.

Real-Life & Interdisciplinary Learning. Students have often asked me "What good are the x and y in the real word? How are they helping me to find a job?" In the teaching of mathematics, it is imperative to bring in applications be they science, business or real-life problems, to foster conceptual understanding as well as convince students of the power and usefulness of mathematics.
Beane says that students are to "... integrate learning experiences into their schemes of meaning...And knowledge is called forth in
familiarity, imageability and variable type (discreet or continuous quantities). The questions in the software are carefully prepared
to incorporate such features i.e. real-life and scientific phenomenon that students are familiar with or can relate to.

Problem-based Learning. Problem solving is a form of higher-order thinking and depends on a student's resources, heuristics,
control, and worldviews (Schoenfeld, 1985). My software aims at developing better heuristics and control in students as well as
fostering the ability to identify relevant information, to transform words into symbolic equations, to assign suitable variables and
notation for immediate recall of significant information, to discern the reversal error (Rosnick, 1981), and to apply the optimum
algebraic skills. Through working with the word problems, students will learn to plan and sequence their tasks, justify their
answers, and test their final answers by integrating algebraic and geometric methods.

Howard Gardner's Visual Intelligence. Gardner (1983) notes that many students have preferred ways of learning depending on
their "intelligence" which could be kinesthetic, spatial or visual, musical, verbal, intrapersonal, interpersonal or naturalistic. This
software captures the visual intelligence of the student through the many vivid representations of graphs created by Maple (Char
visual literacy is "a cognitive process that includes mental rehearsal, introspection and visualization .....whereby each exposure to
the visual image permits the observer to become a keener interpreter of the visual display".

My Interactive Straight-Line Equation Software

This software consists of 4 modules, namely, A: Slope by visualization or calculation, B: Graphical to algebraic form, C:
Applications and D: Word-problem solving. The graphs were drawn with Maple. First the grid was drawn with tiny circles each
representing integer coordinates or some multiples of integers. A set of horizontal points was generated using the Maple "seq"
function and the corresponding points were drawn with the "plot" function. These two functions were placed inside a loop to
draw subsequent lines of points forming a grid. The line $y = mx + b$ was then drawn and the whole graph was exported to
Hyperstudio. (See Appendix I for Maple Program). Hyperlogo in Hyperstudio is used in achieving the more sophisticated
interactive features such as keeping track of the number of times a student has answered an item or analyzing if the response is
correct and furnishing a corrective feedback. The following table shows the correspondence between the features of this software
and Kuittinen's (1998) four criteria or demands for a good CAI.

Visit [http://fcis.oise.utoronto.ca/~vlawrence/stlines.html](http://fcis.oise.utoronto.ca/~vlawrence/stlines.html) to view sample computer screens.

If you have Quick Time 5 on your machine, you may try out a sample of the interactive software at [http://fcis.oise.utoronto.ca/~vlawrence/hypertrl.html](http://fcis.oise.utoronto.ca/~vlawrence/hypertrl.html)

Proposed Study

A class of grade 10 students who have covered the content of straight line equations will be given a pre-test of 8 questions, 1 on slope by inspection, 1 by calculation, 1 on transformation from graphical to algebraic form, 1 from algebraic to graphic form, 1 on formulation of equation given relationships expressed in words, 1 on the interpretations of a graph representing a scientific phenomenon, and 2 on word-problems. From the results of the pre-test, weak and average students (selected few) will be solicited for interviews. The whole class is then exposed to the interactive software but think-aloud protocols or audio-video taping may be employed to the selected few who work individually or in pairs. Students are then given a questionnaire about their learning experience with the software, followed by a post-test and a final interview (selected few), the latter to probe further into their misconceptions captured in computer files, audio-video taping and post-test.

Pilot Tests & Findings

In the first pilot study, 57 grade 9 students (from 3 classes) wrote a pre-test followed by treatments of modules B (graphic to algebraic) and C (Applications). Students were then given a questionnaire in my absence, followed by a post-test. A quantitative analysis of the pre and post-test using the comparison t test for two means from dependent (correlated) samples pointed to a significant difference in the scores or gains. Feedback from questionnaires revealed that 91% of the students affirmed that the software had enhanced their learning.

In the second pilot test, three grade 10 students were interviewed individually followed by a pre-test. Each then interacted individually with module D (problem-solving) followed by a questionnaire and a post-test. Both feedback from the questionnaire
and results of the post-test indicated significant gains in learning. Analysis of "captured files" also revealed certain misconceptions held and difficulties encountered by students, some of which were the inability to reduce \((9A + 6S = 7500)\), relating to time frames (to add or subtract when leaving a point at a later time), handling special cases (solving \(C=40+0.2D\) and \(C=30+0.25D\) did not see coefficient of 1 in C provides direct subtraction or equating), false commutation (length is 2 cm less than width as \(L = 2-w\)), faulty conversion between decimal and percent etc.

In general the students agreed that the software had helped them to attain a better conceptual understanding of straight-line equations, had improved their graphing, graphic interpretive, algebraic and problem-solving skills, in particular, the transformation of relationship in words to symbols. They also indicated that they view mathematics as more meaningful and have less fear of word-problem solving.

**Conclusions**

In view of positive pilot study results, this interactive software will not only enhance the learning of straight-line equations related to graphical interpretive and problem-solving skills but also foster a better understanding of scientific principles and usefulness of mathematics in the real world. Misconceptions and students' ways of thinking can shed light to how teachers should teach and serve as a resource for curriculum designers and planners. To accommodate students' learning in this computer technology era, software must not only cover all aspects of a topic; it must link them, actively and interactively engaging the user as a builder of his own knowledge. These principles of software design can be applied to other topics in the mathematics curriculum, in particular the extension to quadratic, exponential, logarithmic and trigonometric functions.

**Appendix I**

This MAPLE program generates the graph consisting of the grid points, coordinate axes and the straight line \(y = 10x + 20\)

```maple
with(plots):
for j from 1 to 6
do
  yval := 10*j:
  yrlist := [seq([i, yval], i = 1..4)]:
  hlines := hlines union {plot(yrlist, style=point, symbol=circle, colour=blue)}:
od:
display(hlines);

e := plot(10*x + 20, x=0..4):
display({e} union hlines);
```

Abstract: The flexible nature of hypermedia allows it to be tailored to an individual's needs. Despite the many degrees of navigational freedom, however, users of hypermedia often find difficulty locating information, feel disoriented, or even become "lost in hyperspace" within such large seas of data. Research findings suggest that the disorientation problem could be solved if users are able to hold a conceptual overview of the hypermedia structure. Variables such as the different ways of representing information structure cues and cognitive styles may affect learners' cognitive abilities in knowledge structuring and should be taken into account together.

INTRODUCTION

With the development of large information space such as digital libraries, however, users of hypermedia often experience difficulty locating information. Scholars (Beasley & Waugh, 1995; Dias & Sousa, 1997) have suggested that the navigational problem could be solved if users are able to hold a conceptual overview of the hypermedia structure. In other words, if users can substantially construct a structural knowledge (Jonassen, Beissner, & Yacci, 1993) of the information provided in the hypermedia system, their performance could be improved. In a hypermedia context, graphical browsers have been introduced as either schematic (concept map) or spatial (hyperlink) representations of the network. Both methods above represent what Halasz and Moran (1982) have called "conceptual models". Yet, it may not always be easy for novice learners to use an abstract conceptual model. If a supplied conceptual model is not familiar to the learner, then this strategy will not work (Halasz & Moran, 1982). Consideration of this issue suggests the usage of the metaphorical GUI (Carroll & Thomas, 1982; McKnight, Dillon, & Richardson, 1991; Rizk, Streitz & Andre, 1990), e.g., the office metaphor, to help with the development of new cognitive structures from existing ones.

CONCEPT MAP AND METAPHORICAL GUI

Despite of some exciting possibilities in the realm of user-centered learning, there is a fundamental problem regarding hypermedia; it provides too few structural cues for some users (Charney, 1987; McDonald & Stevenson, 1996; Dias & Sousa, 1997). They need to depend on some sort of consistent layout and structure for their understanding and would succumb to confusion or disorientation if their expectations were violated. Designers have to realize what types of structure cues hypermedia could adopt and then evaluate them at the planning stage.

Concept maps (Nielsen, 1990; West, Farmer, & Wolff, 1991) are maps that display experts' knowledge structures graphically. This navigation tool is similar to the cognitive representation formed by the learners and is a mental representation of external spatial relations used to navigate in physical spaces (Dias & Sousa, 1997). In hypermedia-based instruction, concept maps are presented as templates to facilitate the novice's acquisition of experts' knowledge structures. The concept map has been categorized by Jonassen, Beissner, and Yacci (1993) as an organizing strategy which might help learners to construct or reorganize their knowledge structures by showing how concepts relate to each other.
Another type of structural cues is the metaphorical GUI. When a computer user learns a new computer program, he calls upon his prior knowledge (analogies or metaphors) as the basis on which to form a new mental model. Designers can take advantage of users' existing mental models to present ways of conceptualizing computer functions and to design interfaces for computing systems (Carroll & Thomas, 1982). Nepon and Cates (1996) state that appropriate use of graphics embedded in interface metaphors may have the potential to increase "the rate at which users can process, understand, and respond to a display" (p. 1). They note Bielenberg's (1993) view on the "transfer" function of metaphor and suggest that interface designers may use visual metaphors to design a conceptual model in order to conform to users' mental models in a complete and painless manner while the users are learning a new domain. Bishop and Cates (1996) also suggest that a metaphorical GUI helps users to establish expectations for the new computer systems and facilitates the understanding of the systems to be learned by utilizing the users' familiar concepts and experiences.

Apart from the representational aspect of hypermedia, the effects of learners' cognitive characteristics on the navigational problem are another concern in this study.

COGNITIVE STYLE

Wickens (1990) and McDonald and Stevenson (1999) indicate that once the correspondences among the physical presentation of the real world, the user's egocentric view of the real world, and the user's mental representation of the world are broken, disorientation will happen. The physical presentation of the real world is the way that author uses to convey information. The user's egocentric view of the real world could be viewed as an internal issue regarding the way that users interpret what they see. How users interpret what they see highly relate to the individual cognitive styles. Several studies have found that among other individual elements, the effects of cognitive styles, is arguably one of the most important factors that might affect learners' performances, especially in a hypermedia environment (Andris & Stueber, 1994; Chang, 1995; Leader & Klein, 1996). Cognitive style refers to an individual's cognitive tendency for perceiving, processing, and organizing information. A subject's structuring ability or cognitive style might be more strongly manifested in a non-linear environment. When a learner tries to link incoming information with established ideas, the incidences of misconception might increase if the text's organizational pattern can not be used appropriately. Disorientation and confusion thus may occur simultaneously and become potential hazards for studying in a hypermedia environment (Hammond, 1993). In this study, cognitive style will be examined within the dimension of "Wholist" and "Analytic" (Riding & Glass, 1997)

SUMMARY

It is hypothesized that learners' cognitive styles and two types of structure cues could affect learners' feelings of disorientation. Learners' cognitive characteristics play a central role in the regulation of learning processes. Yoder (1994) and other researchers (Rasmussen & Davidson-Shivers, 1998) feel that it is essential for educators to beware of the differences of individual cognitive styles and their effects on performance. However, little is known about the manner in which students employ these characteristics in a hypermedia context to search information, or about the way in which this execution is affected by different information representation approaches (Burton, Moore, & Holmes, 1995).

Anchored Instruction in a Situated Learning Environment

Miwha Lee
Busan National University of Education
Busan, Korea
mlee@bnue.ac.kr

Abstract: The purpose of this study was to design and develop multimedia-based anchored program and to examine the effects of students' and group characteristics on the problem-solving process in anchored instruction with the multimedia program in a situated learning environment. Sixty-eight students were assigned to small groups via a stratified random sampling procedure. The students were working cooperatively as a group on the authentic task of multimedia-based anchored instruction. The results of the analysis showed that group composition as well as students' characteristics significantly exerted differential effects on the problem-solving process. The implications of the results for anchored instruction were discussed.

Introduction

Along with advances in information and communications technology, there has been a shift towards a new paradigm of education and training. The emerging paradigm entails the characteristics that distinguish between industrial-age and information-age educational systems (Kang & Kim, 1999; Reigeluth, 1999). The educational system based on a new paradigm supports a constructivist approach to the teaching and learning process and fosters learner-centered, interactive, contextualized, and meaningful learning environments with diverse, multiple perspectives.

There have been an increasing number of studies on anchored instruction in authentic and situated learning environments with highly interactive and engaging forms of technology-supported contents (e.g., Bransford et al., 1994; Brown et al., 1989; Cognition and Technology Group at Vanderbilt, 1991; 1992; 1993a; 1993b; Crews et al., 1997; McLellan, 1996; Shih, 1997; Ruokamo, 2001; Young, 1993). The anchored instruction approach emphasizes authentic learning in solving complex problems typically found in real world situations and collaborative work in small groups to generate sub-problems and develop solutions utilizing embedded data. This approach can provide students a situated learning environment that facilitates problem-solving as well as problem-definition skills and collaborative efforts among students during group work on the authentic task.

In general, research on anchored instruction has shown positive effects on students' cognitive and social-affective outcomes (e.g., Cognition and Technology Group at Vanderbilt, 1992; 1993a; 1993b; 1997; Hmelo et al., 1993; Lee & Hwang, 2001; Serafino, 1999; Shih, 1997; Ruokamo, 2001). Most of the studies have utilized the Adventure of Jasper Woodbury series developed by Cognition and Technology Group at Vanderbilt as the anchored program. Until recently, however, few studies have investigated anchored instruction with different forms of anchored program for students from a different cultural background. To this end, the present study attempted to develop multimedia-based anchored courseware that is adaptive to elementary school curriculum in Korea and to examine the factors affecting the problem solving process in anchored instruction with multimedia courseware in a situated learning environment.

The purpose of this study was to design and develop multimedia-based anchored courseware and to examine the effects of cognitive style of the student, the type of problem-solving task, and group composition on achievement in anchored instruction with multimedia courseware in a situated learning environment.
environment. The achievement results in understanding of problems, accuracy of problem solving, and reasoning and organization of problem solving of students working on original and analogy tasks were compared in heterogeneous and homogeneous groups featuring individual and group accountability.

Method

Sample

The subjects for the study were sixty-eight students (33 females, 35 males) in the sixth grade at two elementary schools in a metropolitan city in Korea. All the subjects had some previous experience with computers and the Internet at or outside of school in a variety of subject areas. The subjects were assigned to small groups via a stratified random sampling procedure on the basis of pretest results. They remained in the same groups throughout the study.

Procedure

Before the study began, students were asked to complete a background survey regarding students’ previous experience with computers. The pretest was administered to assess students’ previously acquired knowledge with the subject or content areas of the authentic task. Stratified random sampling was used to assign students to heterogeneous and homogeneous groups. Heterogeneous groups consisted of high- and low-score students. Homogeneous groups consisted of students of the same-level score. Students were unaware of the composition of the group. Students also took the Group Embedded Figures Test so as to identify those with field dependence or field independence. Students were then given practice sessions of anchored instruction with multimedia courseware developed for the study. They were instructed to work cooperatively as a group on the authentic task of multimedia courseware, to help each other learn, and to make group decisions on the course of their actions in solving a set of problems. Students worked for five 80-minute instructional sessions.

Multimedia Courseware

For the purpose of this study, multimedia courseware was designed and developed for Anchored Instruction. This courseware appears to be one of the first programs for anchored instruction that was designed to be adaptive to elementary school curriculum in Korea. In developing multimedia courseware, the author attempted to meet the design principles for the development of the anchored program identified by Cognition and Technology Group at Vanderbilt (1990; 1991; 1992; 1993a; 1993b; 1997). The design principles include: (1) video-based presentation format, (2) narrative format, (3) generative learning format, (4) embedded data design, (5) problem complexity, (6) pairs of related adventures, and (7) links across the curriculum. The subject or content areas are cross-curricular, including proportion and ratio in mathematics, geography in the social studies, and environmental awareness in science. The multimedia courseware provides a situated learning environment where students work together as a group on the authentic task so that they can generate and solve a series of problems and sub-problems and relate the solutions to the complex problem. Through their learning process, students can explore the hyperlinked multimedia contents of the anchored program with embedded data. In designing and developing the user interface of the courseware, a special emphasis was placed on user-friendliness and efficiency. A simple, intuitive design with a text-based menu, rather than a complicated design, was preferred (e.g., Harper et al., 1993; Hedberg et al., 1994).
Research Design and Data Analysis

The study employed a randomized block factorial design. The between-subjects factors included Cognitive Style, Task Type, and Group Composition. The within-subjects factor included achievement scores of understanding of problems, accuracy of problem solving, and reasoning and organization of problem solving. The analysis of covariance (ANCOVA) was performed to determine the interaction effects as well as the main effects of cognitive style, task type, and group composition on achievement in understanding of problems, accuracy of problem solving, and reasoning and organization of problem solving with students’ pretest results serving as the covariate. The level of significance was set at .05 in this study.

Results and Discussion

The means and standard deviations for achievement in understanding of problems, accuracy of problem solving, and reasoning and organization of problem solving are presented in Table 1. The results of the analysis of covariance for achievement by cognitive style, task type, and group composition are shown in Table 2.

Understanding of Problems. Significant main effects were found for cognitive style, $F(1, 59) = 4.306, p < .05$, for task type, $F(1, 59) = 6.189, p < .05$, and for group composition, $F(1, 59) = 5.328, p < .05$. Significant interaction effects were also found for cognitive style and group composition, $F(1, 59) = 4.078, p < .05$. These results indicate that students working on the analogy problem-solving task scored higher than did those working on the original problem-solving task and that cognitive style of the student and group composition exerted differential effects on achievement in understanding of problems, as shown in Tables 1 and 2. Field independent and dependent students tended to achieve differentially across the groups of different composition on the posttest of understanding of problems. The students in heterogeneous groups scored higher than did those in homogeneous groups. This pattern is more noticeable among field-independent students than field-dependent students. The mean score of the field-independent students in heterogeneous groups was the highest (4.28); the mean score of the field-dependent students in homogeneous groups was the lowest (2.38).

Accuracy of Problem Solving. There were significant main effects for cognitive style, $F(1, 59) = 6.012, p < .05$, and for task type, $F(1, 59) = 7.303, p < .05$, and significant interaction effects for cognitive style and task type, $F(1, 59) = 2.655, p < .05$. Yet, main effects for group composition were not statistically significant, as seen in Table 2. These results indicate that the achievement of field-independent and field-dependent students was dependent on the type of problem-solving task on which they were working within a group. Field dependent students with analogy task tended to score higher on the accuracy posttest than those with original task (3.85, 2.94, respectively). For field independent students, however, this pattern did not emerge: There were only slight differences between students working on analogy task and those working on original task (4.31, 4.29, respectively).

Reasoning and Organization of Problem Solving. As the results in Table 2 show, no statistically significant effects were found for cognitive style, task type or group composition, or for the interaction among cognitive style, task type and group composition. The results indicate that the differences between the posttest means were not statistically significant, probably due to the relatively large standard deviations, as shown in Table 1. For reasoning and organization of problem solving, the achievement scores of field-independent and field-dependent students were not significantly different from each other, regardless of the type of task and the composition of the group.

This study examined the effects of cognitive style of the student, the type of task, and group composition on achievement in understanding, accuracy, reasoning and organization of problem solving in anchored instruction with multimedia courseware in a situated learning environment. As pointed out earlier, this study appears to be one the first studies that have focused on the factors affecting anchored
instruction at the elementary school level in Korea. The findings of the present study corroborate and extend current knowledge of anchored instruction. The results of the analysis of covariance indicate that group composition as well as students' cognitive style and task type significantly exerted differential effects on the learning outcomes. In general, both field-independent and field-dependent students in heterogeneous groups showed higher achievement than did those in homogeneous groups. With regard to the type of task, students working on analogy tasks tended to understand the problems better and to be more accurate in problem solving than did those working on original tasks. The results show that the effects of cognitive style of students were dependent on the composition of the group and the type of problem-solving task. Thus, the results of the present study allow for a closer examination of the relationship of students' individual and group characteristics in the problem solving process in a situated learning environment, and corroborate and lend further support to the previous studies on anchored instruction (e.g., Bransford et al., 1994; Chinien & Boutin, 1992; Chou & Lin, 1997; Crews et al., 1997; Leader & Klein, 1994; Lin & Davidson, 1994; Liu & Reed, 1994; Mevarech et al., 1991; Ruokamo, 2001; Shih, 1997; Small & Grabowski 1992; Summerville, 1998; Williams et al., 2001).

While important and interesting findings have been revealed, the study needs to be replicated. In addition, there are several suggestions for future research. First, the subjects of the study were relatively homogeneous in terms of the socioeconomic background. The analysis of data from a nationwide probability sample across various student populations might yield more generalizable results. Second, the problem-solving tasks that students were working on in small groups included original and analogy tasks. Future research employing other types of problem-solving tasks may be worth further investigation.

Abstract: User data and contextual information about anatomy education was employed to guide efficient and effective design of learning applications. The research focused on designing educational software to provide students and teachers different anatomy learning modules corresponding to key topics for coursework and professional training. The data collection emphasized user perspective, experience, and demands in anatomy learning. Collective data were sorted and analyzed using multidimensional scaling and cluster analysis. The learning modules' design encompasses both unified core-components required by all users and specific features demanded by some subgroups. This study begins to fill an important void by describing how user requirements were systematically collected and analyzed and then transformed into guidelines informing the iterative design of multiple learning modules. A powerful instrument to design and polish the content and user interface is demonstrated in this study.

Introduction

A key objective of the Visible Human Project at the University of Michigan is to facilitate the use of medical images from the Visible Human (VH) Dataset in anatomy learning. It is our observation that anatomy teaching differs from one group to another in heath sciences due to their unique requirements in the class and professional goals in the field. We are interested in how appropriate and useful content can be provided in the specific context where anatomy is learned. The intent is to use user data of contextual information about anatomy education to improve iterative design (Boyle, 1997), and thus create a learning environment that is efficient and effective.

However, no efficient methods of transforming user requirements to concrete designs have been suggested in previous research. Hence, this study attempts to begin to fill an important void by describing how user requirements, associated with users’ learning experiences, were systematically collected and analyzed and then transformed into guidelines informing the iterative design.
Methods

One or multiple focus group (Morgan, 1997) sessions were conducted with each group of target users: students and faculty in professional schools of nursing, medicine, dentistry, kinesiology and surgery. All eleven researchers then met as a group to share and discuss information gathered in the different focus group sessions. One team member created a matrix for pooling user requirements from all focus groups. After each researcher rated the matrix independently, a summary containing the mean rating from all evaluators for each cell was generated. Examination of these rating data using cluster analysis and multidimensional scaling (MDS) (SYSTAT, 1989) was performed to find target groups who received similar scores in all requirements. Two kinds of hierarchical algorithms, the Complete Linkage and Ward's Method, were used to compare the similarity of all requirements across different users and further group comparable requirements into clusters.

Results

The results from the MDS show that different user groups are distributed into the four quadrants based on their requirements. We observed that users who share similar experience and training objectives in their health care education became a natural group. The two optimized dimensions were interpreted by comparing the attributes of the groups on the opposite ends along each dimension. Thus, the vertical dimension was conceptualized as anatomical scope or breadth of focus; the horizontal dimension was interpreted as level of professional development, novice versus expert (right versus left). These results indicate at least four clusters of users that the design should accommodate.

Results from the hierarchical algorithm show clusters of similar requirements. Each cluster of requirements was composed of numerous related functions and features that should be integrated simultaneously into the learning environment. To make the results in the summary matrix more informative to the interface design, clusters were categorized by level of demand and correlated with characteristics of the users who requested them.

Conclusions

In interpreting the requirement clusters and user clusters resulted from the analysis, we suggested at least two sets of functions and features should be used in the anatomical learning modules. One set of core components used as the base design and framework would be common across groups. Their content was identified in the focus groups as important requirements for learning anatomy by faculty and students across the different disciplines. The second set of functions and features would not be universal across all groups but would fulfill the needs of self-selected users groups that parallel their specialties. To design learning modules with both unified core components and user-specific applications, the program should be flexible, allowing for dynamic insertion of different learning tools for different users. One possible way to achieve this goal is to provide an interface that users can employ to select and enable suitable learning materials.

Interpretations of ideas and feedback from users are powerful in designing and polishing the VH user interface system. In this study, the research design combines both quantitative and qualitative research methods and does not rely solely on one or the other. Through these methods, we were able to (1) identify the group of users who share similar content, (2) suggest the general design framework and special components suitable for specific users, and (3) discern the priority of implementing each requirement. The design described in this paper will continue to evolve throughout the software development process, enabling the research team to link users' needs with the ability to construct an appropriate and customized instructional design.

Abstract: In contrast to traditional types of learning and teaching processes and learning medias, such as printed material for Web and hypermedia learning resources, Web resources and Web-based activities are quite often unfortunately more or less separate parts of the planning process and curriculum documentation in an organization's traditional organizational level of educational. This paper introduces a portal system based on curriculum content. An attempt is made to solve the problem of integrating the access and use of learning through both traditional and modern post-modern types of resources into an online interactive coherent system of curriculum documentation at the organizational-level. At our university, we have developed an Online Curriculum -based Internet Web portal as a pilot for one course in order to integrate all learning resources through Online Curriculum / Online Syllabus, "eCurriculum / eSyllabus", content into one location. The heart of the system is located on the public Internet and the recent beta testing system is currently based on the HTML standard, thus avoiding the commitment of the organization to a single platform for learning resources.

Introduction

Recently, there has been a rapid increase in the use and the will to use and develop different learning types, learning resources, and course contents and even entire course modules that are partly or wholly based on the pedagogical use of computers and computer networks. A very important question to ask is how our curricula and the formats for curriculum representation should be developed in order to support possible new post-modern types of learning and provide easy access for the use of new types of learning resources.

In general, the pedagogical planning process is said to be a process that generates a more or less coherent structural model of resources, systems, and activities for learning and education and the use of different systematic tools in order to achieve the goal.

That the concept of a curriculum and its importance are undoubtedly a central key element in the traditional educational process is quite clear. It can be said that the entire activity of learning is constructed around a curriculum, and the curriculum is the integrating element for the entire educational module or its part - a course or the whole programme. The goals of a curriculum also form the basis for the evaluation and assessment of the outcome of learning. In general, a curriculum can be viewed at the least as the vision of the goals and similarly as the systematic representation of the tools (both mental and material) needed in order to achieve that vision.

The Traditional Ways of Representing Curricula

Often, a curriculum and its different representative formats are also used as the requirements for a course. It may be published in several printed and electronic formats as a book or as an Internet page and given to students or to school or university officials and teachers as a means for the general understanding of the course, its goals, contents, and requirements. It specifies the tasks or achievements during a course, the literature to read in order to pass the course, plus the methods of assessment. The traditional ways of generating and representing curricula, despite the publication platform such as the Internet, can be said to have typically been static. The metaphor has been to publish and not to generate an interactive integrated system of tasks and resources for learning by collecting them all into one location as a tool for easy access through a single resource. In this new situation, rather than that of a static presentation of content, the metaphor for a curriculum could perhaps be more as an interactive, integrative, iteratively developed living tool that is applied in order to achieve certain goals (See e.g., Poldolskij 1997.)
Without a more specific analysis of the ideologies enshrined within a curriculum (such as e.g., PBL) and the different view of education they impose, as well as the need for representative formats of a curriculum, it can be argued: In many cases, the present ways of producing a curriculum, curriculum representations, and the implications of Instructional Design based upon it, are quite well suited to traditional, rather static institutionalised and non-virtual types of learning, such as those forms of learning and teaching traditionally organized in schools and universities.

We have quite good tools, both mental (e.g., well-defined and widely used concepts) and many material tools, for the traditional type of educational activity. We have, for example, rather satisfying ways finding, distributing, storing, using, and representing traditional written material as books or handouts or other types of traditional media. We have generated systems such as libraries and library databases, publication data systems, or ISBN/ISSN numbering systems to easily handle such data; there are such things as traditional course readers, and ways estimating its reliability and value. (Cp. e.g. Velman 1997.)

The New Role of a Curriculum as an Interactive Online Element to Integrate all Resources

But the challenge is to produce curricula, curriculum representations, and Instructional Design for the modern situation in which an increasing amount of party or wholly location-free teaching and learning activity is present and in which the learning resource types that are used and the structure of learning activity (the ways in which learning is organized) are in many ways very different from the traditional format.

It can be said that in the present situation, where there are many new types of learning processes and resources behind all processes, the role and essence of a curriculum as an integrating and clarifying key element in the planning and realization of education is more important than ever before. However, how and by using which kind of tools could this be achieved? Based on that question we started a pilot research project at our university.

How and in which ways should an online tool metaphor curriculum to be generated and represented?

At our university, the University of Lapland, the curriculum for Technology Education for the years 2001 – 2003 has been developed as a pilot project for a new, primarily online curriculum / syllabus, electronic "eCurriculum / eSyllabus", that is located behind a Web (World-Wide Web) portal in order to integrate different post-modern computerized and networked means and resources together with the more traditional resources for learning into a coherent learning structure <URL: http://www.urola.fi/home/kik/opettajankoulutus/tekninen_tyu/>. The ultimate aim is to develop an organizational-level application, a hierarchical tree of Web portals through which different courses can take advantage of the generated model. The portal is primarily used in research projects related to use of different electronic resources and mental tools such as simulations within context of Technology Education (see e.g., Lehtonen 2001), thus providing the integration of those resources and virtual learning activities into a coherent part of student’s daily learning activity. At the beginning, the main question of the process was: What kind of curriculum and its representation would be needed in present post-modern age to integrate different parts of both the traditional and more modern electronic and computerized learning ways, resources, and materials into a meaningful integrative systemic tool for our students? The other main question was how we could integrate as well as possible the traditional ways of curriculum representation with the new ones in order to create as coherent a system as possible for the use for our students. A special interest was also the possibility to link easily the becoming Finnish Virtual University courses <http://www.virtuaalilyliopisto.fi/> as easily as possible to part of our programmes and possibility to offer parts of our programmes through Finnish Virtual University.

The realization of the process involved many phases and was mainly based on Cultural Historical Activity Theory ("CHAT") (e.g., Poldolskij 1998; Kapetelinin & Nardi 1997; Vygotsky 1978). The main questions were to plan and understand the structure of learning activity well enough in order to be able to create the necessary support tools. The questions were divided into three main areas:

1. The users of the tool: Who is or who are the users?
2. The situation and goals the tool is used: For what purpose does the user use the tool and in which kind of situation?
3. The activity for which the tool is used and the logical structure of the tool: In which kind of (psycho)logical (activity) structure is the use is based on?
Definition of Tool Using Roles

The first task was to define for whom the tools, the tools area, and the portal was created. Through this analysis, we were able to define the student roles for the targeted users of the tool.

The main user roles were found to be:

- the basic course student,
- the optional courses student,
- the specializing course student,
- the student entering training,
- the continuing education student (assumed to be mainly based on virtual learning activity).

According to the analysis, these were the most important user roles of system (the additional roles considered were, for example, resources for field teacher searches s, the person seeking a specialist, etc). Through this analysis, the tools and contents were generated to become as targeted as possible in order to fit suitably into the activity structures used by the learner during a specific part of a course. (See Fig. 1 and 2.)

Definition of the Situations and Goals in Which the Tool Is Used

The second question was in which situations students need the portal and the kinds of activities students performed with the tools.

The activity structure of the student analysed was simplified, in that the student wants to get all the necessary resources in order to study a certain course as easily as possible. What does he or she want to find, what does he or she want to do, and how does he or she want to do it?

We can emphasize that obtaining an overall representation for the general plan of achievement and gaining an overall view of what to do, plus obtaining easy access to the tools for the activity, is at least partly formed in the first critical step in a well defined pedagogical process (cp. E.g. Poldolskij 1997). In other words, to be able to say it should be easy to find what to do and where to easily find the needed resources in order to concentrate one's activity as much as possible on the core of the activity itself instead of on some other activity.

The primary answer to this question was that the course portal should be **integrative**: Integrate all the modern electronic and online resources as well as traditionally used resources in order to become as easily accessible as possible. Secondly, the portal should be **iterative**: Include primarily all such data that will be updated during the curriculum and which cannot or is not sensible to represent in printed format in a course catalogue. Such objects would obviously be online linked resources, computer programs, literature, and the more specific course contents that are updated regularly. Thirdly, the portal should be **interactive**: To offer as much as possible sensible interactive solutions to support learners learning activity.

The Logical Structure of the Portal
The third question was upon which kinds of (psycho)logical structure use could be based? The answer was sought by analysing the present activity of students when they sought for similar data and resources from the more traditional representation of the curriculum and syllabuses. Because our students use a printed course reader, the logical structure of the portal was based as much as possible on the structure of the course reader and the terms and course codes found there. The navigation model is based on the following steps: the student role (e.g. basic studies) - a list of basic studies modules - and finally an interactive representation of the curriculum where all the needed resources are linked to the required places.

In addition, an attempt was made to achieve visual similarities between the course reader and the Web portal (see Fig. 3 and 4). The idea was that when one has once learned to use one type of representation or media, one could use that same psychological model in another media format. Because the use of www-material is more based on scanning than continuous reading the text structure contains e.g. clear titles and other helping elements (e.g. Nielsen 2001). Because according the observations the students do print the pages quite often, the format is also optimized for that. E.g. some the link resources contain also the URL section in printable format.

What has been retained as a key point is the attempt to provide a navigation model in which all unnecessary items are done away with in order to reduce the cognitive load of the student as much as possible (e.g. Nielsen 1999; Nielsen 2000a,b; Chandler & Sweller 1991; Sweller & Chandler 1994; Wilson & Cole 1996). However, this is done so that if the student is willing to go directly to a certain offered resources, the aim is to provide as much as possible support for that also by linking some of the most used tools and resources directly from the main portal page and in some cases from a side navigation bars etc.

Online Material Interaction with Traditional Resources

Because of the wide use of more traditional resources of curriculum representation, as course readers or other printed material, the attempt was made to keep the interaction between printed and electronic media as easy as possible. A course reader or any shared paper document (or e.g. email messages to students) contains only one link to a course portal page.

The course reader only contains the most critical parts of courses and the more specified contents and linked resources can be found only in the online version. The organization has made a commitment to store the main page address as long as the curriculum is valid. The most important part of the system is the idea of generating the curriculum and its primary representation into an online format and organizing all the resources and materials through the curriculum representation.

Why HTML Content on the Internet Instead of a Special “Virtual Learning Tool”?

Why did we choose to put the portal onto the public Internet instead of using a special “Virtual Learning Tool”? The reason for using the public Internet instead of an application was that it provides the possibility to avoid commitment to a single program or environment. It also provides the possibility of generating a one-address portal system through which all resources can be accessed easily and being on the public Internet, there is no need to log in. It has the benefit of integrating very different resources into an easy accessible part of a course. It holds one permanent
URL address on the organization’s server, thus providing easy access from any other organization without the fear of changed or moved links, etc. Another benefit is that students only need to know one location in order to access all necessary resources. However, a portal is only a portal. It is only the general structure for integrating elements and tools. If a course needs a Web-authoring tool or a "Virtual Learning Environment", they are linked from the outside. The aim is to keep the portal as small as possible. The portal function is the skeleton for the overall structure of studies; the interactive curriculum representation serves the integration of all resources.

All the pages on the portal are linked from faculty’s main page under “Course portal pages” and the structure of the portals (and sub portals) is the same as in overall structure of the courses in the course reader.

The Present Situation in the Integration of Resources Throughout the Portal

Currently, the portal serves as an integrating element for quite different resources. Dependent of the course module, the portal integrates most of the items listed in the course content:

- More specified course objectives and contents,
- Changes to course literature or articles (e.g. new book or article / required pages of a book or a journal)
- Links to required electronic resources for the course (e.g. Internet links or a link to "Web collaboration spaces" such as BSCW® or "Web learning environment"; many different alternatives are currently in use at our faculty), etc.,
- Registration form for Web learning resources (www-form),
- Readable / printable / downloadable material for the course (includes also e.g. streaming media),
- Links to a additional references for course content (such as external links, virtual galleries, or references),
- Course page feedback form (a html text entry box at the bottom of each page)
- Course feedback form button (standardized www-form in every module),
- Buttons to university library and city libraries,
- ‘Search from library’ buttons after each book to search and reserve each course book easily from the library (sends the book ISBN-number and starts the library information system opening it in a separate browser window)
- Link to course time tables etc.

The portal page contains also direct links for several most used resources; additional navigation elements e.g. site map and contact information and contact form for faculty personal, etc.

Conclusions

The Web portal based on curriculum representation has now been used for year as a pilot study. Despite its visual simplicity, according the beta tests and more precise usability testing, students have been quite satisfied with it (e.g., see the beta version questionnaire <http://www.urova.fi/home/ktk/opettajankoulutus/tekniikantyo/kouluuspalauta/>).

The benefits of the system for our student were found to be:

- "Everything can be found at one location”;
- "Easy to find needed data up to date”
- "Links: E.g. especially library links!"
- "Easier to return essays and exams.” (e.g. Linked BSCW® program) and
- "The possibility to collaborate through Web tools”

Some negative aspects of the system have been mentioned:

- "Not enough computers on the campus, no networked computer at home”;
- "The linked resources like BSCW are too difficult to use” and
- "More pictures”.

The possibility of updating iteratively course contents has also been a great advantage (which makes possible the iterative development of curriculum), otherwise it would have been very difficult to update the course contents or links to several Internet resources and to update or modify course literature easily. Probably the greatest benefit is that despite all modifications to program content, a place where the entire coherent content can be found still exists to students.

Research in the future shall be targeted at developing the students’ tools and the overall function in order to support learning activity as much as possible. The plan for the future includes adding some new tools for students, such as search-functions (requires also better content metadata format; see e.g. Koper 2001), offering some contents also in
mobile Internet (like VML/XHTML) format for mobile phones and PDA's and making it possible to use e.g. redundant mobile streaming audio format instead of text in some contents. No doubt, the future version will be generated using dynamic html with xml content base or a database rather than static html/JavaScript solution. What has been learned is the fact that online curriculum, "eCurriculum", and this kind of integrative tool have proven its essence from the pedagogical perspective. Future development will be carried out in order to develop and support students learning activity with as many easy accessible integrative, interactive and iteratively updated tools and resources as possible.

Authentic Performance of Complex Problem-Solving Tasks with an EPSS

By Chet Leighton and Cynthia McCabe

Teaching People to Design

Just-In-Time Learning (ITEC 805) is a semester-long graduate course that teaches corporate trainers and instructional designers how to design performance improvement interventions. This course is part of a Master’s program in Instructional Technology at San Francisco State University. The course has been offered three times and has been completed by a total of 38 people. Learners produce two major deliverables for this course—a paper of about 20 pages describing a performance problem and the design of a system to address the problem, and a paper of about 5 pages explaining the design strategy.

Based on final grades for the course, participants in this class can be grouped into three broad categories. The A-level performers are 38% of the total students, B-level are 17%, and C-level are 45%. An Electronic Performance Support System (EPSS) was designed and implemented to help the B-level and C-level people improve their performance. (See Leighton, 1996 for a description of the EPSS model.) The JIT Learning EPSS was designed and developed by Infomark Software Corporation with CGM Communications and assistance from several graduate students in the SFSU ITEC Department in the first half of 2001.

The JIT Learning EPSS was implemented with 15 learners in Fall 2001. For this class the grade distribution was 53% in the A-level, 20% in the B-level, and 27% in the C-level. When compared with prior classes, all of the B-level performers improved to A-level and half of the C-level improved to B-level. A formative evaluation of the system was conducted in the winter of 2002. The results suggest that the remaining C-level performers do not have a sufficient mental model of the design task. The next version of the software will focus on helping users develop and assess their mental models before they begin the design task.

Performance Support Systems for Complex Problem-Solving

Designing a performance improvement intervention is a moderately-structured complex problem-solving task (Foshay, 1997; Jonassen, 1997). Typically, a performance problem can be defined clearly, it is clear when the performance problem is solved, and there are multiple ways to design a correct solution.

There are numerous examples of performance support systems used to teach complex problem-solving tasks. There is a subset of cases where the user performs a task primarily involving design, analysis, and/or planning and the output of the task is to produce a deliverable document.

- Broadcast News allows high school students to write news story on real current events (Schank & Kass, 1996). The system includes a tool for writing stories, background information on a story, and a library of information resources. Video advising is provided based on the concept of goal-based scenarios.

- Project-Based Learning Support System (PBLSS) allows high school students to plan and conduct a math or scientific inquiry project (Laffey, Musser, and Tupper, 1998). The system includes guidelines for organizing a project, a tool for writing a project plan, and the ability to publish a project plan as an HTML document. PBLSS is designed to support project-based learning, where students work in groups to define and investigate their own project ideas.

- Air Campaign Planning Advisor (ACPA) allows U.S. Air Force officers to author air campaign plans to attack military targets (Johnson, Birnbaum, Bareiss, and Hinrichs, 2000). A seven-step model is used to structure the process. Information resources, including video-based advising, are organized around questions to address in producing an air campaign plan.

- Tactical Readiness Instruction, Authoring, and Delivery (TRIAD) allows U.S. Navy officers to create tactical documents that are used to share information on tactical problems and solutions (Hannafin, Hill, and McCarthy,
TRIAD includes an authoring tool for producing multimedia documents. An interview process is used to lead the user through writing the various sections of a document.

A common theme among these systems is support for two major activities. First, users must perform the complex problem-solving task that involves design, analysis, and/or planning. Second, users must perform the task of producing a deliverable document that contains the "output" of the problem-solving task.

Underlying the design of these systems is the concept of situated cognition and the Cognitive Apprenticeship framework (Brown, Collins, and Duguid, 1989; Collins, Brown, and Holm, 1991). The EPSS contains a tool for producing the deliverable and uses a series of guidelines and questions to scaffold task performance. Information resources are organized around sub-tasks in order to model performance. Coaching is implemented in several ways: the process is structured through an explicit task model, the guidelines and questions provide implicit structuring as performance occurs, and video-based advising appears in the context of authentic task performance.

The Just-In-Time Learning EPSS

The Just-In-Time Learning EPSS uses a six-step process to design a performance improvement intervention. The first five steps lead the learner through describing the problem situation and explaining the design of the proposed intervention. The last step reviews the design strategy of the intervention. This last step is used to support articulation and reflection on the current design effort, and to explore new design ideas for future efforts.

The format of a typical deliverable produced by the EPSS is like the format of this article. A paper is generated as a series of paragraphs with appropriate subheadings in HTML. The formatting of the document is simple, as the emphasis is on the content not on presentation. Of course, a user can import the HTML into a word processing program to improve the formatting.

Structuring the Performance and Learning Process

The opening web page for the EPSS shows the status of work on each step, or deliverable document. The web page for one of the deliverables is shown in Figure 1. The header across the top of the page reiterates all the steps in the process. Access to performance and learning resources are organized around producing the deliverable.

Resources for a deliverable are organized into three categories, as noted below. The user clicks a symbol to see the questions under a guideline or the documents for a type of resource.

- Guidelines and specific questions to answer in producing the deliverable document
- Performance Resources-- Advice on key design decisions, example documents, and information resources in the form of handout documents and articles to read
- What You Need to Know-- These learning topics represent pre-requisite knowledge required in order to understand how to use the resources and produce the deliverable.

The items under "What You Need to Know" correspond to the learning objectives of the JIT Learning course. A learning topic has information resources like article readings, text discussions, and handout documents. It also includes exercises (self-graded) and assignments (graded by the instructor) for practice. These learning topics allow learners to review the information provided in class.

Scaffolding Task Performance

The combination of guidelines and questions structure the task of writing each deliverable document. By clicking on any question (or the question number following "Continue on Questions to Answer at:"") the user can enter an answer for a question as shown in Figure 2.

![Figure 2 - Entering the Answer for a Question](image)

The software simplifies the task of writing a document by prompting a user to answer a series of questions. When the user clicks "Save" an answer is saved in a relational database. Then the user is prompted to answer the next question. A progress meter showing how many questions have been answered for the deliverable appears on both the Deliverable and Question pages.

At any time the user may click "View My Paper" to produce the output document. All of the individual answers are compiled into a series of paragraphs. Users can save documents in HTML format and import them into a word processing program for additional formatting or revision.

Another scaffold in the system concerns the ability to prepare an outline before writing a paper (via the "Paper or Outline" button in Figure 1). In outline mode, the user's answers are shown side-by-side in a two-column table with the questions. The learner can submit an outline version, get feedback from the instructor, and then revise the outline into a narrative paper.

There are multiple levels to fading these scaffolds. The learner can skip producing an outline and move directly to writing a paper. The learner does not have to use the question and answer page as the writing tool. The Deliverables page could serve as an external support facility and the user could work entirely in a word processing program. By design, the fading of the scaffolds is controlled by the user.

**BEST COPY AVAILABLE**
Coaching and Advising

Video-based advising takes the form of 45 to 90 second video clips with advice on the most frequently encountered design problems for a deliverable. This advising is in the form of a story about a design problem. Most of the videos feature learners who have completed the course telling their own painful stories. They describe a problem situation and then discuss their solution. There are also clips featuring the advice of the instructor. The instructor describes a symptom, the underlying problem, and advice on how to solve that problem. For example, one video clip explains the trap of starting to design the solution before the problem is fully defined.

Formative Evaluation Results

A formative evaluation of the EPSS was conducted in the winter of 2002. Data was collected from twelve participants with a 70-point questionnaire, from database log files with details on how the software was used, and with follow-up interviews.

The average amount of time spent writing papers with the system was 927 minutes, or about 15½ hours. When the participants are ranked by final grade, the top third spent an average of 975 minutes, the middle third spent 494 minutes, and the bottom third spent 1,313 minutes. The following chart shows the average amount of time spent on each of the four major papers (Deliverables) by group. The differences are quite obvious between the three groups. The top group put most of their effort into the problem description, while the bottom group spent most of their time on describing the solution (the Components and Roles and Case Scenario papers). The middle group appears to be quite efficient in using their time. In contrast, given the low quality of their design efforts, the bottom group spent a lot of unproductive time in devising a solution.

On the questionnaires, the bottom group scored themselves higher than the top group in using the feedback from the instructor to improve their project designs. However, their final grades were lower primarily because they did not correct the design flaws identified in feedback on their papers. The Case Scenario papers by the bottom group revealed a weak understanding of the task being performed by their target users. Surprisingly, the bottom group claimed to have more experience doing task analysis than the top group. Even though this topic is covered in a prerequisite course on the ISD model, the bottom group appears to have a weak understanding of task analysis. This limits their ability to effectively use the instructor's feedback in defining problems and designing solutions.

Implications and Future Work

The approach of using guidelines and questions to scaffold the task of writing complex papers was successful in helping improve the overall performance of a class. However, there is still a group at the bottom of the class that needs more help than the EPSS provided. They spend too little time in defining the problem situation and too much time in creating a solution. At the same time, they do not make effective use of the instructor's feedback in correcting design flaws.

This suggests that users who perform poorly have weak mental models of the design task. In the next version of the JIT Learning EPSS we will add functions to help users develop and assess their own mental models before they begin producing a deliverable paper. This will include more emphasis on using the analysis of a target user's task to
better understand the problem domain. We will also add a feedback-and-response function so that users explicitly acknowledge the instructor's feedback and articulate how they will correct design flaws.

Addressing Biodiversity Problems Using Web-Accessible Data: A K–12, Hands-On Exercise

Jennifer Leopold, Anne Maglia, and Jennifer Dropkin
Natural History Museum and Biodiversity Research Center, University of Kansas, Lawrence, KS 66045

Introduction
The new paradigm in science education calls for learning in which 1) students perform real science as they construct meaning and acquire understanding; 2) students develop thinking processes and are encouraged to seek answers that enhance their knowledge and acquire an understanding of the physical universe in which they live; and 3) students are presented with problem-solving activities that incorporate authentic, real-life questions and generalization to broader ideas and applications (North Central Regional Educational Laboratory; www.ncrel.org/sdrs/areas/issues/content/cntareas/science/sc500.htm). Concurrently, the rapid development in technology compels us to include computerization in the classroom. Web-based learning can provide a solution that incorporates all of these objectives.

One of the more common areas for incorporating Web-based discovery in science education is investigating biodiversity, the study of life on Earth. This knowledge is critical to science and society for managing natural resources, sustaining human health, maintaining economic stability, and improving the quality of human life. And the urgency for this knowledge increases daily as the destruction of natural systems accelerates the decline of biological diversity.

Several Web-based projects are dedicated to biodiversity education at the K–12 level. In fact, most museums have attempted to develop some project designed to encourage K–12 biodiversity education, including developing “virtual” museum exhibits, interactive exercises, and “Ask a Scientist” programs. Unfortunately, despite the excellent education programs that museums have developed, they have not taken advantage of their biggest strength—the research data that they collect and curate. Data associated with specimens document the biotic, geological, oceanic, atmospheric, and geospatial information connected to the world’s estimated 1.8 million species. These data should be at the core of any educational endeavor that includes K–12 science education. With the development of robust database management systems and fast and accurate Web accessibility, we now have the ability to make collections data available for public access. This allows us to develop educational exercises that can bring the museum, and the data collected in the fight to preserve biodiversity, directly into the classroom.

Herein we describe an educational exercise for K–12 grade students that uses museum collections data to examine biodiversity problems in the Amazon rain forest. The goals of this exercise are: 1) to make students aware of current biodiversity issues, 2) to educate them about research data housed in natural history museums, 3) to motivate student interest in science, 4) to increase student proficiency with computers, databases, and Web browsers, and 5) to serve as a prototype for developing other exercises that use Web-accessible data to address real problems.

Using Specify Collections Data to Examine Amazonian Biodiversity
In this exercise, students use a straightforward Web interface to access data collected by natural history museums and apply them to understanding conservation issues in the Amazon rain forest. Students are challenged with making decisions based on data they have collected, and are asked to re-evaluate and summarize decisions once additional data are added.

Background.—The Amazon jungle is the world’s largest tropical rain forest, with 2.5 million square miles. Presently, there are at least 500 species of mammals, 475 reptile species, and at least a third of the world’s birds. This area is vital to the economy of many countries in South America, which send much of the natural resources (e.g., timber, petroleum, and gold) to the United States. Unfortunately, the practice of harvesting natural resources has caused severe declines in biodiversity in the region. Because of its importance to so many economies, it is unlikely that industrial practices will change, and therefore, conservationists are trying to compromise with industrialists to preserve as much of the area’s biodiversity as possible. One popular suggested compromise is to sacrifice portions of the Amazon (such as the eastern or
western half) for logging and mining, and leave other areas untouched to maintain their pristine biodiversity. By using the information stored in museum collections, conservationists can make informed decisions about which areas are more prone to extinction or survival.

Traditionally, museum collections data have been difficult to access or laborious to examine. However, recent technological advancements have made Web-accessibility of museum collections data a reality. One such development is the collections management software tool, Specify (www.usobi.org/specify/). Specify is a robust database application that is specifically designed for the management of specimen information. This software provides a single user-interface to all kinds of collections data (e.g., plants, birds, bacteria, etc.) and a single URL for Web-accessibility. Therefore, users do not need to learn different interfaces to examine heterogeneous databases housed in different locations.

Objectives.—Students access museum collections data using the Specify Web-query interface, then use the data collected to generate maps and charts of the number and kinds of species (i.e., species richness) in various regions within the Amazon basin. Students apply the data they uncover to determine which areas in the Amazon are most critical to preserve.

Teaching Strategy.—The presentation begins with an introduction on the topic of biodiversity. Students should understand what extinction is and how it can be both a natural and man-made phenomenon, and what a scientific natural history museum is and what kinds of data museums collect to study biodiversity.

The Amazon rain forest is then discussed as an example of an area with high levels of biodiversity, but that is also in decline. This might include a short history of the continent and discussions of how the Amazon rain forest became so biologically rich. Students then use a search engine to find information on the Internet about the Amazon rain forest and the different kinds of animals and plants found in the area.

Once students are familiar with using the Internet to collect information, and are familiar with the Amazon rain forest, they then access natural history collections representing different taxonomic groups using Specify. Students are shown how to run queries of species by locality to determine species richness (number of species) and endemism (areas of high concentration). Students break into groups, with each group searching for different kinds of organisms. They are then given outline maps onto which each group plots the data they discover. Once all data are collected, students combine the data they find onto a single map that describes species distributions. Depending on the level of computer proficiency, students may also develop charts and graphs of the data using a spreadsheet application. Working together, students can evaluate the data they collected to determine which areas should be conserved, and which areas may be sacrificed. Criteria to choose could include number of species and presence of rare species.

Once students have determined which areas to preserve, the teacher may want to access global climate change databases (e.g., edcwww.cr.usgs.gov/) and generate climate models that can be used to predict how climate changes may affect the Amazon rain forest in the future. The students may then elect to re-evaluate their choices based on possible future climate changes. Students conclude the exercise by writing a description of their findings in a lab report, or summarizing their findings on a poster (for possible presentation in a science fair).

Extensions of the Project.—In the near future we intend to use this same exercise framework with another, more sophisticated, data access tool, WebFormulate (J. Leopold, M. Heimovics, and T. Palmer, "WebFormulate: A Web-Based Visual Continual Query System", [in press]. Proceedings of ACM 11th International WWW Conference). This software will not only allow the students to query natural history specimen collection databases, but will also allow them to specify how often the database should be queried and the conditions by which they want to be notified of the results (e.g., whenever a new species of frog is added to the database). In addition, any user-specified WebFormulate computations or visualizations based on those query results will automatically be updated every time the notification conditions are satisfied. Thus, the students can monitor their analyses on an hourly, daily, weekly, or monthly basis.

Summary

Herein we have briefly described an exercise that addresses our aforementioned educational goals at the K–12 level. We hope that this endeavor not only accomplishes these goals, but also helps to foster the next generation of biodiversity researchers and bioinformaticians.
Teaching with Technology through Collaborative Interdisciplinary Instruction

Mr. Philip Lewis, M.S. and Mr. John Hildreth, M.M.

OVERVIEW:
Incorporating technology into the classroom is paramount at Radford University. Both administrators and faculty have seen pronounced increased in effective teaching through the use of multimedia technology when presenting difficult material. However, not all faculty can be expected to learn complex applications in a timely fashion that would enable effective instruction to any students. Therefore, a unique form of support has developed through Radford University library’s . In a number of situations and courses, technologists and faculty members are teaching 'high tech' classes side by side. Increasingly, this support is giving better opportunities for students to learn and faculty to become more familiar with the technologies that dominate nearly every field.

This paper presents the findings of a class that became a case study in interdisciplinary academics. The course incorporated traditional collegiate education themes with technology through a collaborative, co-instruction effort between a university music professor and multimedia technologist. The course, entitled Introduction to Film Music (MUSC 373, Computer Music Composition), incorporated an historical survey of film music media including literature, recordings and film as well as compositional assignments. In these assignments, students were required to learn the parameters of a certain era’s film music (including the limitations) and then create their own soundtracks.

TIMELINE

Radio       Silent Film       Television       Film

Technologies and composition practices of each medium and time period are presented chronologically and are studied, discussed and experienced through assignments. From Radio to modern film, each era (compositionally and technologically) is delivered.

ASSIGNMENTS: The process
Film excerpts were digitized using a digital video editing workstation. The audio element was removed, and the film was then compressed into a digital format (QuickTime) that the students could import into a software application used to sequentially develop their score to the film. In this manner, the students were able to score the musical and sound excerpts while watching them, just as composers working in the industry do. Assignments were handed in on CD or cassette media and evaluated in class by the professors and peers.

STATEMENT OF PROPOSAL

One way of achieving technology in the classroom is to have collaborative instruction. In this case study, the course was co-taught by two instructors, each an expert in their fields; one in music and the other in media technologies. The benefits of collaborative instruction are manifold:

1. Instructors do not bear the burden of 'learning it all' before they incorporate technology into the classroom.
2. Instructors are involved in faculty development as they simultaneously impart and absorb expertise in their relationship with the co-teacher.
3. The student benefits from the interdisciplinary delivery and application of course materials, part of which include the dual perspectives and expertise of the faculty. Moreover, students enjoy a fresh approach and are better informed as a result.

The course became an intuitive utilization of resources, and the student reaction made it an exceptional experience for all persons involved.

FILM

A 25-minute documentary film was produced from in-class footage of interviews and discussions, as well as instructor interviews, commentary and samples of student work. This film reveals in detail the efforts made by the instructors, outcomes of the assignments by the students and a candid discussion on issues of teaching collaboratively. The film will be screened following the presentation, and participants will be given a copy of the syllabus and class timeline. A discussion will follow.
An examination of the functional capabilities of different user environments in networked classes and the development of a school-based language lesson and self-study system based on this examination

ChunChen LIN*, Shinichi FUJITA**, Seinosuke NARITA**
* Faculty of Foreign Studies, Tokyo University of Foreign Studies, Japan
** Department of Electrical, Electronics and Computer Engineering, School of Science and Engineering Waseda University, Japan

Abstract With the advent of high-speed networks, feasibility studies and development of network-based systems to support class work has been pursued with vigor, resulting in new education environments such as remote lessons and cooperative learning. These studies have largely been carried out by examining an existing environment and constructing one based on the desired functions. However, so-called network-based lesson environments contain many different factors, such as the different computational environments used by teachers and students, network configurations between computers, and a variety of subjects that serve as targets for study. Moreover, these studies largely focus on the actual classes, whereas in the real world of school education, revision of material after each class is vitally important. This aspect has received little attention thus far. This paper examines the function of different environments during the development of a support system for network-based classes. By examining the function of different environments, an actual system supporting language lessons and self-study has been developed, with appropriate self-study environments. This system is divided into a support system for network-based lessons, and a support system for self-study. The lesson support system mainly offers lesson support for teachers, while the self-study support system is geared towards students, providing aids such as the reutilization of data taken from lessons.

1. Introduction
In recent years, as downsizing has lead to notable advances in computational capabilities, multimedia environments based on computers have become commonplace. The lifelike expression of sound, video and animation media, unified on a computational platform, presents itself as an opportunity for effective use in education. Especially in the field of language education, this has enabled the creation of systems that deliver lifelike effects not previously available to the language learner. Numerous applications of multimedia in language education have been trailed and developed, the effectiveness of which is well attested [1,2].

Also, with the realization of high-speed networks, lesson support systems using network capabilities have been brought under development and on a large scale. New education environments, such as remote lessons and cooperative learning, have been realized by use of the internet and intranet [3-6]. Research so far has mainly aimed to construct support systems for remote lessons, using exclusive connections or simply unprotected data exchange on the internet. They aim at re-creating a classroom environment as close to real life as possible, only network-based. These studies basically begin with an existing environment, proceed through to an examination of needed functions, and culminate in the realization of network-based systems for support of lessons. However, lesson support systems include many factors that need to be examined. For example, do the computers used by the teachers and students adequately handle sound and animation? Can the band area necessary for the sending of animation be provided for? Special needs may arise, depending on the nature of the target subject matter. For example, since the target subject matter in the present study is language lessons, one would need to consider the possibility of multi-lingual input and display. Hence, a thorough classification of the environment to be constructed is necessary, even before examining the various functions needed in a network-based lesson support system. It would be impossible to provide a trustworthy support system without following such a procedure.

In addition, to achieve overall learning objectives for students in an educational setting, a three-stage model is proposed, basically consisting of preview, the actual lesson and revision. This is shown in figure 1. In this model, the teacher uses established principles to impart knowledge in stage 2. This stage corresponds to the procedures of current classes. There is a flood of information to convey to the students, but there is little feedback from the students to the teacher, because of the large size of each class. The third stage corresponds to self-study. Students, with the aid of notes they have taken in class and their own comprehension of the material, develop understanding of the imparted knowledge. A truly effective learning support system requires not only support for the lesson itself, but also a support system that includes self-study. To my knowledge, there are no examples of considered application of these matters.
The authors of the present study aim to pursue the research goal of creating a comprehensive “integrated support system for the support of educational environments.” In other words, a learning environment that covers the spectrum of “lesson to self-study, classroom to home.” This paper presents a system supporting language lessons and self-study, developed by the authors. Chapter 2 below examines the functional capabilities of different user environments. Chapter 3 examines the actualization of environments and system architecture.

2. Examination of the functional capabilities of different user environments

2.1 Basic factors

Network-based lessons basically consist of the following three factors:

1. Network environment: This refers to how much network band is available between teachers and students. Satellite communication, exclusive connections, and internet may be used. The issue here is whether sound and animation can be sent from teacher to student and vice versa.

2. The computational environment being used: One needs to consider whether the computers used by the teachers and students allow the transmission of sound and animation.

3. The distance between the teacher and students: This refers not to physical distance, but to whether the teacher and students are separated. Students may be gathered in one spot, or be scattered around different places.

In addition, there are differences among the requirements for different subject matter. For example, in language education, the subject matter currently under consideration, there may be a need for multilingual input and output according to content of each lesson. As figure 2 shows, the user environment consists of the 1) network environment, 2) the computational environment used, 3) distance between the teacher and students, and 4) the subject matter. Classification is done on this basis, but for the sake of simplicity, where the network environment has sufficient network band to enable the sending of sound and video from students to teachers, the computational environment used is assumed to be one where each student has his/her own computer, and that the computers are able to take in sound and video.

2.2 Classification according to the network band and the computational environment used

As shown in Table 1, the horizontal axis indicates the network band from the student to the teacher. The vertical axis shows the network band from the teacher to the student. The analysis has been simplified. It was found that costs would be relatively lower to provide an adequate environment for teachers only. Hence the categories only show “none,” “sound” and “video.” The results of this classification is summarized as follows:

0. Neither the teacher nor the student has access to a computer. The necessary network is not available. Note that even if the learner has a computer that sends out sound and video, it would be useless if the teacher had no computer. Hence, in both cases the category 0 is assigned.

1. The teacher can send sound and video information to the student, but the reverse is not available. This is typical of one-way transmission situations such as lessons in the classroom and satellite broadcasting. In this environment, the student does not necessarily need a computer, but equipment for receiving the teacher’s information, such as projection screens and loudspeakers might become essential.

2. The teacher can send both sound and video to the student, but the student can only send sound to the teacher.

3. Both the teacher and the student can send and receive sound and video. In this case, cameras need to be installed on all computers.

The above classification is based on the network environment and the computational environment used. Cost considerations yield the hierarchy of 0<1<2<3.

2.3 Classification according to the distance between students and the teacher

Using the results from classification according to network environment and computational environment used, we may now obtain a further classification according to the distance between students and the teacher. “Distance between students and the teacher” refers not to the physical distance, but to whether the parties are gathered in the same place. As table 2 indicates, the horizontal axis shows 1) teacher and students in the same place, 2) students in the same place, and 3) students scattered. The vertical axis shows the results of classification according to network environment and computational environment used. In the current analysis, “teacher and students in the same place” approximates the traditional classroom situation. “Students in the same place” represents the situation where students are gathered in a classroom environment, while the teacher is elsewhere, possibly in a studio. The “students scattered” scenario refers to the situation where students are in their own homes. The results of the above classification are as follows:

0' Both the students and the teacher are in the classroom, representing the traditional classroom situation with blackboards and textbooks.

1' This is basically the same as 0', only the teacher may use a personal computer and projector for presentation of material.

2' Both the students and the teacher have access to computers. This enables the transmission

</thead>
<tbody>
<tr>
<td>0’</td>
<td>1’</td>
<td>2’</td>
</tr>
</tbody>
</table>

Table 2: Classification according to distance between students and the teacher
3' Students and teachers are not in the same place. However, students are unable to send information to the teacher. This results in a lesson type with only one-way communication, such as one-way transmission of material via satellite broadcasting or education broadcasts on television.

4' Students and teachers are not in the same place, but there is voice communication between the parties. Gestures and facial expressions cannot be sent.

5' Teachers can send both sound and video to the students, but students can only send sound signals to the teacher. Hence, the teacher is unable to ascertain the students' facial expressions. However, if a moving image camera was installed in the classroom, the teacher would be able to observe the classroom environment.

6' Students are scattered over many locations, but two-way voice communication is available. The teacher is unable to monitor the actual learning environment.

7' Students are scattered over many locations, but two-way voice and video communication is available.

In the aforementioned table, the combinations of "0 - teacher and students in the same place" and "0 - students scattered" indicate situations where there can be no communication between the teacher and students. Hence an X has been assigned.

2.4 An examination of basic functional capabilities

The functional capabilities available in various environments are summarized in Table 3. An explanation of these capabilities follows:

<table>
<thead>
<tr>
<th>Capability Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sound and video transmission from the teacher to students: Sound and video data taken by microphones and video cameras are sent to students. This function is essential when the teacher and students are not in the same place.</td>
<td></td>
</tr>
<tr>
<td>Transmission of handwritten information from the teacher to students: Information written on the blackboard during class is sent to the students. This function becomes very important when further explanation is needed, apart from the handout material prepared beforehand.</td>
<td></td>
</tr>
<tr>
<td>Sound transmission from one student to all other people: This function operates when students are scattered in different locations. When the teacher is asked a question by a student, this function enables all other students to hear and share in the same information.</td>
<td></td>
</tr>
<tr>
<td>Transmission of video from students to the teacher: By sending video from computers equipped with cameras, the teacher is able to monitor the students' learning environment.</td>
<td></td>
</tr>
<tr>
<td>Transmission of text information from the teacher to students: This enables the teacher to send text information beforehand.</td>
<td></td>
</tr>
<tr>
<td>Transmission of image information from the teacher to students: This enables the teacher to send prepared images beforehand, such as photographs.</td>
<td></td>
</tr>
<tr>
<td>Relay of classroom images to the teacher: This is achieved by cameras that take in images of the whole classroom, and relaying these images to the teacher. This enables the teacher to monitor the whole classroom situation.</td>
<td></td>
</tr>
<tr>
<td>Shared cursor: As the teacher explains material during class, this function enables all students to view the position of the mouse point at any given moment.</td>
<td></td>
</tr>
<tr>
<td>Easy-to-operate testing functions: When the teacher and students are in different locations, it is difficult for the teacher to ascertain understanding of the material. With easy-to-operate test functions, the understanding of students can be tested.</td>
<td></td>
</tr>
<tr>
<td>Note system: This function enables students to take notes on their own computer.</td>
<td></td>
</tr>
<tr>
<td>Virtual class list showing seating arrangements: This allows the teacher to check where the students are sitting, enabling the teacher to ascertain information about students.</td>
<td></td>
</tr>
<tr>
<td>A function that facilitates the asking of questions: When a student wants to ask a question, this function is used, which enables the teacher to receive questions.</td>
<td></td>
</tr>
</tbody>
</table>

As the above examination of basic functional capabilities indicates, we are concerned with the retention of two-way communication, which is fundamental in educational classes (functions 1-8, 12). At the same time, the merits of a computational system are also maximized (functions 9, 10, 11).

2.5 Language education and the functional assessment of systems supporting language lessons and self-study
In language education, as the focus shifts from language ability based solely on reading to practical language proficiency, phonetic education has become an essential component. Especially in situations where the learner is not in a country where the target language is spoken, there is no environmental support, and one needs to learn the sounds of the language with cassettes or videotapes. Many institutions offering language education have made use of LL classrooms, and these have served their purpose well. However, with the advent of downsizing, many are shifting from LL to LL/MM classrooms. With the installation of computers in LL classrooms, cassette and videotapes in current use may be digitalized and made available by online retrieval. Also, the availability of online use combined with the use of multimedia language education software is seen as just one of many merits. However, as lessons have shifted to LL/MM classrooms, the size of classrooms has increased, making it hard to read handwriting on blackboards. Especially with languages such as German (with small umlauts) and Thai (with letters which only differ slightly) there are differentiation problems. Also, it would be ideal to have explanations delivered by teachers in the target language stored on the network for self-study, rather than relying solely on notes taken during class. For self-study, a student should be able to store notes taken in class together with stored data of pronunciation drills, enabling a reenactment of the actual classroom experience.

At this point, extra functions are presented in a proposed system supporting language lessons and self-study. These functions are expansions on the basic functions covered in 3 in Table 3. Below is a description of the added functions.

1. Teacher orientated: Virtual class list showing seating arrangements (roll call)  
   Student orientated: Login function
   There is a need to store roll calls on a database, enabling unified treatment of the data. Consideration of teachers’ needs, such as provision of class lists showing seating arrangements, is also a necessity.

2. Teacher orientated: The sending of text information  
   Student orientated: The receiving of text information
   Text information prepared by teachers would be made available online. Multilingual display and multilingual input needs have to be addressed. Text information should be made available at the same time as the lesson contents (to be discussed below). This information would be used for self-study by the student.

3. Teacher orientated: Sending of handwritten information  
   Student orientated: Receiving of handwritten information
   This function allows the teacher to send diagrams to students as they are drawn, via the internet. This should also be made available at the same time as the lesson contents (discussed below), to be used for self-study by the student.

4. Teacher orientated: Sending of video  
   Student orientated: Receiving of video
   This function allows the transmission of video files to students via the network.

5. Teacher and student orientated: Dialogue-based easy-to-operate testing functions
   These functions are centred on the filling in of blanks. These tests are sent by the teacher to the students. After the completion of tests, students are able to compare their own work with the answers prepared in advance by the teacher. The data is then registered on the database server and made available to the user for self-study. Of course, all of this is available for multilingual display and multilingual input.

6. Student orientated: voice recording and replay functions
   These functions allow students to record their own pronunciation during class, and to compare this with the pronunciation in the teaching materials.

7. Student orientated: Note system
   This function enables the student to take his/her own notes in class and to save these.

8. The transmission of lesson contents
   This function enables the transmission of video of the lesson, voice data, text information given out by the teacher, and handwritten information. All the above types of information are to be simultaneously and automatically distributed to all students after each lesson.

3. Composition of the hardware and system architecture

3.1 Composition of the hardware

Figure 3 shows the overall image of our system supporting language lessons and self-study and the Table 4 shows all of the function. As the figure shows, one computer is made available to the teacher, with 50 computers made available to students. A video camera for recording the lesson and a cordless microphone is included. Two servers are provided. One is for the transmission of moving images, the other is a database server for saving all data used during class, as well doubling up as a file server.

1. The teacher’s computer
   The teacher’s computer is a windows machine which is connected to the network.

2. Computers for classroom use
   Computers for self-study can be existing ones, as long as an internet connection is available and Windows is running. It is also acceptable to use a telephone to connect them. Below are some specifications for the various parts of the configuration.

3. Server for database and files
This server has Windows NT as its operating system. Since it is used to store applications that are used in class, a large hard disk is installed. Microsoft Access 2000 database server is also installed, and all types of data used during class are stored here.

(4) Server for the transmission of moving images
This server has Windows NT as its operating system. A video capture card, cordless microphone and camera are installed for the purpose of recording video of the lesson. A tracking device ensures that the recording of the instructor's face remains at a constant size on tape. Real Server has been selected as the server responsible for distributing lesson contents.

(*) Basic functions based on Table 3. (***) Addition functions added for language education

Table 4 Functions available in a system supporting language lessons and self-study

3.2 The development of the environment
The present system was developed using Visual Basic, and the various types of data utilized in class were realized using Microsoft Access 2000. The server for the transmission of moving images was constructed with Real Basic Server. Access for self-study is served by Web Browsers, with Microsoft Internet Information Server.

3.3 Actual installation of the functions
Figure 4 indicates the main screens as seen by the teacher and the students. The following explanations pertain to this diagram.

1. The installation of the virtual class list showing seating arrangements (roll call system) and database access methods
The attendance roll runs on a jet database engine. The attendance database was created with Access. The roll call function begins as the instructor's EDLIN is started up. As the instructor starts up his/her side of the system, a seating diagram is shown, as seen in Figure 5. Students' reports of attendance are then accepted. Students login to EDLIN, and their data is transmitted to the teacher's computer. The IP address of the point of access is noted, and the name of the student is written onto the seat diagram and preserved as data. All this data is preserved, so that the user is free to check his/her own attendance with the attendance button on the student main window. The teacher can use the AttendList to check the names of attendees on that day.

2. The installation of the text transmission function
In order to display multilingual data, this system uses the Rich Text format for text. Text entered by the teacher is saved on file at the touch of the return key, and automatically sent to all students. The time is recorded with the saved file, and the lesson contents transmission function (to be discussed below) uses this time to achieve simultaneity. On Japanese computers, umlauts in German are generally not available on the keyboard, hence the many multilingual input assistance tools, as shown in Figure 6. With the addition of these multilingual assistance tools, many languages can be dealt with. The text box in the main window of Figure 3 shows this function.

3. The installation of the transmission function for handwritten information
This function allows the teacher to transmit to the students (in real time) the data drawn on his/her whiteboard window. When WhiteBoard is activated on the teacher's computer, whiteboards appear on both the teacher's and the students' screens. Data is then transmitted. Also, every ten seconds, information about time and the image on the whiteboard are saved as
an image file. The lesson contents function also refers to this to achieve simultaneity.

4. The installation of the sending/receiving functions for images
When the teacher loads a prepared image and presses the transmission button, the students’ picture windows also start up automatically, displaying the sent image (Figure 7). The file types that can be displayed are JPEG, GIF and BMP.

5. Dialogue-based easy-to-operate test functions
When the teacher presses the MiniTest button, a dialogue-based test window opens, which is simple to operate (Figure 8a). When the teacher enters the questions and sends these, a test window appears on the students’ computers (Figure 8b). When a student completes the answers and sends them back, a student window with the name of the student appears (Figure 8a). If the teacher sends only questions, a question sheet appears on the student’s window (Figure 8c). When answers and inserted and sent, a window with the answers appears on the student’s screen. All this data are stored, and students may use this to revise the contents of the lesson during self-study sessions.

6. Voice recording and voice replaying functions for students
As shown in Figure 4, the student may use the record, stop and replay functions on the student screen to record his/her own voice and to replay this. This function can be used in times of self-study, or utilized to compare one’s own pronunciation with that of multimedia teaching material.

7. When the Note Button is selected, a note window appears, which when utilized and saved, can be used in the next self-study session.

8 Transmission of Lesson Contents
This lesson contents system enables the simultaneous transmission of four types of data: recorded video of the lesson, sound, text and handwritten data. The camera used has a tracking system which focuses on a red mark attached to the teacher’s chest, ensuring that the teacher’s face is always recorded as the same size on tape. Sound is recorded with a cordless microphone, and this ensures the red mark remains unobstructed. Both sound and video data are recorded from the start of the lesson to the very end. When the lesson is finished, a Real Text file with time information is generated, referring to the time recorded on the saved text files. Handwritten data is made into Real Picture files with time information, again using time data on the saved files. Thus text data, handwritten data, together with sound and video data can be arranged for simultaneity. All these are sent simultaneously as SMIL files. Figure 8 displays a screen with lesson contents being transmitted. On the left is Real Text, in the middle is Real Picture, and on the right is a video screen.

4 Conclusion
In this study, the basic functions necessary for network-based learning environments were examined. In addition, further functions necessary for language education were added. We conclude that network-based learning environments must not only re-create the classroom environment, but also provide support for study sessions after class. In particular, language learning cannot take place just by understanding of concepts; repeated practice is necessary. It was for this purpose that the authors of this paper developed the current system. It is a system that supports language lessons and self-study, based on the transmission of lesson contents, and including provisions for self-study. As this system comes into general use, evaluation studies will be conducted as part of the next step in our investigations.

Integrating ICT in Teaching Chinese Language and Literature

Janet Mei-Chuen Lin and Rong-Guey Ho
Department of Information and Computer Education
National Taiwan Normal University, Taipei, Taiwan
E-mail: mjlin@ice.ntnu.edu.tw

Abstract: Eight Chinese Language and Literature teachers participated in this research to make their first attempts at integrating information and communications technologies (ICT) into curriculum. They were provided training in common application tools and then paired up to develop ICT-based courseware for use in classroom teaching. Four units of courseware thus developed were field-taught to 169 students. Results of a questionnaire survey conducted after field-teaching indicate that most students prefer ICT-based lectures to conventional ones because ICT offers such benefits as making the lectures more interesting, enhancing the mood of the class, providing richer material than usual, and improving teacher-student interaction.

The Research Method

A school-university partnership was established in this research to enhance Chinese Language and Literature (CLL) teachers' computer competency and their use of information and communications technologies (ICT) in instruction. The partnership project was operated between the authors' department and Hai-San Junior High School, a typical junior high school located in northern Taiwan. Within this partnership, our department provided three computers and project-related software, set up network connection for these computers, and offered ICT training courses to Hai-San's CLL teachers. Reciprocally, the school provided full administrative support, the computer lab for the training courses, the conference room for seminars, and the equipment to be used for field teaching. The major participants included a professor, three graduate students, four undergraduate students from our department, and eight CLL teachers from Hai-San. All eight participating teachers are female. Their teaching experiences ranged from 8 to 28 years and they ranged in age from 33 to 51.

Considering that the participating teachers had limited prior experience in using computers, we decided to offer them an up front training course in ICT skills. The training course was also open to other interested teachers at Hai-San. The course was 36 hours in length and was divided into 12 sessions. Each session was taught by a graduate student as the lecturer and two undergraduate students as teaching assistants. Teachers were trained in common application tools, including Microsoft Windows (3 hours), Internet tools (email, web browsers, ftp, telnet, etc.) (6 hours), Word (9 hours), PowerPoint (6 hours), FrontPage (9 hours) and Excel (3 hours).

We took care to incorporate as many CLL-related examples and exercises into the training material as possible. For example, when we were teaching the use of browsing tools, we asked the teachers to search for web sites that provided good databases of Chinese idioms and proverbs or that contained a rich collection of famous Chinese calligraphic works; while in teaching Word's features, we taught them how to format a CLL exam paper; we also used a CLL lesson plan as an example in introducing formatting "tables" with Word. Our purpose was to keep reminding these teachers that ICT skills were not to be learned in isolation from the subject area. In addition, we arranged three tutorials to introduce these teachers to useful CLL-related digital resources, including CD titles and web sites. In the tutorials we also demonstrated exemplar cases of ICT integration in other subject areas.

After the training course was completed, the eight teachers paired up to design and develop ICT-based courseware. We assigned one of our students to assist each pair of teachers. Each team picked a unit from the textbook and wrote a lesson plan in which they embedded ICT-integrated learning activities making use of the courseware they plan to develop. The teachers generated ideas and developed the courseware with technical assistance from our students. Individual training on advanced ICT skills were provided to them on an "as needed" basis during the development process, which included skills in using web page design tools, video editing tools, etc.

Among the courseware developed by the four teams, one team focused their courseware on introducing students to an author who has been famous not only for his outstanding literary work but also for his love affairs with several beautiful women in the early 20th century. Another team used PowerPoint to present an article in a storybook-like fashion. They involved their students in the development of courseware by asking them to create illustration for the storybook. Yet another team of teachers asked each of their students to draw a picture to visualize what he/she thought an ideal world would be like. The teachers then scanned the pictures into the computer so they could be shown during classroom discussion. Teachers of the fourth team asked their students to collaborate in writing a play script based on a famous dialogue occurring between an emperor of the Song Dynasty in ancient China and one of his...
loyal military commanders. The script was then presented as PowerPoint slides and shown in the background while the students performed the play. Even though the learning activities supported by the four units of courseware were quite different from one another, all exhibited ingenuity in integrating ICT.

The courseware was used in field teaching to 169 students of six classes at Hai-San Junior High School in April 2001. We invited the principal, the director of the academic affairs, and all CLL teachers to sit in and observe. Six of the eight participating teachers used the courseware they developed in teaching a 45-minute class session each. The presentation equipment, including the computer, the overhead projector and the screen, was set up by our graduate students in advance. Our students also helped operate the computer during field teaching so that the teachers could concentrate on their planned teaching activities without worrying about possible technical problems. All field-teaching sessions were videotaped for later reviews and analyses.

**Findings**

A questionnaire survey was conducted right after field teaching to collect students' feedback. The questionnaire contained 19 questions. Eleven of them focused on contrasting the use of ICT in instruction with conventional lectures; three questions were related to students' attitude toward ICT integration in classroom teaching; and the remaining five questions concerned possible changes in students' motivation toward learning computer knowledge and skills as a result of experiencing ICT integration in subject teaching. The results indicated that most students preferred ICT-based lectures to conventional ones. A large majority of students agreed that integration of ICT helped make the lectures more interesting (97.64%), enhanced the climate of the class (92.91%), offer richer materials than usual (92.91%), and improved teacher-student interaction (83.46%). Most students would like to see the new teaching method used more often in the future (92.91%); they would like students of other classes to have the chance to experience the new teaching method (93.60%); and they hoped that ICT could be used by teachers of other subjects (94.82%). Moreover, 94.26% of students admired their teachers for their computer skills in creating the courseware, and 95.24% of students agreed that they would like to learn more about computers after seeing what their teachers were able to do. As to what other subjects in which the students would prefer seeing frequent use of ICT integration, the top three subjects were History (62.2%), Geography (40.94%) and English (33.07%).

Aside from students' positive feedback, the eight participating teachers took much pride in their own accomplishment, and they found the experience to be most rewarding. Furthermore, their achievements were well recognized by both the principal and the director of the academic affairs. In a seminar held for those teachers who came to observe the field teaching, the eight participating teachers shared their feelings and experiences with their colleagues about how they managed to overcome their own technophobia, how they came up with the idea for developing the courseware, their alternate feelings of frustration and self-fulfillment along the way, and their opinion of what distinguished teaching with ICT from teaching in a regular classroom. They encouraged other teachers to give it a try by emphasizing that "if we can do it, you can too." Most other teachers remarked that they were highly impressed by what their peers were able to do and that they had become much more convinced of the relevance and value of integrating ICT in CLL teaching. They also felt more motivated toward learning computer skills and had more self-confidence in implementing ICT integration.

In the seminar the teachers also discussed about obstacles and barriers to the use of computers and the Internet for instruction. What was identified included lack of computers and Internet connection in teachers' offices and classrooms, lack of proper training for teachers to learn how to use computers or the Internet, lack of release time for teachers to develop useful courseware, insufficient class hours to incorporate frequent use of computer in classroom, and lack of information about useful digital resources for use in teaching or learning CLL. Some teachers were more concerned about the issue of technical support, while some others hoped that there could be one or more multimedia classrooms established and dedicated to CLL teaching to facilitate integration of ICT in the curriculum.

**Conclusions**

Chinese Language and Literature has long been considered the most “traditional” subject in our school, and CLL teachers are often labeled as most reluctant to adopt innovative teaching practices. In this study we guided eight CLL teachers through their first attempts at ICT integration. They have succeeded in convincing themselves as well as their colleagues that integrating ICT into CLL curriculum is indeed practicable. They have also proved that all CLL teachers have the potential of utilizing ICT for enhanced effectiveness in teaching and learning if only they are provided with adequate training and, more importantly, if only they are willing to try.

Abstract: Shadow netWorkspace™ (SNS) is designed and developed as a free, open source, network-based work environment specifically for use in K-12 schools to support schools and learning. In this paper, we describe a learning module utilizing features of SNS and articulate how teacher and students can collaboratively learn and work to build knowledge. The paper also proposes a collaborative knowledge building model that illustrates the significant phases in the learning module. Teachers in the local community are invited to evaluate the feasibility of learning module in terms of its benefits, challenges, the ease and appropriateness of use. Feedback from the evaluation will provide recommendations for the design and development of knowledge building activities.

SNS Learning Communities

Shadow netWorkspace™ (SNS) is an Open Source, network-based work environment designed and developed for use in K-12 schools by the Center for Technology Innovations in Education (CTIE) at the University of Missouri-Columbia. Open Source licensing provides a new framework for the development and evolution of software systems, and network-based learning systems enable schools to change from knowledge-acquisition institutions to knowledge-building learning communities (Laffey et al. 1999). Specifically SNS has developed a network-based software system and is building a community of developers committed to open source licensing and the SNS learning system.

We utilize features of SNS to build collaborative learning modules. They are designed to gain participation of an extended community of researchers, teachers, administrators, and tech coordinators in an effort to gain better understanding of network-based learning systems and their potential impact. Collaboration could happen in two main areas: 1) development and refinement of learning modules, and 2) research and assessment of learning modules. Because a widespread use of technology is to promote learning and facilitate lesson plans, these collaborative efforts can build the body of learning modules available to teachers as well as the information about the utility and efficacy of those modules.

Scardamalia and Bereiter (1993) describe how computer-supported collaborative learning (CSCL) systems can support and optimize both the process and the representation of knowledge-building, learning and collaboration. SNS provides a means for both educators and software developers to create sharable and continuously-improving software that can be easily and flexibly integrated to a local learning community.
Therefore, rather than a rigid learning application, SNS is more likely an adaptable operating system for collaboration and learning.

A Learning Module in SNS

Objectives and Method Review

One collaborative learning module is a note taking and critiquing module that outlines methods for using SNS to facilitate collaborative knowledge building. The objective of this module is to improve students' note taking and critical analysis skills and to encourage effective integration with the content lessons.

Each week, different students are assigned to be the "note-posters". They are responsible for taking their best notes for that given week and posting them into appropriate documents (Shadowdoc) to collaborate and brainstorm within their science class group. Each night, each member of the class is assigned to critique a manageable number (1-3 depending on volume) of note-sets by comparing the posted sets to their own and commenting via the discussion boards. Friday is review day. The class works together to guide the instructor (and vice versa) through the process of combining the note-sets into one document that represents all the key points that the instructor wanted to get across as well as the areas of detail that should be included. This final document could be used for preparing unit assessment.

This exercise aims to create a "progressive discourse" between the students and the instructor. This discourse embodies the concept of formative evaluation within the context of a knowledge-building task (Scardamalia & Bereiter, 1996a). Thinking can be shaped by writing and people tend to think more and write more clearly when they are producing content for others. Critical thinking happens in good discussions. For years, proponents of Writing-Across-the-Curriculum (WAC) have been saying that students learn when they formulate their ideas in writing (Lang, 2000). Writing is reviewable, revisable, and recorded. This effort to optimize the process of building expertise, requires students to be intentional learners. Analyzing their knowledge and organizing new information, with the understanding that their words will be under the scrutiny of their peers, should encourage thoughtfulness and learning. As the students contribute to build a collective knowledge, they will be required to adapt both their intentions and their methods. As they gain understanding they must quickly switch roles from learner to teacher, so that they can help their peers to learn and improve the group artifacts.

Assessment

Assessment of a collaborative activity might be the biggest challenge for teachers when using this teaching method. The reason why it is so difficult to evaluate collaboration is that teachers have to examine not only the process but also the final product of a group's work.

This learning module is intended to fit into a traditional curriculum, so the weekly note-sets could serve as review materials for quizzes or examinations. Concept-mapping assessment could be used as an alternative assessment method. A concept map is a node-link-node representation of content, where nodes represent concepts and links represent relationships between connected concepts (Dansereau, 1995; Jonassen, Beissner, & Yacci, 1993). When large numbers of concepts are connected, a concept map is formed which ideally represents the content and the structure of a student's knowledge framework. For a group of students, concept maps can be viewed as expressing the meaning shared by team members. The concept maps can be scored for (a) number of unique nodes, (b) number of links between nodes, and (c) number of levels based on adaptions of concept map scoring procedures (Ayersman, 1995; Novak & Gowin, 1984; Toro, 1995). As learning occurs from instruction, the growth of learners' knowledge should be reflected in the elaborateness and structure of the notes they construct (Jonassen, 1987). Analyzing the complexity and accuracy of pre- versus post-lesson concept maps can illustrate depth of students' understanding.

Learning and Knowledge Building in SNS
The Knowledge Building pedagogy envisions learning as a social process of collaboration that students can become active learners and more aware of their own and others' processes of constructing knowledge (Brown & Campione, 1994; Scardamalia & Bereiter, 1996b; Pea, 1993). This note-taking learning module, the significant phases of collaborative knowledge building are illustrated in Figure 1: cycles of personal understanding and collaborative knowledge building. This figure represents the processes of internal personal understanding, and socio-cultural knowledge building. This model illustrates the environment where individual's understanding can be adapted and enhanced collaboratively.

SNS Support for Social Knowledge Building Activities

Network-based learning system cannot provide support for individual cognition; Individuals must articulate their understanding and beliefs as public statements before they can interact within network-based learning system. Thoughts must be even more formalized for computer support than for interpersonal interaction (Stahl, 1993). In this module, students can use Shadowdoc to create documents with sections and images and to compile the class notes. The full-featured discussion board in SNS could also be used for representation and interaction.

Figure 1: Collaborative Knowledge Building Using SNS Tools (adapted from Stahl, 2000)

(a) Articulate in Words – SNS tools will facilitate the process of articulating ideas and preserving them in convenient forms. Posting notes will encourage the users to “verbalize” their thoughts in an appropriate expression and accumulate the text to the public statements.

(b) Public Statements – Public statements are the domains where one person confronts other people’s perspectives. Posted notes can represent the different perspectives from which these statements emerge. It also makes explicit the important relationships among personal and group perspectives, as
well as providing meanings for individuals and collaborative teams to articulate their own perspectives. The instructor or other users can co-construct and add/edit commentary or critiques on writing documents.

(c) **Discuss Alternatives** – The SNS tools provide an asynchronous, interactive communication that allows students to respond to notes posted by others. Unlike a tree of divergent opinions, the Shadowdoc or a scaffolded discussion forum can go beyond superficial aimless discussion to converge on shared understandings and acknowledged opinions (dePaula, 1998; Guzdial & Turns, 2000; Hewitt & Teplovs, 1999; Stahl, 2000).

(d) **Argumentation & Rationale** – One note might be against another or provide evidence to support the claim of another note. Donath et al. (1999) suggested the component that supported argumentation and rationale could contribute to participants’ meta-level comprehension of their knowledge-building process.

(e) **Clarify and Negotiate Meanings and Perspectives** – Constructing group knowledge can be fostered by clarifying the meaning of important terms or key concepts (Stahl, 2000). The key concept discussion can make explicit how different participants understand the terms they use and should result in a group glossary of the agreed upon definitions of important terms. After the processes of clarification and negotiation, the key concepts or glossary could become the future debate or the topics for the assessment.

(f) **Collaborative Understanding** – The accumulation of negotiated-shared knowledge results in the establishment of a group perspective. Individuals can then build on this shared knowledge within their own perspective and even begin to critique it and start the whole cycle over.

(g) **Formalize & Objectify into Cultural Artifacts and Representations** – The shared knowledge can be further formalized. It can be represented in another symbolic system or combined into a more comprehensive system of knowledge. For example, the class can build a note-set to outline the key concepts of the unit. The note-set will provide the accepted base for building future knowledge. Other artifacts could include an annotated bibliography, like a knowledge repository.

Remote, Proximal and Simulated Access to Laboratory Hardware – A Pilot Study

Euan Lindsay, Malcolm Good
Department of Mechanical and Manufacturing Engineering
The University of Melbourne
edl@mame.mu.oz.au, mcgood@unimelb.edu.au

Abstract: This paper details a pilot study into alternative forms of access to laboratory hardware for final year undergraduate teaching. Students were given three different assignments to complete using an XY contouring table – the first proximally in the laboratory, the second by simulation of the hardware and the third by remote access to the hardware via the Web. The trial was evaluated using multiple tools, with attention paid to the differences in educational outcomes of the three alternatives. It was observed that students' performances on different criteria varied depending upon the form of access used. Performance on a targeted examination question was also found to be dependent upon the access method.

Context of the Project
This paper outlines the development and implementation of new laboratory classes within the final-year Mechanical Engineering subject 436-405 Advanced Control Systems. In this subject, students learn to design analog and digital controllers for complex mechanical engineering systems. A number of advanced control system topics, such as nonlinear control system analysis and design, multivariable control systems and optimal control are covered in the subject.

In previous years in this subject, the last four weeks of semester were devoted to a ‘case study’ project, in which students would reproduce the results of a relevant recent journal article, and report back to their peers. While this proved to be a useful exercise, it was thought that students would benefit more from direct, personal experience with system design, implementation and experimentation, using physical control system hardware. We also sought to expand upon our previous work in providing alternative access methods to hardware in laboratory classes (Lindsay, et al., 2000).

This paper reports a pilot study involving only nine students. No attempt is made, therefore, to attribute statistical significance to the results. Nevertheless, the results are indicative of meaningful differences in learning outcomes with different access modes.

Theoretical Framework
The development of new assignment material for the course allowed us to pursue a number of objectives. We shared many of the motivations of (Hahn and Spong, 2000), in that we wished to increase students' exposure to control systems, and also to increase the flexibility of this access.

The incorporation of web-based access offered a number of flexibility advantages, both immediately and also for potential future developments. Access to control laboratories via the Internet dates back to 1996 (Aktan, et al., 1996), with a number of studies since being published to show the feasibility of the paradigm, such as (Hahn and Spong, 2000), (Shen, et al., 1999), (Enloe, et al., 1999).

Of particular interest in our development of the projects was to maximise the transparency of the technology involved. (Givens and McShea, 2000) elaborates extensively upon the dual amplification/reduction effect of technology upon human experience. The beneficial effects offered by the access to the physical hardware could be partially or wholly offset by technical difficulties experienced in operating the hardware. The importance of a robust, reliable system is particularly emphasised by Givens and McShea, and was a design priority for this work.

Whilst Givens and McShea do address the issue of amplification vs reduction, the bulk of the literature on this topic does not concentrate on evaluation of learning outcomes. Positive feedback from students is often reported, and indeed is a desirable outcome. However, it is secondary to the students' acquisition of desirable skills and knowledge.

Constructivist theorists such as (Ausubel, 2000) tell us that the acquisition of these skills is dependent on the overall learning experience which the student undergoes – students create new meanings for themselves by assimilating new
experiences into their existing cognitive structures. To promote the flexibility of access, we offered three different learning experiences – proximal access to the hardware, simulated access, and remote access.

In order to assess the effects of the different learning experiences, a number of different evaluation tools were developed – the assessment measures of the assignments and the final examination, as well as student journals, access logs from the hardware, and also direct student feedback.

The System Developed For the Project
In the past, similar work in the Department had been completed from scratch with a custom-built system. For this project, the approach taken was instead to integrate commercially available components to form an overall system. This approach was taken for the hardware as well as the software.

The Hardware
The hardware, illustrated in (Fig 1), consists of two linear positioning tables – a y-axis table mounted on the laboratory bench, and an x-axis table mounted perpendicularly on top of the y-axis. This arrangement provides two degrees of freedom for the “tool point” of the system. The linear tables are powered by servomotors, which are connected by custom-made flexible couplings that deliberately introduce torsional compliance and backlash into the system.

Figure 1: X-Y table system

The servomotors are each controlled by an independent servo drive, located in the cabinet under the bench. These servo drives are in turn controlled by a dSPACE ® DS1102 controller board, which is inside the PC on the table. The PC is used to define tool point profiles and controllers using MATLAB® and Simulink®, and also to provide the web-based control interface.

How the System Works
The system utilises the Simulink Real-Time Workshop® and dSPACE software to compile Simulink models into object code for the DSP board. These models represent the controller for the XY table system. Depending upon operation mode, the DSP board sends either velocity or current command signals to the servocontrollers. The servocontrollers power the servomotors which move the linear tables. See (Fig 2)

Figure 2: Schematic of the control system (in CNC mode)
When the system is in operation, the PC samples the memory of the DSP board and records the values of selected variables such as motor velocities, position commands etc. These variables are stored within the MATLAB workspace on the PC.
Students design their own controllers for the XY table system, implement them in Simulink and compile them to the DSP board. They then initiate data capture runs and collect and analyse the sampled data. The inclusion of Simulink in the software resources allows a wide variety of alternative control strategies to be readily attempted without the need for time-consuming and error-prone hand coding.

A comprehensive Simulink model of the XY table system was developed, including many of the non-linearities of the real hardware. This model was used in the place of the connections to the DSP boards to provide a simulation of the XY table system.

The MATLAB Webserver and the Apache server were also employed, allowing the MATLAB scripts used in controlling the XY table to be called remotely via the web. Specific input and output HTML templates were developed to pass the required commands to the Webserver.

Educational Materials Developed For the Project

Assignments
Three new assignments were developed for the course, each of which involved a different method of interacting with the hardware. The assignments accounted for 50% of the overall mark that students received in this subject.

Assignment One – Proximal
In Assignment One, students were provided the opportunity to control the XY Table within the laboratory. The controllers of the table axes were deliberately mismatched to introduce a correctable contouring error into the performance of the table.

Students began by investigating the response of the table to straight line command profiles. They tuned the feedback gains of the CNC controller to optimise this performance. They then investigated the behaviour of the optimised system attempting to reproduce more complex profiles, and examined the ‘performance envelope’ of their controller – the range of tasks for which the system provided adequate performance.

Assignment Two – Simulation
In Assignment Two, students were provided with a detailed Simulink model representing the XY table. This model allowed students to perform “experiments” as though they had direct access to the laboratory equipment, without the scheduling constraints of accessing a single piece of hardware. The simulated system generated the same sampled data as was available in the laboratory set-up.

Students were asked to investigate ways of improving the contouring performance with alternative control strategies. For some strategies, this required them to perform ‘system identification’ experiments. They were required to select an appropriate measure of performance, and to compare their alternative control strategies using this criterion.

Assignment Three – Remote
In Assignment Three, students were required to physically implement the controllers they developed in Assignment Two. This implementation was through the remote access interface, with feedback from the system provided via a webcam and the sampled output from the MATLAB workspace.

The students were also required to investigate the robustness of the controllers designed using the simulation model, and to tune them as necessary to adapt for the differences between simulation and reality.

Examination Question
Deep learning of the course material is important. This can be assessed by presenting students with problems similar to those encountered in the assignments, the effective solution of which relies upon the same theory and concepts. Question One of the examination for the subject was designed to address the key concepts covered by the assignment work, with sub-sections of the question specifically aimed at the topics in the three different assignments.

Outcomes of the Project
A number of different tools were used to measure outcomes of the project – the assessment of the assignment work, and a follow up examination question; students’ self-reflections from study journals; analysis of access logs; and direct feedback from students, as well as our anecdotal observations of their work.
Assignment outcomes
To allow comparisons to be drawn between the three approaches, the same evaluation tool was used to assess each of the different approaches. To further reduce the variance in the marking process, a single marker was responsible for marking all of the assignments.

Eleven criteria were chosen for the purposes of evaluating the students' work. Each of the criteria is a desirable outcome of the assignment work. Some are generic skills, some are the application of generic skills to a specific task, and some are task specific. Comparisons between the outcomes for the task-specific criteria (such as criterion 1) are less meaningful than those drawn between the more generic criteria (such as criterion 4). Students were given a grade from 1 (very poor) to 5 (very good) for each criterion.

The three assignments were each assessed on the following criteria:
1. Familiarity with the system, and the components thereof.
2. Cognitive achievement – an understanding of concepts – rather than procedural achievement – just "turning the handle".
3. Identification of the important variables/parameters involved in problems associated with the hardware.
4. Generation of multiple viable solutions to given set tasks with the hardware.
5. Evaluation of the alternative solutions to choose an optimal solution.
6. Anticipation of possible exceptions, and formulation of methods of overcoming these exceptions.
7. Adaptation to unforeseen exceptions in a professional way.
8. Understanding of the non-ideal effects of compliance, backlash and friction on control systems
9. Understanding and demonstration of multiple techniques for the design of controllers for MISO systems, and the strengths and weaknesses of both.
10. Demonstrated understanding of the limitations of the system
11. Fluency in the operating language of the control system

The mean performance on each of the criteria for each of the three access modes is shown in (Fig 3).

![Performance Waveform](image)

**Figure 3:** Relative performance on assessment criteria

It can be seen that the Proximal approach and the Simulation approach produced similar outcomes for most criteria, but that the remote approach appears to differ substantially on some criteria. Outcomes are notably poorer on criteria 4 and 5 (the generation and evaluation of multiple solutions), and on criterion 9 (demonstration of multiple design techniques). The remote approach is stronger, however, on criterion 7 (the handling of exceptions). These results must
be regarded as indicative only, because of the small class size and possible lack of uniformity of criterion skill requirements between the assignments.

Examination outcomes
The first question of the Examination was devoted to the same topics covered by the assignment work, with the question having five sub-questions each worth 8 marks. Again, all of the examinations were marked by a single marker to avoid any inter-marker deviation. The marks for each question were averaged, the mean mark for each question being as follows:

<table>
<thead>
<tr>
<th>Question</th>
<th>Topics covered</th>
<th>Avg Mark (/8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>General / Proximal</td>
<td>4.11</td>
</tr>
<tr>
<td>B</td>
<td>Proximal</td>
<td>5.33</td>
</tr>
<tr>
<td>C</td>
<td>Proximal</td>
<td>5.44</td>
</tr>
<tr>
<td>D</td>
<td>Simulation</td>
<td>4.72</td>
</tr>
<tr>
<td>E</td>
<td>Remote</td>
<td>4.78</td>
</tr>
</tbody>
</table>

Again, the performance on the Simulation- and Remote-topic questions was similar. Performance on two of the three Proximal-topic questions was superior, but the performance on Question A was in fact considerably inferior. We suspect that lack of precision in the wording of Question A may have partially accounted for this outcome.

Journals
Students were required to keep a diary of their progress throughout the assignments in this subject, and were rewarded with bonus marks if they did so. This was intended as a tool to help with the cognitive development of students as they progressed, but most of the diaries submitted served more as a chronicle of the work that had been done. Significant also in all journals was the amount of time spent by students in completing the assignments — easily 40 hours over an eight-week period for a number of students. This represents a considerable assignment workload in a subject that has a scheduled contact of two hours per week.

Access Logs
Most of the students involved in the project chose to postpone their use of the equipment until as late as possible in the semester. Comprehensive logs of their access during the remote experiment were taken, recording each command that was sent to the system. These logs showed that the most common pattern of usage was to change the controller, run a single data capture with that controller, and then to change the controller to something different. Multiple data captures using the same controller architecture were rare.

Student Feedback / Anecdotal Observations
There was general consensus amongst the students that the project work required too much time to complete successfully. Students also expressed frustration at any technical difficulties that arose from the hardware or software not functioning as expected, although the complaints were somewhat minor when compared to those experienced by Givens and McShea.

Throughout the remote access assignment, many students displayed a desire to remain in physical proximity to the hardware. Despite having webcam feedback of the position of the table, and the output data files of their commands executing, students still felt the need to walk into the laboratory to visually inspect the hardware. This suggests that the laboratory experience provides a richer set of cues to system behaviour than is available from web-based access. Given the opportunity, students will seek access to such information. We suspect that auditory feedback would result in a worthwhile enhancement of the remote experience.

Overall, students expressed positive responses towards the introduction of the hardware into the course, and were appreciative of the opportunity to apply the theory that they had learned.

Conclusions / Further Work
This study serves as another demonstration of the feasibility of using web-based access to physical hardware for the teaching of control theory and practice at an undergraduate level, in this instance at a final-year advanced elective level. As with previous studies, students provided positive feedback about the value of such initiatives.
Further to this, the results were indicative of some differences in the learning outcomes of students exposed to three different modes of access to physical hardware. Proximal access generally lead to superior outcomes, although the differences from simulated access were small.

Learning outcomes, however, are the product of the overall learning experience, and the mode of access is just one dimension of this experience. Further trials are presently under development within the department to isolate this factor and to compare more rigorously the effects of the three access modes.

Acknowledgments
This work was partially supported by a “Curriculum Transformation/Multimedia Development” Small Grant from the Faculty of Engineering, The University of Melbourne. This work is represented on the Faculty of Engineering’s Multimedia Exemplar Projects site - http://www.sli.unimelb.edu.au/mmdec/index.htm Thanks to Jacinta Richardson for the perl code used in analysing the access logs.

Two approaches to enable the sharing and reuse of resources across institutions

Allison Littlejohn allison.littlejohn@strath.ac.uk
Lorna Campbell lmc@strath.ac.uk
Centre for Academic Practice, University of Strathclyde, Glasgow, Scotland, UK

Over the past few years, the Scottish Higher Education Funding Council has supported a programme of pioneering projects examining staff development in the use of communication and information technology within Higher Education (http://www.scotcit.ac.uk/). Two of these projects have specifically focused on the sharing and reuse of resources, each taking a unique approach, but having the common aim of enabling institutions to adapt existing resources for use across the sector, while taking into account diverse institutional contexts and requirements (Alexander, 1999). The Scottish electronic Staff Development Library (SeSDL) created an online resources base that allows users to upload resources in granular format and to aggregate these resources to create lessons tailored to meet their own requirements. The Enabling Large Scale Implementation of Communications and Information Technology project (ELICIT) produced a series of modular courses that can be adapted to suit institutional needs.

ELICIT: Reuse and adaptation of modular courses produced by “expert” authors

Enabling Large Scale Implementation of Communications and Information Technology (ELICIT http://www.elicit.scotcit.ac.uk) was a 2 year project which aimed to address a shortage of high quality, electronic resources for staff development by developing a common core of short modules which could be adapted and reused across institutions. These resources examine underpinning, educational theories in the use of C&IT for teaching and learning and were designed for reuse in a variety of ways: within accredited courses, staff development workshops, or as online, supplementary information.

A core of modules was created, each consisting of a series of short units with resources materials. The resource materials include case studies, articles and texts, with associated tasks, which can either be linked to online discussions, or can be explored in face-to-face sessions. The modules include:

- an introduction to using and integrating C&IT in teaching, learning and assessment
- using virtual learning environments in teaching, learning and assessment
- using computer mediated conferencing in teaching, learning and assessment
- developing tutor skills for computer mediated conferencing
- developing computer aided assessment
- implementing computer aided assessment.

These modules are freely available for staff developers within the UK’s Higher and Further Education sectors and can be downloaded from the project website in HTML or MS Word, edited to suit individual institutional requirements and implemented within a Virtual Learning Environment (Littlejohn et al, 2001).

SeSDL - Constructing courses from granular resources

The Scottish electronic Staff Development Library project (SeSDL http://www.sesdl.scotcit.ac.uk) takes a radically different approach. SeSDL developed an online resources base, which facilitates the retrieval and reuse of granular staff development materials focused on the use of C&IT for teaching and learning.

SeSDL provides users with guidelines on how to create granular, educational resources, often referred to as learning objects, and then allows them to upload these resources to the electronic library. All resources submitted to the library are described using IMS metadata and classified using an educational taxonomy (Campbell, Littlejohn & Duncan, 2001). Library users can search the resource base for other relevant resources using an advanced or a simple search tool, or a browse tree, which corresponds to the educational taxonomy classifications (see diagram 1). Once users have located relevant resources these granules can be saved to a personal folder where they can be aggregated using a lesson builder tool to form lessons tailored to meet the users institutional requirements (see diagram 2). These lessons can be further customised by the addition of a range of interface styles. Finally, the lessons can be downloaded in the form of IMS content packages, which can be incorporated into the users chosen
virtual learning environment, or alternatively they can be resubmitted to the electronic library where they can be re-used by others.

Despite being promoted primarily as a resource for Scottish HE staff developers, the Scottish electric Staff Development Library project has generated a great deal of interest both nationally and internationally. However, although an initial consultancy procedure indicated overwhelming support for the project, the staff development community has shown some reluctance in submitting individually authored resources to the electronic library. It seems that, while the staff development community may be willing to reuse and share resources produced by projects or expert authors, they seem less willing to share their own materials.

Institutional adoption of these approaches

The reuse and adaptation of modular courses, such as the ELICIT approach, is fairly traditional. It seems as if careful consideration of key design features, such as the development of tasks which are readily adapted for institutional use, may reduce the 'not invented here' syndrome and improve uptake (Haywood et al, 1999; Lee et al, 1999). In comparison, the SeSDL approach, the submission of existing resources by authors for reuse in granular format, is a relatively new method. It too appears to eliminate the 'not invented her syndrome', while reducing the problem of duplication of materials. However, this approach may be impeded by the reticence of staff to contribute resources.

Therefore, whilst the submission of resources by authors in granular format is a radical new approach to institutional sharing and reuse materials, present institutional culture and practice may need to evolve to encourage the adoption of this approach. The authors plan further research to examine factors, which will support the adoption of multiple approaches to sharing, and reuse of learning resources.

WebQuest: an Innovative Way of Applying Information Resources to Furnish Performance Tasks

I. Introduction:
WebQuests are designed to offer interdisciplinary opportunities that enhance student skills of learning by performing tasks, and encourage collegiality and ability of information processing in the K-12 classroom. Through a multimedia presentation, the systems and implementation of WebQuest will be shown. Pros and cons of WebQuest on both the learners and teachers will be discussed. Participants will be facilitated with sites for the research supporting WebQuest in addition to sites on how to create WebQuest.

II. Definition by Dr. Bernard Dodge, the father of WebQuest:
A WebQuest is an inquiry-oriented activity in which some or all of the information that learners interact with comes from resources on the Internet, optionally supplemented with videoconferencing. (Dodge, 1995)

III. Two Systems of WebQuest: (as Appendix I)

Most of us will probably agree that developing cognitive skills is an important goal for education, and is of particular significance for life long learners. It is an area that requires continuous attention and further research. In this speech, I will examine the use of interactive multimedia technology to support cognitive skills development. Specifically, I'm interested in examining how to design interactive multimedia learning environments to provide necessary support for developing higher level cognitive skills. There are many different ways to create interactive multimedia learning environments. Here I will look at two approaches based upon my research and development experience:

1. Engaging learners as multimedia designers using a project-based learning approach. In this environment, students at high, middle, and elementary schools take on the role of a multimedia designer, learn state-of-art multimedia tools, and work in a group to create a multimedia product for others to use. Through the process, they are to acquire design skills and resource management skills as needed in producing a multimedia product.

2. Enhancing problem solving skills through a problem-based multimedia learning environment for middle school science, Alien Rescue. In this environment, sixth graders play the role of young scientists, and are engaged in scientific investigations aimed at finding solutions to complex and meaningful problems. Alien Rescue provides a rich set of cognitive tools for successful use of PBL in 6th-grade classrooms.

I will discuss the design, implementation, and research of each environment. I will share the factors contributed to successful implementations and challenges of designing such multimedia learning environments; and will explain the cognitive support built in each environment. After examining these two approaches and reflecting on our experiences, I believe the following factors are of critical consideration in designing such environments:

- The design of a multimedia learning environment must be solidly grounded in educational theories and research practice.
- Cognitive tools should be built in the environment and they must be included for a purpose.
- High-end cutting edge software tools should be used to create the environment.
- Interactions among the learners, the environment, and the teacher/facilitator must be encouraged and promoted for the environment to be effective.

By sharing our R & D experiences, and learning the audience's experiences (hopefully through the question-and-answer time), I hope we, the multimedia community, will continue to have our dialogs and search for new ways to design effective multimedia learning environments to support cognitive skills development for learners at all ages.
The Challenge of Being an Instructional Designer for New Media Development: A View From the Practitioners

Min Liu
Scott Gibby
Ondrea Quiros
&
Elaine Demps

The University of Texas at Austin

THEORETICAL PERSPECTIVE

The rapid changes in the field of technology are redefining the process of developing technology-enhanced educational materials as well as the roles of developers involved in the process. As educators whose responsibility it is to prepare future designers and developers using new media, and as students who are about to enter the field of instructional design, we must continually update our knowledge and be aware of these changes. In our previous research (Liu, Jones & Hemstreet, 1998), we looked at the multimedia design process, and the different roles involved in the process from a practitioner's perspective. In this study, we chose to focus on the role of an instructional designer, one of the key players in new media development. We looked again to the practitioners in the field to find out how their roles are defined, how they handle their job challenges, and how they adapt to the fast changes of technology and market demands.

Instructional design refers to "the systematic process of translating principles of learning and instruction into plans for instructional materials and activities" (Smith & Ragan, 1993, p. 2). An instructional designer’s task is to plan the instruction so that the student can use cognitive strategies to learn the material actively (West, Farmer, & Wolff, 1991). The term "instructional designer" is less familiar outside the field of instructional technology. Instead, one hears job titles such as industrial designer, curriculum developer, learning specialist, instructional technologist, or sometimes just project manager. Yet, people in these titles are often carrying the responsibilities of an instructional designer, especially if they are involved in developing new media-based instructional products. For some people, "instructional designer" does not say enough; "multimedia producer," "webmaster," "developer of online learning"—these are much more muscular phrases" (Ganzel, 1997, ¶ 14).

The reality that an instructional designer might be called upon to get involved in different phases of producing an educational product could spark this confusion. As such, the instructional designer must understand the needs and wants of the client, the objective and the audience of the finished project, the capabilities of the programmer, graphic artist, and available tools; and must have design and project management skills (Liu, Jones, & Hemstreet, 1998). Job titles other than instructional designer reflect recent technological changes and new trends for creating instructional materials. If a person performing the role of an instructional designer is developing online courses, he or she may be classified as an online learning developer. Regardless of the job title, the role of an instructional designer "depends on the project, the composition of the team, and the skills of the team members. It's kind of a virtual job title for a very real job" (Jopson & Smith, 1997, p. 3). Since the role of an instructional designer has outgrown traditional textbook definitions, the perspectives of practitioners in the field will provide the information needed to accurately assess the evolving responsibilities of an increasingly popular position. Therefore, we are turning to the practitioners to provide this information for students who want to enter the field.
PURPOSE OF THE STUDY

The purpose of this study is to learn from the practitioners the roles and responsibilities of an instructional designer in developing new media enhanced instructional materials. We are particularly interested in the challenges designers are facing and how they handle these challenges. We hope the findings will provide useful and practical information to students who are about to take on the responsibilities of an instructional designer. Our guiding research questions were:

1. What are instructional designers' responsibilities in the field of new media?
2. What challenges do instructional designers face?
3. How do instructional designers meet these challenges?
4. What skills are important for being a good instructional designer?

METHOD

About Interviewees and Procedure

To answer the research questions proposed, we interviewed instructional designers working at various multimedia companies in Austin, Texas. Using the multimedia directory compiled by the Texas Governor's Office of Music, Film, Television, and Multimedia Industries, we identified a list of multimedia companies in the Austin area. We selected companies that produce multimedia educational or training programs, and excluded one-person companies. Since we were interested in the role of an instructional designer, we limited the selection of interview subjects to those who shoulder the responsibilities of instructional designers. A total of eleven interviews were conducted with these individuals. These interviews ranged from 45 minutes to two hours.

All eleven interviewees were actively engaged in instructional design at the time of the interviews. Eight were female and three were male. One designer had a doctoral degree. Eight designers had a master's degree and two had a bachelor degree. Some had as many as 20 years of experience in designing and developing multimedia products while others had as few as just one year. Some designers worked for large technology companies while others worked for small multimedia shops. It was our hope that by looking at the designers working in different settings, we could gain a good understanding of the common challenges they face.

The Development of the Interview Questions

The development of the interview questions began with a survey to the graduate students enrolling in the Instructional Technology Program at the University of Texas - Austin. The survey's purpose was to identify the information and tips that future instructional designers wanted from the practitioners. We also modified and selected relevant interview questions from our previous research (Liu, Jones, & Hemstreet, 1998), which examined the multimedia design and development process from the practitioners' perspective. Combining the two sources of questions, we created and refined the list of interview questions for this study and ensured they would address the four research questions. A total of 141 interview questions were used. Part I of the questions focused on the role of an instructional designer (N=70), which was our primary focus. Part II of the questions (N=71) were used when an instructional designer also performed another role, which is often the case in the field. The questions on instructional designers addressed the following ten aspects: (1) background information, (2) roles and responsibilities, (3) design and production process, (4) interface, instructional, and interaction designs, (5) formative evaluation, (6) teamwork, (7) client, (8) prototype development, (9) personal, and (10) evaluation of instructional designers. Sample questions included: "What are your roles and main duties as an instructional designer?" "What are some major obstacles you face in doing your job?" and "What aspects of your job do you like the most?"
Data Analysis

The analysis of the data followed the guidelines by Miles and Huberman (1994). The interviews were first transcribed, then chunked, and coded. Two researchers independently coded the data. Codes were generated directly from the data through multiple passes of data examination. Two researchers then checked each other's coding and resolved any disagreement in the coding. A third researcher went through all the data and coding for any gaps, missing codes or inconsistency. During this process of checking and rechecking, the codes were refined, revised, and newly developed as emerging themes were added. Patterns from the data were extracted, and the relationships between the coded segments were compared and contrasted. The data were then sorted into categories and sub-categories according to their common themes and shared relationships.

RESULTS AND DISCUSSION

Role and Responsibilities of an Instructional Designer

Responsibilities. Our previous research, examining the multimedia design and development process from the practitioners' perspective, showed that the development process consisted of six main phases: (a) funding, (b) planning, (c) designing, (d) producing, (e) testing, and (f) marketing (Liu, Jones, & Hemstreet, 1998). The findings of our current study indicated that in this entire process of shaping an idea into a finished product, an instructional designer is heavily involved in the phases of planning and designing. They are also involved in the phases of producing and testing. Sometimes designers may also take on the responsibility of writing proposals and seeking funding. There are four major responsibilities an instructional designer performs: (1) working with a client; (2) working with a subject matter expert (SME); (3) working on the design; and (4) working with other members in a team. An instructional designer is often involved in the project from the beginning. He or she interacts with the client to understand what the client wants and works with the SMEs to understand the subject matter of the materials to develop.

Sometimes an instructional designer, working in another role such as a project manager, helps to secure a project. "Generally, I'll get the first contact with the potential client, so there's pre-work involved and just talking to them, finding out what they want, answering their questions, you know, up to the point where we actually have a proposal. 'This is what we propose to do for you' and they say 'yes.'" With a good understanding of the client's needs and the content, an instructional designer will develop a blueprint to be executed by other team members, such as programmers, artists, and video/audio specialists. Such a blueprint comes in the form of a design document which specifies the breakdown of the content, what will appear on each screen, and what media will be used. In short, the role of an instructional designer is to translate the client's needs into a plan that will be used to produce a product which meets the client's needs.

A Typical Day. What a typical day is like for an instructional designer working in the field of new media? We asked the interview subjects this question. Although it is clear that the days could vary from one project to another, some "typical" tasks they do in a day include: checking emails, having meetings, and working at a computer using some software. Here are a few responses to this question that capture what a day is like:

First thing I do in the morning is check my email. Then I'll work on a project or start a project or maybe attend a meeting. Around [the] midday, [the] changes that I've made I either upload to the servers or I update the system that I'm working on. In the afternoon it's basic development. I'll do some research on what I'm doing. I'll try to collect documents, maybe read some material that's necessary for me to do my job, meet with people, things like that.

First thing I do is check email before anything else, and usually voice mail at the same time. I might have some meetings based on that. Somebody's researching a project and I've worked on it so I've got to get them some information. Maybe there's a client meeting. Maybe I'm working on the proposal or a piece of the design.
Work Environment. "Fast-paced," "collaborative," "casual," and "flexible" are the adjectives the practitioners used to describe their work environments. Most designers are young, in their 20's and 30's. Their work is mostly driven by the projects and is fast-paced. When they are working on a project and facing a deadline, they typically work long hours as much as 60 per week or more. A designer must be a team player and a true collaborator, as these practitioners emphasized. A designer needs to be able to work with other designers and team members such as programmers, artists, and video/audio specialists. The work atmosphere is casual in general; few wear suits or ties. Some work in a large, open, studio-like space with music playing in the background. Others are allowed to play games as part of their workday to relax. Some work in physical offices while others work in a virtual office meeting face-to-face only when needed.

Job Satisfaction. What is the reward for being an instructional designer? For some, job satisfaction comes from the interaction with clients. "I love the clients, actually. I mean they cause the most frustrations but I love them." For some, it is the challenge of learning new tools and keeping up with the rapid changes. Others found it rewarding to be in a position where they had an opportunity to deal with multiple aspects of the development process. For many, however, their greatest gratification is in their ability to be creative--to develop a finished educational product from just an idea. One stated, "You have to be creative every single time to give the clients [what they're looking for]. That's a good spot to be in."

Approaches in Design. Although designers follow different models in their work, many emphasized the importance of "learning by doing," "providing experience," and "learning from mistakes" in approaching design. Some employ the techniques of simulations, scenarios, and storytelling, while others create games and puzzles. Engaging a learner through various interaction designs is emphasized. "[W]e focus on providing software that will give the adults an opportunity to interact, where they're not just reading about it and clicking on the next button."

Software Tools used. Students in instructional technology often asked "do we need to know how to use software tools? If we do, what tools do we need to learn?" Our findings showed that it is not only necessary to have some hands-on experience with popular software tools, but it is also important to be proficient in a few. Although instructional designers use simple software such as Microsoft Word to write design documents, it is clear some designers, especially those who graduated more recently, are also able to use more sophisticated tools such as Macromedia Director, Flash, Adobe Photoshop, Premiere, Java, and HTML. Some pointed out that knowledge of these kinds of tools can help them quickly put together a prototype to demonstrate design ideas to the client. "We have at least one designer who is very well versed in Flash, and no matter what she does, she's going to put it together in Flash. She uses together a model of instructional design in Flash. I tend to be a Director guy. If I'm trying to say this is what I want to be animated, I'll slap it together....I can show that to an artist or show it to an audience member or learner and say do you understand this, does this get the message across?" Others said that such knowledge enables the designers to participate in other tasks such as programming or creating graphics when needed. Being flexible and versatile proves very valuable in a small company when one person often wears multiple hats (Liu, Jones, & Hemstreet, 1998).

Challenges of Being an Instructional Designer

Based upon the interviews, it appears that three of the biggest challenges confronting a new media designer arise in dealing with clients, balancing multiple roles, and adapting to rapid technological changes.

Working with a Client. An important task of being an instructional designer is to determine what clients really need, since they may not be familiar with the design process itself. Some clients need assistance in producing a clear definition of the problem they are trying to solve. Other clients may not be aware of the steps and tasks that a designer takes to get to the end product.
Some clients expect the designer to start from scratch and create a polished product within a short time, without providing necessary input. "One of the biggest challenges is... that the people... only want to see the end product. And they expect you to develop something out of nothing. They sometimes don't have the understanding of the development time necessary..." Being able to get feedback from the client and the SMEs about the product throughout the design process is a skill an instructional designer must acquire. Many clients new to the field of new media have an oversimplified view of the design process necessary to tailor a traditional product into a new media concept.

Many of the designers we interviewed keenly felt the responsibility of walking the clients through the process and teaching them along the way. "You have to continue to educate others in what's involved in doing this job," noted one. This education includes explaining the design and production process, helping the clients define the scope of the problem, learning goals, audience, and outcomes. A designer should be able to ask a lot of questions. In addition, a designer should be aware that the client may not be familiar with the industry jargon. Designers should explain the terminology to the client, or simply use everyday language. When instructional designers speak of objectives, goals, entry-level skills and the like, clients often need to hear these terms clarified. As one designer stated, "There's some kind of bridge building time where you figure out what are you really saying."

Another important aspect of this educational process is to help the client make the right design decisions depending on a project's needs. Clients sometimes do not understand the difference between an instructional/training module and merely information presentation. They may want to use multimedia when there is no need to do so. A designer should be able to discuss knowledgeably the possibilities of various technologies and help the client make the appropriate choice. "Sometimes my process in working with a client is to say, I don't think you really need training. I think you're just talking about documentation here." A client also needs to be informed that design decisions will have an impact on the production. For example, a decision of what media to use in the product will affect the cost, and a change in such a decision later in the process may increase the production cost.

When resources and budget are limited, a designer should help the client prioritize what is most important for the instructional value of the product and not be constrained by what media to use. Although the clients usually have the final say in any design decisions as they pay for the development and often know the market better, the designers should offer their "best judgment" based on their expertise, and make sure the clients understand their position, especially in the case of disagreement.

Balancing Multiple Roles. Although many textbooks on instructional design often separate the roles of instructional designer and project manager, the practical experience of the interview participants showed that seldom is one's role limited to that of a designer. About half of the participants were also project managers or performed duties normally associated with that position in addition to being an instructional designer. One stated, "my heaviest responsibility is in ... getting teams up and running, ..." Another said, "...depending on what the project is, how big it is, I'll start assembling the people who I want to work on that one... But I'll continue to be the primary client contact as far as letting them know how it's going."

As part of a team, designers are often called upon to review others' work, find clients, write scripts for video and audio clips, write programming codes, write technical documents, create animation and graphics, work on character development, and train others. That is, an instructional designer in new media often performs multiple roles depending on a project's needs. Many smaller companies require designers to have different skills to maintain efficiency and low cost of operation. Some designers feel it is important to "be able" to do everything, even if they do not end up doing it all. It is interesting to note that within all of these responsibilities lies a main objective
that may tie all the roles together. As one participant put it, "I’m trying to help people understand where we are now, and where we need to go, and help arrive at a formula for getting there."

Adapting Oneself to Technological Changes. Rapid technological advances continuously bring changes and new requirements to the field of instructional design. "[Instructional] design is going to evolve as technological capability evolves." One designer commented, "designers [in her company] will need to be extremely proficient in Adobe Acrobat, some HTML and [Microsoft] Access. We will need to understand technology on a higher level because our business is changing and expanding so rapidly." A designer must not only be able to meet multiple responsibilities and perform different roles in a team, but also keep abreast of these technological changes. He or she must stay very flexible in order to adapt to changes quickly and continuously gain new skills to be competitive. A good designer is a life long learner, who sees the changes, and is willing to adjust herself to the changes so as to produce better products for the audience. The participants mentioned the challenges they faced daily in producing educational products using new technological tools, and the need to stay on top of the field. Their education and experience prepared them to some extent. However, as they emphasized, they must keep learning to stay current. "Really in keeping up with the field is just hard work...You just gotta read and read and read, and you have to care about it."

Meeting the Challenges

Staying on Top of the Field. An important question to these designers is "How do you address the challenges and stay current?" Their formal education in instructional design equipped them with some needed knowledge with hands-on courses being particularly valuable. Their varied backgrounds in graphic art, video production, programming, and teaching helped lay down a solid foundation for being a good designer. Some pointed out that the experience gained from working on numerous projects, and performing different roles in a project helped them learn to be flexible and adapt quickly to new situations.

While on the job, these practitioners try to keep up with changes by taking additional college classes, attending conferences and training, having informal meetings within their company where people share what they have learned, studying products from their competitors, maintaining university connections and involvement, and even learning from the clients.

Attributes of a Good Instructional Designer. The practitioners discussed different qualities a designer should possess. Of those mentioned attributes, there is a consensus that a good designer should be (1) a quick study who is willing to learn new things; (2) a team player who can work with others well; (3) attentive to details; and (4) a good communicator both orally and in writing. Apart from these, the practitioners mentioned they would also look for people who have experience and are self reliant, resourceful problem-solvers. Finally, they want to hire individuals who not only "know what they’re talking about," but also are "passionate about what they do."

Advice to Newcomers. Given the challenges of being an instructional designer, what can students do to prepare themselves for the field of instructional design? Besides taking classes and getting a degree, the designers offered the following practical advice:

- Seek out to gain a variety of experiences.
- Be open to new ideas and familiar with the capabilities of technological tools.
- Learn to write well.
- Enjoy what you do.

CONCLUSION

It is clear that an instructional designer plays a critical role in developing new media-based instructional products. In support of other research (International Board, 1998; Le Maistre, 1998;
Liang, 1999; Liu, Jones, & Hemstreet, 1998; Moallem, 1998), the findings of this study identified four essential competencies for being an instructional designer in new media development:

1. **Communication**: A good designer should have excellent “people” skills and be able to communicate effectively with clients, SMEs, and other team members both verbally and in writing.

2. **Instructional design**: A good designer should be well-versed in several instructional design models and strategies from which to choose a case-specific process. He or she should keep up with new education or training theories and research to apply them in the product development.

3. **Problem-solving/decision making**: The process of developing a quality new media product is full of challenges along the way. A good designer should be able to perform multiple responsibilities, step into new roles when necessary, and overcome obstacles under a deadline. A good designer is a problem-solver.

4. **Knowledge of technology tools**: A good instructional designer should have a basic knowledge of important software tools used in the field and be aware of newly advanced tools as they become available.

The job market for instructional designers will continue to grow and expand, and with it, the definition of an instructional designer will evolve at the same pace that the technology changes. Since the role of an instructional designer is affected by the possibilities that new technologies create daily and how technological tools aid communication, so shall each instructional designer contribute to the task of defining their profession. Therefore, it was to these practicing instructional designers that this study turned in order to understand the evolving responsibilities, expectations, and challenges of today's instructional designers.

Abstract: The design and implementation of advanced tutorware applications is a complex issue requiring detailed information about the studied system, and a solid knowledge base enabling suitable tutorship actions. In this context, existing learning systems do not provide suitable hooks for studying and reacting to information produced in the environment. This restrains research work in the area and produces hard-coded proprietary applications involving raw log analysis.

Our approach is to create a distributed awareness infrastructure providing standard hooks for awareness actuators and tutorware agents reacting to events in the learning environment. We cover different steps in the awareness life cycle: event persistence, information filters, data analysis, knowledge base, and tutorware Bots. In this article we present the overall architecture, outlining the services offered by the platform and explain them in an example that provides intelligent knowledge sequencing in course navigation.

Introduction

The impact of computers and network technologies upon the educational process has been considerable. The possibilities of this new medium are open-ended and richer interactive scenarios have emerged under the umbrella of distance learning environments. In this context, traditional Teacher centred scenarios has been easily mapped to a computer medium in web based learning systems. The traditional lecture/textbook/exam scenario has been broadly implemented in learning environments using Audio or Video broadcast lectures, web contents, and computer evaluation tools.

Whereas traditional approaches have been widely adopted; richer interactive scenarios involving group-centered design and collaborative learning are also being supported and thus benefits from the communication possibilities of network computing. All these learning scenarios have created a fruitful arena for multi-disciplinary research. Nevertheless, proprietary technologies and systems have precluded interoperability between different environments. This has provoked proprietary non-realistic research efforts that suffer the lack of a common technology base for contrasting and comparing results.

Fortunately, standardisation efforts are creating open specifications that set the base for future learning environments. In this line, standardisation efforts have succeed in establishing standards for indexing and packaging contents (LOM and IMS content packaging), and also for defining evaluation tools (QTI). Unfortunately, advanced topics like system monitoring, tutoring systems, or collaborative learning are beyond the scope of existing standard specifications.

We aim to create a generic monitoring awareness service that considerably facilitates data acquisition in distributed learning environments. The system also provides standard hooks for creating filter agents and information bots getting information from the information bus and reacting in different ways according to their task. The system is based on open technologies and provides standard hooks for obtaining and reacting to information in the environment. Although we do not aim to create a standard specification, the overall model could be mapped to create a standard distributed awareness service. The system is constructed on top of available free middleware and is publicly available as an open source project.

As a proof of concept implementation, we have created a prototype intelligent tutoring system that uses the Awareness infrastructure to obtain information from the system and react accordingly to events produced in the environment using tutorware bots. In this paper, we present AWS: a generic distributed awareness service that aims to provide a common base for monitoring applications and proactive applications.
and agents getting information from a common bus. In section 2, we define the services provided by the Awareness infrastructure; in section 3 we explain a system that benefits from the Awareness Service: a prototype intelligent tutoring system extending standard platform hooks. In section 4, we apply the tutoring system to possible simulated scenarios. Finally, we draw interesting conclusions and future trends for the ANTS Awareness service.

ANTS AWS

The Awareness service is a server-side infrastructure supplying the required services to capture and react to information events produced in a distributed learning environment. ANTS AWS is a key component of the ANTS CSCL framework (Garcia, 2001) and thus benefits from applications and components developed for the ANTS System. AWS is however application independent and can thus work with any learning environment.

Based on existing CSCW Awareness systems (Prinz, 1999), AWS include an event repository, a notification service, and an infrastructure to filter or get information from events in the distributed bus. Every application in the monitored system should trigger events to the Information bus (Notification system) following some standardised notation. In an ideal scenario, all these event fields should be standardised by an international committee. This would imply that all chat tools, all question tools, or all content navigation tools should trigger events in a specified compatible format. Monitoring applications could thus directly listen to the information bus and know what is happening in any learning environment.

An initial attempt to achieve such standardisation was accomplished by the initial IMS specification and prototypes (Instructional Management Systems). IMS proposed to use the CORBA Notification system, and defined standard programmatic hooks (Event Agent) for triggering events to IMS groups. Furthermore, it also proposed an initial draft for defining field notation for events thrown by learning tools. Unfortunately, these standardisation efforts did not succeed and IMS spent more efforts in other specifications like LOM, QTI, or content packaging. Due to these lack of standard initiatives, our approach aims to be open and flexible. We do not impose any special notation but require that every application must provide an XML file containing event information about triggered events to the bus.

AWS Services

The overall system is based on sensors/mediator/actuators. The mediator is the central point of the server-side awareness system and is responsible of binding sensors and actuators. We consider two kind of sensors: event sensors and time sensors. Event sensors are activated in response to application events produced in the information bus. An event sensor is created using a subscription following the constraint filter language available in the Notification system. Time sensors are activated by the ANTS time scheduler; we can create a time sensor for a specified date “Sat Jun 23 18:31:06 CEST 2001” or even set repetitive dates “all mondays at 16:00”. The time scheduler notifies the awareness service when a time sensor has been activated.

Actuators represent applications that must be triggered in response to AWS sensors. We provide a set of possible actuators including: Persistent actuator (database), mail actuator, Bot actuator, EJB actuator, CGI Actuator, XMLRPC Actuator and Event Actuator. Nevertheless, the system aims to be extensible and it is straightforward to create new actuators.

In a possible scenario, we could create a subscription telling that we are interested in events produced by the user called “pedro” (event sensor) and we want to make them persistent (actuator). This would log each event coming from user Pedro occurred in the environment. We could also create our own infoBots that would react to events specified by our subscription.

The most important aspect of the AWS is its extensibility; its set of actuators enables us to create different monitoring applications over the information bus. As we will see, the system is a powerful alert tool and establishes the base for filter agents and information bots getting information from the bus and reacting in different ways according to their task.

From awareness to tutorware

As explained before, the ANTS AWS infrastructure supplies the required services to create and use software actuators reacting to events produced in the information bus. In this section, we explain how we have extended the AWS system in order to create a prototype tutorware system. The knowledge of what is happening...
in a running environment is a hot issue that enables users to interpret the context of their own activities. Being aware of user and activity events, is the base to perform proactive reactions in order to improve the existing scenario. Awareness information thus represents the required feedback that facilitates the iterative incremental process of refining a running scenario. Nevertheless, raw data stored as event logs or in a relational database is useless as is; it is necessary to extract relevant knowledge in order to understand what is really important and what is not.

Intelligent Tutoring systems (ITS) represent a challenging problem involving a knowledge-intensive process that requires a significant amount of engineering to encode knowledge into a usable form. This process can be quite complex, expensive, and time-consuming. In fact, the knowledge acquisition bottleneck is one of the major challenges for real-world AI systems like ITS (Wenger, 1987).

We believe that our overall awareness model and distributed services can be used to smooth and alleviate the knowledge acquisition bottleneck in many learning environments. Furthermore, we have create a prototype tutorware system extending AWS services that demonstrates our overall approach.

Intelligent Tutoring Systems

Whereas “intelligent” tutors may be far to be achieved, machine-learning techniques can be applied as a useful tool for facilitating the knowledge acquisition task to educational practitioners. We find essential the combination of a domain expert and machine learning algorithms to create useful ITS systems. This kind of supervised learning can devise interesting results difficult to achieve without these powerful tools.

We will follow the Wenger’s structure of a classic ITS model. Wenger’s three main components of an ITS are: an expert module that represents domain expertise, a student model that represents the student’s knowledge state and expertise, and a tutor, or pedagogical module that structures the interaction between the tutor and the student (Wenger, 87). In this article we concentrate on the knowledge acquisition problem of intelligent tutoring systems by “pushing the frontier” of technology for distributed awareness services. The major goals of our prototype tutorware system are:

1) Benefit and extend AWS services in order to receive and store selected event information from a running learning environment.
2) Use machine-learning techniques to isolate key feature knowledge from the stored data.
3) Develop a tool to automatically generate simulated scenarios for training.
4) Implement a prototype tutorware example that benefits from the available infrastructure.

Information retrieval: Using AWS subscriptions the user can specify which events he is interested in, and how they should be persistently stored. AWS provides a persistent EJB actuator that stores events in a database. We can thus specify that we are interested in events in a concrete workspace, and that we want those events to be stored using the Persistent Actuator. From this point, all events in that workspace will be saved in the persistent event store transparently to the user.

Data Analysis: Using data filters and machine learning algorithms (Clustering, classifiers) the user must identify key variables that produce seamless groups. From the stored event data is thus obtained a knowledge base or trained algorithms that can onwards classify users from their behaviours. Raw data stored as logs or in a relational database is useless as is; it is necessary to perform filters in the data to retrieve key classification variables. We have created data filters for six grouping variables:

1. Time connected to the system or to a specific workspace for each user.
2. User activity (number of events) in the system or in a specific workspace.
3. Tool activity (number of events for this tool) in the system or in a specific workspace.
4. Thing activity (number of events for this thing) in the system or in a specific workspace.
5. Used tools in the system (total) or in a specific workspace.
6. Navigation time (specific for the contents tool) or time navigating a specific course.

Of course, it is possible to develop more filter variables depending on the specific problem to study. As possible filters to develop, we have considered the possibility of specifying different strengths for events triggered by a concrete tool.
Figure 1. Data Analysis module

The data analysis module receives two input data sources and generates three output files. The input sources are a persistent event log and a XML Filter file defining what filter variables should be used, what clustering algorithms should be applied, the number of resulting clusters, and the date range where events should be studied.

We are using the freely available WEKA (Witten, 1999) machine learning algorithms and tools. “Weka” stands for the Waikato Environment for Knowledge Analysis and provides Java APIs for accessing to algorithms as well as a visual environment for studying and processing data sets. WEKA algorithms require a standard file format called arff using a special notation; our data-analysis phase extract key variables found in the XML filter file, and generate a WEKA compatible arff file. Using this file, we apply clustering algorithms to the data set in order to obtain student grouping. The results are stored in the output file with a comprehensive format.

Output data generated by clustering algorithms give us information about prior probability, Normal Distribution Mean, and standard deviation for each variable in every classified cluster. This is important to define what variables are important in each cluster, and also permit us to know prototype data about existing clusters. We obtain information for each cluster regarding each studied variable, as well as a correspondence list of student to clusters. We can thus know in which cluster every student is located using these filter variables. Finally, we can also know what is the prototype student in every cluster. A pedagogical expert should conveniently study all this information in order to find relevant variables that produce seamless groups. Once the expert find a seamless classification, this knowledge can be used to later categorise other group of students in the same scenario. The third output file generated by the Data Analysis module is a Java serialized trained algorithm that our bots will use to classify students in the running learning environment.

Data analysis is the most important phase in the overall model. If the pedagogic expert can choose the key variables that create seamless groups, this information can be later used to categorise students in the same scenario. Useful tutor reactions can thus be accomplished using this important information. In a context where massive information is stored about a high number of students, it is a hard task for educators to study raw logs even with the help of visualization interfaces. Machine learning algorithms can facilitate this task by telling the educator what students fall in a specific group. This information can be later used to perform appropriate reactions in order to improve the learning scenario.

Scenario simulation: In order to demonstrate the usability of the framework we have created a tool that generates simulated event data. We also tested AWS using real data with the assessment of educational experts. We aim to provide a technological infrastructure that is ready to be used by pedagogical experts. It is thus an interesting research work for educational experts to use such tool in running scenarios. Furthermore, the commercial EduStance learning environment is including AWS as its standard monitoring and knowledge analysis system.

In our case, we wanted to provide simulated tests as a proof of concept implementation. The tests should incorporate user guidance as well as provide a random generation factor. Our approach is to employ filter variables found in the data analysis module in order to define the generated output data.

Tutorware example: intelligent contents

Once we have developed the required infrastructure to obtain knowledge from the running environment, our major aim is to create a simple Tutorware sample that benefits from the overall infrastructure. Among other efforts to bring ITS to WWW, we have found relevant the technique called intelligent knowledge
sequencing and problem sequencing (Brusilovsky, 1992). Intelligent knowledge sequencing implies adaptive selection of the next topic to be learned using the student model and the knowledge about the learning material. In hypermedia systems, this technique is mapped in a straightforward approach by sequencing hypermedia pages or hypernodes. Normally, the student is provided with dynamic "intelligent buttons" that activate the knowledge sequencing mechanism.

Because our approach is to work with open standards, we decided to benefit from IMS content packaging specification. More concretely, we have used the IMS Table of contents (TOC) that is included in every packaged content unit. In the specification it is specified that one content unit can include several tables of contents. These TOCs can be used to create different paths in a course and thus provide different navigational alternatives for a packaged material.

```xml
<organizations default="TOC1">
  <tableofcontents identifier="TOC1">
    (...)
  </tableofcontents>
  <tableofcontents identifier="TOC2">
    (...)
  </tableofcontents>
</organizations>
```

Figure 2. IMS Table of Contents

In general, when a course is designed and developed by domain experts and educational experts, different content paths can be defined depending on student's skills and knowledge state. In our prototype tutorware system, the expert model of Wenger's categorization is comprised in the course's table of contents.

![Figure 3. Tutor Architecture](image)

The Student model is obtained from the data analysis phase as a trained algorithm, ready to classify students related to their previously studied behaviours. The Tutor model is in fact quite simple: every clustered group correspond to a content path defined in the course TOC. For each student, the tutor module ask the Student model in which group is included, and consequently redirects the sequence to the appropriate path found in the IMS TOC.

In order to make the system more realistic and broaden our test case, we have created an adaptative cluster bot that periodically revises the knowledge base to be always up-to-date. If one or several students change their behaviours and thus belong to another group, the bot will redirect them to the appropriate knowledge sequence. The system is not static and provides adaptative revision of the Student model. Finally, we outline that AWS services have played an essential role in the Tutorware sample:

- In the data acquisition phase, binding an event sensor subscription with a persistent actuator provides the needed server-side logging mechanisms for the distributed learning environment. In our case, however, events are generated by the event simulation tool and directly stored in the database.
- In the knowledge acquisition phase, the filter component is a very important service that pedagogical experts can use to obtain key variables that construct seamless groups. The knowledge acquisition phase can be combined with the use of visualization and data-analysis tools such as WEKA data exploration interface.
- Bot development can also be facilitated using event and time sensors. In our case, the adaptative cluster bot, must periodically reprocess event data in order to decide to what group belongs every
student. Using a repetitive time sensor the bot is triggered and can thus re-evaluate knowledge in order to classify users according to their actions.

**Conclusions**

One of the hot issues in future learning environments will be how to extract and interpret useful knowledge from the running systems. This required information feedback is the base for system improvements as well as a key information source for Intelligent Tutoring Systems.

Data mining and machine learning algorithms can alleviate the knowledge acquisition bottleneck inherent to these complex environments. Nevertheless, such environments require powerful distributed awareness and monitoring services enabling fine-grained monitoring and reactions over a plethora of heterogeneous learning tools.

We have created a technological infrastructure providing a well-defined event repository, a time scheduler, and a server-side Mediator enabling to bind event and time sensors with generic Actuator agents. We also created a Data acquisition component using clustering algorithms that permits to filter data and produce a suitable Student Model. At last, we have implemented a prototype example of an intelligent knowledge sequencing ITS that extracts information from the Student model and the standard IMS table of contents to dynamically define content paths.

We focus on the data and knowledge acquisition bottleneck existing in nowadays learning environments. We provide a technological solution that can considerably facilitate the development of monitoring and proactive agents working in the running environment. We believe that such infrastructure can be useful in a number of learning scenarios. First of all, alleviating knowledge acquisition over massive logs is a considerable service for educators; technology can help them to identify groups or student profiles. Furthermore, Intelligent Tutoring systems supported by human expert intelligence can really improve and refine learning scenarios.

We are collaborating with commercial vendors and educational experts in order to validate and use these systems in real life experiments. Furthermore, we find interesting to include domain expertise and pedagogical information on well-defined data sources such as LOM and IMS content packaging. Tutorware bots can thus access well-defined information using standard widespread specifications. To conclude, we find very interesting to apply machine learning techniques and tutoring systems to collaborative learning scenarios with richer interactions and collaborative communication tools and interactive simulations.

Case Study

The Human Touch: Incorporating Service-Learning into an Online Course

Can a student learn how to build rapport with an older adult through an online course? Can students’ firmly held stereotypes about what being old is like be affected by a web site? Can a distance education student coordinate a warm hug between a third grader and a frail older adult in an electronic chat room?

Technology has made access to many types of learning possible. In courses that focus on human service, where field experience has been a widely used element in constructivist learning, the online distance education student misses the opportunity to learn from the rich, often unpredictable interactions of the physical and social world of human service. (Wulff, Burke, & Hurley, 2001) Virtual reality and simulations, still technologically inaccessible to many, are also limited by the perceptions and understandings of the author and instructional designer. No one could program the many unexpected challenges of 12 students at a distance responsible for setting up a three part service-learning project with older adults in their local communities!

This project, funded by the Corporation for National Service, Learn & Serve Higher Education, through a grant to The Association for Gerontology in Higher Education in partnership with Generations Together/University of Pittsburgh developed a service-learning model that extended service-learning to gerontology distance education students. The project integrated a service-learning component into the online course “Therapeutic Interventions with the Elderly.”

http://www.hper.indiana.edu/lehuber/r366r566/service/index.htm

Service-Learning is an experiential learning opportunity that integrates community service into students’ academic learning. Service-learning gives students an opportunity to apply disciplinary practices, theories, and concepts in real-world contexts. Students in the community interact and learn from people in social service-agencies, schools, cultural centers, and grass roots organizations. (Jacoby, 1996)

The services provided by students in this class included welcoming older adults to the community, one on one student/older adult interaction, introduction of gerontological curriculum into an elementary school, an intergenerational activity with the older adults at the elementary school, and recognition by the community of the uniqueness and potential contributions of its older citizens.

Important Features

Important elements of any service-learning class include:
1. Service is clearly connected to the academic component, treated as a text via readings, discussions, speakers, etc.
2. A reciprocal relationship between the university and the community makes each a partner in the education of students.
3. Service meets a genuine community need as defined by the community-based organization.
4. The philanthropic and civic content of the students' service is discussed and examined. It is the practice of citizenship, broadly defined, that distinguishes service-learning from practica or internships, which focus more on professional preparation. (COPSL, 2000)

Important elements specific to this online class include:

1. **Overcoming barriers to distance education.** Distance education students frequently report feelings of isolation and lack of connectivity. While web-based courses offer flexibility for the already-employed or student at a distance, these students miss out on class activities and field trips that offer opportunities for guided hands-on practice with older adults. Adding a structured service-learning component greatly enhanced the understanding of course concepts through application and critical reflection.

2. **Increased understanding of course concepts.** This course is about applying knowledge about aging to therapeutic activity intervention with older adults. This project was effective in taking students' understanding of the assessment, analysis, planning, implementation and evaluation elements of therapeutic activity intervention to a deeper, more holistic level. By becoming completely immersed in an extensive project, students had the opportunity to apply concepts and knowledge from each content area of the course.

3. **Increased understanding of aging and the aged.** This project offered the opportunity to develop two different one-to-one sustained relationships with older adults. Past experience in this course, as well as reports from other faculty, report a positive affective experience from ongoing one-to-one relationships with older adults, as opposed to students coming in as a group to offer a one-time activity with a group of older adults. The rationale behind selecting two different older adults of varying functional abilities was to give students an appreciation of the difference between aging with disease as opposed to normal, or even successful aging. Students with limited experience with older adults often underestimate the individuality and heterogeneity of the older adult population.

4. **Building competence.** Besides the ability to work knowledgeably with older adults, practicing activity directors need to be able to offer intergenerational activities, develop community partnerships, and obtain media recognition for facility events. This project went beyond requiring student contact with older adults to building student competence in areas of needed expertise.

A description of the problem

**Pedagogical Needs**

In any learning environment, there is a need to engage the student. Theoretical constructs in web-based learning have particularly focused on the need for learning to be problem-based, and the importance of learner-centered instruction. (Bonk & Cummings, 1998) After a semester pilot-testing the course “Therapeutic Interventions with the Elderly,” it was clear that incorporating principles of learner-centered instruction would benefit what
was learned and how it was learned. Of particular importance in this course which focuses on human service were building in opportunities to learn communication and interaction skills with older adults.

Of Bonk and Cummings' Twelve Learner-Centered Web Recommendations, the most salient for this course were:

- **Facilitate don’t dictate**. Students at a distance were responsible for every aspect of the service-learning assignment. I facilitated where possible with phone calls, letters, and additional materials. In contrast, two students were local IU students. I had set up their project in advance over the summer so that I had a model to use for trouble shooting community partner relationships at a distance. These two students were the least engaged in the project, showing the importance facilitation of student ownership and leadership of the project over dictating project elements.

- **Use public and private forms of feedback**. Students posted all reflective journals and analytical papers in public spaces. I gave both public and private feedback on assignments, giving students a shared understanding of expectations as well as the opportunity to learn from students already employed in the field.

- **Varying the forms of electronic mentoring and apprenticeship.** Students learned from each other, through peer feedback, but also learned from older adults, activity directors, family members, and grade school teachers. The best lessons were those learned from the older adults with whom they partnered; achieving the ultimate goal of the course, an appreciation and respect for the dignity of the aged.

- **Employing recursive assignments that built on personal experience.** In addition to asking for personal memories of experiences related to aging, students shared barriers and successes in their common service-learning experiences. All assignments asked students to integrate and synthesize course concepts with personal experience, and students learned from peer application of theory to practice.

- **Varying the forms of electronic writing, reflection, and other pedagogical activities.** Students wrote journals, participated in asynchronous discussion forums, wrote press releases, and one page analytical papers in addition to service-learning activities.

- **Provide clear expectations and prompt task structuring.** Before the beginning of the semester, students were mailed a “Course in a Box” including:
  - A 56 page booklet outlining every detail of the service-learning assignments and analytical papers.
  - A video showing an associate instructor completing one of the service-learning assignments with an older adult

Community needs met by the service-learning activities in this course

- **Integrate older adults into the community.** Bloomington has been identified as one of the top 20 places to retire in the US. In the past 3 years, 4 new residential facilities for older adults have been built; previously there was only one such facility. Many of the residents of these facilities are new to the area. Because they live in a facility, many remain uninvolved in community citizenry.

While many of the communities of the DE students might not have experienced the in-migration of older adults that Bloomington has, older adults that are in facilities are
segregated from the greater community. Most experience a sense of isolation and disconnect from community life. Many have few contacts with other generations. The community loses a potential active, interested citizen. Thus, the primary community need addressed by this project is the integration of facility-residing older adults into community life, benefiting both older adults and their respective communities.

- **Provide intergenerational opportunities to three different age groups.** Because of changes to the nuclear family and an increasingly mobile society, many adults and children have few opportunities to interact with those of other generations. This project provided interaction opportunities to three generations: older adults, college students, and elementary school students.

- **Integrate gerontology into grade school curriculum.** Today’s children are ill-prepared to live in a world where 1 out of every 4 people are over 65. Very little material about aging is available in the K-12 curriculum, and many children hold misconceptions and stereotypes about aging and the aged. This project provided one unit from a series called “Positively Aging” developed by the University of Texas. The unit is called “All About Them,” and describes the diversity of the older adult population. It address stereotypes and myths about aging, and engages children in critical thinking activities to develop their understanding of the aging process.

**Who, What, When, Why, How**

At the beginning of the semester, students identified a facility in which older adults reside, and working with the Activity Director, identified two residents with whom to work during the semester. Working with Newcomers Club or similar community partner they assembled a “Welcome Basket” for each resident, welcoming and introducing the resident to community life. When they brought the basket to the resident, they collected a narrative autobiography as they heard the story of the resident’s life. On their next visit, the student and older adult created a “Visible Lives” storyboard, introducing the resident to the community as well as to staff and residents within the facility. “Visible Lives” is a collage of artifacts from a person’s life, a way for a person to tell their life story as they would like to tell and share it. (Nguyen, Hill, & Cole, 2000). Photos of the class project are available at http://www.hper.indiana.edu/lehuber/r366r566/service/pictures_1.htm

The resident was then “introduced” to the community by participating in an intergenerational celebration at a local grade school facilitated by the DE student. Grade school students and teachers prepared for this activity through a curriculum packet, “All About Them” from the “Positively Aging” curriculum project (http://salud.uthscsa.edu:8900/public/posag2/) which led students to appreciate the diversity among aged individuals.

Students then prepared a media release for their local media about the project, which further integrated the older adults into the community, as well as providing project dissemination.

After each activity, students used web-based communication to reflect on their experiences. At the end of the semester, the class had a weeklong asynchronous class “party,” complete with jokes, snacks, Christmas wish lists and reflections on the experiences of the semester.
Joke punchline: Dad says, Where's Susie?  
The little girl says, Susie ran out of gas about halfway down the block and there's another dog pushing her home.

Hope that was not too bad, my grandfather told me that one.  
Anyway, my favorite snack is cashews and I am eating them now.  
My greatest barrier that I ran across while taking this class was definately using the Internet for communication purposes. I have had tremendous difficulty with this but that's it. The class itself was great.  
The greatest success that I received from this class was gaining new friends and learning more about myself and how growing doesn't bother me.  
What I want for Christmas up until yesterday was a guitar but I received that yesterday for my graduation present. Now I guess I will ask for a Red Rider B-B GUN! Don't worry I won't shoot my eye out. HA,HA.  
Great party

Implications for the local setting

Building a service-learning component into an online course makes something already time-consuming (online teaching) even MORE time-consuming! At the beginning of the fall semester I had decided this type of model to increase student involvement in a human services online course was just too problematic. As the semester ended, overwhelming positive student feedback made me reconsider. Over the previous summer, I had developed substantive materials to guide students in their service activities and online reflections. I will continue to use those materials, but give students a choice about service-learning. Students who are already employed will find this type of project useful in accomplishing learning and professional objectives, and can implement the assignment in their place of employment. Some undergraduates, themselves not well integrated into their community, might find it easier to write a long paper than develop community partners. From an instructional time management point of view, it might be easier to grade those long papers than try to develop and maintain community partners at a distance. From the learner’s perspective, developing community contacts might be more frustrating than rich with learning opportunities.

Implications for others outside the local setting

Service-learning is a valuable concept for online learning as well for traditional brick and mortar learning environments. Human services can hardly be adequately taught solely through electronic communication. Many courses involve a field experience, but that places an unrepaid obligation to mentor on kind souls at-a-distance. Service-learning asks for mentoring, but promises student service in return.
Like many ideas in instructional technology, this model program deserves consideration by others inspired to provide the best possible learning environment and opportunities for students. Also like many ideas in instructional technology, this program comes with the caveat that it is time consuming, potentially frustrating, and not guaranteed to succeed for each student.

The turning point in my decision to continue to include this component came with the following email from a student: (http://oncourse.iu.edu/fal2001/oncourse.asp)

Dr. Huber, first let me say thank you for this project! It was great! Both my Buddy and I had such a good experience. I don’t know who’s more excited about the outcome, her or me! ...Some of the nurses came to me tonight to tell me what a difference they had seen in the resident known as Buddy One. They had been worried about her withdrawal associated with the deterioration of sight. They had to tell me what a difference the Visible Lives project made in this Resident, who by their accounts, is now eager to greet the day and filled with enthusiasm to finish our projects. She talked a lot this past week about how she can still do things that matter. Just thought you might enjoy that tidbit as much as I do. Thanks again, Cheryl.

Viewing the Reviewing

An observational study of the use of an interactive digital video to help teach the concepts of Design Inspection Reviews

Matthew Love
Digital Media Research Centre
Sheffield Hallam University
Howard Street, Sheffield, England
m.love@shu.ac.uk

Abstract: “Design Inspection Reviews” are structured meetings in which participants follow certain rules of procedure and behaviour when conducting detailed readings of design plans to identify errors and misunderstandings. The technique is widely used in the software engineering industry, where it is demonstrably more effective than testing at identifying errors in software, but it is by no means restricted to this domain. Similar practices can be found in many other creative industries.

This paper reports on an interactive multimedia program used to reinforce the teaching of the technique to software engineering and computer network students. The results of the end-of-studies examination papers of the student group that used the multimedia program are compared to those of the previous group. The results appear to show an improvement of over 7% for the Review topic question for exams that were otherwise comparable in standard. The quality of the research data and the validity of its conclusion are discussed.

Introduction

A common saying is “prevention is better than a cure”. In the industrial design environment this is certainly true. It is known to be far more cost effective to take extra time to identify problems at the design stage rather than try to work around the problems at the product installation or user operational stages. For example, this has been a central tenant of the quality assurance movement of the last two decades, as typified by the ISO 9000 standard.

The truth of the saying has been known to the software development industry for many years. Fagan [1976] describes the application of Design Inspection Review techniques at IBM. Recent surveys of industrial practice show Design Reviews are today very widely used for ensuring quality of software. Indeed [Love, 1999] found that the reviews are the top-most used approach for ensuring quality, more widely adopted than internal quality audits and statistical quality control procedures.

Using lectures to teach the basics of Design Inspection Reviews can be ‘dry’ and for the student a rather passive experience. This paper describes the concepts and technologies of an interactive video that was developed to allow students to “chair” a Review meeting for themselves, giving individual viewers the opportunity to judge when the rules of the technique are being broken. The author makes observations on the success of the use of the interactive video, drawing upon data from examination results. However, these are only observations – the difficulties of drawing empirical conclusions are noted.

Although the paper uses examples from software design to illustrate Design Inspection Reviews, the principles of the Review technique - and of multimedia program used to teach it - can be applied to many other situations.

Design Inspection Reviews

The premise of the Design Inspection Review technique is that the author / designer / originator is often too ‘close’ to their own piece of work to be able to properly and objectively judge its fitness for purpose or technical qualities. Instead a small group of people assist the author to find all significant errors, omissions, inconsistencies and areas of
confusion in the product [Kelly, 1993]. Research has shown that an effective Inspection Review regime is more than paid back by reductions in the subsequent test-and-correct phase [Freedman, 1990].

The Design Inspection Review technique has three central tenants

- The inspection team must be knowledgeable about both the product requirements and about the tools and methods used to design it. They must also have a vested interest in wanting to find problems before the product design is released. Typically this means that the team is comprised of direct peers of the author, plus the author him/herself. Fagan [1976, 1986] and Freedman & Weinberg [1990] recommend that anyone with line management responsibilities over the other team members should not be present as this could inhibit the open discussion of problems. Crawford-Hines [1996] dissents, pointing out that in industries such as software where seniority of position often is based on technical prowess, an immediate supervisor may have valuable expertise to share.

- The Review is carried out according to schedule typically comprising of six phases: planning; participant briefing; individual preparation; inspection and defect recording; rework; and, if necessary, re-inspection. Each phase is structured towards the efficient use of time and towards the successful identification (rather than the solving) of problems. For example, the use of checklists of common errors is strongly recommended (together with a department-level process to review those lists to help Inspectors learn from other reviews about likely sources of problems). To ensure breadth of consideration, the team members are each allocated specific viewpoints from which to review the product: accuracy of working, ergonomics, and future maintainability, etc.

- A number of conduct rules apply to the Inspection meeting itself. Two examples are:-

  In the months leading up to the Review the author will have invested many hours in their work. It represents, and reflects, their skills. At the Review meeting it is perhaps natural for the author to want to show to their colleagues f the complex or inventive parts of the solution. However, an author-lead discussion may not identify that the author either misunderstood or completely overlooked parts of the requirement specification. A rule of the meeting is that the Chair leads the discussion and the author just responds to questions.

  The product should only be inspected when the author believes it to be defect-free and ready for release. It can be a significant challenge to his/her “ego” if the reviewers do then finds serious errors. The author may become defensive and attribute problems to others. Alternatively, they might even counter-attack and question the technical skills of the reviewer. In either case the effective, free-flowing discussion of potential problems would be lost. To prevent this the Chair of the meeting must ensure that all communication - verbal, and non-verbal too ~ must suggest that “there is a problem with the product” and not “there is a problem with the producer”.

This paper refers to the technique under the general title of “Design Inspection Review”. Over the years a number of variants - Fagan Inspections, Formal Technical Reviews, Active Design Reviews, Phased Inspections - have been proposed. Interested readers are referred to Freedman and Weinberg [1990] as the most comprehensive printed work. The Software Inspection and Review Organization web site has useful information though is a little dated [SIRO, 1996]. The WWW Formal Technical Review Archive [FTRA, 2001] is a further source of online information. Trainers may find Powerpoint presentations of Design Inspection Reviews [Johnson, 1998] useful.

Previous approach to teaching Design Inspection Reviews

Students on one of the undergraduate computing degrees at Sheffield Hallam University, England, are taught a version of Design Inspection Review based on Freedman & Weinberg. Students attend a lecture that describes the principles, and (prior to the development of a multimedia teaching tool) then attended classes in groups of around twenty where six volunteers would read aloud the dialogue of a “play” written by a course tutor. In the play the “characters” break many of the procedural and behavioural rules described in the lecture. All the students – the readers and the others - were encouraged take the perspective of the Chair of the meeting, and to interrupt when they identified transgressions. The tutor led the class in discussions as to the likely consequences. The class would then resuming with reading the script.

These classes appeared to be popular with the students, with lively discussions in most sessions. However, there were some notable problems with the format:
Tutors found it hard to get all students involved equally. Typically, a few noisy or confident students would dominate the discussions.

An educational aim was that the "play" should help inculcate in the students a sense of appropriate use of tone and language when making criticism. As with many issues of chairing a meeting, it is a matter of judgement knowing how far to let a discussion run before interjecting. However, the first student to interject pre-empted the other students from making this judgement.

Students found it hard to revise the topic when preparing for end-of-year examinations. Perhaps because they were actively involved in reading and discussing the script, few took notes. Although the scripts themselves were available for aiding their revision, if a student did not pick up on a particular issue during the class session it is believed unlikely that they would spot it when re-reading the script weeks later.

**A modified approach to teaching: A multimedia program**

A multimedia program was created to address the problems identified above. A re-scripted version of the Design Inspection Review play was enacted, videoed, digitised and placed onto a CD, together with a media-controlling program to manage the interaction. The intent of the program was to permit individual students to take the role of "chair" of the meeting. They could interrupt the video whenever they thought that one of the Inspection rules was being broken and then use clickable buttons to identify the problem. The program would confirm the correctness or otherwise of the interjection, and give further feedback on the features of that class of problem. An important part of the design of the multimedia program was to guide students towards noticing problems that they had missed on the first viewing.

The original concept for the program interaction was to create a 'network' of navigation paths through the video presentation. After students had interrupted the video and used the buttons and menus to identify what rule they thought was being broken, the program would supply a little further information (as text or extra video) about the consequences of this problem and where to get further information. It would then restart with a different video clip that showed a corrective action being taken. For example, if the viewer, in their role as "chair", indicated that the language of criticism was too harsh then the next clip would start with an unseen voice (the "chair's" voice) asking for more moderate tones. The subsequent clip would then progress towards a desired outcome. However, if the interjection was made at an inappropriate time the next clip would have a similar start, but the subsequent language might be so polite as to fail to uncover the next defect. In this design, not all the restart clips led to desirable outcomes.

The network concept was not used in the final version of the program. It turned out that too many scripts were required for the time available to the project. It was also hard to find "natural" ways of giving feedback about the correctness of student interjections, especially if students selected faults that were not intended to be the primary problem at that point. A further problem was that the student might undermine the value of the package by navigating a route that missed all the important teaching points. Instead the program was designed to reflect that Inspection meetings have six sub-phases, and that most errors are most likely to occur in specific phases. For example, the attendance of an inappropriately skilled reviewer is likely to be detected at the meeting start-up phase.

In the modified program design the student were presented with a predefined sequence of six video clips of between one and two minutes. They could interact to identify problems either as they came across them or at the end of the clip. If they interacted during a clip the video would be paused and feedback given as above, but on restart the same clip would be shown. Students could opt to see the clip again from its beginning, or from just before where they left off. To handle unexpected interjections, the machine would respond that "this problem can happen, but it isn't happening here". A central part of the interaction was that the program did not tell the viewer whether or not they had identified all the problems present in a clip. This was to encourage the student to be critical in their interactions rather than routinely identifying, say, two problems per scene, and simulates "real life", where some sections of Design Inspection Meetings might run smoothly and require little correction, whilst others might require many interjections.
At the end of the whole program, the package lists which errors had been detected and which had been missed. Students then have the choice of watching again extracts of clips that contained identified or missed problems. The program concludes by giving a “score” based on the percentage of problems identified on the first viewing of the scenes. This “score”, though, is not considered a strong metric of performance (it takes no account of whether the problems was spotted during the showing of the clip or at the end, for example) and is not collected for evaluation purposes.

Technical details of the creation of the Multimedia product

A standard home VHS-S video camera was used to film a group of students role-playing an inspection meeting. Scenes from the video were played back through the camera and saved in AVI digital format by a computer (a Pentium II with 256Mb RAM and 4 Gbytes of unused disk space – a fairly standard specification machine, but equipped with a digital video capture card). Adobe Premier software was used to edit together different ‘takes’ of the same piece of script, either to remove errors and hesitations in the acting or to give different camera angles such as close-ups on individual speakers. The resulting sections of video film were saved in Real format. This editing and re-encoding into Real format reduced the storage size of the clips from several gigabytes to a few hundred megabytes.

A computer program written in Macromedia’s Director language was used to control the playing of the video to a computer screen. A series of menu buttons were displayed beside the video (see figure 2). Director allows both the buttons and the actions taken when they are pressed to be varied by the program, so the buttons could be made to be appropriate to the content of the video being shown at the time.

The video clips and program were written to CDs, which students could borrow to watch on a home or university machine. Alternatively they could download a copy across a network to watch on a university machine (downloading across a standard modem to a home machine would take prohibitively long). The two delivery formats gave identical results when watched. We did not try to stream the video because with current technologies there can be a significant delay – often around 20 seconds – before sufficient video is received to start the viewing. Eventually, advances in technologies may overcome this difficulty, and allow on-demand access to interactive learning materials without any administrative overheads.

None of the above technical steps were found to be difficult. They were all within the leaning capability of the program’s author, a Final Year undergraduate Software Engineering student. It is noteworthy, too, how little attention needed to be paid to the filming environment. Acceptable results were gained using just the normal fluorescent lights of the meeting room and the camera’s built-in microphone. We did use a room with carpets to soften the sound and reduce the noise of chairs scraping.
Evaluation of the learning from the package

Learning from the multimedia teaching tool, measured eight weeks after the use of the video, was evaluated by repeating the same examination question given to the cohort prior to the use of the video onto the examination paper of the cohort that did have it available. This is shown as Q1 in the tables below. To check that any change in performance levels was not due just to question familiarity, a question from an unrelated topic was also repeated (Q2). The other questions were from different topics or gave a different emphasis to the same topic, and were not directly comparable. This is emphasised in the tables by labelling them Q3-Q7 and Qiii-Qvii respectively. The two papers each required the students to answer four questions from a choice of seven.

The same group of tutors taught and examined the course, and the teaching approaches were broadly the same except for the topic of Inspection. The author of this paper was not a tutor on the course for either year, do direct experimenter influence is reduced. It is stressed, however, that still this was not intended to be a strict experiment and a number of important variables were not controlled. For example, students in the later year group had access to any new literature published during the later year. For this reason, this research paper makes observational findings based on data, it does not claim that these are empirically derived results.

Tables 1 and 2 respectively show the examination results from the year before the use of the video and for the year of use. For each question they show the number of student answers, the question’s “popularity” (i.e. the percentage of students choosing to answer the question) and the mean of the marks given to the students’ responses. Similar data is shown for the exam overall, and for overall but excluding the Inspection question. To make the tables simpler to understand Q3-Q7 and Qiii-Qvii are presented in decreasing mean-score order. The questions did not appear in this order on the examination papers.

Table 2 Results for cohort that had video available

Tables 1 & 2 show that mean mark for the Inspection question (Q1) for the cohort before the video was 51.2 and was 58.7 after. It can also be seen that the mean mark for the "control" question (Q2) is only 0.2% different, suggesting that repeating a question does not itself explain the rise in mark for Q1. It can further be seen that the exam overall excluding the Inspection question is only 0.8% different between the two cohorts, suggesting that the two examinations were of more-or-less comparable levels of difficulty. Hence it might be concluded that the change in Q1's result from 51.2 to 58.7 is due to the change in method of teaching, i.e. due to the introduction of the interactive video CD. Under the United Kingdom examination system, a 7.5 mark improvement represents not far off a whole degree-classification difference, and is a worthy achievement.

(A less favourable interpretation could also be postulated: perhaps it was not the use of the video that lead to the improvement in answers to Q1, but that the previous use of the "play" so confused the students that their 'previous-cohort' mark was actually depressed. The research does not have the evidence to refute this conclusion. It can only be stated that the professional judgement of the teaching team is that this was not the case.)

An examination of the data was made to see if the profile of marks within the Inspection question had changed for those students who declared that they had watched the video. A total of 51 students out of 202 either told staff that they had downloaded a copy or signed as having borrowed a CD. Figure 2 presents a comparison of the exam results in graphical format. In the previous year the score for the Inspection question, at 51.2, was nearly equal to the mean of
Conclusions

The “headline” conclusion of this paper is that eight weeks after teaching of a topic was supplemented by an interactive video, the marks for the relevant question on the examination paper were raised from 51.2 to 58.7 (and to 61.5 for those who explicitly said that they had seen the video). This is after discounting factors such as experimenter influence, differences in the overall standard of the examination papers, or the re-use of a question leading to students being better prepared.

The author is careful to state that whilst the above conclusion is based on numerical data this does not amount to empirical evidence, and has pointed out many factors that invalidate the results from being a correctly-formed “scientific experiment”.

On a different aspect, a second finding of the research was the ease with which the interactive video was conceived and implemented. The researchers were surprised how few technical difficulties were met in the filming and digitising of the video, or in writing the presentational program. The largest difficulty was a pedagogic issue, namely of deciding the program’s content.

The overall conclusion is that the apparent gain in retained learning of over 7% is noted, and that the project does merit the design of a carefully structured empirical study.

Promoting Student Learning through Peer Tutoring – A Case Study

Joe Luca, Edith Cowan University, Multimedia Department, Australia

Barney Clarkson, Edith Cowan University, Multimedia Department, Australia
b.clarkson@cowan.edu.au

Abstract: The literature abounds with information about peer tutoring and the benefits that it can bring to student learning. This case study sought to explore ways of using peer tutoring to enhance the learning experience of a group of higher education students in a multimedia course, who had access to learning resources in an on-line environment. It illustrates how easily and effectively the basic principles of peer tutoring can be adapted and implemented following explicit guidelines from the literature.

Introduction

It is ironic that schools and tertiary institutions are often chided for not providing a real world experience for students, yet they can provide a perfectly realistic learning environment for students to tutor others. This permits authentic practice of a number of useful generic skills like working collaboratively with peers, which can enhance teamwork and interpersonal skills. This study presents support for using peer tutoring and peer assessment for students in higher education. After all, evidence suggests that peer tutoring can greatly enhance the learning experience of both the student tutor and learner (Goodlad, 1999; Topping, 1996).

At a time when there is a push for higher education institutions “to do more with less” and promote the development of students’ generic skills (Australian National Training Authority, 1998; Bennett, Dunne, & Carre, 1999; Candy, Crebert, & O’Leary, 1994; Dearing, 1997; Mayer, 1992), peer tutoring can provide an effective system which not only assists student tutors and tutees to learn better, but also helps promote the development of generic skills, as well as freeing up time for tutors (Topping, 1996). This provides an alternative teaching and learning approach in which students take a pro-active role in thinking, questioning and sharing knowledge.

In this paper, we examine design issues needed when implementing a teaching program using peer learning, and also present the results of our evaluation. We begin by considering some theoretical underpinnings and design aspects of implementing peer tutoring and learning.

Peer Tutoring – theory and design aspects

The concept of learning through peer tutoring is based on a social constructivist view of learning that emphasises the role of the students to generate learning where students coach peers through social interaction within their zones of proximal development (Vygotsky, 1978). Rather than applying a stimulus/response process, users are actively engaged in making meaning through cognitive accommodation and/or assimilation (Piaget, 1969). Vygotsky argued that learning comes about through social negotiation within a cultural context, with language as the primary enabling tool. This social constructivist philosophy has been expanded on recently, introducing the notion of cognitive apprenticeship (Brown, Collins, & Duguid, 1989) through which students learn in a manner similar to traditional apprenticeships. The students access expertise through mentors, whose role is to facilitate rather than teach, and the aim of learning is to solve realistic and practical problems in an authentic setting. For a peer tutor, this setting is a very realistic human setting. Just as in traditional apprenticeships, learners engage in activities ‘on-the-job’ rather than through the didactic teaching of abstract concepts. The argument is that students are better equipped to approach non-familiar problems and produce solutions that are appropriate to a given culture. Peer tutoring is aligned with these aspects of social constructivist theory by enhancing social negotiation with the student tutor and tutee, where knowledge construction is promoted through communication and dialogue, which is helpful for the tutees.
Peer tutoring is also valuable for the tutor, ie "learning is enhanced through teaching". In an evaluation study conducted by Hartman (1990), a reported outcome of peer tutoring was an increase in student motivation toward learning. These results are supported by Whitmah (1982), Annis (1983) and Benware & Deci (1984) who argue that peer tutoring can be the most intellectually rewarding experience of a student's career, and that they perform better on higher order conceptual understanding scales than students who read the material simply for study purposes. The benefits of peer tutoring are summarised by Goodlad (1999) as follows:

- Student tutees found lessons more interesting, easier to follow, more enjoyable and seemed to learn more;
- Student tutors practiced communication skills, felt that they were doing something useful with their knowledge, got to know people from different social backgrounds, gained insights into how other students saw subjects, increased self-confidence and reinforced subject knowledge;
- Teachers found lessons easier to handle, teaching was more enjoyable and reported that pupils seemed to learn more.

Implementing a peer-tutoring program is not a trivial process, as there are many salient issues. Topping (1996) describes nine different peer tutoring formats suiting different circumstances ie cross-year small-group tutoring, a personalised system of instruction, supplemental instruction, same year dyadic fixed-role tutoring, same year dyadic reciprocal peer tutoring, dyadic cross year fixed-role tutoring, same year group tutoring, peer assisted writing and peer assisted distance learning. In our case study, the personalised system of instruction was akin to type seven, ie implemented at the same year group level, where tutors assisted tutees who were working at their own pace on set exercises.

Even though different formats meet different needs, there is a commonality of purpose as well. Goodlad (1999) lists seven “golden rules” as criteria for designing and implementing peer-tutoring schemes. His criteria are:

1. Clearly define the aims of the tutoring scheme by writing a statement of intent which shows “who is teaching what to whom and for what purpose”;
2. Define roles and responsibilities in the scheme being implemented, which may include rules for matching or pairing students by sex, friendship or ethnicity;
3. Train the tutors in task/content requirements and also in tutoring techniques such as “pause, prompt and praise”;
4. Structure the content so that there are clearly defined, meaningful tasks for the tutees which involve maximum participation and reinforcement;
5. Support the tutors with regular feedback through de-briefing sessions and well structured materials;
6. Keep logistics as simple as possible ie make the scheduled time and space for meetings convenient to all parties;
7. Evaluate the scheme.

Context of Study

“IMM 1122 - Publishing on Web”, was designed as an introductory unit to teach media students at Edith Cowan University how to publish information on the web. Students were required to create web pages that incorporated graphics, sound and animation, design suitable media for web delivery and use a variety of web development tools to build well-designed sites. An outline of the weekly topics included: Introduction to HTML, Designing a Web Page, Tables, Frames, Creating Forms, Programming with Javascript, WWW Images, Bandwidth and Compression, Flash and using Word, PowerPoint and Acrobat for on-line publishing. All notes, exercises and the syllabus were made available to the students through the use of a web site.

There were 110 students from a wide variety of backgrounds in the course, which comprised of a one-hour lecture and a two-hour tutorial. This required four academic tutors to run five classes, with about twenty-three students in each class. The unit is an elective in the “Communications and Multimedia” course, and can be taken by first, second or third year students. Also, students taking this unit are from disparate backgrounds ie some students in the program have the intention of majoring in Media Studies, Film & Television or Photomedia, while others would be majoring in Multimedia, Computer Science or Information Systems. So, in the same class it is possible to have a third year student majoring in Multimedia and Computer Science alongside a first year student majoring in Media Studies and Photomedia. This large discrepancy in student expertise and background created a great diversity of abilities, which suggested implementing a peer-tutoring program.
The students were required to complete three assessment tasks. Two assessments were based on developing web-based portfolios, showing their "digital achievements" which could serve as potential CV's for employment opportunities. The peer tutors were involved in the third assessment block of weekly tasks which required students to complete ten tasks (worth 3 marks each), based on the previous week’s work. Academic tutors would then assess each student’s work during the tutorial session, which was a time intensive task and took up most of the academic tutors’ time during the two-hour tutorial. Tutors would discuss the task with students and give them a mark and justification. Students could ask questions, but generally the amount of time spent on each student was only five or ten minutes. While this was in progress, it was difficult for students having problems to ask their normal academic tutor any questions.

So, given that there was a large discrepancy in student abilities, and also that academic tutors were busy assessing weekly tasks, it seemed appropriate to implement a peer-tutoring scheme in this context.

Implementation

Within the syllabus, clear guidelines were given to students about peer tutor responsibilities and assessment of these. Four peer tutors were required in each class, which had 20-25 students. The scheme commenced in week three of the semester, which allowed time for nominations, and was based on a short competency test given by the academic tutors.

What was the incentive for peer tutors wanting to take on this responsibility? Simple - they were "bribed"! Successful peer tutors would be exempt from doing weekly workshop activities (worth 3 marks each). However, to remain as peer tutors they were expected to obtain positive feedback from their peers. This was acquired through an online database at the end of each tutorial session. If they obtained two consecutive weeks of poor feedback they were warned that they could be taken off the role. This commitment was established through a "Student Contract" which had these criteria and was signed by both peer tutor and lecturer.

Goodlad’s (1999) "seven golden rules", were generally adhered to except for training tutors in tutoring techniques and supporting tutors with regular feedback. Over the semester, it was found that all the tutors across all the classes were keen to maintain their role and worked hard at maintaining a high standard of delivery. However, as time was always limited in the tutorial sessions, not much feedback was given to the peer tutors. This was largely due to weekly student feedback being so positive in the early weeks, and then gradually tapering off.

Student Feedback – Tutees

Student tutees were asked to complete a post-course questionnaire, of which thirty-five were collected. Students were asked to rate a range of questions using a Likert scale (0-2-4-6-8-10) from 0 (low) to 10 (high). Key results are shown in Figure 1 and summarised as follows:

- “I think the peer tutors were successful” had an average of 6.4, and is clearly bi-modal. Students were largely strongly positive or strongly negative about the peer-tutoring program. By closely examining the responses, it appeared that students who were capable and didn’t need help felt that peer tutoring was a waste of time. Also, a small number of weaker students also criticised the peer tutors, who felt that peer tutors should have done more for them. However, the majority of weaker students rated the peer tutoring system highly, and felt that it supported their learning
- Students who needed help rated the peer tutoring system highly (10 or close to 10), whereas the more able students who didn’t need as much help rated the peer tutoring system low (0 or close to 0), and considered it irrelevant or of little use
- “I think that peer tutors can explain concepts better than academic tutors” had a wide range but an average score of 5.0, which implied that there were probably multiple diverse feelings about this issue
- “This unit helped me learn the subject content” and also “I would recommend this unit to other students” both gained high scores of 8.0 and 7.3 respectively, which implied that overall the unit was perceived as being useful. We attributed a good part of that success to the support provided by the peer tutoring system.
Students were also asked to give written opinions about what they thought about the peer assessment program. Positive comments included:

- Peer tutoring was a good idea. Less wait for help and they did the same work as us so they knew the material
- Peer tutors were an effective concept. Offers a less formal way of problem solving on a more personal and intimate level. Also, it doesn't hinder the tutors marking of weekly tasks
- They did a good job. I think in helping others, they also learn new stuff, too. Very co-operative in helping to solve problems.
- Peer tutoring system worked well for the students who were struggling. Our peer tutors very patient and spent time explaining things to students
- Peer tutors are an effective concept. They offer a less formal way of problem solving on a more personal and intimate level, also it doesn't hinder the tutor's marking of the weekly tasks
- I think using the peer tutors was excellent, as the tutor cannot be in two places at once
- :> good, cool thing!
- Peer tutors are good for a go-between student and tutor. Sometimes if the peer tutor doesn't know the answer we work on it together to solve it.

Negative comments included:

- It would have helped if the peer tutor ever came. First few weeks were good but then it dropped off
no-one knew who they were; the system died without a sound. While they did a good job, there wasn’t any real
definition of they were supposed to be doing, and a lot of them were just plain bored!
• They need to do more – offer more help to people
• They need to be more prominent. Also, maybe we should be able to email them!
• I found I did not need much basic help. I tended to work problems out myself
• I didn’t use a peer tutor, the books were easy to follow
• Good idea, but maybe need to make it clearer who they are and what they are there for

Considering some of the negative comments given by the students, it appears that Goodlad’s (1999) “seven golden
rules” were not applied as well as we had wanted. Clearly some students were unsure about who the peer tutors were and
what their specific roles were. A closer analysis of the data, showed that these comments were class dependent, ie how
the academic tutor in each class introduced and promoted the peer tutoring system probably affected its implementation.

Student Feedback – Peer Tutors

Peer tutors were also asked to complete a post-course questionnaire. Ten responses were collected which
represented about two thirds of the peer tutors. These students were asked to rate questions using a Likert scale from 0 (low) to 10 (high). The results are shown in Table 2.

<table>
<thead>
<tr>
<th>Question Asked</th>
<th>Average Score /10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Being a peer tutor helped me learn the subject content ie HTML, Flash etc.</td>
<td>10</td>
</tr>
<tr>
<td>Being a peer tutor helped me practice and develop communication &amp; interpersonal skills</td>
<td>10</td>
</tr>
<tr>
<td>Using peer tutors would be useful in other units</td>
<td>10</td>
</tr>
<tr>
<td>The idea of assessing the peer tutors with an on-line database was successful</td>
<td>4</td>
</tr>
</tbody>
</table>

Table 1: Average scores of post-course questionnaire

Participants were also asked to give written opinions about improving the system. Comments included:
• Not a bad idea in theory, although many people possibly didn’t use us enough and it got boring
• More feedback on our performance would have been useful
• I didn’t know if students were filling out feedback on our efforts, so I wasn’t sure if my help was satisfactory?
• Would have liked more information about how the system worked before we started
• Have the peer tutor tied with the same students all semester. This way it would be easier to help them, as you know
  where they are at, their history and motivation. This also would help in developing some trust between the peer tutor
  and the student which would help smooth things out at assignment time when both are stressed
• The tutors need more tasks to perform. The students were not using us enough.

Clearly, all the peer tutors felt peer tutoring had been a useful exercise and the experience had helped them learn the
content and develop better communication and interpersonal skills. Also, they felt that peer tutoring should be
implementation across other units. However, they were not so content with the level of feedback received, as they were
unsure if they were “doing a good job”. Clearly, it is critical to keep tutors well informed of their progress to maintain
their motivation and level of success. This is stipulated by Goodlad (1999) in point five “Support the tutors with regular
feedback through de-briefing sessions…”.

Conclusions

Both peer tutors and tutees, as other studies predicted, tended to enjoy the peer tutoring process and were
largely supportive. It is difficult to determine if tutor support was based on the “rewards” attached to being a peer tutor
(ie not having to do the weekly tasks), or a case of being intellectually and interpersonally stimulated by the exercise. To
avoid problems it seems evident that Goodlad’s (1999) principles are worth following when implementing peer-tutoring
strategies. Also, in larger implementations such as this, where there were over 100 students and multiple academic tutors
required, clear instructions, regular follow-up and even training sessions are needed to ensure an on-going peer-tutoring implementation. This should reduce inconsistencies across classes, as noticed in the student feedback where some students were unaware of the role peer tutors. In the next implementation, we would be more specific and procedural about giving peer tutors training and support with clear feedback about their progress.

In summary incorporating peer tutoring into this tertiary course was not taxing when we used the “seven golden rules” outlined by Goodlad (1999). Further, the rules appeared to be robust criteria. The results in this case study showed strong positive feedback for and support from the peer tutors, high student satisfaction with the course, and, obviously, satisfaction for the academic staff. It demonstrates how easily peer tutoring can be integrated with reasonable success into an existing unit of work with tertiary students.

Turning a Current Trend into a Valuable Instrument:
Multidimensional Educational Multimedia based on XML

Ulrike Lucke, Djamshid Tavangarian
Department of Computer Science, Chair for Computer Architecture
University of Rostock
Germany
ulrike.lucke | tav @informatik.uni-rostock.de

Abstract: This paper gives an overview on the work of the joint project „Wissenswerkstatt Rechensysteme“ (WWR, engl.: Knowledge Factory for Computing Systems), that is done by twelve German universities under leadership of the University of Rostock. The project is based on an innovative and multidimensional module concept. Its primary goal is to offer a large number of widely scalable teaching and learning modules in the field of computer engineering, which may be easily combined to courses. Moreover, an infrastructure for the management and use of the educational material is developed. The concept is completely based on the Extensible Markup Language (XML).

Introduction

The integration of computers and networks into education has led to the creation of numerous educational multimedia systems, reaching from isolated solutions (Mayer et al. 1998) and combined platforms (Neumann et al. 2001) up to complete studies via internet (Open University 2002). Projects like these are now followed by several current works, which are trying to develop complex, flexible, expandable and easily usable educational multimedia material based on the existing experiences.

There are a lot of tools for the realization of educational contents. For the presentation via internet, HTML and dynamical elements like JavaScript or media plug-ins are well suited. Moreover, authoring tools allow to create material with a high amount of interactivity or dynamical multimedia components. Programming languages like Java or C++ are rarely used for the implementation of educational software. A new possibility is the integration of different multimedia elements into a XML description (Pawlowski 2001) and their transformation into different output formats.

The goal of the (mostly expensive) production of multimedia courseware is the development of flexible platforms, which are suited for several methods of learning. Within the project „Wissenswerkstatt Rechensysteme“ (Lucke et al. 2001b), these requirements are fulfilled by use of the Extensible Markup Language (XML).

Project Overview

The work was started in April 2001. Recently, the conceptual phase has been finished, and the implementation of educational material and tools is going on. The following paper gives an overview on the whole WWR project: the structure of modules and courses, their implementation, and the architecture to develop and deploy this material. Some further aspects of this project are presented in more detail in other Ed-Media papers: the integration of our module concept and didactical aspects into existing XML description languages (Dettlaff-Günther et al. 2002), the criteria and results of an evaluation of existing learning environments and content management systems (Wiesner et al. 2002), and an inquiry of the integration of external simulators and experiments into the project’s run time environment (Kalfa et al. 2002).

Compared to other works, there are mainly the following differences to WWR: The innovative concept of multidimensional modules simplifies the reuse of modules, since the extent of a module is not statically defined by
